This 12th annual ED-MEDIA conference serves as a multidisciplinary forum for the discussion and exchange of information on the research, development, and application of all topics related to multimedia, hypermedia, and telecommunications/distance education. This document contains the 705 papers from attendees representing more than 50 countries from 6 of the 7 continents of the world. The papers cover a range of topics, including: computer-assisted instructional design; distance education; authoring; information seeking; technology integration; media in education; interactive learning environments; cognitive and pedagogical issues; computer-mediated communication; professional development; evaluating instructional effectiveness; teaching and learning strategies; learner centered instruction; hypermedia systems and design; and computer supported cooperative work. (AEF)
ED-MEDIA 2000
World Conference on Educational Multimedia, Hypermedia & Telecommunications

ED-MEDIA 2000-World Conference on Educational Multimedia, Hypermedia & Telecommunications is an international conference, sponsored by the Association for the Advancement of Computing in Education (AACE). This annual conference serves as a multi-disciplinary forum for the discussion and exchange of information on the research, development, and applications on all topics related to multimedia, hypermedia and telecommunications/distance education. ED-MEDIA, the premiere international conference in the field, spans all disciplines and levels of education and attracts more than 1,000 attendees from over 50 countries.

The ED-MEDIA 2000 CD contains the last 5 proceedings books published by the Association for the Advancement of Computing in Education. The files are in the following formats:

ABOUT AACE

AACE (founded in 1981) is an international, educational, and professional organization dedicated to the advancement of the knowledge, theory, and quality of learning and teaching at all levels with information technology.

This purpose is accomplished through the encouragement of scholarly inquiry related to information technology in education and the dissemination of research results and their applications through:

- Publications
Join with fellow professionals from around the world to receive AACE benefits of membership and to share knowledge and ideas on research and applications in information technology and education.

AACE's membership includes researchers, developers, and practitioners in schools, colleges, and universities; administrators, policy decision-makers, trainers, adult educators, and other specialists in education, industry, and the government with an interest in advancing knowledge and learning with information technology in education.

Preface

Bienvenue à Montréal et à ED-MEDIA 2000!

Whether your counting system indicates that we have begun the 21st century, or we are ending the 20th, we have the opportunity at this historic moment to look backward as well as forward. This 12th ED-MEDIA conference enables us to view the growth of new technologies education from the perspective of a novel idea to a major element in our educational process. This ED-MEDIA conference is poised to join the ranks of the successful previous 11 conferences.

The Conference is organized by the Association for the Advancement of Computing in Education (AACE) and over the years has developed a strong international following. The Conference has grown hand in hand with the emergence of new learning technologies and now represents the premier event for this field in the world. This year's attendees come from 6 of the 7 continents of the globe and represent more than 50 countries. And we probably would have participation from Antarctica had there not been prime research weather there.

The interest in educational media around the globe is evidenced by the number of submissions, the extent of the topics covered by these papers both long and short as well as proposals for demos and panels. We received over 600 proposals of full and short papers, workshops, tutorials and posters from nearly 50 different countries. Our review process, which itself is well automated with web-based submissions, reviews and responses, usually includes 3 referees from our international panel of expert reviewers on the Program Committee. Those submissions selected for presentation represent work of the highest quality. In addition, we are extremely proud of the presentations scheduled for keynote and invited talks as they truly represent the best and the brightest in the history, depth and breadth of our discipline as well as the international aspect of our conference. We are extremely proud to have a keynote presenter, for the first time, from the African continent.

You may wonder what Program Chairs do during those dark months between the last conference and the present one. We have had the opportunity to review the proposed presentations, work with authors to hone their presentations, help develop interesting panels, invite provocative keynoters and of course, worry about details so that your experience at this conference and with these proceedings will provide you with a worthwhile overview of your field.

One of our opportunities is to review the entire conference as it emerges and to do a bit of research ourselves into the nature of the field as represented by your submissions. In this era of everything, we expected the WWW and Internet to be the most popular terms. A simple keyword search indicated they came close and were the hands down winner if you include distance education. But other trends also emerge. The concept of collaborative learning in setting, teamwork, and teaching style is a topic of interest. While prototype and application development endure as does programming, new areas of support for cognition and learning styles as well as integration of technological support across the curriculum are emerging themes.

Where is the ED in EDMEDIA now? It has moved from being the target for ready-to-use media to becoming a foundation and an inspiration in designing new ones: numbers of papers base their work on learning and instruction theories as well as on good teaching practices, or refer to them for
evaluation. We see that interacting has replaced using technologies, in two ways: interacting with other people over computer networks, and interacting with smart software. In both cases, these smart interactions represent meaningful and subtle conversations that make them more interesting. People are no longer users, but are choosers defined by the roles they play in action: learners, teachers, managers, etc. Beyond tools and infrastructures, ED-MEDIA 2000 presents all that is at stake with technologies in education: collaboration or commercialization, equal access or disparities, cultural differences.

The best papers for ED-MEDIA 2000 could be considered those that received a 4.5 (out of 5.0) or above on our reviewer rating scheme. From among those, the award winning papers are selected. If we look to them as a indication of where our field is situated at the cusp of the 21st century, we can note that educational technology researchers can be found around the world and well represented by both men and women. The studies documented by these papers are well founded research methodologies into a variety of areas including an adaptive navigation support system for the world wide web, techniques for annotation of learner created hyperlinks or trails, the use of agents in teaching and learning, and an investigation into the learning sequences students select and their relationship to learning styles.

It is incumbent upon researchers in educational multimedia to know where we have been and to know where the discipline is currently focused, but it is also necessary to plan for the future. One challenge for the future does emerge. Evaluations of systems are often done on a small scale, relying on local review and evaluation. We acknowledge that research into large scale and long term evaluations is difficult as populations move and times change, but we would like to encourage the attendees to ED-MEDIA 2000 and the readers of this proceedings to consider techniques and strategies and programs to extend the breadth and depth of their evaluation techniques and processes.

As Conference Program Co-chairs, we have been aided considerably by a number of volunteers and helpers who have given tirelessly of their time. In particular we must thank the Conference Steering Committee of Gary Marks, Ivan Tomek, Tom Reeves, Betty Collis and Erik Duval who led and coordinated the conference this year. We would like to thank the Chairs of the various Program Committees: Niki Davis, Panels Chair; Sam Rebelsky, Workshops/Tutorials Chair; and Martyn Wild, Posters/Demos Chair. We would also like to thank the crew behind the scenes from AACE for their tireless efforts in coordinating and managing the huge number of administrative functions that a conference like this necessarily involves.

We look forward to meeting with you during the conference and trust that you will take the time to renew old acquaintances, meet new friends, be inspired by peers and take home some new ideas and activities to report back at ED-MEDIA 2001 in Finland, June 25-30.

KEYNOTE

SPEAKERS
# TABLE OF CONTENTS

The applicability and Utility of Fault Tree Analysis  
*Mandir Aaron, Concordia University, Canada*

When is an Interactive Scenario a Matter of Interface Design  
*Christian Adriano, State University of Campinas, Brazil; Adriano Adriano, Federal University of Santa Maria, Brazil; Ivan Riuarte, State University of Campinas, Brazil*

Changing Interaction Paradigms in Annotation Environments  
*Christian Adriano, State University of Campinas, Brazil; Alberto Raposo, State University of Campinas, Brazil; Ivan Riuarte, State University of Campinas, Brazil; Leo Magalhães, State University of Campinas, Brazil*

An interactive system model of an online system for teaching & learning developed as a scoping / costing instrument  
*Anne A'Herran, James Cook University, Australia*

Research & evaluation of online systems for teaching & learning  
*Anne A'Herran, James Cook University, Australia*

Validating a theory-based design for online instruction: Aligning tool use and learning outcomes  
*Archad Ahmad, McGill University, Canada*

Creation of a Simple Intranet for University Educational Use  
*Hassan Ahmadi Torshizi, Islamic Azad University, Iran; Bagher Azghand, Islamic Azad University, Iran*

The relationship between learners' personality types to their performance in computer-mediated distance education  
*Justin Ahn, Fairfield University, USA; MiLee Ahn, Hanyang University, South Korea*

What tools for adaptative multimedia telelearning  
*Rachide Alhoun, Universite Mohamed V-Souissi, Morocco; Mohamed Amine Benkiran, Universite Mohamed V, Morocco; Aboukhaled Mahamane Ato, Universite Mohamed V, Morocco*

Design of Educational Multimedia: A Review of Literature  
*Almed Ali-Hamazyan, University of Hertfordshire, UK; Jill Hawley, University of Hertfordshire, UK; Sara Jones, University of Hertfordshire, UK; David Messer, University of Hertfordshire, UK*

Learning Strategies for Multimedia Instruction  
*Mohamed Ali, Athabasca University, Canada*

Tutoring Skills for Instructors in Distance Delivery  
*Mohamed Ali, Athabasca University, Canada*

The Cosmos Web-based Explanatory Library(CosWbEL)  
*Sahal Al-Shaidani, University of Skelton, UK*

Interactive Fiction: Model Development and an Example Created with DHTML and Microsoft Agent  
*Alan Armitage, University of Natal, South Africa; Deshman Govender, University of Natal, South Africa*

Web-Based: Instructional Effectiveness  
*Nella Anderson, Western State College, USA*

Building Electronic Catalogs and Retail Storefronts: Enlivening the Electronic Commerce Course with Cooperative Learning-Based Projects  
*Rebecca Angeles, Montclair State University, USA; Dennis Adams, Montclair State University, USA*

Development of an Introductory Financial Accounting Text in Print-based and Electronic Multimedia Environments  
*David Arman, School of Business, Athabasca University, Canada*

The Interaction and the Learners' Sense of Distance in the  
*Shaker Arad, University of Tsukuba, Japan; Minoru Yoshio, University of Tsukuba, Japan; Noriko Kanakubo, Tsukuba Women's University, Japan*

Conceptual Visualisation in a Task-Based Information Support System  
*Lara Areyo, University of Twente, The Netherlands; Donina Deheus, Winston-Salem State University, USA; Ivan Velos, Sofia University, Bulgaria*

The Biotechnology Project: A Case Study on Integrating the Use of The Internet for Research and On-Line Communication in a Brazilian School  
*Cristiana Assumpção, Columbia University, USA*

Understanding of Adults' Metacognitive Knowledge About Information Seeking Skills via Internet  
*Petek Alpay, Hacettepe University, Turkey; Serpil Yalçınalp, Information Technologies and Electronics Research Institute, Turkey*
«DARWIN'S WORLD»: Hypermedia Technology To Enhance Scientific Thinking In The Kids
Michel Aube, Université de Sherbrooke, Canada; Robert David, Université de Sherbrooke, Canada

Teacher Education by Hypermedia learning Environments – An Example from Germany
Stefan Auffanger, University of Hamburg, Germany

Utilization of BBS for ESL class
Akin Beaufill, Keio Gijhka Gide High School, Japan

Training students to become web authors: Evaluation of a training model
Patricia Barker, San Jose State University, USA

Dynamic Coordination Policy for Cooperative Learning Systems
YeongTae Baek, Kimpco College, Korea; SeilHoon Lee, Inha Technical College, Korea; KyungSeob Yoon, Inha Technical College, Korea; ChangJong Wang, Inha University, Korea

A Generic Pedagogical Agent Architecture That Supports Conversational Authoring
Jeremy Barr, University of Washington, USA; Steven Tanimoto, University of Washington, USA

Relationship between academics' educational beliefs and their design and use of computer facilitated learning
John D Bain, Griffith University, Australia; Carmel McNaught, RMIT University, Australia; Colleen Mills, Griffith University, Australia; Gillian Lueckenhansen, La Trobe University, Australia

Designing Teaching Webs: Advantages, Problems and Pitfalls
Philip Barker, University of Teesside, UK

The Supporting Collaborative Community Model: Implications For Online Learning
Julene Basrett, Brigham Young University, USA; Joanna Hall, Utah State University, USA

Trends in Multimedia; Hypermedia & Telecommunication - development of a methodological design for an empirical study
Peter Baumgartner, Innsbruck University, Austria; Andreas HOLZINGER, Graz University, Austria; Gig SEARLE, Graz University, Austria

On the logic of Bricolage - a case study in system design
Peter Baumgartner, University Innsbruck, Austria; Stefan Salzgeber, University Innsbruck, Austria; Dolf Widyra, Widyra Graphik, Germany

Learning in the Labyrinth: Hypertext and the Changing Roles of Instructor and Learner in Higher Education
Sian Bayne, University of Bristol, UK; Ray Land, University of Edinburgh, UK

Help in the Search for Information in Hypermedia Documents
Alain Beaufill & François-Marie Bérandel, Institut National de Recherche Pédagogique, France

A Study of the Influences and Barriers to Faculty Use of Instructional Technology in Higher Education
Thomas Bev, State University of West Georgia, USA

Public broadcasting archives and documents used for educational purposes
Pierre C. Béanger, Radio-Canad;i, Canada; Carol Peirer, Radio-Canada, Canada

A Learner Centred Assessment of Quality for Online Education: Course Climate
Karen Belfir, Technical University of British Columbia, Canada

Assessing the Use of Technology to Enhance Learning in Higher Education
Karen Belfir, Technical University of British Columbia, Canada

An Assessment of the Potential of Electronic Discussion Groups to Enhance Learning in a Classroom-based Course
John F. Bennett, Stephens College, USA

Weaving the World into the Curriculum: Using Technology to Internationalize the Art, Music and Social Studies Curriculum
Linda Bennett, University of Missouri-Columbia, USA; Jonathan Pye, University of Missouri-Columbia, USA

From "Learning-by-Viewing" to "Learning-by-Doing": A Video Annotation Educational Technology Tool
Ofer Bergman, The Open University of Israel, Israel; Ruth Bryth-Marom, The Open University of Israel, Israel; Ashana Liptold, The Open University of Israel, Israel; Doron Hadar, Ben Gurion University, Israel; Amnon Dekel, Interdisciplinary Center, Israel

A Seed is Planted: Multimedia Data and Analysis of After School Multimedia Arts Education
A Seed is Planted: Multimedia Data and Analysis of After School Multimedia Arts Education
A Seed is Planted: Multimedia Data and Analysis of After School Multim
j. David Belts, University of Arizona, USA
The Essen Learning Model - A Step Towards a Standard Model of Learning Processes
Markus Bick, University of Essen, Germany; Heimo H. Adelsberger, University of Essen, Germany; Jan M. Pawlowski, University of Essen, Germany

The eMINTS Project: Enhancing Missouri's Instructional Networked Teaching Strategies -- Promising Developments and Projected Outcomes
Adam Bickford, OJEDA/University of Missouri Extension, USA; Bill Elder, OJEDA/University of Missouri Extension, USA; Barbara Hammer, OJEDA/University of Missouri Extension, USA; Patrick McGinly, OJEDA/University of Missouri Extension, USA; Priscilla McKinley, OJEDA/University of Missouri Extension, USA; Susan Mitchell, OJEDA/University of Missouri Extension, USA

Enhancing Learner-Centered Design of Hypermedia Artefacts
José Bidarra, Universidade Aberta, Portugal; Teresa Chambel, University of Lisbon - FCUL, Portugal; Nuno Guimarães, University of Lisbon - FCUL, Portugal

Experiences with The Universal Machine: A Multimedia Introduction to Computing
Glenn Blank, Lehigh University, USA; Robert Barnes, Lehigh University, USA

When frames collide: adapting cognitive frame analysis to a child’s comprehension of narrative video.
Janet Blaster, McGill University, Canada

Censorship or Self-discipline on the Internet? Strategies for limiting access to morally undesirable Internet resources.
John Bratthug, University of Minnesota, USA

LEZI: a Tool for Easy Development of Interactive Video for Education
Mario A. Bechich, University of Lecce, Italy; Roberto Patano, University of Lecce, Italy; Paolo Paolini, Politecnico di Milano, Italy; Elisabetta Andressi, University of Lecce, Italy; Triziana Montarano, University of Lecce, Italy

Using Speech Recognition to Support Online Learning of Second/Foreign Languages
Francis Bunkawski, IC Education, Inc., Canada; Quinn Cheung, IC Education, Inc., Canada; Liam Cheung, IC Education, Inc., Canada

New Views on Community and Collaboration: Building and Sharing Dynamic Worlds in Cyberspace
Paula Bonta, LCSI, Canada; Richard Borovsky, MIT Media Lab, USA; Susan Einhorn, Consultant, Canada; Brian Silverman, MIT Media Lab, USA

A Building-Block Method For Structured Courseware Development
E. W. Boots, TNO-Human Factors, The Netherlands; Y. Barnard, TNO-Human Factors, The Netherlands

Integrating ARCS Motivational Strategies into CALL Courseware for Holistic Practice: A Study
Isabel Borns, SDSU, USA; Maria Carnel, SDSU, USA

Using Multimedia to Support Reflection on Past Events for Young Children
Christos Bouras, CTI, Greece; Vaggelis Kapoulas, CTI, Greece; Agisilaos Kondirari, CTI, Greece; Alfredo Sevasti, CTI, Greece; Maria Ramalho, STARLAB, Belgium; Walter Van de Velde, STARLAB, Belgium

Collaborative University Teaching over the Internet
Jacqueline Bourdeau, University du Quebec a Chicoutimi, Canada

The Baker's Dozen: Design Principles for Collaborative Telelearning
Jacqueline Bourdeau, University du Quebec a Chicoutimi, CANADA; Laura Winer, McGill University, CANADA; Martine Chaminard, Centre collegial de formation a distance, CANADA; Jesus Vasquez-Alalod, Universite de Montreal, CANADA; Barbara Wason, Bergen University, Norway

Meta Groupware Design for CSCL Environments
Gregory Bourjot, Laboratoire Trigo, France; Alain Derycke, Laboratoire Trigo, France

Patterns for learning, and metadesign: key challenges for learning environment designers
Tom Boyle, University of North London, England

Reeves Ten-Dimensional Model: Application for the Design and Development of Web-Based Learning Scenario on Learning Theories
Caroline Brassard, Universite du Québec a Chicoutimi, Canada; Jacqueline Bourdeau, Universite du Québec a Chicoutimi, Canada; Pauline Ménier, Universite du Québec a Chicoutimi, Canada

Haptic Virtual Reality for Training Veterinary Students
Stephen Brewster, University of Glasgow, UK; Michelle Montgomery Masters, University of Glasgow, UK; Alistair Glendye, University of Glasgow, UK; Stuart Reid, University of Glasgow, UK; Nik Krig, University of Glasgow, UK

The Creative Network: the development of a collaborative learning community for mature professionals
Helen Brown, University of Central England, Birmingham Institute of Art and Design, England
The forgotten partner: the role of visual, graphic and design principles in educational multimedia course instruction
Ian Brown, University of Wollongong, Australia

Online Education in Schools: Expectations, Facts, and Fiction
Peter A. Bruck, Techno-Z FH Research & Development, Austria; Guntram Geier, Techno-Z FH Research & Development, Austria; Thomas Olesch, Techno-Z FH Research & Development, Austria

Breathing New Life Into The Classroom
Lawrence Bundy, Nebraska Department of Education, USA

Interaction: The Key to Successful Distance Learning
Al Byers, Virginia Tech, USA

A CD/Web-Based Team Project for Undergraduate Business Ethics Students
Martin Calkins, S.J., Santa Clara University, USA; David Armstrong, Santa Clara University, USA

Facilitation in CMC: Differences in Gender Discourse
Katy Campbell, University of Alberta, Canada; John Boeglin, University of Alberta, Canada

The hypermedia conversation: reflecting upon, building and communicating ill-defined arguments
Milton Campos, Université de Montréal, Canada

The hypermedia conversation: reflecting upon, building and communicating ill-defined arguments
Milton Campos, Université de Montréal, Canada

The 7 C’s Model For Learnware Development
Tom Curry, University of Waterloo, Canada; Kevin Harrigan, University of Waterloo, Canada

SEBASTIAN: Educational System Based on Internet Technology
José Luis Carrasco Sánchez, Universidad Carlos III de Madrid, España; Liliana Patricia Santacruz Valencia, Universidad Carlos III de Madrid, España; Carlos García Rubio, Universidad Carlos III de Madrid, España; Peter T. Breuer, Universidad Carlos III de Madrid, España; Carlos Delgado Kloos, Universidad Carlos III de Madrid, España; Carmen Fernández Panadero, Universidad Carlos III de Madrid, España.

WWW-Based Tools to Manage Teaching Units in the PLAN-G Distance Learning Platform
Clara Carrillo, University of Girona, Spain; Ramon Fabregat, University of Girona, Spain; Jose-Luis Marzo, University of Girona, Spain

Improving Collaboration in Face-to-Face Groups using Technology
Robert W. Cavenagh, Jr, Dickinson College, USA

Educational Applications of Hypervideo
Teresa Chamblee, University of Lisbon, Portugal

Collaboration between T&T3 Project Team and ETU/CeLTS at HKIEd in Promoting Teaching Skills and IT for HE
Thomas YH Chan, Lingnan University, Hong Kong, China; Jihunne WY Wong, Hong Kong Institute of Education, Hong Kong, China; Edson Sze, Hong Kong Institute of Education, Hong Kong, China

A Web-Based Interactive Environment Based on Virtual Reality Simulation for Constructive Learning
Chi-Cheng Chang, Tamkang University, Taiwan, ROC

Assessing the Effects of Web-Based Interactive Learning Environment Based on Virtual Reality Simulation for Constructive Learning
Chi-Cheng Chang, Tamkang University, Taiwan, ROC

Evaluation of Web-Based Distributed Collaborative Learning Community Based on Knowledge Building for Academic Growth of College Students
Chi-Cheng Chang, Tamkang University, Taiwan, ROC

A Concept-Mapping Methodology to Eliminate Dangling Questions in Asynchronous Learning Forum
Chi-Kai Chang, Department of MIS, Da Yeh University, ROC

Teaching Symbol Recognition with Interactive Java GUI
Li Chao, University of Houston-Victoria, USA

VirtUOS: A Multi-user Desktop VR Environment for Experiential, Simulation-Oriented Learning
Yuen San Chee, National University of Singapore, Singapore; Yong Beng Khoo, National University of Singapore, Singapore

The Construction and Evaluation of an Internet-Based Knowledge Integration System (IKIS) For A CAI Graduate Course
Mai Chen & Tanya Scott, Concordia University, Canada
Design decisions in the development of modular instructional content: Describing the transition from local to global learning systems
Paul Cholomsky, Concordia University, Canada

Patterns Of Learner-Learner Interactions In Distance Learning Networks
C. Candace Chen, University of Hawaii, USA

An Electronic Support System for Designers and Developers: Neurocognitive Learning Science at Your Fingertips
N. James Christman, University of Phoenix, USA; Edward Kazlawkas, University of Southern California, USA

Multimedia Application to Motor Skill Learning
Li & Cheu, National College of Physical Education and Sports, Taiwan; Wun-chou Chen, National College of Physical Education and Sports, Taiwan

Design and integration of interactive multimedia learning environment: content, ergonomic, evaluation and collaborative issues
Isabelle Claire, University of Moncton, Canada; Nkembo Roger, University of Sherbrooke, Canada; Dufresne Andre, University of Montreal, Canada

Kabisa: A computer-based training program for diagnostic reasoning in tropical medicine
Geraldine Clarebou, University of Leuven, Belgium; Jan Elem, University of Leuven, Belgium; Joost Loozich, University of Leuven, Belgium; Ivo Van den Ende, Institute of Tropical Medicine, Belgium; Stefano Legarni, Italy

WEB-LTT: Web-Based Support for Learning Theory and Instructional Design
Ken Clinkenbeard, University of Bergen, Norway; J. Michael Spector, University of Bergen, Norway

Holding the storyline in an educational hypermedia
Luigi Colle, University Of Trento, Italy; Andrea Molinari, University Of Trento, Italy; Luisa Tomasi, University Of Trento

Interactive Flows in Language Learning on the Internet
Helioiss Collina, Catholic University of Sao Paulo, Brazil

The Design, Assessment, and Implementation of a Web-Based Course
Lea Combs, Kennesaw State University, USA

Evaluation of a support tool for musical problem-seeking
John Cook, University of North London, UK

Instructional Technology in the Classroom: New Directions for Foreign Language Faculty
Jesamine Cooke-Plagwitz, University of South Carolina, USA

The effects of on-line collaborative learning on the critical thinking skills of senior, undergraduate journalism students at linked universities, world-wide.
Marion Coomey, Middlesex University, United Kingdom

Remote Controlled Teaching Experiments, in Science and Engineering Subjects, Accessible over the World-Wide-Web - The PEARL project.
Maryn Cooper, Open University, UK

SOS: Supporting Academics in improving their through a Customisable Subject Online Survey
Robert M. Cordey, University of Wollongong, Australia; Ray Stace, University of Wollongong, Australia; Albert Ip, University of Melbourne, Australia; Sandra Wills, University of Wollongong, Australia

Radical Constructivism and Beyond the Information Given: Emergent Models From a Postgraduate Web-based Course
Shirley Current-Aguirre, University of Wollongong, Australia; John Hedberg, University of Wollongong, Australia

Realism and Credibility in a Simulation-Based Virtual Physics Laboratory (VPLab): An Empirical Study
Marc Couture, Té-té-université, Canada; Alexandre Francil, Université de Montréal, Canada

Design Patterns of Web-based Instruction
Lester Cowley, University of Port Elizabeth, South Africa; Janet Wesson, University of Port Elizabeth, South Africa

The Best Practices Web-Based Tool: Using Technology and Constructivism to Create 4th grade
Instruction that Supports Historical Thinking
Mega Creadman, UCLA, USA; Elizabeth Wellman, UCLA, USA

Designing an On-Line Campus (OLC) from the learners' perspective
Gary Cuckovich, University of Greenwich, United Kingdom; Malcolm Ryan, University of Greenwich, United Kingdom; Ann Allen, University of Greenwich, United Kingdom

Carl Conner, McMaster University, Canada; Brian Campbell, Mount Allison University, Canada
Learning Object Containers: a suggested method of transporting metadata with a learning object.
Dwane Currie; Acadia University, Canada; Craig Place; Acadia University, Canada

Synchronous and asynchronous discussion: What are the differences in student participation?
Gayle Davidson-Shivers, Univ. of South Alabama, USA; Lyn Mullenberg, Univ. of South Alabama, USA; Erica Tseker, Univ. of South Alabama, USA

The Adaptation and Use of a WWW-Based Course Management System within Two Different Types of Faculties at the University of Twente
Wim De Boer, University of Twente, The Netherlands; Betty Collis, University of Twente, The Netherlands

Designing Adaptable Learning Environments for the Web: A Case Study
Thea De la Teja, LICEF Research Center, Canada; André Longpré, LICEF Research Center, Canada; Gilbert Paquette, LICEF Research Center, Canada

Supporting a community of practice: the role of workers as learners
Maarten de Laat, University of Nijmegen, Netherlands; Frank de Jong, Education and Knowledge Center of the Dutch Police, Netherlands; Julian ter Heurte, Education and Knowledge Center of the Dutch Police, Netherlands

Ignacio de Miguel, University of Valladolid, Spain; Carlos Jesus Fuertes, University of Valladolid, Spain; Abel Prieto, University of Valladolid, Spain; Patricia Fernandez, University of Valladolid, Spain; Miguel Lopez, University of Valladolid, Spain; Fernando Gonzalez, University of Valladolid, Spain; Juan Carlos Ayuado, University of Valladolid, Spain; Ruben M. Lorenzo, University of Valladolid, Spain; Evaristo J. Abur, University of Valladolid, Spain

E-Study: The design of an international online knowledge community
Sjoerd de Vries, University of Twente, The Netherlands; Maurice van Egeraad, University of Twente, The Netherlands; Dimitar Bogdanov, Bulgarian Academy of Sciences, Bulgaria; Paul Bloomer, University of Twente, The Netherlands; Laarneke Roosink, University of Twente, The Netherlands

French Deanie, Southwest Texas University, USA

Posting Visual Cues on Threaded-Message Boards in Science Curricula: Enhancing Transfer of Theory Knowledge to Clinical Practice
Gregory A. DeBourgh, University of San Francisco, USA

Prototype Tools for Programming
Fadi Deek, New Jersey Institute of Technology, USA; James McHugh, New Jersey Institute of Technology, USA

Preparing our teachers for distance education
Christina Dehler, Concordia University, Canada; Christina De Simone, Concordia University, Canada

Architectural Aspects of An Interactive Multimedia Environment for Training Employees in Internet/Intranet Technologies
Gregory Derkenne, University of Patras, Greece; John Garifalaklis, University of Patras, Greece; Jim Prentzas, University of Patras, Greece; Spyros Siotas, University of Patras, Greece; Athanasios Tsakaldis, University of Patras, Greece

The «BacVerto or «Blue Box - A Knowledge Recycling Bin for Students
Céline Dejardins, Centre de recherche LICEF, Canada; Éléonore Wallace, Centre de recherche LICEF, Canada; Claude Ricciardi-Rigault, Centre de recherche LICEF, Canada

Building Global Information Communities: the University of Iowa Center for Electronic Resources in African Studies (CERAS)
Barbara Dewey, University of Iowa Libraries, USA

Navigating Scholarship: A Study of Discipline-Based Web Gateways in Large Research Libraries
Barbara Dewey, University of Iowa Libraries, USA

The University of Iowa Science Information Literacy Initiative
Barbara Dewey, University of Iowa Libraries, USA

Suffering Remotely
Ross Dewill, UNITEC, Institute of Technology, New Zealand; Stuart Young, UNITEC, Institute of Technology, New Zealand; Man McSporran, UNITEC, Institute of Technology, New Zealand

Introducing a Distance Learning version of a Postgraduate Program on Networking in Argentina
Dean Javier Diaz, University of La Plata, Argentina; Maria Alejandra Orovio, University of La Plata, Argentina; Ana Paula Amado, University of La Plata, Argentina

Increasing Explorativity by Generation
Stephan Detzel, University of Saarland, Germany; Andreas Kerren, University of Saarland, Germany
The study of Newtonian Mechanics in junior high school. A new technology-based learning environment.
Panagiotis Dimitriadis, University Of Athens, Greece; Lamperti Papatheo, University Of Athens, Greece; Kostas Kamposouris-Papamichalis, University Of Athens, Greece; Gianna Karamikas, University Of Athens, Greece; George Kalokas, University Of Athens, Greece

The Bones Of The Skull: Creating Anatomical Models With Quicktime VR
Marilyn Dispense The University Of San Francisco, USA, James Daman, The University Of Colorado, USA, Jerry Moon, The University Of Iowa, USA

Authoring Educational Hypermedia Using a Semantic Network
Duncan Millier, Metropolitan University England; Mark Dixon, Leeds Metropolitan University England

The impact of establishing a virtual university: a case study at NUST
Nomusa Dholo, National University of Science and Technology, Zimbabwe

A Distributed Maritime Simulation Training Environment based on HLA
Mirko Doberman, Computer Graphics Center ZGDV, Germany; Harro Kucharz, MarineSoft GmbH, Germany

Supporting developers of inquiry based instruction: Performance support on the Web
Jackie Dobrowolzky, Un. of Colorado at Denver, USA; Scott Grabinger, Un. of Colorado at Denver, USA; Jenn Light, Un. of Colorado at Denver, USA

Accessing Advocacy Virtually and Physically
Tanis Don, Canadian Association of Independent Living Centers, Canada; Scott Wilson, Computer Master, Canada

Streaming Video: Pedagogy and Technology
Trevor DeKuer, University of Calgary, Canada; Mike Matson, University of Calgary, Canada; Jacques Morin, George Washington University, United States

Human Anatomy Predissection Lecture-On-Demand at The National University of Singapore
Giles Doran, National University of Singapore, Singapore

Leading Your Faculty Down the Information Highway
Thomas Donahue, University of St. Thomas, USA

Is the expression "Instructional Engineering" justified?
Syvane Dor, École de technologie supérieure, Canada; Joëlle Basque, Tél-Université, Canada

Student Technology Services: A Case Study in Experiential Learning
Joseph Douglas, University of Wisconsin-Milwaukee, USA; John A. Groezl, University of Wisconsin-Milwaukee, USA

Technology Across the Curriculum
Gerald Drake, George Mason University, USA

ExploraGraph and CINEMA
Aude Duprene, Univ. of Montreal, Canada; Claire Isabelle, Univ. of Moncton, Canada; Roger Nkambou, Univ. of Montreal, Canada; Yan Laporte, Univ. of Montreal, Canada; Frank Ferron, Univ. of Montreal, Canada

ExploraGraph: A flexible and adaptive interface to support distance learning.
Aude Duprene, University of Montreal, Canada; Gilbert Paquette, LICEF Recherche Center, Tél-université, Canada

The Effect of Level of Technology Training on Teachers' Attitudes Toward Using and Integrating Technology
Ronald Dagan, University at Albany/SUNY, United States; Jennifer Richardson, University at Albany/SUNY, United States; Dianna L. Newman, University at Albany/SUNY, United States

Future Special Education Teachers' Abilities to Integrate New Technology Into Teaching Reading
Comprehension
Catherine Dussault, Université de Quebec a Chicoutimi, Canada; Jacqueline Bourdeau, Université de Quebec a Chicoutimi, Canada

School Festival on the Internet - Project-based and cooperative learning -
Hironori Egii, Keio University, Japan; Yoshitomo Tsuchi, Kamogata High School, Japan; Yuuki Nishimura, Keio University, Japan; Kieishin Itoh, Keio University, Japan

ITBeaknit: An Educational Middleware Framework for Bridging Software Technology and Education
Abdulmohsin El-Saddik, Darmstadt University of Technology, Germany; Stephen Fischer, Darmstadt University of Technology, Germany; Ralf Steinmetz, German National Research Center: GMD-IPSI, Germany

The PadiEuNet-project: Problems with the validation of socio-constructivist design principles in ecological settings
Jan Elen, University of Leuven, Belgium; Geraldine Clarebout, University of Leuven, Belgium
LearnScope and the Development of Virtual Learning Communities
Allan Ellis, Southern Cross University, Australia; Robyn Weatherby, NSW Dept of Education and Training, Australia

Integrating WWW Technology into Classroom Teaching: Students' Perspectives of the Usefulness of their Course Websites
Manol ElTigii, Syracuse University, USA

Evaluation of a Systematic Tele-Tutor Training
Bruno Emanu, University of Amsterdam, The Netherlands; Noor Christoph, University of Amsterdam, The Netherlands; Jacobijn Sandberg, University of Amsterdam, The Netherlands

Providing Quality Distance Education in an Outcomes-Oriented Program
Virginia Engeman, Fort Lewis College, USA; Virginia Engeman, Fort Lewis College, USA

A Model of Successful Technology Integration in a School System: Plano's Curriculum Integration Project
Yoram Eshet, Tel Hai College, Israel; Joel Klein, The Open University of Israel, Israel; Lyn Henderson, James Cook University, Australia; Sara Jalal, Independent Multimedia Producer, USA

Perceptions of a Fearless Experimenter: Students' Perceptions of Creating Electronic Portfolios
Sue Eckridge, University of the Pacific, USA; Ray Poy, University of the Pacific, USA

Helping K-12 Teachers Integrate Internet Technology into Their Classrooms
Christopher Essen, Indiana University, USA

A Course Website One Year Later: Lessons Learned
Christopher Essen, Indiana University, USA; Brian Beatty, Indiana University, USA; Pamela Song, Indiana University, USA

ALIS: An adaptable learning and information system
Shahriar Fakher, FernUni-Hagen, Germany

Examining Medical Students' Attitudes and Learning Experiences in BioWorld
Sonia Farmann, McGill University, Canada; Suzanne Lajoie, McGill University, Canada; David Fleischer, Faculty of Medicine, McGill University, Canada

CyberARTS: A Integrated Arts Curriculum
Tito Faria, Don Mills Collegiate Institute, Canada; Shalom Eisenstat, Don Mills Collegiate Institute, Canada

"Next Steps"
Josephine Ferazzoli Farrell, State University of New York at Oswego, USA

Managing Electronic Resources - Auto-registration for Distance Learning
Richard Foster, Rochester Institute of Technology, US; Damon Bedow, Rochester Institute of Technology, US; Randy Operbeck, Rochester Institute of Technology, US

The Aristotelian Project
Gordon Faulkner, Rutgers University, USA; Sumathi Gopal, Rutgers University, USA; Abraham Ittycheriah, Rutgers University, USA; Richard Mammano, Rutgers University, USA; Attila Medai, Rutgers University, USA; Mirislav Novak, Rutgers University, USA

Conversation, the constructivist perspective
Gary Ferguson-Smith, University of Wollongong, Australia; David Adibon, Apollo Parkways Primary School, Australia; Christine Brown, University of Wollongong, Australia; Barry Harper, University of Wollongong, Australia; John Hedberg, University of Wollongong, Australia

Evaluating motivational aspects of a web-based English language course through the Website
Motivational Analysis Checklist (WebMAC)
Annie Ferreira, Catholic University of Sao Paulo, Brazil

User Studies: Evaluating the Use of EPSS Tools for Self-Management by Children
Gail Fitzgerald, University of Missouri-Columbia, USA; Louis P. Somrak, Arkansas State University, USA; Hsingyi Peng, University of Missouri-Columbia, USA

Interactive Training Materials for Early Childhood Educators: Cases, Tools, and Reflection
Gail Fitzgerald, University of Missouri-Columbia, USA; Louis Somrak, Arkansas State University, USA

Integrating computer ethics into the computer science and computer engineering curricula
John Fodor, Educational Multimedia Resources, Inc., USA

How to Prepare Teachers for Integrating Multimedia and Technology into K-12 Classrooms
Barbara Foster, Spalding University, USA

A Catalyst for Collaboration: Supporting Technology in Teaching through Partnerships
Louis Fox, University of Washington, USA; Tom Lewis, University of Washington, USA; Scott Macklin, University of Washington, USA
Development and Implementation of Computerized Instructional Materials: The Mismatch Between Formal and Informal Technology Support Structures in a Medical College
Cynthia Frank, The University of Arizona, U.S.A.

Adapting an internet based learning environment to a hybrid approach
Katrin Franv, TU Dresden, Germany; Hagen Wadlig, TU Dresden, Germany; Olaf Neumann, TU Dresden, Germany

Health Issues for Human Computer Interaction in Electronic Learning Environments
Joy Fraser, Athabasca University, Canada; Pete Holt, Athabasca University, Canada; James Mackintosh, Simon Fraser University, Canada

Putting Curriculum in Control: Interactive Courseware Development with the TechDisc Instructional Design Template
Trink Friedrich, Senseware, Inc., United States; Bill Wann, Senseware, Inc., United States; Karen Korth, University of South Dakota, United States; Mike Hoadley, University of South Dakota, United States; Dan Eastmond, University of South Dakota, United States

Distance Learning Development Teams
Anthony Friesth, Thomas Jefferson University, USA

OCCA: Development of an Institutional Strategy for ‘Mass Customization’ of Online Learning
Paul Frisby, University of Melbourne, Australia; Robert Kemm, University of Melbourne, Australia

Virtual Reality Simulation of Reovirus
Denis Gadbois, University of Calgary, Canada; David Rittenhouse, Advanced Media for Learning, Canada; Dave Goulden, NTL Alliance, Calgary, Canada

Orienting Tasks to Enable Hypertext Learning
James Gad, University of Northern Colorado, USA

The Reflection Assistant: Investigating the Effects of Reflection Activities in Problem Solving Environments
Claudia Gama, University of Sussex, UK

Pedagogical and Instructional Modeling via On-line Assistants
Penny Garcia, University of Wisconsin/Oshkosh, USA

Designing Synchronous Interactive Learning Teleconferences: Digital Field Experiences At The Columbus Zoo, An Informal Science Contextual Setting
Tamara J. Garcia-Barbosa, The Ohio State University, USA; Andrea K. Balas, The Ohio State University, USA; Dr. Barbara S. Thomson, The Ohio State University, USA

A Split-Brain Humand Computer Interface
Gregory Garvey, Quinnipiac/Concordia University, USA/Canada

Using Virtual Reality to Assist Air Travelers With Disabilities
Clark Germann, Metropolitan State College of Denver, USA; Jane Breida, Metropolitan State College of Denver, USA

Gender and Race: The Accuracy of Internet Clip Art
Carol Gilley, University of Arkansas, USA; Elaine Terrell, University of Arkansas, USA

Implementing Interactive Multimedia Courses for the WWW Using Streaming and SMIL Technology
Themis Cinarasakis, University of Macedonia, Greece; Konstantinos Tarabanis, University of Macedonia, Greece; Flavio Samaras, University of Macedonia, Greece

Blazing Trails on the World Wide Web
Carine Glynn, Grinnell College, USA; Rade Heck, Grinnell College, USA; Sarah Luebke, Grinnell College, USA; Fire Where Authors, Grinnell College, USA

Establishing and Operating an Institutional Centre for Instructional Technology
Diane Goode, University of Western Ontario, Canada; Michael Clark, University of Western Ontario, Canada

How To Be Innovative Designing Educational And Interactive Environments For Children
Gloria Elena Gomez Escobar, University of Las Andes, Colombia
A New Education Framework Within IMS-Specifications
Antonio Gomez Skamieta, University of Murcia, Spain; Eduardo Martinez Gracia, University of Murcia, Spain; Pedro Garcia Lopez, University Rovira i Virgili, Spain

A Multimedia Matrix Model For Designing Instructional Strategies and Learning Experiences for Students of Human Movement Studies
Halima Goss, Queensland University of Technology (QUT), Australia; Graham Kerr, Queensland University of Technology (QUT), Australia

Information Literacy in a Virtual Environment: a Web-Based Approach
Ann Graftstein, CUNY-College of Staten Island, United States

Art and Technology in the Classroom: The Activities and Impact of a National Project.
Neal Grandgenett, University of Nebraska at Omaha, U.S.; Sherwood Dowling, National Museum of American Art, USA

Being Social in an Anti-Social Environment: Is Cooperative Learning Really Possible Using Computer-Mediated Communication?
Joseph Greggs, Jones International University, USA

Virtual Study Groups (VSG), an approach to networked collaborative learning
Monica Gutierrez, Open University of Catalonia (UOC), Spain; Ferran Gimenez, UOC, Spain; Thanasis Daradoumis, UOC, Spain; Joan Manel Marquez, UOC, Spain

Visual Navigation for the Curriculum Based Learning Process
Kathleen Gwo, University of Montreal, Canada; Claude Frasson, University of Montreal, Canada; Marc Kaltenbach, University of Montreal, Canada; Jan Gees, University of Montreal, Canada

A Comparison of Static and Dynamic Media Types for Process Oriented Learning Tasks
Silvia Gutermans Schur, Swiss Federal Institute of Technology, Zurich; Hans Joerg Zwembok, Swiss Federal Institute of Technology, Zurich; Holm Kneuser, Swiss Federal Institute of Technology, Zurich

Teaching Dynamics of Dairy Herd Health and Management
Claudia Hafirkamp-Wise, Cornell University, USA; Heather C Allore, Cornell University, USA; Yfyo T Grohn, Cornell University, USA; Linda D Warnick, Cornell University, USA

Expert Review at a Distance: A Hybrid Approach
David Halpin, Virginia Tech, USA; Al Byers, Virginia Tech, USA

Scenarios of a New Dimension of Learning by the Co-operative Structuring of Knowledge
Thorsten Hampel, University of Paderborn, Germany

Prototypical Development of Multimedia Explorations with Preventative Medicine as an Example
Thorsten, Hampel, University of Paderborn, Germany; Thomas von der Borch, University of Paderborn, Germany

Keep facilitatng pupils and English teachers appropriately
Bo Han, National Teachers' College Inner Mongolia, China

A Comprehensive Model for Improving Technology in Teacher Education
Robert (Bob) Hannafin, College of William and Mary, USA; Robert (Bob) Haney, College of William and Mary, USA

Interactive Analogy Learning from Visualizations
Steven Hansen, Auburn University, USA; N. Hari Narayanan, Auburn University, USA

Designing Interactive Learning Environments to include construction tools for personally meaningful artefacts
Barry Harper, University of Wollongong, Australia; John Hedberg, University of Wollongong, Australia; Rob Wright, University of Wollongong, Australia

Time-Expanded Audio For Learning
Kevin Harrigan, University of Waterloo, Canada

Mariner A 3-Dimensional Navigation Language
Janet Hartman, Illinois State University, United States; Joaquin Vila, Illinois State University, United States

Course Production Applying Object Oriented Software Engineering Techniques
Ronald Hassert, University of Luebeck, Germany; Huberta Kriegenburger, University of Luebeck, Germany; Michael Herzog, University of Luebeck, Germany

Cognitive Flexibility Hypertext and the Role of the Learning Task
Douglas M. Harper, Richard Stockton College, United States; David H. Jonassen, The Pennsylvania State University, United States; Roy Clariana, The Pennsylvania State University, United States

A Framework for Evaluating the Usability of Political Web Sites: Towards Improving Cyberdemocracy
Shahin Hasan, University of Strathclyde, Scotland; Feng Li, PhD, University of Strathclyde, Scotland

Assured Quality Strategies in Web-based Accredited Programs
Judy Lee, University of Central Florida, USA

Web-based Foreign Language Learning in a Cooperative Environment: The Effects of Ability and Group Composition on Reading, Writing, and Listening Comprehension
Minha Lee, Pusan National University of Education, Korea

Professional Development through Flexible Delivery
Geraldine Lejos, University of Wollongong, Australia

Training Students to Be Self-Learners in Educational Hypermedia and Technology Courses
Amy S. C. Leh, California State University San Bernardino, USA

Effective Use of Client-Server Software and Teaching Strategies in Online Courses
Amy S. C. Leh, California State University San Bernardino, USA; Laura Howell Young, California State University San Bernardino, USA

Integration of varied cognitive activities in a multimedia environnement : the PHYLOGENE example.
Dominique Lemme, Institut National De Recherche Pédagogique, France; Monique Dupuis, Institut National De Recherche Pédagogique, France; Jean-François Redet, Iafm De Versailles, France; Nasra Salmon, Institut National De Recherche Pédagogique, France

How does one evaluate the effectiveness of electronic learning in a South African context?
Cecil Leonard, University of the Western Cape, South Africa

Stepnet: quality newspapers and web-based learning in the Netherlands
Jan Leipelt, Meulenhoff Educatief, The Netherlands

Mathematical Statistics in the Net - The Pythagoras Learning Environment
Jarkko Leivaara, Tampere University of Technology, Finland

Towards a Design Methodology for Distributed Virtual Laboratories
Charles Levert, Ecole Polytechnique, Canada; Samuel Pierre, Ecole Polytechnique, Canada
Using Technology to Teach Linear Algebra
Lawrence Levine, Stevens Institute of Technology, USA

Towards an Intelligent Authoring Shell on Reuse
Kam Wing Li, University of South Australia, Australia; Warren James, University of South Australia, Australia

Understanding collaborative learning in CMC: A research in an elementary classroom.
Qing Li, University of Toronto, Canada

A meta-analysis of computer programming on cognitive outcomes: An updated synthesis
Yuen-Kuang Liao, National Hsinchu Teachers College, Taiwan, R.O.C.

A meta-analysis of gender differences on attitudes toward computers for studies using Loyd and Gressard's CAS
Yuen-Kuang Liao, National Hsinchu Teachers College, Taiwan, R.O.C.

The Art of Technology: The Technology of Art
Lay Lichtman, Victoria University, Australia

T2 - Planning and Managing Online Courses and Learning Resources
Andrew Litchfield, Macquarie University, Australia

The status of online professional development available to support higher education staff.
Andrew Litchfield, Macquarie University, Australia; Peta Spear, Macquarie University, Australia

e. Learning@mq: Staff Development to Integrate Online Media into Learning and Teaching at Macquarie University
Andrew Litchfield, Macquarie University, Australia

Supporting the millennium teacher: faculty development in the use of information and communications technologies
Allison Littlejohn, University of Strathclyde, Scotland

Exploring the Use of Virtual Multimedia Examinations in Teaching and Learning: Results from the Fielding Testing
Min Lin, University of Texas-Austin, USA; Erini Papathanasiou, Cyprus; Winnie Hsu, Univ. of Texas-Austin, USA; John Kappelman, University of Texas-Austin, USA

Custom-Authored Hypermedia Exercises for Use in College Classrooms
Amy Lobben, Central Michigan University, USA

Groupware Tools: Web File System Allows Students to Access Information Anywhere, Anytime
Tymne Lobo, Sitescape, Inc., Canada

Learner as designer-producer: Physical and health education students experience Web-based learning resource development
Lari Lockyer, University of Wollongong, Australia; Yvonne Kerr, University of Wollongong, Australia

The development of an on-line learning community of physical and health education professionals.
Lari Lockyer, University of Wollongong, Australia; Gregg Rowland, University of Wollongong, Australia; John Patterson, University of Wollongong, Australia

Intensive Ecommerce Business Training Course
Joe Luca, Edith Cowan University, Australia; Larry Quick, Dow Digital, Australia; Renee Ellis, Dow Digital, Australia

Teaching Information Literacy to Undergraduates: Stand-alone Courses or Across the Curriculum?
Barbara Lyman, Southwest Texas State University, USA

Using Virtual Reality in Teaching Secondary School Physics
Bruce Ma, City University of Hong Kong, Hong Kong; Peter Mak, STFA Tam Pak Yu College, Hong Kong

Distance Learning via Interactive Video Conferencing for the Small College: Pitfalls and Possibilities
Kate MacDonald, Massachusetts College of Pharmacy & Health Sciences, USA; Michelle Chapman, Massachusetts College of Pharmacy & Health Sciences, USA; Francis Rogers, Massachusetts College of Pharmacy & Health Sciences, USA; Lynne Sylvia, Massachusetts College of Pharmacy & Health Sciences, USA; James May, Massachusetts College of Pharmacy & Health Sciences, USA

A Game-play Intranet-based Multimedia Teaching Support System for Information Systems Training
Hung Yin Mak, Hong Kong Baptist University, Hong Kong SAR; Andrew Mallard, Brunel University, United Kingdom

A Web-based Hypermedia Pedagogical Course
Alia N. Makarova, St-Petersburg State Pedagogical University, Russia

Multimedia Performance-Based Language Assessment: The Computerized Oral Proficiency Instrument (COPI)
Valerie Malabonga, Center for Applied Linguistics, USA; Dorry Kenyon, Center for Applied Linguistics, USA
Combining Instructional Models and Enabling Technologies to Embed Best Practices in Course Instructional Design

Paul M. Malone, University of Waterloo, Canada; Catherine F. Sihryer, University of Waterloo, Canada; Vivian Rossner-Morrill, University of Waterloo, Canada

Phase Theory: A Teleological Taxonomy Of Web Course Management For Distance Education

Bruce Mann, Memorial University of Newfoundland, Canada

Divided Attention in Multimedia Learning

Bruce Mann, Memorial University, Canada; Paul Newbous, Edith Cowan University, Australia; Jeremy Page, Edith Cowan University, Australia; Alistair Campbell, Edith Cowan University, Australia

Info Pursuits

Kerrie Manning, Leichhardt High School, Australia; Rosemary Ward, UTS, Australia; Tony Ward, Award Consulting Enterprises, Australia

Reconfiguring the Academic Library for the New World of Learning

James Marwan, College of Staten Island, CUNY, USA

To teach remotely by controlling the didactic interaction of a student with a multiapplication environment

Nathalie Masseux, Auerere University Institute of Teacher Training, France

Content Area Integration: A Step Toward Emiratisation

Res H. McBride, Dubai Women's College, United Arab Emirates; Michael Ford, Dubai Women's College, United Arab Emirates; David Thomson, Dubai Women's College, United Arab Emirates; Raymond Yarrow, Dubai Women's College, United Arab Emirates; Laila Hawker, Dubai Women's College, United Arab Emirates

TRIAD: Tactical Readiness Instruction, Authoring, and Delivery

James McCarthy, Simayst, Inc., USA; Michael Haanafin, University of Georgia, USA; Terry Stannard, Klein Associates, USA; Jack Wayne, Simayst, Inc., USA; Paul Radtke, Naval Air Warfare Center Training Systems Division, USA

The Inadvertent Branding of a University Web-based

Kevin McClain, University of Virginia, USA

Evaluating the Influence of Web Based Seminar Preparation for Undergraduate History Students

Pauline McCormack, University of Newcastle upon Tyne, UK; Dr Donald A. Spaeth, University of Glasgow, UK

Using Instructional Technology: What do the students think?

Cynthia McCourt, George Mason University, USA; Sharon Alayne Widmayer, George Mason University, USA

Agents For Education: the Problem Of Synthetic Personality

Peter McKenna, Liverpool Hope University College, England; Atif Waraich, Liverpool Hope University College, England

The Total Student Experience

Patricia McNames, Indiana University Southeast, USA

Preparing Learners for Self-Regulation and Professional Practice: Design Recommendations

Catherine McLoughlin, University of New England, Australia; Barbara McCarthy, University of New England, Australia

Developing Professional Skills And Competencies In Tertiary Learners Through On-Line Assessment And Peer Support

Catherine McLoughlin, University of New England, Australia; Joe Luca, Edith Cowan University, Australia

Fostering teacher inquiry and reflective learning processes through technology enhanced scaffolding in a multimedia environment

Catherine McLoughlin, University of New England, Australia; John Baird, The University of Melbourne, Australia; Keith Pidgeon, The University of Melbourne, Australia; Maralyn Wooley, The University of Melbourne, Australia

Supporting constructivist learning through learner support on-line

Catherine McLoughlin, University of New England, Australia; Koos Winnips, University of Twente, Netherlands; Ron Oliver, Edith Cowan University, Australia

Developing Web-based Learning Strategies: a comparison between the Web and traditional learning environments

Mark McMahon, Edith Cowan University, Australia

Courseware Management Tools and Customised Web Pages: Rationale, Comparisons and Evaluation

Mark McMahon, Edith Cowan University, Australia; Joe Luca, Edith Cowan University, Australia

The distance educator's tool box: An overview of technologies for on-line learning

Thomas Fox McManus, Saginaw Valley State University, USA

High Tech Classrooms-Going The Distance with Distance Education

Patricia McNames, Indiana University Southeast, USA
Developing new roles for university teachers: Grass-roots local staff development serviced by top-down investment and policy
Carmel McNaught, RMIT University, Australia; Paul Kennedy, RMIT University, Australia

Collaborative links between distributed databases. Developing a framework for an inventory of computer-facilitated learning (CFL) materials across the higher education sector in Australia
Carmel McNaught, RMIT University, Australia; Rob Phillip, Murdoch University, Australia; Darren Rossiter, Queensland University of Technology, Australia; Jenny Winn, Queensland University of Technology, Australia

Dynamic Databases as Knowledge Construction and Communication Tools in Online Courses
Sara McNeil, University of Houston, USA; Bernard Robin, University of Houston, USA

Students' Perceptions of Self-Change During an Online Course
Sara McNeil, University of Houston, USA; Bernard Robin, University of Houston, USA

An on-line introduction to quantitative methods
Maira McPherson, Lakehead University, Canada; William Montefahl, Lakehead University, Canada

The third time is the charm: the evolving nature of web design
Martha Meacham, St. Edwards University, USA

Supporting Collaborative Telelearning Research using Server Logs
Oyvind Meistad, University of Bergen, Norway; Barbara Wasson, University of Bergen, Norway

Evaluating Hypermedia Systems, Models and Methodologies in Education
Emilia Mendes, The University of Auckland, New Zealand

A Study of the Use of Online Supported Learning Facilities at Charles Sturt University
John Messing, Charles Sturt University, Australia

The price a distance education student pays when using electronic learning resources
John Messing, Charles Sturt University, Australia

Principles of cognitive evaluation for an educational CD-ROM for history
Christina Metaxaki-Kassimides, University of Thrace, Greece; Eleonora Competa, University of Thrace, Greece; Stamvoulia Lidia, University of Athens, Greece; Georgios Koymenokaky, University of Athens, Greece

Authoring Multimedia, Designing Animations for Physics Education
Donald J. Metz, University of Winnipeg, Canada

Dynamic Communication Layer Between Virtual Laboratory and Intelligent Agents
Kaufmann Mendi, Université de Sherbrooke, Canada; Roger Nkambou, Université de Sherbrooke, Canada

One teacher, one text, four lessons: a case study of collaboration and innovation in a multilingual New Zealand classroom.
Duncan Meyer, Long Bay College, New Zealand; Glenda Jacobs, UNITEC, New Zealand

Description of a web-based program suitable for easy adaptation for on-line delivery of many educational resources.
Geoffrey Meyer, University of Western Australia, Australia

Telematic Education in Nursing Education
Salome Meyer, University of Pretoria, South Africa; Salome Meyer, University of Pretoria, South Africa

A Rule-based Method to Shift between Learning Protocols
Yongwu Miao, GMD German National Research Center for Information Technology, Germany; Jörg Haake, GMD - German National Research Center for Information Technology, Germany; Ralf Steinmetz, GMD - German National Research Center for Information Technology, Germany

Design, Delivery, and Evaluation of Online Courses: A Primer
Jenild Miller, United States International University, USA

Discovering xyAlgebra: Intelligent Interactive Internet Instruction
John Miller, The City College of CUNY, USA

Technology Acculturation Among Adolescents: The School And Home Environments
Leslie Miller, Rice University, USA; Heidi Schweingruber, Rice University, USA; Christine Brandenburg, Rice University, USA

Problem-based Learning and Flash 4.0: An Experiment in Science Education
Leslie Miller, Rice University, USA; Janice Meyers, Rice University, USA; Donna Smith, Rice University, USA

On-Line Education Using Video Broadcasting Delivered from Perth Campus, Algonquin College
Maika Laikhen Miller, Algonquin College, Canada; Dave Osborne, Algonquin College, Canada; Ian McCormick, Algonquin College, Canada

Unlocking the Gates of the Kingdom: Designing Web Sites for Accessiblity
Steven C. Mills, University of Kansas, USA
Gender and instructional use of computers
Amanda Mitra, Wake Forest University, USA

From Brawn to Brain: Towards an Emerging Minds-on Approach in Integrated Distributed Learning Environments (IDLE)
Marja Mononen-Autioinen, University of Helsinki, Finland; Seppo Tella, University of Helsinki, Finland

Using Scenarios to create a CAL Design Method
Michelle Montgomery Masters, University of Glasgow, UK

TLC: Teachers' And Learners' Collaborascope – A Platform For Analysing And Evaluating Online Education
Michelle Montgomery Masters, University of Glasgow, UK; Stewart Macmillan, University of Glasgow, UK; Prof Malcolm Atkinson, University of Glasgow, UK

Educational Multimedia Systems for Students with Autism
David Moore, Leeds Metropolitan University, UK; Paul McGrath, Leeds Metropolitan University, UK; John Thorpe, Leeds Metropolitan University, UK

Meaningful Design for Meaningful Learning: Applying Cognitive Theory to Multimedia Explanations
Roxana Moreno, University of California, Santa Barbara, USA; Richard Mayer, University of California, Santa Barbara, USA

Life-Like Pedagogical Agents in Constructivist Multimedia Environments: Cognitive Consequences of their Interaction
Roxana Moreno, University of California, Santa Barbara, USA; Richard Mayer, University of California, Santa Barbara, USA; James Lester, North Carolina State University, USA

Why don't we weight them?
Jack E. Morin, The University of Calgary, Canada; Janice Bakal, The University of Calgary, Canada

The third dimension for world of knowledge: an acceptable way to get in.
Mikhail Morozov, Mari State Technical University, Russia; Aleksander Markov, Mari State Technical University, Russia

Using Mobile Computer Technology and Internet Tools to Promote Constructivist Teaching
Chryzella Mowrz, Columbia University, USA

Distributed Repository of Programming Examples
Tomasz Miedlener, Acadia University, Canada; Vicky Shin, Acadia University, Canada

Finding out the intention of a user of Educational Hypermedia
Duncan Muller, Leeds Metropolitan University, England; David Hobbs, Leeds Metropolitan University, England; David Moore, Leeds Metropolitan University, England

Learning Legal Case Solving with the Computer Program PROSA
Antoinette J. Muntjewerff, University of Amsterdam, The Netherlands

Role Play, Discussion, and Analysis: Project-based Learning in a Web-based Course
Karen Murphy, Texas A&M University, USA; Yakut Gazi, Texas A&M University, USA

Representing Oral Traditions through Interactive Multimedia - an example from Hindustani Classical Music
John Myers, Simon's Rock College, USA

Difficulties Students are Having with Cognitive Processes in Problem Based Learning Environments.
Sean Naidu, The University of Melbourne, Australia; Iain McAlpine, The University of Melbourne, Australia

Scaffolding Student Learning in Information-Dense Technology-Enhanced Teaching and Learning Environments
Sean Naidu, The University of Melbourne, Australia; Mike Keppel, The University of Melbourne, Australia; Gregor Kennedy, The University of Melbourne, Australia

Ability grouping for teaching computer literacy classes
Michin Nakamichi, Osaka University, JAPAN; Akira Harada, Osaka University, JAPAN

Scenario Building to Design a Distance Learning Program
Lisa Need, EDS, USA

Using a Web Site to Increase Student Motivation to Write and Enhance the Reading/Writing Relationship
Susan Nelson, Elm Street Elementary School, USA; Harrison Yang, State University of New York at Oswego, USA

Learner Engagement in Mixed-Mode Delivery Models
John C. Nesbit, Technical University of British Columbia, Canada
Increasing interaction through computer-mediated communication in distance education
Kook-chi NG, The Open University of Hong Kong, Hong Kong SAR, China

Initiating and Sustaining Collaboration in Technology: Critical Elements
Paula Nichols, Lamar University, U.S.A.; Stephanie Yearwood, Lamar University, USA

SMILE: Giving Internet Instruction a Human Face
Matthew Nickerson, Southern Utah University, USA

TELSI, Web-based software for collaborative learning
Gunnlaug Nistad, Norwegian State Center for Adult Education, Norway; Bo Aslaksen, Majorna Vuxengymnasium, Sweden; Åsa Ström, Undervisningsministerium, Denmark

Development of Speech Input System for Web-based Courseware
Ryuichi Nishimura, Nara Institute of Science and Technology, Japan; Shoji Kajita, Nagoya University, Japan; Kazuya Takeda, Nagoya University, Japan; Fumitada Itakura, Nagoya University, Japan

Integrating Learning agents in a virtual laboratory
Roger Nkambou, Université de Sherbrooke, Canada; Van Laporte, Université de Sherbrooke, Canada

SGML Based Course Development: Balancing Instructional Design and Technological Requirements
Selig Norman, Open Learning Agency, Canada

A Framework for Generating Non-trivial Interactive Mathematical Exercises in the Web: Dynamic Exercises
Ossi Nykänen, Tampere University of Technology, Finland

CoCoA2: Computer Supported Collaborative Language Learning Environment Based on Online Proofreading
Hiroaki Ogata, Tokushima University, Japan; Yosuke Hada, Tokushima University, Japan; Yoneo Yano, Tokushima University, Japan

A Case Study of Student Tool Use During Hypermedia-Based Problem Solving
Kevin Oliver, Virginia Tech, USA

The Instructional Portal Project
Kevin Oliver, Virginia Tech, USA

Exploring the Development of Students’ Generic Skills Development in Higher Education Using A Web-based Learning Environment
Ron Oliver, Edith Cowan University, Australia; Jan Harrington, Edith Cowan University, Australia; Catherine McLaughlin, University of New England, Australia

The ANTA Flexible Toolbox Project: Developing Sustainable and Scalable Online Learning Materials for Vocational Education and Training
Ron Oliver, Edith Cowan University, Australia; Stephen Towers, Queensland Open Learning Network, Australia; Nick Pearl, Australian National Training Authority, Australia

Information and Communications Technology Literacy – Getting serious about IT
Ron Oliver, Edith Cowan University, Australia; Stephen Towers, Queensland Open Learning Network, Australia; Helen Oliver, Edith Cowan University, Australia

Assessment of online interaction: helping or hindering the goals of educators and learners?
Meg O’Reilly, Southern Cross University, Australia

Commercialization of Higher Education
Dan O’Shea, YouthStream Media Networks

Integrating and Adapting Multimedia Resources
Mary Panko, UNEITEC Institute of Technology, New Zealand

DISCETECH–BIMBOTECH an experimental project for introducing innovative technology within the Italian school system
Paolo Paolini, Politecnico di Milano, Italy; Pierluigi Della Vigna, Politecnico di Milano, Italy; Francesca Colina, Politecnico di Milano, Italy; Paolo Masotti, Politecnico di Milano, Italy; Silvia Mocola, Politecnico di Milano, Italy

Added value services on the Greek Web for schools
Georgios Papadopoulos, Hellenic Pedagogical Institute, Greece; Michalis Karanamis, Hellenic Pedagogical Institute, Greece; Petros Rassias, Hellenic Pedagogical Institute, Greece

Explora: An Open Virtual Campus
Gilbert Paquette, Télé-université, Canada; Ileana De la Teja, Télé-université, Canada; Audé Dufresne, Université de Montréal, Canada

Multiple Representations in Interactive Learning Environments: two Case Studies
Alan Parkes, Lancaster University, UK; Konstantinos Drakakis, Lancaster University, UK; George Marcello, Lancaster University, UK
A Multi-Method Strategy for the Assessment of Adult Literacy Software
Graham Passmore, University of Toronto, Canada; Wayne Lawstuck, McMaster University, Canada; Geoffrey Rockwell, McMaster University, Canada; Sandy Shaw, McMaster University, Canada

World Wide Web Course Delivery in Developing Countries: A South African Perspective
Shaun Pather, University of Durban Westville, South Africa; Geoff Erwin, University of Durban Westville, South Africa

Students' engagement behaviours in computer-assisted mass lectures
Nopporn Pausarvarrd, James Cook University, Australia; Lynette Henderson, James Cook University, Australia

The Essen Learning Model - a Multi-Level Development Model
Jan M. Pauwelski, University of Essen, Germany

Online Conferencing: Variations on Structure and Participation
Pingyi Peng, University of Missouri-Columbia, USA; Gail Fitzgerald, University of Missouri-Columbia, USA; Louis Semran, Arkansas State University, USA

A Constructivist Framework for WWW-based learning Environments that Combine Streaming Media and WWW functionalities
Oscar Peters, University of Twente, The Netherlands; Betty Collis, University of Twente, The Netherlands

Choosing the Tools Wisely: Learning the Lessons the Hard Way
Denise Peterson, South Dakota State University, US; Lea Romerom-Holmes, South Dakota State University, US

Microsoft Office as a Learning and Teaching Tool
Craig Plant, Acadia University, Canada; Michael Shaw, Acadia University, Canada

An XML-based Approach for Web-based Self Assessment
Nathalie Poesio, FerrnUniversitaet Hagen, Germany; Bernd Kraemer, FerrnUniversitaet Hagen, Germany

A Learning Experiment Using A&O Open Learning Environment
Seppo Poijolaainen, Tampere University of Technology, Finland; Heikki Raaham, Tampere University of Technology, Finland; Ossi Nykäinen, Tampere University of Technology, Finland; Kaija Pohonen, Tampere University of Technology, Finland; Veera-Matti Harhikainen, Tampere University of Technology, Finland

Students' expectations and perceptions of efficacy for self-regulated learning in mediated learning environments: Partial results of an evaluation
Laura Helena Porras, Universidad de las Americas, Puebla, Mexico

Getting Published in the Field of Instructional Technology
Robert V. Price, Texas Tech University, USA; Nancy Maushak, Texas Tech University, USA

An Online Model For Precalculus
Hari Puspaka, Valdosta State University, USA; Denise Reid, Valdosta State University, USA

The TOMUS model of multimedia: an empirical investigation
Helena C. Purchase, The University of Queensland, Australia; Daniel Naumann, The University of Queensland, Australia

IMAGUS: An Environment To Design Video Applications For Digital Libraries
Andre Luis Alves Baschi, Pontificia Universidade Catolica do Rio Grande do Sul, Brazil; Lucia Maria Martins Giraffa, Pontificia Universidade Catolica do Rio Grande do Sul, Brazil

Narrative and Visual Design of Web-based Learning Materials
Andy Reilly, The Open University, United Kingdom; Alison George, The Open University, United Kingdom

Art, Poetry, and Instructional Media
Thomas Reimertz, Rosemount High School, USA; Brad Hokanson, University of Minnesota, USA

Didactical Activities and Strategies in the Use of WWW-based Course-Support Environments: Design Guidelines for Instructors
Elke Remmers, University of Twente, The Netherlands; Betty Collis, University of Twente, The Netherlands

From the "Invisible Web" to Google: Techniques for Improving Web Searching
Judie Repton, Georgia Southern University, USA; Randal Carson, Georgia Southern University, USA; Elizabeth Down, Georgia Southern University, USA; Kenneth Clark, Georgia Southern University, USA

Moving an Australian Dual Mode University to the Online Environment: A Case Study
Shirley Reocho, The University of Southern Queensland, Australia; Jacqueline McDonald, The University of Southern Queensland, Australia

Learning Code
Suzanne Rhodes, Human Code, USA

An Empirical Test On The Use Of Directed World Wide Web Navigation Guidance
David Ribeiro Lamas, Universidade Fernandes Pessoa, Portugal; Jennifer Ferrums-Smith, University of Portsmouth, UK; David Heathcote, Bournemouth University, UK; Pedro Ribeiro Gomes, Universidade Fernandes Pessoa, Portugal
A Java-Based Hypermedia Framework for Delivering Fluid Power Training via the Internet
Thomas Richard, University of Bath, United Kingdom; Edmund Hughes, University of Bath, United Kingdom; Derek Tilley, University of Bath, United Kingdom

The Affordances and Constraints of Asynchronous Learning Networks: Looking at Interaction in an Online Learning Environment
Jennifer Richardson, Empire State College, USA; Craig Tunwall, Empire State College, USA; Carol Carnwath, Empire State College, USA

Evaluating Software for the New Millennium: An Example from Project Links
Jennifer Richardson, University at Albany, USA; Karen Swan, University at Albany, USA; Dianna Newman, University at Albany, USA

How to Make the Most of Online Interaction
Jennifer Richardson, University at Albany/SUNY, USA; Karen Swan, University at Albany/SUNY, USA

CAMPUS: An innovative Web-based approach for simulative, flexible, case-oriented education in Medicine
Jeni Riedel, University of Heidelberg, Germany; Reiner Singer, University of Heidelberg, Germany; Franz Josef Lehen, University of Heidelberg, Germany; Heiko Geitz, University of Heidelberg, Germany; Burkhard Toenshoff, University of Heidelberg, Germany

Students as Producers: Changing the Way we Teach and Learn
Gail Rung, University of Florida, USA; Sebastian Fusi, University of Florida, USA; Melissa McCullister, University of Florida, USA; Tamara Pearson, University of Florida, USA; Elbaum Al-Khamees, University of Florida, USA

Meaningful Learning in a Virtual University by Using High Speed Internet Connections
Raija Rinne-Filipula, CERN, Switzerland; Anne-Maria Korhonen, CERN, Switzerland

The GPB project: A successful PhD seminar using Videoconference in real time and a list to communicate between the classes
Claire Regege, University of Quebec in Montreal, Canada

Teaching Image Ethics in Multimedia Programs
Paula Roberts, University of South Australia, Australia; Jenny Webber, University of South Australia, Australia

Report on Learning Technology Standards
Rahm Robson, Oregon State University, USA

Evaluating the effects of web-based collaboration in a distance education program
Paul Rades, Indiana University, Bloomington, USA; Hyun Chung, Indiana University, Bloomington, USA; Carrie Chapman, Indiana University, Bloomington, USA; Dennis Krajczynski, Indiana University, Bloomington, USA

Instructional Design Agents - An Integration of Artificial Intelligence and Educational Technology
Erika Rogers, California Polytechnic State University, USA; Carol Schoett, California Polytechnic State University, USA; Emilia Pasic, California Polytechnic State University, USA; Sharon Lanaghan, California Polytechnic State University, USA

Automating Online Course Evaluations Over the WWW
Guido Rolliro, University of Siegen, Germany; Bernd Freisleben, University of Siegen, Germany

Mathematical Abilities and Development of Mathematical Word Problem-Solving Skills in a Technology-Based Learning Environment: Methods and Main Results
Heikki Ruokamo, Tampere University of Technology, Finland

The design, development and implementation of education in Edubox (r)
Eileen Rasmussen, Open University of the Netherlands, The Netherlands; Peter B. Stolpe, Open University of the Netherlands, The Netherlands

Is computer-mediated communication (CMC) really open and flexible?
Malcolm Ryan, University of Greenwich, UK

You CAN Get There From Here - Developing Assessments from Skill Standards
Peter Saltland, Bellevue Community College, USA; Lauren Herbs, The Chauncey Group International, Inc, USA

A distributed notebook system for vocabulary learning
Tomoaki Sagioka, University of Electro-Communications, Japan; Tsunio Minakata, Tamagawa University, Japan; Kazuya Hasegawa, University of Electro-Communications, Japan

Collaborative Hybrid CD-ROM/Internet in a "Learning by Doing and Creating" environment
Nicolella Sala, Academy of Arts, University of Applied Science, Switzerland, Switzerland

Multimedia Training, Virtual Instrumentation and Remote Laboratory a New Approach to the Electronic Courseware
Nicolella Sala, Academy of Arts, University of Applied Science, Switzerland, Switzerland

BEST COPY AVAILABLE
A Case Study on Building an Organizational Learning and Information Support System (OLISS)
Mark Salisburg, University of New Mexico, USA; Jan Plais, University of New Mexico, USA

Developing and Evaluating an On-line Cross Cultural Collaborative Course
Adrian Salas, Auckland University of Technology, New Zealand; Jenny Bryar, Auckland University of Technology, New Zealand; Grant Carran, Auckland University of Technology, New Zealand

A Study of Usability Evaluation for Interactive Computer Mediated Teletraining Systems
Francois Sandoz-Guermou, INSA, France; Gerard Benchet, INSA, France

Methodological Resources Assistant: How To Apply Instructional Design To Our Web-Based Materials
Albert Sangra, Universitat Oberta De Catalunya, Spain; Andreu Bellot, Universitat Oberta De Catalunya, Spain; Josep Duart, Universitat Oberta De Catalunya, Spain

Teaching and learning in a virtual campus: The model of the Universitat Oberta de Catalunya
Albert Sangra, Universitat Oberta De Catalunya, Spain; Lourdes Guardia, Universitat Oberta De Catalunya, Spain

Rethink Education: How we make our learners instructors
Sisa Santama, Delft University of Technology, The Netherlands; Ralph Gemang, Delft University of Technology, The Netherlands

Cooperation Model for Learning: A System of Patterns
Flávia Santoro, Universidade Federal do Rio de Janeiro, Brazil; Marcus Borges, Universidade Federal do Rio de Janeiro, Brazil; Nuno Santos, Universidade do Estado do Rio de Janeiro, Brazil

Initiating Constructivist Learning Strategies Through Computer Generated Concept Mapping
F. Thomas Scaife, King's College, USA

Austrian Literature Moving to Cyberspace – A Framework for Building an Open Distance Learning Website using Platform Independent Standards Like XML
Alexander Sbath, Vienna University of Technology, Austria; Klaus Zelkowitz, University Salzburg, Austria; A Min Tja, Vienna University of Technology, Austria; Johann Stockinger, Ministry for Science, Austria

Technological tests of educational theories: A research role for the Generative Virtual Classroom
Lynette Schavemaker, University of Technology, Sydney, Australia

Certifying Technological Proficiencies of K-12 Teachers
Carol Schäfer, California Polytechnic State University, San Luis Obispo, USA

Support Environment for Distributed Case Studies
Manfred Schöttler, University of Erlangen-Nuremberg, Germany; Freimut Bodendorf, University of Erlangen-Nuremberg, Germany

Organisation, collaboration and learning: Shaping education and learning in virtual environments
Friedrich Scheuermann, University of Innsbruck, Austria; Ken Larsson, Stockholm University/KTH, Sweden; Roxanne Torn, The Pennsylvania State University, USA

Flaming, Banter, and Bonding: Understanding the Rhetoric of Electronic Groups
Rae Schöke, Central Connecticut State University, USA

Strategies for Teaching and Learning: Lessons Gained from an Ethnography of Graduate Classes in an Interactive Distance Learning Studio
Lorraine C. Schmerling, University of West Florida, USA; Richard W. Schmerling, Valdosta State University, USA

From Student Needs to Instructor Roles: An Ethnographic Viewpoint
Richard Schmerling, Valdosta State University, USA; Lorraine Schmerling, University of West Florida, USA

Creating an On-line MBA Program
Robert Schramm, University of Wisconsin-Whitewater, USA; Roger Yin, University of Wisconsin-Whitewater, USA

Introduction of a New Media Concept for a Teaching Profession Degree in Computer Science: A Formative Evaluation
Axel Hunger, Gerhard Mercator University Duisburg, Germany; Stefan Werner, Gerhard Mercator University Duisburg, Germany; Andre Brüser, Gerhard Mercator University Duisburg, Germany; Frank Scharrer, Gerhard Mercator University Duisburg, Germany

Use of Telecommunications Technology in Radiation Accident Simulation
Domenic Soma, Boston University School of Medicine, USA; Kirsten Levy, Boston University School of Medicine, USA; Erwin Hirsh, Boston University School of Medicine, USA; Richard Agbabian, University of Massachusetts Medical School, USA; Tracey Razou, Boston University School of Medicine, USA

Building and Transforming Educational Web Sites with SATIRIC and Contextual Patterns
Jared Seaman, Grinnell College, USA; Vivek Venugopal, Grinnell College, USA; Samuel Rabelsky, Grinnell College, USA
Teaching data analysis using thin client technology for remote access
Robert Seidman, San Diego State University, USA; K. Michael Peddercore, San Diego State University, USA

Developing an Educational Multimedia Digital Library: Content Preparation, Indexing, and Usage
P. P. Tempel, University of Maryland, USA; B. R. Allen, University of Maryland, USA; A. Ross, University of Maryland, USA

NSA Partnership With Cal State L.A.: Courseware Conversion And Evaluation Project
Penelope Semrau, California State University, Los Angeles, USA; Barbara Boyer, California State University, Los Angeles, USA

Computing Environments For Metalearning: Interconnecting Hypermedia Concept Maps
Perla Señas Señas, Universidad Nacional del Sur, Argentina; Norma Moroni, Universidad Nacional del Sur, Argentina

The Internet Chemistry Set: Web-based remote laboratories for distance education in chemistry
Fred Sensee, Frostburg State University, USA; Chris Bender, Frostburg State University, USA

Educational Technology And Its Terminology: New Developments In The End Of The 20th Century
Peter SereinthoP, University of Utah, USA

Multifunctionality Of Educational Technology Applications
Peter SereinthoP, University of Utah, USA

Student Satisfaction and Perceived Learning in Internet-Based Higher Education
Peter Shea, State University of New York, USA; Eric Frederickson, State University of New York, USA; Alexandre Picetti, State University of New York, USA

A Distance-Learning Model Based on Web Mining
Ruijun Shen, Jiaotong University of Shanghai of PRC, China; Qijun Wang, Jiaotong University of Shanghai of PRC, China

Deploying Web-Based Assessments
Eric Shephard, Question Mark Corporation, USA

Scenario-based prototyping: a user-centered method for the design of CALL systems
Jian-Eun Shin, University of Manchester, UK; David G. Wastell, University of Manchester, UK

Flexibility and Facilities in Children's Electronic Textbooks
Norziahbhaibah Shirahuddin, University of Strathclyde, Scotland; Utara Malaysia, Malaysia; Monica Landoni, PhD, University of Strathclyde, Scotland

Multimedia Guide to Fractal Geometry
Vladimir Shchuk, Belarusian State Pedagogical University, Belarus

Project-Based Learning + Multimedia: Adding Value to Students' Education
Michael Simonini, Silicon Valley Network, USA; William R. Penuel, SRI International, USA

The Search for the Skunk Ape: An Information Literacy WebQuest
Charlotte Slater, The Walden Institute, USA; Pamela Sasseville, Florida Gulf Coast University, USA

What Is So Revolutionary About The Internet In Education?
Peter B. Sloep, Open University of The Netherlands, The Netherlands; Eileen Russman, Open University of The Netherlands, The Netherlands

Online Learning in a 3-D Robotics Workshop: The NASA ROVer Ranch
Stephanie Smith, NASA/LinCom, USA

OATS: Operational Amplifier Tutorial Simulation; a dynamic presentation
Sarah Sneederman, Concordia University, Canada; Gary Boyd, Concordia University, Canada; George Joo, Concordia University, Canada

Online Mentoring - A Case Study Involving Cognitive Apprenticeship and a Technology Enabled Learning Environment
Kathleen Snyder, IBM T.J. Watson Research Center, USA; Robert Farrell, IBM T. J. Watson Research Center, USA; Norma Baker, Project Executive Programs and Support, IBM Corporation, USA

The NURAXI Web-based learning environment architecture
Lorenzo Sommaruga, Mediatech S.r.l., Italy; Nadia Catenacci, Mediatech S.r.l., Italy; Sylvain Girodon, CRS4, Italy; Claude Moulin, Mediatech S.r.l., Italy

The Munchhausen-Trick: Learning Internet by Internet
Ralfh Steg, TU Chemnitz, Germany; Dietrich Thie, TU Chemnitz, Germany

An Online Environment that Scaffolds Moving from Novice to Expert Collaborative Learners
Joseph B. South, Brigham Young University, USA; Laurie Miller Nelson, Brigham Young University, USA; The Digital Learning Environment Research and Development Group, Brigham Young University, USA
How to show Web pages for learners: Teaching and Learning with Web Recorder

Toshio Sogno, IBM Research, Japan; Chie Ohkawa, Tamagawa Gakuen, Japan; Yoshinori Aoki, IBM Research, Japan; Yoshiharu Masuda, IBM Japan, Ltd., Japan; Amane Nakagawa, IBM Research, Japan

In defence of 'shovelware': A powerful tool in staff development for online teaching and learning

Heather Sparrow, Edith Cowen University, Australia; Jan Harrington, Edith Cowen University, Australia; Tony Hemington, Edith Cowen University, Australia

Evaluating the Impact of System Dynamics Based Learning Environments

Abstract: Scholars have been predicting a revolution in the academic publishing world since the early 1990's, including university centered distribution, extensive online peer review, and innovative multimedia enhancements. Online journals have indeed proliferated, yet interactive multimedia electronic journals (imej journals) have not yet become widespread, nor have they approached their potential for scholarly communication. In this article, we discuss the obstacles in the way of imej journals for academic publication, predict some technological changes that should hasten their adoption, and argue for their promotion as an excellent forum for disseminating, verifying, and refining scholarly research.

1. The Predicted Revolution in Scholarly Publication

For over a decade, academics have been predicting a revolution in scholarly publication. In 1991 Ann Okerson, then Director of the Office of Scientific and Academic Publishing of the Association of Research Libraries, concurred with the growing opinion that paper journals were becoming obsolete, advocating a "university-based system into which scholars from all disciplines would place their findings" (Okerson 1991). Andrew Odlyzko of AT&T Research Labs predicted the "impending demise of traditional scholarly journals" (Odlyzko 1995) while Princeton's Stevan Harnad advocated a system of "scholarly skywriting in the post-Gutenberg galaxy," where academics would share, critique, and add to each other's findings in an electronically-accelerated process of research and publication (Harnad 1990, 1997). A number of models for network-based electronic publishing were proposed, generally envisioning university-centered distribution, lower publication costs, 24-hour computer access to documents, faster review processes, a hierarchy of publication stages according to the level of peer review, extensive online discussion and updates, powerful search techniques, and multimedia enhancements (Bailey 1994). Though no single publication model has dominated the scene, many of these changes have been evolving. Certainly, the number of online journals has exploded in the past ten years, with initiatives like Project Muse, JSTOR, Project Gutenberg, ACM's Digital Library, OCLC, Springer Link, Ginsparg's preprint library, and on and on.

Nevertheless, a closer look at existing online journals shows that they fall short of the predictions. Online academic journals (that is, those that have no traditional print counterparts) do not enjoy the acceptance and respect that would make them competitive with hard copy publications. Nor have electronic journals taken advantage of the added value and marketable difference that multimedia enhancements could offer. Were the predictions overblown, or must we simply be patient for changes that will inevitably come? What is the state of the art in interactive multimedia journals for academia, and what can we hope for in the next ten years?

2. Today's Multimedia Journals

Let us first put our interest in online multimedia publication in context. In 1998, The IMEJ of Computer-Enhanced Learning -- an interactive multimedia electronic journal -- was founded at Wake Forest University, spurred by the university's campus-wide distribution of laptop computers and a growing interest in educational technology. Our belief was that imej journals (pronounced "image") have much to offer to education and scholarship, and we wanted to see by our own experience if this publication model was viable. We envisioned a journal that seemed ideal for the subject of computer-enhanced learning, where readers with
practical questions about the value of technology in education could see and experiment with what others have done -- trying out simulations, taking sample quizzes, manipulating 3-D images, and hearing teachers explain their pedagogical innovations in their own words. In the two years since the journal's inception, we have been monitoring the growth of interactive multimedia publications in academia and evaluating our own attempts to produce a journal that lives up to our vision for online scholarly publication.

Our most recent informal search of existing electronic journals shows that, although the word multimedia is used generously to describe online publications, there is still relatively little real multimedia development, particularly of the interactive sort. Nearly all journals that describe themselves as "multimedia" have only tables, graphs, and pictures, and the term interactive generally implies the ability to post comments to authors on a bulletin board, the availability of email popup windows, the use of hyperlinks to related subjects, and occasionally the linking of footnote numbers to the footnotes at the end of the paper.

We expected to find a good amount of multimedia material in scientific and medical publications, where the usefulness of 3-D images and simulations is easy to imagine (Eason et al. 1997) (Wilkinson 1998), but our findings were disappointing. The Springer Link electronic library (www.link.springer.de) has an extensive collection of scientific journals and marks each with a symbol indicating where supplementary electronic material is included. However, a sampling of these revealed mostly .pdf and image files, a number of videos, and only one rotating molecule as an example of interactivity. The Royal Chemical Society's Web site (www.rsc.org/is/journals/1.htm) similarly marks its journals containing supplementary electronic material, but once again we found only image and document files. McGill University has a site for The Online Journal of Cardiology (www.mnmp.mcgill.ca) with links to teaching videos, a Virtual Stethoscope, online quizzes, and moving Xray images, but all this material appears to be their own production rather than submitted research publications. Among the journals we found, two with a significant multimedia interactivity were the Internet Journal of Chemistry (IJC, www.ijc.com) and the Radiology Society of North America Electronic Journal (RSNA EJ, http://ej.rsna.org ). IJC lists its multimedia element under a separate link, categorizing them as images, interactive chemical structures, interactive graphs, movies, etc. From this list of categories there are links to the articles containing the multimedia enhancements. RSNA EJ contains a number of animated radiology images using video, VRML, or Java-based simulations.

Multimedia has possibilities in the humanities as well. A few music journals such as EOL (Ethnomusicology Online, http://research.umbc.edu/efhm/eol.html) take advantage of sound files. In the creative vein, some journals exploring interactive narrative and art have sprung up, such as Cultronix (http://english-www.hss.cmu.edu/cultronix/) at Carnegie Mellon or Labyrinth at the University of Southern California (www.annenberg.edu/labyrinth). But overall, it is difficult to find examples of the type of journal predicted since the early 1990's. Even The Journal of Interactive Media in Education (http://www-jime.open.ac.uk), an early and well-produced entry into the field of multimedia publication, appears to be backing away from multimedia interactivity in recent issues. Its 1999 volume has only one article marked as containing an interactive element, as opposed to seven in 1998. Admittedly, our survey was informal and necessarily incomplete. We invite our readers to let us know of examples of interactive multimedia that we may have missed. Our intent is not to indict the quality of the journals mentioned here, but instead to raise our central questions: Have we expected too much too soon in imej journals? What are the obstacles to their development, and will they eventually be overcome?

3. Obstacles in the Way of imej Journals

The obstacles in the way of the success of imej journals are both technical and human. On the technical side, the problems include bandwidth limitations, the speed of technological change, and compatibility issues. To be widely accepted, imej journals must be more user-friendly than they currently are. Videos are still too small (in display size), too jerky, and too long to download, especially for readers accessing electronic journals through modems. The adoption of cable modems, DSL, and faster network connections in our homes, along with improved compression, streaming media delivery, dedicated media servers, and bandwidth load balancing will eventually bring the technology up to user expectations.

Standardization issues may take longer to resolve, and the phenomenon of rapidly-evolving technology will leave vestiges of obsolete platforms in archived online journals. In our first issue of IMEJ, for example, we used VRML requiring Cosmo Player for viewing, an already obsolete medium. The Java language continues to evolve month-by-month, requiring constant upgrades to the plug-in. Despite the best efforts of an
Some of the most attractive and fastest-evolving multimedia features are the very ones where standardization has not settled in, including audio/visual media delivery and dynamic HTML. In the media player wars, Internet Explorer and Netscape have still not reconciled to a common way of handling Java security and DHTML. The adoption of the W3C standard and the next version of both browsers will bring them closer to this goal (www.webstandards.org/dhtml.html). In the meantime, it is feasible, though time consuming, to offer multimedia supplements in multiple platforms to accommodate as many readers as possible.

Clearly, the technical obstacles are challenging, but we believe that they can and will be overcome. The human problems, as one might expect, may be more difficult to solve. The user-compatibility issue is complicated by the fact that production of an article in an imej journal, in the final stages, is a collaborative work between the authors and the journal's multimedia developers. Even if a journal adopts multimedia and browser standards to serve the greatest number of readers -- or better yet, if multimedia elements are offered in a choice of all commonly-used platforms -- the journal's multimedia developers must get the raw material from the authors. From our experience at The IMEJ of Computer-Enhanced Learning, we have seen that authors generally work on their accustomed platforms with their favorite tools, and they prefer to give us multimedia material they have already prepared or that they can prepare easily in their usual manner. One author gives us a Lotus ScreenCam file, a second provides a video, and a third author sends a PowerPoint presentation. In this setting, it is all the more difficult to set production standards or offer multiple versions. Authors are also understandably particular about how their work is transformed by multimedia additions. The author and editor/multimedia developer may have a different view of the article, and what one might consider a multimedia enhancement, the other might consider superfluous.

The last obstacle is the Catch 22. Generally, the scholars who have the best material to offer to imej journals are reluctant to publish in them because they fear electronic publications will be considered minor league by their colleagues. But at the same time, imej journals cannot enter the major leagues until they attract better quality publications. How do we find our way out of this dilemma? We see some possible remedies, but they can only work over time.

As computer use becomes the norm in the academic world, and as programs for media production become more user friendly and better standardized, some of the production problems of imej journals will be alleviated. Just as scholars now typically do their own word processing and document production, it is likely that they will also do a large part of their own multimedia production in the future. Templates for journal publications will make it possible for authors to submit their material in prescribed formats. Work has already been done in this direction. We at IMEJ have templates for article production, though they are used in-house rather than as a submission mechanism for authors.

New Web authoring tools, markup languages, and network protocols are now under development, and their standardization will be important for the viability of imej journals. The W3C consortium has been working on its recommendation for the next version of HTML, to integrate XML -- a language facilitating collaborative Web page development -- and cascading style sheets. A companion network protocol called WebDAV is being worked on as a collaboration of researchers at IBM, Merant (formerly Intersolv), INSO, Microsoft, Novell, Rational, and the University of California at Irvine (http://msdn.microsoft.com/workshop/standards/webdav.asp). WebDAV, which stands for Web Distributed Authoring and Versioning, will allow multiple developers to work on Web documents, including multimedia components, from distributed locations with the necessary mechanisms for locking and advanced features for searching based on XML metadata properties. A standard for WebDAV is being developed by an Internet Engineering Task Force, promising a tool well-suited for the collaborative production inherent in imej journals.

To gain scholarly and professional acceptance of imej journals, we must be careful about being identified with commercial or non-academic sites. Technically, we can learn from these sites and the polish of their presentation. Microsoft's MSDN Show, for example, blends entertainment and education by means of online source code, videos, and synchronized video transcripts. The Discovery Channel Web site offers excerpts from and supplements to its TV programs. CSPAN's Booknotes presents interviews of the latest authors. These sites are useful and educational, but combine information with entertainment and advertising, which contributes to the notion that Web publications are meant to sell us something or amuse us.

Scholarly publications must establish a different presence among the electronic media, using the power of multimedia to elucidate rather than entertain. imej editors can earn their credibility by careful peer review, substantive content, purposeful use of multimedia, and polished technical production. Peer review is in a sense
the easy part, facilitated by ease and speed of communication in the electronic environment. But first, there must be something to review. *imej* journals must attract high quality submissions in spite of their unestablished reputations, and this we believe they can do by exciting the interest of those who enjoy taking a chance on innovation and creativity. By gradually attracting the work of energetic, risk-taking scholars and accumulating a body of credible work, the first *imej* journals can slowly but steadily show the potential that multimedia interactivity holds to promote scholarship and learning, and fulfill the promise of this new forum for academic publication.

4. How Are We Doing So Far?

A biannual publication, *The IMEJ of Computer-Enhanced Learning* released its third issue in April of 2000. The first issue had eleven articles, the second had nine, and the third had seven. The smaller number of articles over time has resulted from our realization of the amount of time required for multimedia development. Aside from the peer review of articles, all the editing and production for the journal is done by Wake Forest professors, Academic Computing Specialists, and student assistants as a sideline from their regular work, motivated by an interest in multimedia development and computer-enhanced learning. No subscription fee is charged for journal access. Wake Forest University supports the journal's costs as an investment in educational technology.

We regularly receive email from readers interested in joining our project in an editorial capacity, and so far sixteen volunteers have been added to our pool of reviewers, twelve from the United States and the remainder from Greece, New Zealand, Germany, and Canada. Our readership is steadily growing, as evidenced by a trace of accesses to our server. Hits have grown by about 50% since the launch of the journal, with a steady increase in unique visitors.

Figure 1: Home page of *The IMEJ of Computer-Enhanced Learning*
The number of yearly submissions to IMEJ is small, and our experience in this regard is not unique among electronic journals. In a May 1999 issue of The Chronicle of Higher Education, Vincent Kiernan reports that electronic publications, such as The Chicago Journal of Theoretical Computer Science, Earth Interactions (both from MIT Press) and Open University's Journal of Interactive Media in Education, receive only about a dozen submissions per year. Kiernan suggests that a perception of impermanence and a fear that such publications will not count toward tenure and promotion are the main drawbacks. Electronic journals that are also published in hard copy versions seem to have the greatest success. Connections with online archives, where preprints of articles can be posted directly by authors, are a boost to an emerging electronic journal as well. The Journal of High Energy Physics (http://jhep.sissa.it/), for example, selects papers from the physics electronic archive at Los Alamos National Laboratory, where authors can post their preprints by filling out a form. By this means they receive a large number of articles.

The majority of the articles for IMEJ thus far have been gleaned from presentations at EDMEDIA conferences where, with the endorsement of AACE, we have selected representative "best works" to be updated and augmented for publication in interactive multimedia form. This has helped us to overcome the startup problems any new journal faces, particularly one in a relatively new and academically non-traditional medium. We hope that we have begun to show proof of the production quality and editorial standards possible in an imej journal, and we are approaching the critical mass of articles needed to convince contributors that our journal is a credible -- even a desirable -- place to submit their best work.

5. What Lies Ahead?

Where do we hope to go with imej journals in the next ten years? What is the best that imej journals might have to offer?

Initially, prognosticators were most excited about the increased level of scholarly discourse that online discussions and peer review offered in electronic publication. Computers have undoubtedly increased the ease and amount of communication among researchers. But in our opinion, bulletin board discussions and electronic peer review are not where the greatest potential lies in imej journals within academia.

It is in the presentation of research results themselves where we stand to gain the most in interactive multimedia publications. We imagine scholarly journals that offer more direct access to and verification of our colleagues' research. Experiments can be replicated with the reader's own data. Computer programs can be run and their reported efficiency checked on a variety of input. Graphs can be redisplayed with new data. Simulations can be tested. Medical procedures can be demonstrated. Molecules can be rotated. Architectural spaces can be explored. Art work can be studied. Atomic and subatomic particles can be visualized. Sounds can be played and examined graphically. Eventually, even surfaces can be explored tactilely. This mutual testing, replication, experimentation, and verification of research results among scholars inspires further research and creative collaborations across disciplines and across the globe. We believe that such advances in scholarship and learning are truly worth our efforts to overcome the obstacles that lie in the way.

Abstract: We have developed a collaborative learning environment (CLE) as a student-centred approach to lecture replacement, with a special focus on assisting students' learning of difficult concepts. The majority of the program is structured around cost-efficient web-delivered tutorials incorporating re-usable interactive components. These are supported by several stand-alone computer-based learning tutorials including ones that we developed to allow students to construct their own models of physiological mechanisms, together with computer-facilitated semester-long investigative projects to enhance their communication and critical reasoning skills. Each week for two hours during two semesters, students work in groups of three with an iMac computer. The computer-facilitated tasks are designed to support and extend their three weekly lectures by encouraging peer-learning and peer-teaching. In this article, the successful attributes of this collaborative learning environment are described and evaluated. In addition, relationships between the use of CLE and the students' approaches to learning are being investigated.
Introduction

Tertiary institutions are moving increasingly towards the delivery of courses using computers to provide students with the opportunities to learn at their own pace, together with a reduction in traditional lectures. There is also a trend to provide asynchronous access to courses via the Internet. There is broad recognition that traditional forms of university course delivery are inappropriate in preparing students for a dynamic workforce in a post-industrialist, knowledge society (Drucker 1995, Lohrey 1995). Where it has been successfully implemented, collaborative learning is recognised as a potent transition factor in supporting the development of higher order cognitive abilities (Johnson & Johnson 1992). Despite this recognition, evidence of direct positive effects on student learning remains largely anecdotal (Meloth 1999). Face-to-face collaborative learning, with academics as facilitators, is an area where campus-based universities have a major advantage in tertiary education. We contend that to provide such collaborative learning opportunities has advantages over relying only on electronic communication in virtual study groups. However, amidst contracting resources and increasingly crowded curricula, there is an understandable reluctance to establish the substantially different and potentially risky conditions of learning necessary for successful collaborative learning (Cooper & Sweet 1999).

We have now evolved a collaborative learning environment (CLE) in which we develop and present computer-facilitated learning as a means of effectively broadening the learning opportunities of science students studying physiology. Since 1993 our efforts in computer-assisted learning have aimed to extend, enhance and replace some of the students’ lecture experiences with multimedia-based tutorials in an environment that encourages peer-learning and peer-teaching. A global aim in our science teaching in physiology is to use the curriculum to develop in our graduates some understanding of the abilities required of them as practicing scientists. Emphasis is given to understanding the experimental, research, theoretical, communication and critical reasoning base of the discipline.

An attribute of key importance to development of our CLE was to bring different experiences to students learning. This diversity was essential to address the wide range of backgrounds of the students entering our courses, such as their achievement levels, approaches to learning and cultural backgrounds. Our approaches included introducing scientific principles and methods for investigating physiology (eg simulated experiments), and using a diverse range of computer-aided interactive teaching formats. Importantly these approaches were not designed to stand alone, rather to integrate with other learning resources such as lectures and printed texts. Students were also encouraged to engage in continuous reflection and evaluation.

Our concept of a collaborative learning environment consists of: a friendly and informal physical workspace that is conducive for group interactions, with an optimum group size of three students per computer; an economical production model that provides a coherent set of weekly web-based problems; supplementary standalone highly-interactive multimedia tutorials dealing with essential concepts; a tutor to guide and assist (not teach); and extension after hours into the virtual classroom of the internet using electronic communications. Results so far suggest that the introduction of our collaboratively based approaches to course delivery has had a significant positive effect on student learning outcomes. These outcomes include not only traditional examination results, but also more ‘authentic’ (Wiggins 1992) methods of assessment such as observation of group role fulfillment and student audit trails of problem solving processes.

Background

The Department of Physiology at the University of Melbourne has played a leading role in computer-assisted learning over many years. In 1985 we first tried to improve our practical class teaching of physiology with pilot studies using the Apple II and a computer-oscilloscope for recording from human nerves, accompanied by a computer-aided tutorial relating the theory and practical experience (Delbridge & Kemm, 1985). However, it was not until 1992 when we purchased 64 Mac IIci computers, each with a MacLab physiological recording system, that we really had the computer performance to significantly improve our students’ practical classes and then consider multimedia tutorials as an additional option.

Since 1993 we have been continually successful with our applications for competitive government and University funds to produce standalone multimedia tutorials that aim to help students understand difficult physiological concepts. The Physiology Department has always been a leader in multimedia development at the University of Melbourne and produced the first site-licensed multimedia tutorial sold internationally in 1993. Since then we have been producing and evaluating a series of tutorials that require students to build and test their own models of physiological processes, and the first of these is now being distributed internationally (Weaver et al, 1999). However, although these initiatives have proven to be very effective, production of these highly interactive tutorials was slow and expensive, so they could not be used to provide two semesters of coursework for our science students within the time frame and budget available.
In 1997, the Department introduced fortnightly scheduled 3-hour sessions of computer assisted learning. Initially these CAL sessions were used to revise lecture material. Tutorials were based on HyperCard programs, produced in-house by one of the authors (using Chemistry's 'Tutorial Tools' by Paul Fritze), and a variety of other standalone tutorials obtained nationally and internationally. However, although the in-house tutorials were well received, the standard of external tutorials received a very mixed response.

In 1998, we produced a coherent set of in-house tutorials specifically designed for our students, supplemented by a select few of the best available standalone tutorials. Content was delivered economically on an Intranet for a Web browser, using templates and tools developed in association with Paul Fritze of the University's Multimedia Education Unit. The model for tutorials was that students work on a problem in groups of three with the computer providing questions, feedback and hints as they proceeded with calculations and exploring issues. These 1.5 hr/week CAL sessions were not compulsory and were held in a Science Faculty multimedia computer laboratory remote from the Department. There was no formal assessment of this course component. Attendance fell over each semester, largely because of the many technical problems experienced with the unsatisfactory maintenance of the software and hardware and the remoteness of the laboratory from the support systems within the Department. There was no significant change in student performance.

For the 1999 teaching year the Department of Physiology equipped a refurbished laboratory with 15 iMac computers and a G3 server. Additionally, we introduced group learning of a topic covered in the curriculum, and assessed student participation in the collaborative learning process to encourage attendance. The duration of these computer assisted learning sessions was increased to 2 hours. All this helped staff to provide better support and to emphasise that the CLE was as important as lectures for learning physiology.

In 2000, we are reflecting on all aspects of the Web delivered course and upgrading it where appropriate with new interactive Web components that will allow us to provide more directed feedback to students with different backgrounds and achievement levels (Fritze & Kemm, 2000). We are continuing to develop a few highly interactive multimedia modules dealing with difficult concepts for which students develop their own mechanistic models.

The Current Status of the Evolved Collaborative Learning Environment

The evolution of our collaborative learning environment is the result of adjustments made in response to many surveys and educational experts' observations of how students go about their learning when facilitated by computer programs. The CLE sessions can be regarded as a medium between students who actively construct meaning and skills, using resources of the environment that include discipline content, methods and experiences, such as laboratory work, demonstrations, real-life experience and particularly social interactions.

CLE Sessions and the Physical Environment:

Students attended sessions of 2 hours weekly, with 12 sessions in each of two semesters. This part of the course was first assessed in 1999 and counted for 5% of the course marks (see section on Assessment). Most of the 360 students enrolled for CLE. Attendance was remained high throughout semester in the Department's own facility.

Each collaborative learning environment (CLE) session accommodated 42 students normally working in groups of three on a computer assisted learning (CAL) package presented on an iMac computer. Groups of three were chosen as is claimed to be the optimum group size for interactive computer programs. A G3 Server used AppleShare 6.1 IP to network the 14 students' iMacs and the tutor's iMac. The tables and benches were arranged to encourage groups to talk and argue in a relatively noisy working environment. The tutor's approach further emphasised the friendly and relatively informal learning environment. A wide range of textbooks was provided as student resources. The head CAL tutor and developers were located next door to the laboratory.

Computer Assisted Learning (CAL) Components:

Our overall approach to our CAL development used a constructivist approach and addressed both pedagogical and instructional design issues from the outset, such as using guidelines from the work of Reeves and Harmon (1994) that was designed for the evaluation of completed multimedia. We used a group development model with assistance from education experts, instructional designers, as well as academics and multimedia authors who developed and delivered the material on the Web. We used an iterative process, to adjust tutorials in line with results of formative assessment with students throughout the development.

A true multi-media approach was adopted where students used a combination of paper based work textbook referencing and interactive computer delivered tasks, side by side. The idea was to develop activities that would allow students to build on their own knowledge within their own learning framework, with the computer available as a virtual tutor to help them check their answers, provide a level of tutorial feedback and to
pose further questions to stimulate their interpretations. The problems were initially based on the areas of
difficulties in physiology that staff had previously identified in conventional tutorials.

Students were presented with problems to investigate that required them to examine experimental data,
perform calculations, answer questions and keep written records of their work. A wide variety of tasks were
presented on the Web, occupying about 1.5 hours of each CLE session. Production of sufficient material for 24
weeks required an efficient production method that could be easily modified on reflection after evaluation.

These weekly problems were supplemented by a variety of highly interactive standalone tutorials that
could occupy up to one hour of CAL activities. These included two of our set of highly interactive cell-model
building multimedia tutorials (Weaver et al, 1996; Kemm et al, 1997; Weaver et al, 1999a & 1999b) as well as
externally produced modules. Students were given the opportunity at the end of the session and during the last
session of each semester to test their knowledge with a variety of multiple choice and open-ended questions.

**Semester-long Tasks:**

*In Semester 1:* Students formed extended groups (of six) to investigate one of four problems, such as the
consequences of blood doping on physiological systems. This semester long project was introduced with the
aim of students learning to be perceptive in their reading of short excerpts of scientific writing. They were
required to determine the key phrases in the passage, their relative importance and then to write a concise clear
report on their interpretation of that piece. This project was designed to assist students to develop generic skills
in determining the level of knowledge required and writing abilities to communicate their knowledge more
effectively.

Each group was given a weekly series of tasks, researching the material and progressively developing
their interpretation. 30-minute periods at the end of each CLE session were designated for these assignments.
Students submitted work on the various stages to their own private computer-based discussion forum. They
were provided with weekly feedback on their progressive submissions as a computer checklist, and at the end of
six weeks submitted their report to another group for peer review. The reviewing group was within the same
class and had worked on the same question, therefore were 'expert reviewers'.

We used the learning framework 'TopClass' to allow students to communicate within their group, and
to keep track of their progressive work submissions on a semester long project. Science students study such a
wide range of subjects that it is difficult for them to form cohesive groups to assist their learning (contrasted
with professional courses, eg. dentistry), so that electronic communication is encouraged to reinforce the
exchanges that occur in the weekly CLE sessions.

The key learning issues were to work cohesively as a group and make consensus decisions about
identifying and ranking key concepts, being able to express themselves concisely, unambiguously, accurately
and be able to read another text with some insight as to what is expected... In essence, we aimed to improve
their collective skills in negotiation, communication, reading, and writing and reviewing their science.

*In Semester 2:* We chose to build on the collective skills of collation and consensus writing undertaken in the 1st
semester with a course aimed at providing students with some insight into critically reading their Physiology.
We formally applied reasoning skills to a graded series of reading tasks using the interactive program 'Reason!'.
Although we have reported on this process applied to third year students (van Gelder et al, 1999), the
introduction at this time was only done as a trial. The second year students were not as successful in applying
'Reason!', and some modifications will be needed to allow this less sophisticated group to gain more benefit
from the process.

**Course Assessment:**

*CLE Assessment:* The CLE assessment (5% of total) was aimed at rewarding students who effectively
participated in these sessions. The mark was based on attendance and tutors' records of student participation (by
observation of a group's activities and their submissions, together with individual student's roles in discussion
and record keeping). A student must have attended the majority of sessions be deemed to have participated
effectively in group learning (tutor's observations and computer submissions) to have gained a score of greater
than 3/5 (rated as good in Table 1).

*Examinations:* These are described in a following Section, which discusses attempts to relate the participation
in CLE with examination performance.
Evaluation Strategies

We have a number of evaluation strategies in place and collected data in 1998 and 1999, as part of our overall action research strategy dealing with global learning outcomes from the CLE as well as in students' extension of cell model building skills to new or hypothetical situations. We used a comprehensive set of methods to collate and assess information, in order to gain a broad understanding of student reactions and to obtain a more detailed examination of student learning processes and actions. We obtained human ethics approval for our surveys and to log important student activities in the computer tutorials.

The tutor-facilitators play a key role in the implementation of the program so their impressions of the course are most relevant to understanding student reactions. They made observations and kept records of students' work and participation in the CLE sessions. Formative evaluation continued throughout with regular formal meetings between the main developer and tutors, as well as many informal interactions amongst the students, tutors and the academic developers whose nearby location enabled and encouraged this latter process.

We have found that students cooperate well with questionnaires and interviews if they are fully informed and can see that they are developmental and that timely feedback will assist their own learning. This is unlike their less enthusiastic response to repeated general University circulated questionnaires on teaching quality in each course.

Student Questionnaires

Questionnaires specific to the CLE were used to survey students' attitudes to various aspects of the CAL tutorials and the CLE sessions, in consultation with our educational advisors. These were supplemented by focus group interviews with students.

In addition we investigated students' self-assessment of their approaches to learning. We used a modified study process questionnaire to extend the investigation of deep, achieving and surface learning-approaches (Biggs, 1987) so it included additional learner characteristics. This is discussed in application to one of standalone interactive tutorials (Kemm et al, 1997). Such additional information will be used to further analyse the results reported in this article at a later time.

The student questionnaires were modified each semester from initially determining general reactions to the style and depth of coverage of the tutorials, to focus on particular issues that were relevant to the efficacy of the collaborative learning environment. The study process questionnaire was administered once each year. The last questionnaires had approximately 70 questions designed to reveal students' attitudes and use of the CLE, covering aspects such their pattern of work with the CLE, development of independent learning skills, relevance of the CLE to their learning compared with lectures, and their attitudes to group work. Additionally we had some specific questions about their use of the feedback screens in their learning and about the nature of some tutorials, as part of our interest in learning which tutorial styles worked best and for which students. Most questions required students to rank their responses on a 5-point scale, supplemented by several open-ended questions.

Results

Influences on Assessment:

The aim was to determine whether any part of the CLE assisted students to have a better examination outcome. In all courses, examinations consist of multiple choice questions (MCQ), short answers questions (about 10 min) and essays (about 30 minutes). The written examination questions were set so that one question related to material only covered in lectures, one specifically designed around material obtained in CLE sessions and one question specifically aligned to the semester long CLE project (choice of the four projects undertaken).

Multiple choice questions (MCQ), covering the whole syllabus, were no different in their coverage from previous years. Faculty Scores for student's 1st year performance (average of best 75% of subjects) were used to give an idea of the students' previous achievement levels.

Table 1 shows the influence of effective participation in the CLE sessions on the student performance. Student groups were divided into "levels of achievement" based on their previous 1st year academic performance. Subgroups based on CLE participation ratings used scores of 3.5 and 3, a score that should distinguish combined attendance and participation from non-attendance or attendance alone (see course assessment). The data in Table 1 shows a marked polarisation in the mean scores between these subgroups. Thus we are confident that the subgroups did reflect those students who were involved in the material and the learning process, and those who were not. The data suggests that there is an improvement in exam outcome for all groups with good CLE participation, with a greater proportional change for the "lower achieving" students. The examination marks have the CLE component removed and are normalised, so a perfect score is 100%.
Table 1: Influence of collaborative group interactive CLE sessions on the results with each subgroup

Table 2 shows the distribution of examination marks for science students dependent on their participation in the CLE sessions. The data shows a shift to higher grades for those students participating in CLE, again most significantly for the lower achieving students. Of interest is that 55% of the students in this group who attended and participated in CLE passed. By contrast only 35% passed of the group who chose not to participate/attend.

Table 2: Effects of CLE participation on distribution of examination results of science students taking 2nd year Physiology.

Table 3 shows the influence of the CLE participation on the major components of the examination, and the improvement is apparent across both the written and multiple choice components. We had hoped that the semester long written assignment in particular may have enhanced the Science students' performance in the written part of the examination. If this were true then the written part of the exam should have been done better by the group taking CLE, but the MCQ mark might be expected to be independent of CLE participation. The data however show improvement in both the written and multiple choice exam components for those in the high participation group. Accordingly, from the performance data alone, there is no such clear-cut distinction that might indicate the influence of the different components in the CLE. It is suggested that the apparent improvement in learning skills was influenced by the different components of the CLE (e.g. the CAL tutorials).

Table 3: Influence of CLE Participation on Components of the Examination

The final observation from the assessment was a marked reduction in the failure-rate to <15% compared with 25% over many previous years. It should be noted that we have not been able to reduce this failure rate in previous modifications of our teaching to assist the students most at risk who, as might be expected, were those students with a poor 1st year performance.
Successful Attributes of the CLE

As will be seen from the data analysis above, it was not possible to attribute changes in learning outcomes to any particular aspect of our CLE. We know from previous experience that many factors can be detrimental, such as the students not realising that concepts and material covered in the CLE are as important as lectures, and that students are intolerant of poor quality material or unreliable hardware or software. We believe that the successful learning outcomes are due to a combination of successful attributes of the CLE, identified by the student surveys and observations, and these are presented in the following sections.

The Physical Environment for the CLE:

The ease of installation and reliability of the iMac computers and the G3 Server has been crucial to the success of the project. They required minimal maintenance since the beginning of 1999. Also, attention to software protection and automatic overnight reinstatement of any student modifications of the desktop eliminated significant problems that we had in teaching in an open-access laboratory in previous years.

Our surveys showed that 74% of students preferred to work in groups, showing a minority of students still liked to work alone. At the beginning of the 1st semester, more high achieving students preferred to work alone but many changed their minds, having experienced the benefits of group work. There may also be cultural differences in these preferences. Focus group interviews confirmed these results and the major advantage seen from group work were the interactions and discussions, which were confirmed by the noise levels in the classes.

The scheduling of sessions for group-work was crucial for collaboration, since our experience of other courses with open-access computer laboratory sessions shows that most students tend to work alone, a few in pairs and rarely in larger groups. We believe this is a critical issue to encourage collaborative learning, especially in Science where the diversity of courses that students undertake make it difficult for them to find collaborators with similar timetables.

The CLE sessions induced a 'sense of belonging' to a community within a course where the students come from quite disparate backgrounds, generating more of the interactions that exist in our more selective professional courses. There was identification within each session of 40, rather than just being an anonymous student amongst the class of 350. The open discussions and studying together also reinforced a common approach to scientific investigation and enhanced their appreciation of the philosophical approaches to learning.

The modern, pleasant and comfortable surroundings were found to encourage lively interaction, the main features being the open layout, lighting, carpets and comfortable seating. Furthermore, its location within the Department and easy access to support staff and academics next door showed the commitment of the Department to assisting the students. This sense of personalised support was reinforced by having a tutor look after each class and by providing easy email access by students to staff specialists. Lastly reference should be given to hugely successful paisley 60s style couch in the adjoining corridor, where many successful physiology and non-physiology related communication skills were reinforced.

Web Delivered CAL Components:

It is not possible to relate the learning outcomes to any specific CAL components. There is insufficient space to describe all the characteristics of the computer-assisted web components that worked well with our students in the CLE sessions, but the highlights are as follows, including some representative screen shots:

Weekly tasks not only had a Web-delivered component, but also were accompanied by a paper task sheet indicating the scope of the task for the session. This gave the students some take-away material that could be used in later study/reflection. In addition students were required to keep a record book and make notes, and do calculations as they progressed, so further reinforcing their learning and providing their own records.

The developed Web-authoring tools were essential for producing the core of the material for the 24-weeks of CLE sessions in a cost-effective manner. A single important feature over stand-alone programs is that both material and tasks could be updated relatively easily to incorporate new knowledge, or change emphasis in tasks with changes in the staff presenting lectures. The Interactive Web Objects were controlled by scripts that were readily modified by standard text editors and we used Dreamweaver to manage the website. This meant that 'authoring' of the web pages did not require a programmer, but an academic with some skills in word processing and HTML could be employed instead. This allowed the focus to be on appropriate pedagogy and relevant physiological content. The collaboration between the Multimedia Education Unit and the Physiology Department was essential to both bodies, providing Physiology with a suite of Web based tools while allowing the authors the feedback to develop and test them using pedagogical requirements firmly grounded in the context of the real course.
Students indicated that the diversity of tasks and web-presentations were stimulating and very helpful for their learning. These included calculations with relevant human data, interactive graphing of relationships, open-ended answers to questions, sorting sequences of processes, building models of cellular functions. Fig. 1 shows a screen showing one of a sequence of tasks requiring investigation about cell communication. This requires association of modes of cell communication with a diagram as a simple revision task.

Figure 1: Set of Tasks listed, one of which is shown requiring matching of mechanisms to diagrams.

A popular format (Fig. 2) was the sorting of sequences of events in a physiological process, which students found challenging and rewarding and generated much discussion as they explored many of the possible solutions. As developers, we did not predict this preference. This emphasised that continuous evaluation of what is working is essential, since academics often misjudge what students will find useful and challenging.

Our students have a poor understanding of the significance of the shape of graphs, so we use a free form drawing tool (Fig. 3) to allow them to represent changes that they might expect in important relationships. Here they have drawn the straight line as the change they expect in the supplied curve.

Students used the textual feedback on what was appropriate or inappropriate about their responses and found this to be very helpful in their learning. The feedback was designed to progressively reinforce students' development of an appropriate framework for their solutions to problems - such as their own summaries with the key features of negative feedback control by hormones (see insets in all Figures).

While the students found the content challenging, the computer-aided tutorials gave them a better idea than lectures of the level of understanding required to understand physiological mechanisms.

Students developed appropriate learning strategies: such as exploring mechanisms using interactive programs, reinforcing lecture material by more study, and by reflection of the material and by redoing components of the CAL.
Standalone Interactive Multimedia Components:

Students found the interactive model-building standalone tutorials to be challenging and very helpful for understanding some difficult concepts. However, their approaches to using these tutorials is being researched separately and is too extensive to fully report here. Previous investigations, (Kemm et al, 1997), showed that students were unable to construct hypothetical cells from their experience of constructing a cell to secrete stomach acid. A revision tutorial that shows the principles in the operation of membrane transporters was then developed to allow students to think out their solutions (Fig. 4) and apply this knowledge to new cell models, such as for the operation of cells in the proximal tubule of kidney (Fig. 5). We are currently investigating this transfer of model building skills in a controlled study to see if we can increase the number of students who think out solutions rather than simply use trial and error. We use audit trails to investigate the actual steps students take in arriving at their model solutions. In later modules, more emphasis has been given to placing the cell modelling tasks in context with overall requirements of the tissues in which they are found.

Another approach to model building is to develop neural circuits underlying the operation of physiological control systems. Students found our first version of a tutorial on the control of blood pressure very difficult. Our analysis of audit trails and questionnaires showed that we needed to separate their learning of how the elements of the model worked, using a simple 'playground' (Fig. 6) that also allowed them to develop a negative feedback neural circuit. They were then better able to deal with the complex neural feedback pathway involved in the regulation of blood pressure when moving from a lying to standing position.

Semester-long Tasks:

Students undertook the semester long task of writing about a topical issue with enthusiasm. There was lively discussion, although they were quite frustrated by some features of the TopClass Framework which meant it proved less than optimal for their purposes. There was considerable variation in the standards of both the final submissions and the quality of peer reviews, but students generally produced good work. Not many were...
able to identify all of the requirements, such as: the key issues in their problem, the relative importance of various factors, and to produce concise and unambiguous writing about the problem. In 2000 we have introduced a new means of for students to develop their submissions, receive feedback and to track their efforts using more effective interactive Web tools (OCCA described in Fritze & Kemm, 2000).

Discussion:

Learning Outcomes:

It is extraordinarily difficult to use traditional quantitative methods to show differences in learning outcomes attributable to a particular curriculum intervention by using traditional statistical methods (Reeves, 1993). Even if there are reasonable control groups, large numbers are often necessary to overcome the many confounding factors influencing the students in studying in a course, although there have been occasional successes such as (Reeves et al, 1997).

In our study, we were fortunate to have a self-selected control group who did not participate effectively in the CLE. Although less than ideal, we were not permitted to design an experiment in which some students are not offered this learning opportunity. Nevertheless, the self-selected group did represent a broad coverage of student achievement and there was no difference in sub-groupings based on prior achievements (first year Faculty Score). The significant results show that effective CLE participation was associated with an improvement in learning outcomes of some groups of students when compared with performance in another subject in the same year.

These improvements were observed in students across the achievement scale with students always doing better if they attended and took CLE. A significant outcome was a marked reduction in the failure-rate to <15% compared with an average of 25% over many previous years. It is of consequence that while CLE enhanced the outcome of the Physiology students most likely to fail (43% ± 2 to 52% ± 2) the same improvement was not evident in their Biochemistry mark, a closely related subject (51% ± 2 and 51% ± 2). This preliminary information gives further support to the notion that the CLE has enhanced learning in Physiology in this low achieving group. It is of note that we have not been able to reduce this failure rate in previous modifications of our teaching to assist the students most at risk. Perhaps the more diverse learning strategies provided these students with new and additional ways to understand and communicate physiology.

It was not possible to identify the improved learning with any particular aspect of the CLE. We believe that it is the combination of computer and human facilitated learning environment within which students work together and discuss the subject on a regular basis that has contributed to a general improvement in learning skills and attitudes

Important Characteristics of our Collaborative Learning Environment:

The important characteristics that we believed supported our successful implementation were:

- The choice of an appropriate and flexible set of delivery tools that allowed development of an appropriate pedagogy for students to learn effectively from their tasks. It was important not to allow development to be held up by awaiting the 'latest' version of any delivery tool, but to work our way around it to ensure that one could deliver an appropriate task on time, even if resorting to a greater dependence on written tasks. Our productivity exceeded that in our prior multimedia developments.
- Using the computer's interactivity to focus on concepts not easily covered in lectures, with the CAL not designed to replace all lectures or students' use of textbooks and other resources.
- A generation of a pleasant and friendly learning space was crucial to encouraging students to openly discuss issues and to discover the power of peer-learning and peer-teaching, with supportive staff.
- Choice of reliable software and hardware (eg our experience with iMacs, compared with previous years, meant staff could concentrate on learning issues and not solving technical problems).
- Students needed to recognise that learning in CLE sessions was as important as attending and learning from lectures. Assessment was an important signal that encouraged students to attend, but it must be make it so competitive that students no longer wish to collaborate. We found that allocating 5% for participation in CLE sessions did encourage the CAL to be taken more seriously than previous years, but increasing this will bring on more issues of equity and accuracy of assessment methods.
- The proximity of the developers to the CLE laboratory provided opportunities for them to obtain a deeper understanding to the cultural and individual characteristics of the learning experiences.
- Students openly showed their enjoyment of the learning environment and there was always lively discussion of physiology (and not extraneous social matters). This also encouraged both the tutors' and the developers' interest in further improving the collaborative learning experience in line with the students' survey results and informal feedback. The use of scheduled classes was imperative to allow students to establish and maintain working relationships with their group.
Conclusions and Future Directions

We have found that there is significant value in using scheduled face-to-face on-campus collaborative learning, to complement student's individual self-paced asynchronous learning, that is facilitated by computer tutorials and resources. Continuing investigation of our collaborative learning environment has the potential to build on existing initial successes and to provide some credible evidence and advice to support the management of such positive educational change. Additional evaluation of what works and why with each of our computer tutorials, and with which students, will allow us to make more use of adaptive feedback with new embedded Web objects (Fritze & Kemm, 2000). Thus we could provide more appropriate learning challenges to students who have different approaches to learning and have different achievement levels.

While our results appear promising, in order to maximise the benefit of this innovation there is a need to investigate empirically which factors provide the most positive influences. This could allow the development of a transferable framework for establishing even more successful collaborative learning environments. In particular, we need to learn more about where to allocate human and other resources in order to have optimal effect on student achievement (Thomas, Sammons & Mortimore 1995). In addition to existing teaching processes, this would entail a carefully planned action research project that will provide some more precise and actionable indicators of key factors. More specifically, it would help to create more educative links between instruction, learning and assessment essential for the development of 'deeper' and more durable learning abilities by students (Boud 1994, Loacker, Cromwell, & O'Brien 1986). Such data would be a valuable contribution to other academic staff taking up the challenge of introducing more progressive teaching approaches that foster greater levels of self-directed and higher order learning such as collaborative problem solving and active reflection and metacognitive analysis (Slavin 1990, Mezirow 1994). It would also provide a local infrastructure and an adaptable generic model for generating useful ongoing measures to inform quality assurance and continuous improvement processes.

Overall, we will continue to use an iterative approach to the development of collaborative learning tasks that address effective pedagogy in a campus-based computer-facilitated learning environment. We will use a pragmatic mix of available tools (such as commercial products that support emerging standards for delivery of interactive multimedia) and locally developed solutions that address our own needs. In particular, our aim is to provide a more inclusive curriculum with learning opportunities for the wide range of abilities and learning styles of our students.

Abstract: The purpose of this paper is to discuss the applicability and utility of Fault Tree Analysis in the diffusion of a technological innovation in a higher education setting. Diffusion of innovation literature suggests that the involvement of the intended users in the diffusion process will increase the subsequent use of the innovation. The educational literature has suggested there are six factors which inhibit or influence the use of technology in schools: time; expertise; access; resources; support (Leggett & Persichitte, 1998) and perceived need (Sherwood, 1999). By modifying the Fault Tree Analysis process to be more inclusive, it is theorized that the process will be both applicable and utile and that intended users of the technology in question will be more likely to successfully integrate the innovation into their educational milieu.

I begin with these quotes in order to establish the arc of thought that my research will follow. The first quote highlights the promise of a panacea that many people see in any new technology destined for use in educational settings. Substitute "computer technology", or any other previous new technology touted as the greatest thing to hit education, for "motion picture" and a statement made in 1922 becomes as relevant, repeated and potentially unrealistic today. People seem all too ready to accept technology as something which is value-free and necessary (Cornell, 1999; Kerr, 1996). Perhaps even more disturbing, is the idea that if a technology can do something it therefore follows that it should be done. If medical technology was used with as little thought for consequences there would be a huge public outcry yet very little such outcry occurs in education. As Postman writes in his book "The End of Education" (1996, p. 41), the role that new technology should play in schools or anywhere else is something that needs to be discussed without the "hyperactive fantasies of cheerleaders". He goes on to call computers and their accompanying technology "Faustian bargains". We must be more mindful regarding the choices and decisions we make concerning our use of technology in education lest we end up with something cheered about by many but wholly inadequate and inappropriate for the majority of our needs. I have attempted to apply this mindfulness in my examination of the applicability and utility of Fault Tree Analysis.

Like Postman's "Faustian bargains", Polley (in Albright & Graf, 1992) also felt that perhaps far too much emphasis was placed on the acquisition of technology without first fully understanding what those acquisitions would imply. Polley's words illustrate that the unchecked and poorly thought out use of information technology in the schools has
resulted in somewhat of a backlash. Yet this backlash has occurred throughout history with very little consequence. Polley’s statement is but one of many such examples of disappointment people feel in the reality new technology often provides. There is a large contingent of technological cautionaries attempting to temper the frequently unchecked enthusiasm the technological advocates put forth. Critics (see, for example, Winner, 1998, 1999; Postman, 1988, 1996; Oppenheimer, 1997; McKibben, 1992; Mander, 1992) of the heavy and costly emphasis of placing the latest information technologies into the schools argue that with so little evidence for their effectiveness, this effort would be much better placed on other aspects of schooling.

Experience with technology seems to indicate that the crux of the problem lies between acquisition and use. It is clear that the diffusion of innovation is not merely a matter of purchase. What happens between the promise and the reality? Why do some technologies take hold and others collect dust in a corner? Why is it that some schools, such as Appleby Elementary School in Marathon, New York (Sherwood, 1999) and even entire school districts, such as Chittenden, Vermont, for example, which is widely renowned for its use of technology (Brauer, 1995) are able to seamlessly integrate technology into their curricula while others can only manage the most rudimentary use of technology? This situation regarding the use of technology in education does not only apply to the elementary grades. It seems particularly acute in the higher education setting. Dalton (1989) notes that in spite of the impact computer technology has had on society in general, the impact on the practice of education has been relatively minor. According to Spotts and Bowman (1995), the influence of technology on higher education pedagogy has been weak to almost nonexistent. The results of a survey measuring instructional technology awareness and use amongst faculty members indicated that, while faculty recognize the importance of instructional technology, they do not currently use, nor plan to use, instructional technology in their teaching (Spotts & Bowman, 1995). The results also indicated that, while the majority of faculty have a high degree of knowledge and experience concerning older technology such as video and film, fewer than 20% of them actually use any technology on a regular basis.

Recent findings are somewhat more encouraging but use still seems to be concentrated on the communication aspects of computers (e-mail, presentations, etc.) rather than on integration with the curriculum (Mitra, Steffensmeier, Lenzmeier & Massoni, 1999). Faculty has long been resistant to advanced technology-based education and while, as Rickard (1999) argues, faculty seem more willing to use new technology and are even engaging in the development of such courses, there remains a well-entrenched skepticism not in the technology necessarily but in the ability of the educational institution in which they work to support its use. Support for the technology, then, seems to be one area to which attention should be paid. Fault Tree Analysis, by virtue of its inclusivity (at least my variation of it to promote inclusivity) and involvement of members from the entire focal system, engenders this notion of support. Others believe that too much is being invested, at too great a speed, in technology that has yet to be proved to increase educational quality and productivity (Larson, in Rickard, 1999). Larson also argues that where evidence does exist that technology "can actually help improve educational quality [it is really just the tendency of technology to make course material more engaging" (para. 12). In other words, paying more attention to engaging our students in the learning process may, even without technology, be all that is needed to make education more effective. If one applies this rationale to Fault Tree Analysis, which engages participants in the process, it may add value to the process of diffusion.

Mumford’s understanding, gained sixty-five years ago, that the society in which a technology is to be implemented needs to be in agreement over the implementation process and desired outcomes, may hold the key to successful technological diffusion in educational settings. The process of Fault Tree Analysis and the modifications which have been proposed clearly attempts to achieve this agreement. The supposition that the manner in which technology is introduced, and the elements at play in the context in which this introduction occurs, will, by virtue of its systemic nature, come to the fore while conducting the Fault Tree Analysis. Fault Tree Analysis is “a logic diagramming technique relating combinations of possible events (or subsystems within a system) which interact to produce a predefined undesired event [and can be] generally thought of as a technique for increasing the likelihood of success in any system by analyzing the most likely modes of failure, in order to prevent future failures”. (Stephens, 1972, p. 2). The main purpose of this technique is to improve the likelihood of success in any system by understanding potential areas and causes for failure, with the goal being to prevent future failures. The first step in Fault Tree Analysis is system definition – a definition which includes a discussion of the factors, both positive and negative, which serve to influence the system. I believe, and there is literature (c.f., Akrich, 1993; Burt, 1973; Van Den Akker, Keursten, & Plomp, 1991; Walsh, 1991; Walsh & Bayma, 1996) to substantiate and support this belief, that Mumford’s words concerning the importance of social context highlight what is frequently an absent element in the diffusion of new information technologies into educational settings – the direct involvement of the intended users of the innovation. The modifications I have proposed to Fault Tree Analysis clearly attempts to address this void. It seems apparent that, in spite of the critics and the lack of concrete and unconfounded proof of effectiveness, information technologies are going to be bought and attempts are going to be made to integrate them into educational settings (an effect that has been described as the
"bandwagon effect" (Abrahmson & Rosenkopf, 1993) – it therefore behooves us to research and understand the most effective ways in which this can be accomplished.

The above is not to say that technological determinism is inevitable, but past patterns of use of technology seemingly indicate that educators use what is offered, perhaps looking for a solution to the "problem" of education. Given this initial willingness to use technology (though history also indicates that continued use rarely occurs), finding ways to help ensure responsible and productive use is crucial. An understanding of why one wants to use a particular innovation, how and even if it should be used and whether, given ideal circumstances, it will succeed when used is essential. As others have indicated, I too believe that there is far too much emphasis on technology for technology's sake without nearly enough emphasis on the surroundings in which the technology will be utilized or even if it should be utilized at all. Technology may not be entirely pernicious but it is also most certainly not a panacea. In any case, it is rarely innocuous. Some circumstances warrant the use of technology but some situations would be better off without technological intervention. Fault Tree Analysis and the subsequent validation of this analysis by the members of the focal system appears to be an excellent tool by which we can gain insight into these very crucial elements, thereby significantly adding to our understanding of how best to implement technology into educational settings.

The first teacher ever, the priest in preliterate Mesopotamia who sat down outside the temple with the kids and began to draw figures with a twig in the sand, would be perfectly at home in most classrooms in the world today. Of course, there is a blackboard, but otherwise there has been little change in tools and none in respect to methods. The one new teaching tool in the intervening 8,000 years has been the printed book. And that few teachers really know how to use--or else they would not continue to lecture on what is already in the book.

The priest in ancient Mesopotamia was also the first doctor. If he returned today to a modern operating room in the hospital, he would not conclude that he could do as well. Yet today's doctors are no better men than the first doctors were. They certainly are no better than the "father of medicine," Hippocrates. They stand on his shoulders. They know more, and above all, they know better. They have a different methodology. They have different tools. As a result, they do entirely different things, and do them differently.

Drucker, 1969, p. 347

Whether or not one fully agrees with Drucker, the contrast between medicine and education is striking and it is also obvious to any educator or student that there is truth to his idea that very little has changed in today's classrooms. One need only sit in on a majority of university classes to see that generally, as was the case hundreds of years ago, the teacher talks while the pupils listen. That is not to say, of course, that new technologies have not been developed and attempts at use have not been made. In fact, introducing, implementing and ultimately integrating technology into classrooms, as well as businesses, government facilities, etc., is not a new phenomenon. From slate to radio to the overhead projector to the multi-media computer platform, a variety of technologies have been introduced into various environments with varying degrees of success and failure (Cuban, 1986; 1993; Pellegrino & Altman, 1997; Cornell, 1999; Rickard, 1999). It is not sufficient to have functional equipment – the equipment must be accepted and integrated in order for it to be used. The best of intentions are one thing – actual use another. Recently, Drucker (1999) reiterated the same conclusions he made in 1969 regarding the use of technology in education, though on this occasion he turns primarily to the influence the information revolution has had on the business community. According to Drucker, while routinization of traditional processes has occurred, "almost none of the effects of information envisaged forty years ago have actually happened (1999, par. 16). He argues, though, that the psychological impact of technology has been far greater, especially on the manner in which children learn. Drucker maintains, as he did in 1969, that the manner in which schools teach is inconsistent with the way children learn. In other words, schools are still behind where they should be.

Five critical factors, culled from decades of literature, inhibiting the use of technology in the schools have been identified by Leggett and Persichitte (1998). These factors are: time; expertise; access; resources and support. Perceived need has also been identified as an essential factor when it comes to the successful integration of technology (Sherwood, 1999). Technology programmes therefore need to be developed which are systemic and intentional or purposive (Coughlin, 1999). Based on the findings in the literature regarding examples of the failure of diffusion of information technology in different settings, and using the above six characteristics as a means of categorizing the findings, it may be possible to develop a model of successful diffusion of innovation easily applicable and suited to the needs of educational institutions implementing a new technology. It will be interesting to see if the Fault Tree Analysis uncovers these factors as those contributing to the failure (or potential failure) of the innovation in question.
Large sums of money and huge investments of time are being expended on technology in the schools with, seemingly, very little success (Coughlin, 1999; Sherwood, 1999). In light of the technological failures in the past and the continued amount of money that is being spent on technology, Fault Tree Analysis may prove to be a viable and practicable method schools can use when dealing with the influx of a new technological innovation, thereby saving huge amounts of time, money and frustration. While practitioners and researchers alike currently agree that there are problems with the use of technology in the schools and efforts have been made to look into these problems, there has been no systemic and systematic study of failure of the sort Fault Tree Analysis offers. Education is clearly a success-oriented endeavour. Indeed, it has oft been said that if one focuses on failure, one probably will. Fault Tree Analysis may focus on failure but it does so with the goal of success in mind. Furthermore, the very process of Fault Tree Analysis improves the individual sense of ownership and control over the technological diffusion, loss of which, as previously discussed, teachers fear. The process, which includes direct involvement and system-wide representation, also serves to build a cohesive team which improves and strengthens the social environment into which the technology is being diffused (Jonassen, Tessmer & Hannum, 1999; Stephens, 1972; Wood, Stephens & Barker, 1979) – factors which have been previously identified as essential in the diffusion of innovation. The current study clearly involves the individuals to whom the innovation is being targeted. Fault Tree Analysis appears to be the ideal method to address some of the problems of technological diffusion in educational settings. I believe that this technique will prove to be a useful tool in helping schools face the daunting challenge of integrating technology into their educational environments.

Fault Tree Analysis Site

The site chosen for this study is a college in Montreal. The college is a multicultural institution and reflects the international and cosmopolitan nature of the city in which it is situated. In the last five years courses have been offered on how to use the internal, e-mail, web page design, FirstClass, etc. Most have met with an enthusiastic response but little follow through. Loss of interest seems to be a particularly common problem. The technological innovation currently challenging the administrators is the use of the Internet as an integral element of the teaching process. Their goal is to increase the use of the Internet in the current classroom model as well as develop on-line courses with an eye towards increasing the schools potential for distance education courses. Fault Tree Analysis seems to be a practical tool that may help the college face their goal of technological integration. Testing its applicability and utility in this environment will provide a rich basis upon which applicability can be assessed.

Using Fault Tree Analysis, I will attempt to gain an understanding of the college's outlook on the diffusion of technology into their system. I believe that this technique will prove to be a useful tool in helping schools face the daunting challenge of integrating technology into their educational environments. Examining and understanding how technological innovations fail will, according to advocates of Fault Tree Analysis, increase future probability of success. Participating in the fault tree process, will provide faculty members at the college with a unique opportunity to have a voice in the manner in which a new technology is introduced in their environment. They will be given an opportunity to have a direct say in how, and even whether, a new technology will be implemented. They will be involved in a direct and concrete manner. They will not only be asked their opinion but will be asked to shape the final result as well. The participants (the majority of whom are faculty members) will also see that administrators are being willing and cooperative partners in the decision-making process of technological implementation. Lawler, Rossett and Hoffman (1998) have clearly indicated the importance of a supportive environment in the integration of technology in an educational environment.

Significance of the Research

The potential significance of this research is fourfold. Firstly, this is the first study that will examine in a rigorous fashion the applicability and utility of Fault Tree Analysis. It is the first study to apply this method specifically to the diffusion of a technological innovation in an educational setting. In previous documented uses of Fault Tree Analysis, the purpose was to analyze a problem using Fault Tree Analysis, not to study Fault Tree Analysis itself as a tool. In addition to being the first "process" study of Fault Tree Analysis, this study also investigates an innovation in the process for the first time – specifically, it addresses the utility of contributions from the focal system, beyond the appointed FTA team, and the match or mismatch between the contributions of the two groups.
Secondly, the research will also have practical significance to the technology planners, implementers and faculty at the college. The results of this study will be directly applicable to a reality-based situation. The members of the focal system will have developed a plan of how best to proceed with the diffusion of the innovation in question – a plan shaped by the direct input and validation of the intended users of the technology – elements which the diffusion literature indicates as crucial to the process of implementation.

Thirdly, by providing a detailed description of the Fault Tree Analysis process (as experienced by the members of the focal system and experienced and observed by the researcher), this study will attempt to fill a gap in the literature concerning the diffusion of technology into educational settings. The research clearly indicates that the best way to proceed to ensure use when implementing technology is to directly involve the intended users in the decision-making and implementation stages of the plan. Stephens' original model of Fault Tree Analysis, while including members of the focal system on the FTA team, does not allow for the direct contribution of the members of the entire system – the modification proposed herein clearly does. This study will be examining whether what has been identified as important in theory, works in practice.

Finally, based on the results of this study, a model of Fault Tree Analysis in the process of diffusion of innovation in a higher education setting will be proposed which can then serve to inform the diffusion of innovation literature and have direct utility in other educational systems.

Conclusion

The purpose of this research is to determine the applicability and utility of Fault Tree Analysis in the diffusion of technological innovations in educational settings. Once the applicability and utility is established it is believed that the development of a fault tree may, by feeding into the systemic process of diffusion of innovation and as feedback and feedforward loops, help shape the way technology is integrated, implemented and perhaps even developed in the future. Developing a fault tree of a school currently dealing with the influx of technology may help to provide insight into how and why people adapt to and adopt a new technology. It may also serve to highlight the roadblocks people face and whether or not these impediments are different than those identified in the diffusion of innovation literature. Insight gained from such an analysis may, in the medium and long term, allow for more effective implementation, training and use expectation policies. Underlying my belief in the importance of Fault Tree Analysis is that by merely illuminating to the participants the reasons for failure and the areas in which they are most likely to occur is sufficient to cause a shift in behaviour and attitude.

The important contribution this research in general, and in specific relation to the educational milieu, is clear. If we are to discern the impact technology has had and will have in higher education processes, understanding the elements that influence that impact and providing a systemic approach to address the needs of the technology’s intended users will have strong sociological, economical, educational and policy-making benefits. If we know how to uncover, and then correct, the failure events that influence the acceptance and integration of technology, savings of time, effort and money can be had by overcoming the impediments to the diffusion of technology in educational settings before they have a chance to occur.

Diffusion of innovation occurs for a multitude of reasons and within a variety of contexts. Understanding loci of failure and the contexts in which they occur will help allow for a much more efficient process of technological integration. Understanding these failure elements may also help us recognize when technology is not warranted and feel confident in the decision not to use it. This Fault Tree Analysis will serve to help gain insight into the implementation process of technological innovation. This insight and the subsequent development of a systemic diffusion of innovation model using Fault Tree Analysis may help to inform policy and decision makers in their implementation strategies – necessary and desirable goals in light of the speed at which new technologies are being developed and introduced to schools in North America and the frequent failure these implementations meet.

Changing Interaction Paradigms in Annotation Environments

Abstract: Implementation of novel learning scenarios frequently implies the adoption of new interaction paradigms provided by new media. Changes on media bring several issues to educational metaphors, such as deciding which characteristics should be maintained, removed and improved. This paper discusses these issues by means of a case study comparing evolving scenarios for the annotation metaphor: from paper-based to hypertext and virtual reality.

Introduction

The design of innovative educational environments involves providing novel learning scenarios, which most of the time requires the support of new interaction paradigms. We start from the aspect stated by the following hypothesis: changes on the medium enable the introduction of new interaction paradigms and further opportunities to improve educational metaphors.

By using “metaphor” we mean the transposition of the meaning of one thing to a different one. For instance, the "text metaphor" supposes a place with visual information (words, graphs, etc.). "Paradigm" is understood as a model for relationships among metaphors and rules responsible to turn them into concrete entities. In other words, a metaphor implies a model (paradigm) and a paradigm is not easily grasped without metaphors (Winograd 98). Metaphors and paradigms exist only over a medium that provides perceivable features. In parallel, media inexorably affect the corresponding interaction paradigm, because each medium is identified by a proper set of rules, which defines possible paradigms. In the case of hypertext paradigm the decisive importance of media in defining the corresponding paradigms is shown. This paradigm was described by Vannevar Bush (Bush 45) to be implemented on microfilm medium, but it really succeeded when a more adequate medium was adopted (the digital text).

Therefore, the adoption of new media requires a careful study of how they affect the current paradigm. A second problem is then stated: how to deal with metaphors in consequence of changes on paradigms and media? Which characteristics should be maintained, eliminated and improved in the new implementation of the metaphor?

The first difficulty is the different features of source and target media, causing trouble to see beyond well-known metaphors and use all the functionality of the target medium (Halasz & Moran 82). For example, considering a word processor as a typewriter would not make it clear that there could be facilities such as "copy" and "paste". This problem is particularly serious in the shift of computer applications towards a 3D paradigm, because we tend to use 2D desktop-like metaphors of current systems to guide the development of 3D interactive environments. In order to decide on features that must be supported by new metaphors, a careful study of how media affect new interaction paradigms is necessary.

The next section presents a discussion about different interaction paradigms within daily practices. These ideas are then analyzed by means of a case study on different scenarios for the annotation metaphor. This metaphor usually appears in text-based educational environments (Adriano et al. 99, Davis & Huttenlocher 98, Harger 96), but it lacks appreciation for some new media, like 3D virtual environments.
Interaction Paradigm Ruptures

The rupture of interaction paradigms has been a recurrent fact throughout the history of many artifacts for knowledge transmission. A good example was the advent of the medieval codex (sewn paper pages, not much different from the current books), substituting the parchment of antiquity. Among the consequences of this change, there was the possibility for readers to work simultaneously with several books and make annotations on them. Such facility was not feasible with the parchment because readers had to use both hands to keep it opened (Chartier 97). Even though soundly benefic, some historical changes were not immediate and a lot of years are needed to overcome the natural resistance to the new interaction paradigm. Thus, in order to minimize resistance and provide adequate paradigms for new media, it is necessary to understand how current metaphors are affected.

In search for paradigm ruptures within daily practices, Michel de Certeau, in an anthropological study (Certeau 90), identified the following ruptures in modes of describing places: place vs. space, map vs. trail, frontier vs. bridge. These ruptures obey the following patterns: from personal to unpersonal, from biased to unbiased, from transient to permanent and from static to dynamic. These patterns distinguish different uses for the narrative metaphor. The word metaphor (from the greek metaphorai) denote "public means of transportation", which is the sense applied to the narrative and annotation metaphors. The former conveys the speaker to the described places, while the latter helps the reader move among cores of ideas in a text.

According to Certeau, a place is a referential, static, and permanent organization of things. On the other hand, a space is perceived when vectors of direction, velocity and time are used. The "city place", for example, is composed of streets, parks and buildings, while the "city space" involves the circulation of people and a sum of every citizen's instantaneous impressions. Similarly, the "text place" is the stylistic design of paragraphs, phrases and figures. The "text space" is the interaction with the written word, like annotating, discussing and summarizing. A similar analysis, but with interchanged terminology, was made by (Harrison & Dourish 96). According to them, a place is a space with some additional features, like social meaning and cultural knowledge about individual roles.

The distinction between trail and map stems from narratives of space and place. Trail was the prevailing paradigm in medieval descriptions of geographic extensions, which involved cities where to visit, stop, rest and pray. Nowadays, the map paradigm prevails, describing regions by global landmarks like meridians, names of cities, roads, etc. Annotations on paper compose a total and reduced vision of a commented text, which corresponds to the map paradigm. The trail paradigm imposes the traverse of links in order to obtain an annotation.

Narratives of region demarcations inhabit the paradigms of frontier and bridge. A region is a meeting of actions and there are as many regions as the number of possible inter-actions. The frontier delimits the static division among parts, like geographic references (rivers and mountains). The bridge separates by the opportunity of interacting or crossing, like the narrative of Columbus' navigation to the Antilles. As with the case of hyperlinks in a hypertext, an annotation-place is a bridge between two regions, the annotation and the text. On the other hand, annotations on paper are ruled by the frontier paradigm.

The ideas of Certeau seem very appropriate to guide our case study about changing interaction paradigms for the annotation metaphor, which is the topic of the following section.

Case Study: Annotation Metaphor

Annotations are contents appended to a text; they have well-defined boundaries and are resultant of some cognitive effort. Removing an annotation inflicts no damage to the corresponding text. Annotation-places are responsible to structure groupings of annotations, provide contexts and define interaction paradigms. Annotation-places are also superstructures holding relevant metadata about annotations.

The learning scenarios for this case study were built in CALM (Computer Aided Learning Material) (Adriano et al. 99), a recommender-like system developed at the University of Campinas.
Text-Based Annotations

A learning scenario in CALM starts with a student selecting learning goals. A learning goal is a set of subjects of interest, which are mapped to topics recommended by the system. The student sets a specific goal by choosing one topic to accomplish. The learning goal is accomplished by doing delivered study units. A study unit is composed of a topic, a list of related topics, some tests and exercises, which are defined according to the student's learning goal and a history of previous interactions.

Annotations are made during the study unit. In the context of a study unit, three interactive learning scenarios based on annotations were investigated: commenting, authoring and discussing. The first one corresponds to annotating to raise a doubt or include a link to another point in the material. In this scenario, the underlying text being annotated is self-contained with respect to the specific objective it intends to accomplish. Therefore, the original text is not modified. Two annotation-places support this scenario: bridge and in-line (Fig. 1), a and c, respectively.

![Figure 1: Three annotation scenarios in CALM.](image)

Annotations on paper use the frontier paradigm that distinguishes annotations by a colored pen or a handwriting style. The bridge paradigm cannot be established over paper medium. The frontier paradigm is adopted in the digital text by means of the in-line annotation-place (Fig. 1), c. Shifts between these paradigms depend on the necessity to reduce the stylistic pollution (excess of annotations) or to undermine the difficulty of navigation (excess of links). This scenario demonstrates the necessity to modify features of a metaphor according to media changes.

The second scenario is the collaborative authoring by means of in-line annotations. This scenario requires a total vision of the work (the vision of author). Insofar, it is paramount not to miss the distinction between what is annotation and what is text. The association of two paradigms, frontier and map, obtains the desired vision. These paradigms support an appropriate annotation-place that not only provides version and date information, but also displays the annotation contents within the commented text. The frontier paradigm displays the annotation distinguished from the text contents and the map paradigm organizes the annotations under an authoring vision. Since text on paper already supports both paradigms, this scenario demonstrates the necessity to maintain features of a metaphor when changing the medium.
The third scenario comprehends the discussion by means of annotations (Fig. 1). A newsgroup-like annotation-place was implemented to organize the annotations hierarchically. The text is the motivation of discussion and it must not be modified. Therefore, this new accomplishment of the annotation metaphor could not be done over the hypertext paradigm that would mean inserting hyperlinks in the text. The annotation-place for discussion permits the insertion of annotations without modifying the text. This annotation-place shares the paradigm of trail with the hypertext, but they diverge with respect to the paradigms of place and space. A "space of discussion" is necessarily dynamic, while the non-modifiable hypertext defines only a place (static). This is an example of an innovation in consequence of changing the medium, since the paper medium cannot support such scenario.

Virtual Reality Annotations

A motivation for the shift towards a 3D paradigm would be the need to introduce more appropriate and novel interaction among metaphors in a learning situation. For learning situations in which interaction is greatly based on real objects, a text based-scenario becomes too cumbersome, due to highly descriptive narratives of positions, appearance and movement. Virtual reality based learning can bring convenient interaction and visualization features (McLellan 96).

Moving the annotation to a 3D environment would impose at first a creation of a 3D metaphor for the annotation-place. Which are then the implications of having the annotation-place as a 3D metaphor?

As in the case of text-based annotations, it is necessary to investigate how the 3D spatial notion affects interaction paradigms in order to decide about features of annotation metaphors. The ideas of Certeau were also shown to be an appropriate strategy to define interaction paradigms in 3D environments (Jensen 99).

The implemented learning scenario is a virtual reality model based on VRML (VRML 97), combining a 3D paradigm with the world metaphor. The consequences to the annotation metaphor and the annotation-place are numerous. First, annotation-places are connected to objects that provide richer context to the annotations. For example, a grocery shopping list will probably be placed on the refrigerator door or on some other agreed place in the kitchen. Second, relations between annotation-places can be drawn more easily, based on the objects they are attached. Third, the expected readers of the annotations can be selected by these different relationships. For example, a virtual classroom may have an annotation place on the entrance door, available to every one at school, a group-available annotation-place on the blackboard, and also a private one on each student desk.

We implemented an illustrative prototype of an annotation-place located on a refrigerator door. Such place enables addition, removal and edition of annotations that are located all over the door. When moving the mouse over an annotation, its author name, date and keywords are displayed. A click on annotation displays its content in an editable dialog (Fig. 2).

![Figure 2: VR-based annotations.](image)
The implemented 3D-annotation environment corresponds to the commenting scenario discussed in the previous section. Regarding the paradigm ruptures described by Certeau, the 3D annotation is dynamic in every aspect. It is considered a space due to the interaction opportunities for editing, removing or adding annotations. The paradigm of bridge is present in the links relating the post-it like object and the annotation contents. The trail paradigm was used because it is difficult to offer a total vision of textual information (map) in 3D environments.

Conclusions

Thinking of annotations as metaphors subjected to paradigms, and these latter as direct outcomes of adopting and combining media, is a complementary approach to investigate the effects of changing paradigms when designing interactive learning scenarios. Annotations on paper and the classic 3M post-its are well-proofed successful implementations of the annotation metaphor. Moving them to digital media is still a challenge that needs further understanding on how actors in an educational environment perceive spaces and places for annotation. Corroborating these ideas, there is some work investigating effects of interfaces for annotation (Wohjan et al. 98), student learning improvement by use of annotations (Armel & Shrock 96), and architectures for annotate-capable documents (Phelps & Wilensky 97).

The 3D prototype was an interesting experience and opened the possibility for innovative uses of annotation-places such as: audio and video annotations, 3D annotation-places for authoring and discussion, and annotation-places defining a specific text format (e.g., via XML - Extensible Markup Language with an appropriate style definition).

The study of paradigm ruptures can also be applied to other educational metaphors, such as interface agents, user avatars, 3D spatial notion, etc. When interaction paradigms for certain metaphors become clear to designers of educational environments, new media will be better used and the risk of rejection to changes will be reduced. Therefore, it will be given a further step towards the definition of a more general paradigm to be used in the transmission and manipulation of knowledge in the digital era.

Abstract: The transition from text-based computer systems with a narrow band of interactivity, to multimedia systems with much broader potential for interaction, has urged designers to consider human-factor issues to increase usability. In terms of machine intelligence, multimedia technology is no different from earlier text-based systems. But in terms of human use, there is a strong need for the development of guidelines in designing those systems and more research is required in this field. This section starts by highlighting some multimedia design issues such as design layers, navigation, interactivity, and user control, then the researcher describes three categories of multimedia design, which are: learning design, interface design, and screen design. The summary highlights important issues for consideration by multimedia designers, pitfalls to be avoided, and areas where more research is needed.

1. Introduction

The advent of interactive multimedia has resulted in a greater consideration of presentation and interaction styles and methods (Ring and Ring, 1997). The design of multimedia learning environments may be considered in two broad design layers: the conceptual design layer and the presentation design layer. The conceptual design layer deals with the structural organisation of the learning environment and involves creating the deep learning architecture of the system, the presentation design layer however, deals with the realisation of the system as a computer based artefact. In presentation design, the abstractions of conceptual design are mapped onto a real multimedia environment (Boyle, 1997).

Since interactive multimedia uses a variety of media and sophisticated interactions via several sensory channels, and taking into account the fact that learner’s brains have limited capabilities, it can easily be overloaded with information, Ring and Ring emphasise that designers of interactive multimedia must understand the memory limitations of the learners and should think about how to create meaningful environments that require minimal effort to learn and remember (Ring and Ring, 1997). As users have different types of language, background, values, and traditions, each needs to work at different paces and in different styles. Vossen states that effective multimedia design requires the involvement of a systematic and comprehensive approach to analyse the context of use which includes modelling all the components and aspects such as the user, task, and setting. He identifies four elements of multimedia design: content, structure, access, and style (Vossen et al, 1997).
2. Design for Interaction

The major difference between traditional instruction and instruction delivered by multimedia is interaction (Schwier and Misanchuk, 1993). Good design of interactive multimedia is measured by interactivity which makes the application more useful. The powerful feature of multimedia is that it allows individual learners to be active participants in the multimedia application, by enabling them to interact with, and control the flow of information within the application. Hannafin emphasises that it is important to design as much meaningful interactivity as possible into a multimedia application (Hannafin, 1989). McAteer and Shaw see that the well designed human-computer interface prompts the user to explore and learn (McAteer and Shaw, 1995).

Gillham and Buckner identify interactivity as a term that implies an existing involvement in the way the information is presented and retrieved (Gillham and Buckner, 1997). Deegan states that multimedia systems are generally designed to be interactive in that they allow users to interrogate the programme in a linear and non-linear way (Deegan et al, 1996). Some useful guidelines which are believed to promote learner’s interactivity are provided by (Poncelet and Proctor, 1993).

3. Design for User Control

Multimedia designers are concerned with user control which is believed to be a central topic to the design of interactive instruction, it includes the aspects of interface and instructional design (Stoney and Wild, 1997). McKerlie and Preece state that learner control takes three forms: control over the structure, control over the media, and control over the working environment (McKerlie and Preece, 1993). It is suggested to put control in the hand of the user to enhance learning. Laurillard believes that learners should be given more control over the content by providing the ability to navigate through the multimedia application at their own pace (Laurillard, 1987). In addition, McAteer and Shaw advise designers to put as much control of the package as possible in the hands of the user, so they can proceed at their own pace, but they point out that this control should be at a certain point (McAteer and Shaw, 1995). Merideth and Richards indicate as a result of their study that multimedia positively impact students’ learning by giving the learners control over the learning materials and by supporting their higher order thinking skills (Merideth and Richards, 1997).

4. Design of Educational Multimedia

The following is a description of the three categories of the design of educational multimedia. Theses are: learning design, interface design, and screen design.

4.1 Learning Design

As multimedia resources add pedagogical value to the learning materials, the instructional design has a significant impact on the quality of learning. Hedberg suggests that consideration must be given to the cognitive load placed on the user if designers want the user to access the information effectively and efficiently. He believes that improvement in learning outcomes can be supported by allowing learners to focus on metacognitive processes as a component support incorporated within the interface (Hedberg et al, 1994). Harasim argues that the use of new technology does not improve educational outcomes by itself. She sees the need to focus on new designs for learning as well as new ways to design the technological environments that can support learners’ cognitive process (Harasim, 1995).

Edward states that computer based learning (CBL) has a long history from the early text based to today’s virtual reality multimedia offering. He believes that the majority of multimedia learning packages are concerned with teaching and testing the acquisition of large scale factual information. He suggests the need for designing multimedia learning packages that facilitate conceptual understanding approaches (Edwards, 1997). Kennedy claims that many educators think that interactive multimedia learning programmes have failed to
deliver their promised potential, he refers to the use of an inappropriate design model for computer assisted learning (CAL) and hypermedia. He sees that these instructional design models, are developed from the assumptions that underlie the behavioural/objectivist pedagogy of teaching and learning (Kennedy, 1995).

Suni and Ross argue that instructional design is a systematic process for creating learning and instructional principles, and combine them into instructional materials (Suni and Ross, 1997). This argument is supported by Boyle who sees three stages of instructional development: needs analysis, selection of instructional methods and materials, and evaluation (Boyle, 1997).

Fortunately hypertext and hypermedia authoring packages allow designers of multimedia courseware to design the learning materials in a structured and unstructured way, and allow them to design the programme giving greater flexibility for the learners to structure the learning environment to suit their own learning needs, benefited from the non-linearity of the programme (Stanton and Stammers, 1989). In this regard, Jonassen believes that there is a benefit of hypertext in which it permits text presentation to be locally modified by the learners in order to meet their individual needs (Jonassen, 1986).

A classifications of instructional design models can help in deciding on an appropriate multimedia design to achieve the educational objectives for any specified course. Developers must understand and distinguish between various learning and instructional strategies. Boyle discusses two approaches to the design of computer based learning environments: traditional instructional design and constructivism. He believes that the traditional instructional design has been criticised. He sees constructivism as a dominant paradigm in educational multimedia design, it has a much stronger base in the psychology of learning and cognitive development (Boyle, 1997).

Midoro warns educators against creating multimedia systems for doing old tasks. He suggests the use such systems to open up new possibilities. He urges researchers to fully exploit the multimedia features to enhance the teaching and the learning practices (Midoro, 1993). Compagnoni and Ehrlich conclude in their study two significant issues. The first one is that individuals with better visualisation skills were faster in accessing information in hypertext learning systems compared to those with poorer visualisation skills. The second one is that, hypertext seems to cause learning by browsing, which is a better strategy compared to the use of predetermined menus (Compagnoni and Ehrlich, 1989).

Montgomery identifies four characteristics which seem to contribute to the success of any multimedia courseware package. These are engaging the learner, the ability to provide immediate access to information, the ability to provide alternative explanations or examples, finally a practice to provide practical opportunities for skill development (Montgomery et al, 1993). Authoring packages allow the use of multimedia components such as sound, graphics, and moving images which provide a powerful opportunity. McAteer and Shaw however, warn that authors might be seduced into focusing on the impressive technology and losing sight of engaging, informing and educating the students (McAteer and Shaw, 1995).

4.2 Interface Design

A multimedia learning package is meaningless if there is no means to navigate through it or experience it. User interface design as described by Lisa Lopuck “is the process of ergonomically and strategically presenting media in order to communicate a message” (Lopuck, 1996). The emergence of interactive multimedia has raised several new issues in interface design. Ring and Ring emphasise that interfaces of interactive multimedia products should be aesthetically pleasing, and should offer the learner sophisticated interactions insuring the ease of use. They state that good interface design makes use of a variety of functions and visual entities to enhance both interactivity and appearance. They argue that the goal of the interface is to facilitate interaction and to make the organisational structure and content visible (Ring and Ring, 1997).

Davies stresses that designers should create a conceptual model “which is the overall view of the system, or part of the system, as conceptualised by the designer”. Also they should create a mental model “which is how users actually view the system which will vary with the level and experience of the user”. The reason for the creation
of conceptual and mental models is to make the interaction as comfortable and efficient as possible (Davies et al., 1994). The goal of the mental model is “to create an environment that facilitates the mapping of the designers model onto the user model” (Ring and Ring, 1997). If users can easily build mental models of multimedia computer assisted learning environments they will perceive the systems as user friendly and easy to learn. If the models are too complex, the system will be perceived as confusing and unfriendly. The mental model should not focus on what the computer is doing, but rather on what is going on in the context, objects, and other representations (Calvi, 1997).

Designers of multimedia learning programmes should help users to develop an appropriate conceptual model by providing them with a familiar, clear, and consistent metaphor that represents the way the system actually works and behaves. There is now general agreement that consistency enhances usability (Waterworth, 1992). Some common metaphors are “office”, “book”, “encyclopaedia”, “tutorial”, “discovery”, “exploration”, etc. The desktop metaphor is used at the top level of the application, and it should be enhanced with application-specific actions or replaced with other appropriate real-world metaphors. After an application is opened, it should use a real-world metaphor appropriate to its functions. For example, in an inventory application, displays might reflect the actual equipment they represent, and equipment could be placed or removed from locations which look like shelves and slots.

The issue of users being disoriented “getting lost in the hypermedia/multimedia application” has been a concern. Conklin warns interface designers from the disorientation problems which may get the user lost in the program, or make the user not sure where he/she is in relation to other parts of the program network (Conklin, 1987). However, Mayes sees that the disadvantage of disorientation may be an advantage for the learner in some type of exploratory learning. The problem may not be whether a map can be found but how a map can be created by the learner (Mayes et al., 1990). Calvi believes that getting lost in the hyperspace is not only about multimedia or hypermedia systems, she sees that printed text books do entail a certain degree of disorientation (Calvi, 1997).

In addition, Riley believes that there is a risk that learners will lose their bearings and be “lost in the hyperspace”. He suggests that designers should provide sufficient navigational aids for users to navigate a program with ease (Riley, 1995). However, some research indicates that designing multimedia and hypermedia with complete user control leads to a deeper level of understanding (Suni and Ross, 1997). Elliott sees a great weakness in the use of hypermedia applications which lies in the degree of learners’ control, he suggests that to give direction when a user engages with the application can overcome this weakness (Elliott et al., 1995). Further guidelines on learner control are given by (Orr et al., 1994).

One of the most common ways of identifying or accessing information in a multimedia programme is by navigating its interface. By creating a motivating style for interaction control and access, learners may quickly learn where to look in the programme to interact with the interface. Calvin believes that an easy navigation depends upon learners’ ability to abstract the application and its display in order to build a conceptual representation of its architecture (Calvin, 1997). Search suggests the need to develop interfaces with orientation cues that help learners navigate through the multimedia applications (Search, 1993).

4.3 Screen Design

Good screen design attempts to impose a consistency on the layout of the screens of a multimedia program. Visual organisation of media in the application will undoubtedly influences the ease and quality of learning, and has an important impact on cognitive load (Stoney and Wild, 1997). McAteer and Shaw believe that consistency in screen design and visual organisation of media in the application influences the ease and quality of learning (McAteer and Shaw, 1995). Preece suggests that organising information in an easily accessible form can reduce the time taken to find a specific piece of information (Preece, 1990).

Screens include some visual parts and areas that should be associated with specific tasks such as titles or headings, information area, instruction area, navigation area, and feedback area. Hannafin and Hooper emphasise that designers should consider the visual aspects including the design and placement of text, graphics, and various navigational elements and keep the screen as simple and uncluttered as possible.
(Hannafin and Hooper, 1989). Milheim and Lavix define some aspects of screen design which include the location of various components on each screen, and the consistency of those locations throughout the multimedia programme (Milheim and Lavix, 1992).

The importance of screen design has been emphasised by many researchers. Mukherjee and Edmonds stress that screen design is becoming a very important issue when developing multimedia learning materials in many different content areas. They introduce a broadened definition of screen design which includes the coordination of textual and graphical elements to easily present the content of the learning materials to learners (Mukherjee and Edmonds, 1993). Milheim and Lavix believe that if an instructional screen in a multimedia application provides effective instruction, visual aesthetics, and appropriate navigational tools, it will undoubtedly allow for maximum learning from the materials whilst providing the learner with adequate control of the learning process (Milheim and Lavix, 1992). Hannafin and Hooper stress that screen design should assist the user to easily facilitate the process of accessing the information providing the user with cognitive benefits to perceive, organise, and integrate information (Hannafin and Hooper, 1989).

The proper use of colours is a very important issue for multimedia design, and they should be considered carefully. Boyle states that the aim of the use of appropriate colours is to ensure an effective and pleasing visual display (Boyle, 1997). Durrett and Stimmel indicate that the excessive use of colours may have a negative effect on learning (Durrett, Stimmel, 1987). Whilst the use of certain colour combinations can lead to a complete lack of perception (McAteer, Shaw, 1995). Some authors (Milheim and Lavix, 1992; Orr et al., 1994) provided some guidelines for using colours.

In summary, good screen design can fulfil the following requirements: (1) focus learners’ attention, (2) develop and maintain interest, (3) promote processing, (4) promote engagement between the learner and the lesson content, (5) help learners find and organise information, and (6) facilitate lesson navigation (Hannafin and Hooper, 1989; Mukherjee and Edmonds, 1993).

5. Summary

5.1 Designer Considerations

♦ Create a meaningful environment that requires minimal effort, by modelling all the components and aspects (user, task, and educational environment).
♦ Constructivism is better than the traditional design in which it considers the student as a main participant in the knowledge system, through interacting with a given situation.
♦ Designers should create conceptual and mental models by providing learners with familiar metaphors which represent the way the system actually works and behaves.
♦ Screens should be designed with consistency and with visual organisation of text, graphics, and various navigational elements.
♦ Simplicity of the design influences the ease and quality of learning and has an important impact on learners’ cognitive load.

5.1 Pitfalls for Designing Educational Multimedia

♦ Design for complete user control can lead to disorientation.
♦ The use of an inappropriate design models may mean that the program will fail to deliver the promised potential of multimedia.
♦ The impressive technology of multimedia may lead designers to lose sight of engaging, informing, and educating the students.
♦ Current authoring packages provide templates which help designers in laying out the screen in a matter of minutes, but they do not necessarily guard against bad design.

5.3 Further Studies
There is a need to carry out controlled studies to establish the effectiveness of user control paradigms (total control, guided navigation) and instructional design models. To date little work has been done to analyse the effects of educational setting, environment, and learner culture on multimedia design. The authors' studies highlight the importance of cultural issues in the effectiveness of the design of multimedia learning materials. In addition, a new focus is needed on design for learning in the new technological environment, for example using virtual reality in learning. More research is needed on how to upgrade design guidelines into authoring packages.

Abstract: This paper features a study on the use of electronic catalogs and retail storefronts as a concrete collaborative class project for the Electronic Commerce Course in the Business curriculum and a survey of the MBA students that undertook this project in response to the course requirements. The survey results provide positive indications for the achievement of the goals of collaborative inquiry, team-based and active learning, constructivist pedagogical approach, and learning by doing. The technical details of the project are also described in the study.

Introduction

The Internet is providing an extraordinary environment for designing teaching and learning experiences. This paper will focus on how the World Wide Web (WWW) could be utilized for teaching Electronic Commerce (E-Commerce) in Management Information Systems (MIS) program of the Business curriculum. The opening of the Internet to businesses in the early nineties initiated the E-Commerce phenomena that has not only revolutionized the conduct of business online but also overhauled the way E-Commerce-related business courses need to be taught. The unusual aspect of these courses is that the WWW is primarily the environment in which online establishments also conduct their business. This means students can actually simulate the conduct of business via the same environment where their learning takes place. Not only that---the instructional setting can also take advantage of web hosting services used to support online businesses to supplement if not entirely replace inadequate university information technology infrastructure that needs to undergird the activities of electronic merchants.

This paper reports the experiences of the MBA students at the School of Business, Montclair State University, in building electronic storefronts using Merchandizer software, which is a requirement in their Management Information Systems course that has an E-Commerce theme. The survey technique, student feedback was gathered from two MBA classes that took the course during the summer and fall 1999. Data was conducted to measure students’ perceptions of the quality of their overall learning experience and their ability to gain collaborative team work skills, discipline-specific skills in building an electronic storefront and catalog, skills in using the Merchandizer software, and various forms of thinking skills.

The E-Commerce course could be taught by combining the pedagogical principles that surround a number of appropriate teaching strategies: cooperative learning, constructivist approach, active learning, and learning by doing. These strategies can be used to structure and coordinate electronic learning spaces. In a cooperative learning environment, the instructor organizes content and topical activities around tasks, problems, and projects that student teams with a balanced mix of abilities and backgrounds are designed to undertake (Adams and Hamm, 1996). Cooperative learning also provides valuable opportunities for students to work together across gender and ethnic lines as long as communication skills, prior achievement, expectations, friendships, and group status are factored in (Chizhik, 1999). A meta-analysis of university-level and adult-learning courses found that use of collaborative
learning concepts promoted higher achievement, higher-level reasoning, more frequent generation of ideas and solutions, and greater transfer of learning than did individualistic or competitive learning strategies (Johnson et al., 1991). Team members' social skills, also called "interpersonal intelligence" according to Howard Gardner, encompassing interpersonal communication, task management, group interaction, and conflict resolution are constantly honed throughout the process.

The constructivist pedagogical approach invites students to build personal meanings out of the material taught and encourages them to reflect on how new knowledge builds on their previous base of understanding (Pankratius and Young, 1995). In a group setting, the constructivist approach could lead to the social creation of knowledge as a basis of learning.

"The yeast of knowledge, openness, and enterprise raises the need for a multiplicity of learning media and technological tools" (Adams and Hamm, 1996). The very wealth of Web site building tools that is now available allows students to experiment and "play" through "learning by doing" activities and significantly changes the whole instructional experience. Students have more control over the end product via the software tools and they assume greater responsibility over their learning process (Adams and Hamm, 1996). MIS instructors are strongly encouraged to move towards the "learning by doing" mode which is, by far, the most effective way of teaching students "how to" skills. While this is clear to most teachers, it is not easy to do unless certain prerequisites are in place: professional development, teacher preparation, technological infrastructure support (hardware, software, and helpline service), an appropriate incentive system that will reward the countless hours that will go into a more technologically-oriented class (as opposed to a traditional lecture-style one), and above all, an overarching plan that clearly defines the role of technology in the pedagogical process (Adams and Hamm, 1995).

Merchandizer Software Features

Students are asked to build an electronic retail storefront for either consumer-to-business or business-to-business commerce. What this means is that the store can sell a product that individual consumers may be interested in buying such as an Amazon.com for books or a CdNow.com for musical CD-ROMs. Or, the storefront could be an electronic catalog for firms interested in buying materials they need in running their business such as office supplies, for instance---staplers, bond paper, paper clips, etc.---in other words, these will be businesses buying from another business. The product used in the project is Merchandizer Software, which is an online solution that allows users to build and manage an electronic storefront with just a browser software such as Netscape Communicator or Microsoft Internet Explorer and an Internet connection which an Internet Service Provider (ISP) or web hosting service can provide for a fee. In designing the site, students could either enter all product information using a step-by-step wizard or they could work directly with hypertext markup language (HTML) forms to both make and modify their sites. In building the electronic catalog itself, students either enter information manually using the wizard templates or they may import extensive information using Microsoft Access database tables which are loaded onto the servers.

Merchandizer software makes use of frames or windows appearing within the browser’s display area, each of which displays the contents of a different HTML file (Carey, 1998). The software also allows storebuilders to divide their product lines in a hierarchical fashion, first into groups, then, into subgroups, and finally, into catalog items. The group and subgroup headers become navigational links in one frame, displaying product pages or other HTML pages or entire web sites altogether created by the students. The frame concept facilitates the navigation of the customer through the storefront.

Once groups, subgroups, and catalog items have been defined, students enter product information either of two ways. They can enter the information using simple electronic forms that allow them to submit information like product name, code, description, and price. Alternatively, they could use preformatted Microsoft Access tables that essentially mimic the wizard online templates. These tables are more convenient to fill out when merchants have hundreds or even thousands of product items to enter. Since students are building only prototype stores with a limited product line, they end of using the forms, although the use of the Access table is demonstrated to them should they be interested in trying it.

Merchandizer has features like a search function that will allow hypothetical customers to search the storefront using any word or phrase related to the products on sale. Merchandizer also incorporates a shipping table for UPS directly into the software so that the students do not have to be concerned with this. They need to specify the appropriate sales tax, though. Merchandizer keeps track of all sales transactions, customers, and prospects (those who visit but do not buy). A report generating facility gives students information on the most saleable products, customers who buy most from the store, aggregate sales figures for the week or the month, and areas of
interest of prospects, among other things. The software can also autogenerate email messages to prospects about special promotional activities the store is conducting.

Version 3.0 of Merchandizer offers students a wide range of features to play with to simulate a real online store even more realistically: easy translation of the web site into any language; ability to insert forms with special buying instructions before the shopper checks out; offer global coupon numbers to shoppers so that they can accumulate their purchases and eventually received discounts on items; ability to submit the store site to top search engines; more managerial report forms that can be generated from the sales transaction data; a personalization field for each catalog item for shopper input that will be carried over to the order tables; ease of uploading and downloading Access tables, among other more advanced features.

Hip Hip software, the company behind the Merchandizer storefront building tool, is also a web hosting service. A merchant that does not have networking facilities to support the store could subscribe to this service and pay a one-time setup fee and monthly maintenance fees that vary depending on the number of catalog items supported in the store. Hip Hip software offers educational pricing for universities interested in using their hosting services for the purpose of instruction. This arrangement is a boon for universities and colleges that do not have adequate information technology infrastructure to allow E-Commerce instructors to mount interesting student projects.

The web hosting service is important because of the backend office component of the online store. Sales transaction information submitted by customers and personal information keyed in by interested prospects who do not purchase during their visit to the store need to be stored in web servers so that the order could be processed and sales prospects could be reached through promotional email messages in the future. Backend office processing requires the availability of web servers that can store order transaction data in databases that can later be accessed using some form of structured query language so that reports and statistics could be generated for managerial decision making. The extensive requirements of the storefront make the storefront project too challenging for the normal capabilities of a typical university’s academic technology support group. It is far better to sign up with the web hosting service—if reasonable fees could be negotiated with the company—and have their technical support staff provide the services necessary for optimizing all functionalities and features of the storefront.

Methodology

This study used the survey technique using a written questionnaire, which was administered to two classes of the MIS 503, Management Information Systems course at the MBA level. Data was gathered during the Summer and Fall of 1999. Both classes had the theme of “Electronic Commerce” and the project assigned to the students was the construction of an online retail storefront for either consumer-to-business or business-to-business commerce. Students were assigned in teams of four to five students. Each team was in charge of a storefront web site, which was maintained and supported by Hip Hip Software. The technical support staff that advises the students and oversees the web servers that host the software and product information entered by the students is located in Miami, Florida. Survey data was analyzed using descriptive statistics, correlations, and simple regressions among key variables.

Findings

The sample size consists of 43 students in the MBA program of the School of Business, Montclair State University, who all took the INFO 503 class in Management Information Systems, with special emphasis on Electronic Commerce. The students were at various stages in the MBA program and majority of them hold full-time jobs in industry.

Students were asked to respond to a five-point Likert scale for different items where 1=Strongly disagree, 2=Disagree to some extent, 3=Uncertain, 4=Agree to some extent, and 5=Strongly agree. Most of the students felt that the retail storefront project was an important learning experience overall (mean=4.44). Students found the project instructive in terms of teaching them new ways of doing business over the World Wide Web (mean=4.35). They also thought that the project taught them skills they could use after the completion of the course, particularly the setting up of an online Web site for a product or service (mean=4.30). They also felt the project gave them a chance to create Web site content that was meaningful to the entire team (mean=4.30). In the construction of the storefront site, they thought that they learned the following specific skill sets in decreasing order of importance: design issues for creating an online catalog (mean=4.30); overall planning issues for preparing an online retail web
The next important set of findings relate to the students' perceptions of how this project enhanced their ability to collaborate with peers in a team setting. Most students found the project a good venue for encouraging collaborative teamwork (mean=4.40). Communication skills were paramount in getting the work done (mean=4.33). While standards for personal accountability were set within the team setting (mean=4.30), members made sure they also helped each other out (mean=4.28). The project clearly taught the students a variety of group process skills: (a) looking out for the best interest of all concerned over and above one's own personal interests (mean=4.26); (b) arriving at mutually acceptable solutions (mean=4.26); (c) dividing the work equitably among members (mean=4.23); (d) practising interpersonal social skills (mean=4.21); (e) learning from members' different ways of thinking (mean=4.21); (f) learning positive interdependence (mean=4.21); (g) respecting a diversity of opinions (mean=4.16); and (h) striving for goals as a team rather than as individuals (mean=4.12).

They gained a better understanding E-Commerce as a subarea of Management Information Systems (MIS) in the School of Business curriculum (mean=4.07). The storefront project, which is a natural cross-over between marketing and MIS, made them more aware of the interdisciplinary connections within the business curriculum (mean=3.95). They perceived the project as a venue for learning about E-Commerce vendors of hardware and software (mean=4.28), consulting services (mean=4.12), professional associations (mean=3.79), and job openings (mean=3.63).

It is very likely that the positive experiences reported, thus far would not have been possible if the Merchandizer storefront software itself was difficult to use. Most students found learning the software a fairly easy task (mean=4.19) and that they found it was a reachable goal to be skillful in the use of it (mean=4.14). The Merchandizer software templates were easy to understand (mean=4.07) so that students were able to learn them on their own without extensive instruction (mean=4.05).

Two important attributes of students in the sample were measured: frequency of computer use and length of time spent working with the computer. In a simple regression procedure, it was found that frequency of computer use significantly predicts students' perception of the ease of learning the Merchandizer software at the significance level of p<.10 (F=3.24284; p=.0791). In two other simple regression runs, it was found that the students' perception of the project as having enhanced collaborative team work predicts their perception of the storefront as being an important learning experience overall (F=11.42868; p=.0016) and their ability to create a web site with content that is meaningful to the entire team (F=3.59981; p=.0648). Then, students' perception of Merchandizer as an application software that was easy to use predicted their organizing skills in arranging web site information so that the site could be presented more effectively (F=12.27518; p=.0011).

When taken together as two independent variables in a regression equation, both the students' perception of the project as having enhanced collaborative team work and their perception of Merchandizer as an application software that was easy to use predicted a number of dependent variables. Significance levels were tightest for their organizing skills in arranging web site information so that the site could be presented more effectively (F=7.28378; p=.0020) and their perception of the storefront as being an important learning experience overall (F=7.4604; p=.0022). Both independent variables in a regression equation also significantly predicted student's perception that the storefront project encouraged creative thinking (F=4.12519; p=.0235), their perception that the project enhanced their integrating skills or their ability to put information or content together (F=3.40767; p=.0430), and their ability to collaborate with peers in a team setting (mean=4.40). Communication skills were paramount in getting the work done (mean=4.33). While standards for personal accountability were set within the team setting (mean=4.30), members made sure they also helped each other out (mean=4.28). The project clearly taught the students a variety of group process skills: (a) looking out for the best interest of all concerned over and above one's own personal interests (mean=4.26); (b) arriving at mutually acceptable solutions (mean=4.26); (c) dividing the work equitably among members (mean=4.23); (d) practising interpersonal social skills (mean=4.21); (e) learning from members' different ways of thinking (mean=4.21); (f) learning positive interdependence (mean=4.21); (g) respecting a diversity of opinions (mean=4.16); and (h) striving for goals as a team rather than as individuals (mean=4.12).
members (.5038); learning different ways of thinking in the team (.5784); and learning how to achieve goals as a team (.5380).

Learning different ways of thinking in the team correlated strongly with four other variables: perceiving the project as encouraging collaborative team work (.7333); learning to communicate with team members (.7026); learning positive interdependence in the team (.8792); and learning interpersonal social skills (.8245).

Conclusion

This paper has shown concrete data supporting the promise of the use of the WWW for instructional purposes in the area of E-Commerce in the business curriculum. Not only does the WWW provide an environment that perfectly simulates the subject of the course itself, but the web hosting service arrangement also provides information technology infrastructure support to universities that are resource poor or unable to afford the hardware, software, and manpower requirements of mounting E-Commerce projects. The survey results provide positive indications for the achievement of the goals of collaborative inquiry, team-based and active learning, constructivist pedagogical approach, and learning by doing.

Teacher Education by Hypermedia learning Environments – An Example from Germany

Stefan Aufenanger, University of Hamburg/Germany, Stefan@aufenanger.de

In Germany the problem of teacher education for school in the information society has been recognized in the last years. But there are many obstacles to change concepts of traditional curricula for teacher education, to train the teacher educators, to implement new media at the university, and so on. The necessity of educating teachers and teacher students for using computers and the internet for educational purposes became also aware by the government. There are many interested teachers but there are not enough teacher educators to face that challenge. Media in general and television especially are rarely used in German schools. German teachers mostly think of electronic media as a virus which is infecting the children with not good ideas so they try to keep them out of their classroom. Only the computer and the internet had changed some teachers mind. The pressure of using computers in every day life and in all areas of economy is now reaching the schools. Now schools are equipped with computers and internet access but teachers are rarely prepared to pedagogical settings for the use of its.

Supported by a grant from the Bertelsmann Stiftung in Germany seven universities in Germany have built a network to cooperate in teacher education or media education for teachers, respectively. Teacher educators of he Department of Education of each of the seven universities came together to develop a concept for educating teachers for media education and computer technology at schools. The challenge of that network is to develop and to implement a curricula that could be accepted by each of the seven universities. All participating universities have a center for media education and some experiences for teaching with computers and internet but all have not enough capacities and resources to implement a whole curricula for teaching the teachers in media education and computer technologies. For that reason the network could offer each university the chance to develop a curriculum on the one hand, and to implement that curriculum on the other hand, if new media would be used. The aim of the network is in general to exchange experiences in media education for teachers, and especially to develop together hypermedia learning environments for that topic. If each part of the networking would develop one part of the curriculum and one part of a hypermedia learning module system resources could be better shared and different views to the same topic could be offered.

In a first step the general task of the network was break down to the theme “Teaching and Learning in the Informational Age”. In a second step the main issues of that theme has been outlined. So it is important to understand what are the main topics of the informational age. Or it had to be clarified what are the main concepts of teaching with computers and concepts of learning with computers. In a further step different concepts for the educational approach has been developed.

The aims of the curricula has been formulated as follows:

- To help teachers to get media competencies
- To have an understanding of media education and the pedagogical aspects of computers use
- To create learning environments for better learning with computers and the internet
- To manage the hardware and the software problems and to be aware of school development for the new media
One decision was to use hypermedia learning environments for teacher education at the universities. That's the aspect of distant learning which

Three working groups have been put on the way: one for the educational aspects, one for the didactic aspects, and one for the information technology aspects. The paper will concentrate on the work of first working group.

The members of that working group decided to develop a modular system in which each aspect of the theme can be produced if the resources need are available. Two of the possible modules will be presented. The first one is called 'media competencies' and offers a concept of the competencies which are necessary to use the new media - f.e. computers and the internet - in a probate way. The learning environment offers the user the different dimensions of media competencies - a cognitive dimension, a social dimension, an ethical dimension, an esthetical dimension, an affective dimension, and the dimension of handling media - by a hypermedia text with different examples for each dimension.

The second example is a case-based learning environment called 'media ethics'. The user will be confronted with a critical case of media content which could harm children. The underlying learning theory of that hypermedia learning environment is taken from Roger Schank's case-based multimedia learning approach. It is the aim of that hypermedia text to challenge the user to find a solution which is not given to her or him but which has to be constructed by her or him.

These two examples will show how that modular system will work. The aim of the workgroups is to develop a pool of modules which could be used by each department of education. The process of implementation in teacher education will be evaluated. First results will be presented.
Dynamic Coordination Policy for Cooperative Learning System

Abstract: Most of these cooperative learning systems have a static type that the learning policy decided the beginning of system development. In this paper, we proposed the model of coordination policy that can change policy dynamically through separating of coordination and implementation. The proposed coordination policy model provided interaction structure which import two concept of virtual bus to cooperative learning system developers and defined CPDL (Coordination Policy Definition Language) to model coordination policy.

1. Introduction

Through the improvement of computer system capabilities and extension of information network communication system, it is increased to request of Computer Supported Cooperative Work (CSCW) applications which support that a number of people globally distributed make a decision and do their cooperative work through the sharing their information (ACM, 1998). Especially, the research about cooperative learning to get educative effectiveness is being actively performed (Makrakis, 1998).

Most of these cooperative learning systems have a static type that the learning policy decided the beginning of system development (Sistemas & Borges & Santos, 1999). There is a problem that these static policy models can't change dynamically when people perform learning system. Because it is possible to static modification, it includes problem that every policy for cooperative learning should be decided before the execution of learning system. This prevents performing of the original facility of cooperative learning.

In this paper, therefore, we propose the model of coordination policy that can change policy dynamically through separating of coordination and implementation. The proposed coordination policy model provides interaction structure which import two concept of virtual bus to cooperative learning system developers and defines CPDL (Coordination Policy Definition Language) to model coordination policy. Also, using rule base method not procedural method to control and process defined policy with CPDL, it is possible to process flexibly about changing status dynamically.

2. Coordination Policy

It is the aim that cooperative learning system easily provides works for learning happens to between many learners using computer. Cooperative learning is coordinated by special policy. In other words, cooperative learning can restrict role and interaction of participating learners. So, in order that cooperative learning system supports group learning effectively, it should include these rules in software. These rules are coordination policies. Coordination policy include access control, concurrency control, floor control, role/session constraints, exception handling (Edwards, 1995, Gustafsson & Shahmehi, 1996, Sikkel, 1997).
Coordination policy can be made by working type and organization structure of learning groups, and that can be coordinated by other policy according to learning stage. The development of cooperative learning system is made by communication of experts, developers, or users for defining of coordination policy generally. These method are defined when system is developed, this policy is called once-and-for-all policy which is applied every case. A lot of research is being progressed about very various cooperative learning system in CSCW during past 10 years. Most of these systems developed by once-and-for-all policy. These approaches don't provide flexible cooperative learning because the decided policy on system development applies to every case. So, it is required development of cooperative learning system which import method separates system and policy.

3. Dynamic Coordination Policy

In this chapter, we propose coordination policy model. A necessary coordination policy on overall cooperative learning is separated learning group policy and learner policy in proposed model. And it is possible that dynamic policy changing through separating system implementation

3.1 CPDL (Coordination Policy Description Language)

CPDL is a language to define learning group policy and learner policy. It is used to define policy about overall cooperative learning. As developer of cooperative learning system defines policy with CPDL besides general application such as white board or tele-conferencing, he can provide cooperative learning applications with new policy to learner without modification of application in spite of dynamic change. Policy with CPDL consist of part about type of learning group, definition of sharing application to use in learning group, definition of necessary events in learning group and each rules.

Policy about learning group type

The type of learning group consists of title of learning group, its role, stage of learning group, list of application, number of learners, openness of learning group, control method of right to speak, sorts of events, and rules of learning group. Role of learning group and stage of learning group operation is defined List 1. Objects and events used group can composed of object definition list and event definition list. And numbers of learner which can participate groups are able to be defined overall number of learners and each role base number of learners. Group property has only one property either PUBLIC or PROTECTED. If group property is PROTECTED, group can restrict learners participate groups using secret numbers. The control of right to speak among learners groups are TOKEN_CONTROL, ROUND-ROBIN, FREE method.

List 1: Group Grammar

- Group_definition ::= Group identifier : Title role_list stage_list object_list participantNum group_attribute floor_control event_list rule_definition
- role_list ::= ROLES : id_list
- stage_list ::= STAGES : id_list
- object_list ::= OBJECTS : object_definitionlist / nothing
- event_list ::= EVENTS : event_definitionlist / nothing
- id_list ::= identifier, id_list l identifier
- object_definitionlist ::= object_definition / object_definition object_definitionlist
- participantNum ::= P_N total_number number_per_roles
- number_per_roles ::= (identifier => total_number) +
- group_attribute ::= PUBLIC / PROTECTED : password
- floor_control ::= TOKEN_CONTROL | ROUND-ROBIN | FREE

Objects and event definition

Group can share object and it can different from sharing application according to role. Also it can use object to different right though it shares same object. Object definition consists of object name, class name, role, and right used object.

List 2: Object Grammar

- object_definition ::= OBJECT : objectname classname objectactivity right
- objectname ::= NAME : identifier
- classname ::= CLASS : identifier
- objectactivity ::= USING_BY : identifier
- right ::= W | R
Events happen to interaction process of learners and participated groups. And appropriate processes of events need to support smooth learning activity. The event type is consisted of events source, events destination, and field list consisting of events.

**List 3 : Event Grammar**

```plaintext
event_definition ::= EVENT identifier : simple_event
simple_event ::= event_src event_dsts event_fieldlist
event_src ::= SRC : context_list
event_dst ::= DST : context_list
event_fieldlist ::= FIELDS : fieldlist / nothing
fieldlist ::= FIELD : fieldlist / nothing
```

**Rule definition for group activity**

It defines that how interaction of learners happen to learning group and pass event of learners process through rules. The rules consist of condition and behavior list. If the condition is satisfied, the descriptive behavior is performed to appropriate learner. In the case of learner, the target can be restricted to itself, and can be the learner performing the specific roles and all learners. The condition is appropriated to the case of input or output of specific data.

**List 4 : Rules using group**

```plaintext
rule_definition ::= RULES : rule_list
rule_list ::= rule_declare / rule_declare rule_list
rule_declare ::= RULE : rule
rule ::= targetlist : condition => actionlist WHEN stage BY actor
targetlist ::= LOCAL / ALL / midis!
condition ::= mode :- datatype
mode ::= IN / OUT
datatype ::= session_command / media_data / event_data
session_command ::= JOIN / LEAVE / LIST_MEMBER / GET_ACT_INFO / SET_STAGE / GET_MEMBER_INFO / LIST_POSSIBLE_ROLES / IS_MEMBER / TOKEN_OWNER / END_ACTIVITY
media_data ::= connector_name
connector_name ::= string
event_data ::= identifier
stage ::= ALL / id_list
actor ::= ALL / id_list
actionlist ::= action_declare / action_declare actionlist
action_declare ::= string
```

### 3.2 Two way coordination policy

Learners participated in cooperative learning has common topic. So, coordination policy about group affects on interaction among all participants. Also, learners interact with other people according to purpose and policy of itself. However, because the legacy study defined only group coordination policy, individual policies of each learner don’t be considered.

In this paper, it supports both group coordination policy and individual policies of each learner, coordination policy of overall cooperative learning perform through harmony of two coordination policy. To this, the bus concept is imported. The bus consists of collaboration bus that affects on learning group coordination policy and coordination bus which affect on learner’s policy. Because learners participating group is connected with collaboration bus, it is controlled by collaboration bus learning group coordination policy. Coordination bus is connected between cooperative learning applications like whiteboard and tele-conferencing and private coordinator for controlling learner policy. So, because each application is connected Coordination bus, it is controlled by Coordination bus learner coordination policy.

**Learning group coordination policy**

Learning group policy is defined with CPDL by group creator. Group policy defined by group creator apply to every learner participated in group and use the basic policy of group activity. So, it has higher priority than learner policy and is valid as long as a group exists. The following is item group coordination policy.

- **Group Name**
- **used Role in group**
- **used shared object in group**
- **the number of all learner and learner per role participated in group**
- **property of group**
- **group title**
- **type of right to speak**
- **a way of processing when the defined events are generated**
Learner coordination policy
Learner policy defines rule about transferred data by system. So, most of learner coordination policy is rule definition.

3.3 Coordinator
Cooperative learning policy is described by CPDL and it is managed and is executed by Coordinator. Composition of Coordinator is illustrated in Figure 1. Coordinator consists of text editor, translator, coordination manager, working memory, reasoning engine, knowledge base and actor. Text editor is a tool that learner can describe with CPDL. Translator is a parser that converts CPDL into coordination grammar type. Coordination manager controls policies of overall cooperative learning.

4. Experiments
We implement cooperative learning system to show propriety of the proposed dynamic coordination policy. And we show that possible interaction of users groups according to learning group policy and learner policy through processing of implemented system.

4.1 Development environment and cooperative learning system
Experiment environment consists of one teacher, two learners, and one attendance, and in this class, teacher decides the type of cooperative learning group and group policy. The overall cooperative learning system consists of white board and video-conferencing using real time stream. And, audio/video data of system and image data of whiteboard is controlled flowing according to group policy.

To do cooperative learning, first teacher decides cooperative learning group policy. After that, if group is created, learners and attendants participates group, and decide their policy. The necessary information which makes group is consisted of group name, roles to be used by group, working steps of group, number of learners and role to participate group, information of objects to be used by learners of group, control type of right to speak, group property, definition of event to use group, and rules of group activity. These group types and group policy are described in List 5 using designed CPDL in this paper.

List 5 : Group policy of education system
Classroom : “Overview of CSCW”
ROLES : Lecturer Student Attendant
STAGES : Teaching Question Discussion Reporting
EVENTS :
EVENT CommandTeaching
SRC : Lecturer
DST : Student Attendant
FILEDS :
FIELD : Content
EVENT ReportResult
SRC : Student
DST : Student
FILEDS :
FIELD : Content
RULES :
RULE :
LOCAL : IN : REQUEST_TOKEN WHEN Teaching BY Student => “Deny Request”

BEST COPY AVAILABLE
In the case of lecture step, group rules ignore request of right to speak of learners, and in the case of discussion step, if learners try to pass to teacher discussion result, it describe CPDL which can receive discussion result. Also, during lecture, teacher can pass image data from learner or attendance, but data transmission through audio data and whiteboard restrict for smooth lecture.

4.2 Group creation

CPDL described in List 5 change to necessary information for group creation through parser. The necessary information for group creation consists of rules to be used group policy management as saving knowledge base. The Parser uses template such as List 6 to change CPDL type to CLIPS(C Language Integrated Production System) (Friedman-Hill, 1998) type.

List 6 : Template for changing CPDL to CLIPS
(deftemplate ROLELIST (multislot rolelist))
(deftemplate STAGELIST (multislot stagelist))
(deftemplate OBJECTLIST (multislot objectlist))
(deftemplate EVENTLIST (multislot eventlist))
(deftemplate STAGES (slot (stage)))
(deftemplate RULE (slot targetlist)
(slot mode)
(slot datatype)
(slot WHEN)
(multislot by))

The contents of CPDL is changed by parser is transmitted manager handling a portion and then, it used. List 7 are rules to connect definition rules with CPDL with java method. This rule becomes of knowledge base of Jess, it is applied appropriate rule about several accident happen during group activity.

List 7 : The changed rule of CLIPS type
(defrule Group_RULE1
  (RULE (targetlist LOCAL)(mode IN)(datatype REQUEST TOKEN)
  (WHEN Teaching)(By Student))
  (STAGES (stage Teaching))
  => (printout t "Deny Request" crlf)
  (call RequestHandling LOCAL IN REQUEST TOKEN Teaching Student
  Deny_Request))
(defrule Group_RULE2
  (RULE (targetlist ALL)(mode IN)(datatype CommandTeaching)
  (WHEN ALL)(By Lecturer))
  (STAGES (stage ALL))
  => (printout t "Command by Lecture" crlf)
  (call RequestHandling ALL IN CommandTeaching ALL Lecturer Command by Lecture))
(defrule Group_RULE3
  (RULE (targetlist LOCAL)(mode IN)(datatype sound)
  (WHEN Teaching)(By Student Attendant))
  (STAGES (stage Teaching))
  => (printout t "Prohibit sound" crlf)
  (call RequestHandling LOCAL IN sound Teaching Student Attendant Prohibit sound))

4.3 Participation of learner

Learner can owns policy on group activity and defines owns group activity in addition to group policy defined by group chairman. When the change of event is receiving to a teacher, Learner-A’s System makes the overall application step change by generating “Change Mode” message. Also, if received data from learner or attendant in question time, System should not show the received data and if don’t show the received data on whiteboard in reporting the result of conversation, learner-A describes like the following list.

RULES :
RULE:
LOCAL : IN :- CommandTeaching WHEN ALL BY Lecturer
=> "Change Mode"
RULE:
LOCAL : IN => whiteboard WHEN Question BY Student Attendant
=> "Prohibit whiteboard"
RULE:
LOCAL : IN => whiteboard WHEN Report BY Student Attendant
=> "Prohibit whiteboard"

Learner-B like learner-A changes the application step on receiving step change event in overall step. Also, if received the voice data from learner or attendant in question time, it describes with CPDL like the following list for no receiving the receiving data.

RULES:
RULE:
LOCAL : IN => Command Teaching WHEN ALL BY Lecturer
=> "Change Mode"
RULE:
LOCAL : IN => sound WHEN QUESTION BY Student Attendant
=> "Prohibit sound"

CPDL of learner A and B convert CLIPS using template like group CPDL and it saves in Knowledge Base. If the condition is satisfied, Reasoning Engine transmits message, and makes it launch java object connected message.

4.4 Policy change of teacher

In the case of adding new policy after it decided policy, System can execute new policy just compiling new rules and adding to knowledge base without recompiling overall policy. For example, if group stage is not "Teaching" group stage, and try to prohibit access of other users, it add the following CPDL

RULE:
LOCAL : IN => JOIN WHEN Question BY Student Attendant
=> "Prohibit JOIN"
RULE:
LOCAL : IN => JOIN WHEN Discussion BY Student Attendant
=> "Prohibit JOIN"
RULE:
LOCAL : IN => JOIN WHEN Reporting BY Student Attendant
=> "Prohibit JOIN"

5. Conclusion

In this paper, we proposed the model of coordination policy that can change policy dynamically through separating of coordination and implementation. The proposed coordination policy model provided interaction structure which import two concept of virtual bus to cooperative learning system developers and defined CPDL (Coordination Policy Definition Language) to model coordination policy. Also, using rule base method not procedural method to control and process defined policy with CPDL, it was possible to process flexibly about changing status dynamically. The proposed coordination policy model solves problem of static policy model, which it can’t change policies dynamically on the execution of learning system, and can provide various learning step and learning way through changing coordination policy dynamically.

Email: Philip.Barker@tees.ac.uk

Abstract: This paper discusses the growing importance of teaching webs - both as an augmentation aid to conventional teaching and as a replacement for 'stand and deliver' courses. The development of teaching webs is discussed within the framework of a case study relating to the development of an intranet/Internet facility to support the teaching of a two-semester, final-year, BSc degree module in human-computer interaction. Some of the advantages, problems and pitfalls of this approach to educational delivery are briefly discussed.

1. Introduction

Increasingly, the Internet and other related technologies such as intranets and extranets are being used as support aids to facilitate the delivery of teaching and learning materials (Hopkins, 1998; French et al, 1999). Indeed, web-based training (WBT) and Internet-based training (IBT) are now rapidly becoming two of the most popular mechanisms for making training materials available within both academic and commercial organisations (Steed, 1999; Horton, 2000). There are two main ways in which WBT and IBT are currently being used. First, as an augmentation aid in order to facilitate the delivery of conventional courses (Gillham et al, 1999; Hall and Dalgleish, 1999). Second, as a complete and integrated solution to the presentation of courses that are to be used by students in a self-study environment or in an open learning fashion (Barker, 1999a; 1999b; Duggleby, 2000). This latter technique forms the basis of many of the new Web-based approaches to distance learning using the principles of 'electronic classrooms' and 'virtual university' environments (Whittington and Sclater, 1998; Barker, 1998). Although these are important, this paper is primarily concerned with the first of these two approaches. It considers the various ways in which a teaching web - running on an Internet and/or an intranet server - might be used in order to improve the quality of the educational experiences available to students studying within a conventional university environment and who are exposed to conventional 'stand and deliver' lecture courses as their main mechanism of information delivery.

Internet-based technologies can be used for a variety of purposes within an educational setting. Typical uses include: making reference material available, providing access to course documentation and the collection of student demographic data. In contrast to these basic information provision and data acquisition roles, the purpose of a 'teaching web' is to facilitate the development of knowledge and skills within the user population for which it is designed. As well as achieving knowledge and skill transfer, teaching webs are intended to monitor, assess and record students' progress and performance - giving appropriate feedback both to students and course administrators. As well as providing access to teaching and learning materials, teaching webs must therefore be closely integrated with assessment tools and databases that can keep records of performance data.

Creating teaching webs is a much more difficult task than just authoring some informational pages and mounting them on an Internet or intranet server. Because of the more complex tasks that are involved, this paper describes and discusses some of the principles involved in creating a teaching web. It illustrates these principles by means of a case study that describes a dynamic teaching web facility that we have recently built in order to support the teaching of the subject of human-computer interaction (HCI). As well as describing the operational system, the paper outlines some of the advantages of using this approach and identifies a number of problems and pitfalls that we have encountered.
2. Creating Teaching Webs

Before a teaching web is constructed it is necessary to make a number of important decisions relating to how, if at all, the development process should proceed. It is also necessary to decide upon the form the web should take, its content, structure and the way in which it should be produced. Some of the more important initial questions that need to be answered therefore include:

- Can the development of a web be justified?
- What institutional infrastructures currently exist to support a web?
- What parts of an existing course, if any, should be made available on the web?
- What type of platform is to be used?
- What financial, human and technical resources will be available?
- What materials currently exist?
- Should these be imported into the web facility?
- Can they be imported into the new system?
- What relevant 'off-the-shelf' web-based teaching materials currently exist?
- Can these be easily imported into the new system?
- What new materials need to be developed?
- What types of facility should they include?
- What development tools are available?
- What will be the roles of teaching staff?
- How will students access the course materials?

The questions listed above are presented in order to stimulate thoughts and ideas about what, in any given situation, has to be done in order to establish a successful operational teaching web facility. These questions will not be discussed and debated in any depth here. Instead, the intention of this paper is to concentrate on just three basic areas: the hardware support that is needed; the range of software development tools that are required; and the organisational infrastructures that need to be in place in order to facilitate the use of a teaching web. Each of these issues is briefly discussed below.

Hardware Resources

The important types of hardware resource that need to be decided upon include: the nature of the servers that are to be employed; the network infrastructure that has to be in place; the types of computer terminal that will be used to gain access to the web; and, whether or not remote access via modems will be supported. In the HCI case study that is presented in the following section, an in-house server farm was used to host the main part of the teaching web. However, some use was also made of external Information Service Providers - as and when this became necessary for certain parts of the course. A campus-wide Novell network was employed as a means of providing access to the servers. Both desktop computers (local and remote) and laptop computers were used (by students and staff) to access the network and the teaching webs held on the servers. For remote access, the public switched network was employed - this required modems at both ends of the connection.

Software Resources

Prior to the advent of sophisticated authoring packages (such as HotMetal Pro, FrontPage and DreamWeaver), the creation of learning materials in HTML format for use on a web was quite a labour-intensive process. Although it was not difficult, it was both tedious and prone to errors. Nowadays, however, it is a relatively easy matter to create learning materials as Word Documents and then import them into an appropriate HTML development system for integration and linking with other relevant resources. In addition, the wide range of browser plug-ins and add-ons that is now available means that interactive learning materials can still be developed in particular development environments (such as Delphi, ToolBook, Director, and so on) and then 'run' by the browser. Of course, the availability of JavaScript and Java programming tools means that enhanced interactivity can be built into web-based materials without placing too great an overhead on the server that is used to deliver the course materials. In situations where special types of interactivity and data storage mechanisms have to be implemented, server-side
Software may need to be developed using languages such as Perl or C. For the HCI case study that is discussed in
the next section, all of these techniques were used. However, apart from the browser software (both Internet
Explorer and Netscape Navigator were used), the three packages that were most heavily used were SoftQuad’s
HotMetal Pro, FrontPage and Microsoft’s Word for Windows.

Organisational Infrastructures

In addition to the technical infrastructures mentioned above, a number of organisational infrastructures have to exist
in order to facilitate the effective use of teaching webs. Undoubtedly the most important of these relate to the
administrative infrastructure and the organisation of the teaching and learning environment. One of the main
administrative issues that we had to consider in the HCI teaching web was the way in which students’ ‘attendance’
and assessment data were collected and managed - and subsequently integrated into overall organisation-wide
student performance measures. As is discussed later, this was achieved through the use of electronic registers and
assessment mechanisms; the results being stored and processed centrally on one of the servers. An important
consideration from the perspective of the teaching and learning environment was the flexible way in which the
teaching web allowed the integration of new and old mechanisms of course delivery. As is discussed later, although
lectures were given, attendance at them was not compulsory since all of the HCI course was available on and could
be accessed via the teaching web.

3. Case Study – The HCI Teaching Web

This section contains a short description of a teaching web that we have developed to support the teaching and self-
supported study of material relating to the subject of human-computer interaction. The web has been operational for
about three years. Despite this, we do not feel that it is yet complete! We continue to modify and fine-tune its
content and structure in order to improve its performance and its appeal to students. In the remainder of this section,
the following major perspectives are briefly discussed: web structure; resources available; notice boards and
schedules; monitoring and assessment; technical and academic support; data files; providing access to additional
support materials; future developments; and potential application areas.

Web Structure

The HCI teaching web is organised primarily as a hierarchical structure embedded within which are numerous cross-
references that are implemented as hyperlinks. From the options available on the home page (see table 1), users can
navigate to those parts of the web that are of particular interest to them at any given time. This may involve
browsing the online material associated with any of the 40 lectures or participating (in self-study mode) in one of the
20 practical classes. The exercises contained in these are based on the principle of active learning. This involves
students having to do things (relating to HCI) for themselves - sometimes individually and sometimes in groups.
Each practical class usually has associated with it appropriate support data, a hints file and a worked solutions file.
As is discussed later, students are required to submit an electronic register for each of the practicals that they
attempt; they must also fill in an electronic checklist for every practical that they complete. The home page for the
HCI Teaching Web is available for inspection at the following Internet address:

http://www-scm.tees.ac.uk/users/philip.barker/hcihome.htm

Because the bulk of the HCI material is made available using an in-house intranet facility, the links from the above
Web address are all password protected so that only authorised users can gain access to the underlying resources.

Resources Available

The nature of the resources available on the teaching web is reflected in the ‘contents’ list that appears on the home
page when students access the web using their browsers. The options currently available are listed in table 1.
A Riddle - Why Study (HCI)?
Aims and Objectives of the Course
Course Description
Course Content
Computer Accounts
Lecture Material
Practical Classes
The Electronic Register, Checklists and Schedules
Books on HCI
Other Information Sources
The HCI Notice Board
Past Examination Papers
Research Opportunities in HCI

Table 1: The Main Options on the Home Page of the HCI Teaching Web

The two most heavily used options in this list are the 'Practical Classes' and the 'Lecture Material'. Each of these options leads to a screen-based, interactive, rectilinear matrix of options ('Practical 1' through 'Practical 20' and 'Lecture 1' through 'Lecture 40', respectively) that give students access to the underlying course material. This can be browsed, printed or copied to students' individual machines for later use. In principle, all of the material that students need to study the HCI course is available in electronic form from the teaching web.

Notice Boards and Schedules

One of the reasons for introducing the HCI teaching web was to encourage greater degrees of independent, self-managed learning. Students are therefore encouraged to be flexible with respect to how and when they study. Naturally, although flexibility is encouraged, some mechanisms need to be available in order to ensure that students 'move forward' with respect to progressing through the course. Two embedded web-based bulletin boards are therefore used to provide sources of 'motivation' for students. The first of these is the 'HCI Notice Board'; this is used to post both general messages and news items that are relevant to the course. The second online bulletin board is the 'Schedules Notice Board'. This is used as a means of giving students details of the 'recommended' start dates and completion dates for Practical Classes and Lecture Units.

Monitoring and Assessment

As was mentioned previously, the HCI teaching web provides two basic automated mechanisms for monitoring what students are doing as they progress through the course. First, there is the electronic register that keeps details of students' 'attendance' at the 'virtual' laboratory classes. Second, there are the online checklists that students complete at the end of each laboratory session. Each of these monitoring tools is implemented as a HTML form. Form handlers on the server are then used to process the data that is submitted by students. The form handlers are fairly standard CGI scripts that are written in Perl. The data that is obtained from these monitoring and assessment processes is extracted and imported into a database that can be used (in conjunction with dynamic HTML programming techniques) to generate feedback both for course administrators and for students.

Technical and Academic Support

Students using the HCI teaching web are provided with a range of academic and technical support facilities that they can call upon as and when they need to. Two basic types of support mechanism are used: face-to-face and online (Duggleby, 2000). Face-to-face support is provided both by means of a help-desk facility (that is manned during
normal working hours) and through a series of regular time-tabled 'come if you need to', open-access laboratory sessions. Online support is provided both through email and, at particular times of day, via online chat facilities.

Data Files

An important aspect of the HCI work that students undertake during the course is the development of practical competencies with respect to various types of data manipulation and data analysis. In order to facilitate this, the teaching web facility makes available a large data bank of material of various sorts that students can use as part of their practical exercises. Typical examples of the material that is held on the underlying intranet include: raw questionnaire data, spreadsheet files and experimental data from HCI experiments (such as reading rates and reaction times for various visual and audible stimuli).

Additional Support Material

The intranet facility that is associated with the HCI teaching web provides a powerful mechanism for making available a wide range of ancillary course support materials. Typical examples of the types of resource we provide to students include: electronic documents (relating to particular course topics) that are hyperlinked to other Internet resources; image sequences that are chosen to illustrate particular end-user interfaces to various consumer products (such as MP3 audio players, digital radios and mobile telephones); and hyperlinked reference lists for students to follow up as part of their self-managed study activities.

Future Developments

Although the HCI teaching web has now been operational for over three years, there are still a number of features and improvements that we feel we would like to make to the system. These fall into short-term and long-term development goals. The two most important short-term future developments that we would like to make are: (1) the addition of a 'user-friendly' help system that would provide new users with general help, guided walk-throughs and advice relating to using the system; and (2) the provision of a topic index and global web search facility to enable students to search the teaching web in order to locate particular items of interest to them. Some prototype software to test out each of these requirements has already been written and evaluated. From the perspective of longer-term developments, the most important major change that we would like to make would be to incorporate XML as the basic mark-up language (Eckstein, 1999). We believe this is important because it will facilitate the preparation of the catalogues and indexes that we need in order to implement efficient and effective searching of the teaching web. In our view, the use of XML will also simplify data exchange with respect to the administrative tasks associated with monitoring and assessment - and subsequent reporting of feedback to both students and teaching staff.

Potential Application Areas

We believe that during the next few years there will be tremendous opportunities for using teaching webs in a wide variety of different contexts both within conventional educational environments and for the support of lifelong learning and continuing professional development (Barker, 1999b; Barker et al, 1998). One important application area that we are currently exploring is the utility of such webs within the context of patient education within hospital and health-care environments (Kaur, 1999; Barker and van Schaik, 2000). Within this project we have obtained some interesting results and we are very optimistic about future developments in this and other related areas.

4. Conclusions

There have been a number of advantages associated with the introduction of a teaching web into the HCI course described in this paper - there have also been a number of 'problems and pitfalls'! One of the major advantages is the fact that because all the course materials are available online in electronic form, students can gain access to them at any time they wish to. Furthermore, because the intranet facility can be accessed over the Internet, both local (campus-based) and remote (from home) access is available. Another important feature of the teaching web is the support it offers for self-managed study and the realisation of the constructivist approach to learning. Students can
download copies of the HCI teaching web and store it on their own computers - usually on a 100-megabyte Omega ZIP disk. They can then modify and extend their personal version of the web in ways that are appropriate to their own individual needs.

In our view, the advantages associated with using teaching webs are an ongoing motivation for their further future development. However, there are a number of drawbacks associated with their use and implementation. From the perspective of a staff member, developing ‘quality’ web pages for use in teaching webs is undoubtedly a very time consuming process. Naturally, this can substantially detract from an academic’s primary role as a teacher and researcher. It is therefore unfair to expect the ‘average’ academic to develop the specialist skills needed to produce such pages. Institutional support with respect to HTML and multimedia resource development is therefore a necessary pre-requisite if this approach to teaching and learning is to succeed. Admittedly, there are automation tools available (such as Microsoft’s FrontPage and MacroMedia’s DreamWeaver) that can help the development process. Unfortunately, however, there are also many pitfalls associated with the use of these - if the intent of a development project is to produce highly portable code that is independent of any particular manufacturer’s development environment. Of course, there are also numerous security issues that need to be addressed - for example, the use of CGI scripts may be allowed on an in-house intranet server but is a facility that is often not available on many Internet servers. This again can create problems with respect to having a system that is totally portable and transparent to its users.

We still have many technical problems to solve in our future work. Despite this, we strongly believe that the benefits associated with using an interactive teaching web (to support the ideas underlying constructivist learning principles) far outweigh the problems and pitfalls that we have encountered with respect to the realisation of this approach to teaching and learning. We are therefore very optimistic about the future development plans that we have with respect to enhancing the quality of the learning environments that we offer to our students through the use of teaching webs.

Abstract: This paper describes the development of an internet-based 3-D service system for students. Starting as an information service for just one major field of study (business education), the anarchic implementation process permanently enlarged the system boundaries. From the viewpoint of technical rationality, the system design of the reported project was badly planned and designed. It is argued, that following the directions of a technical engineer approach would have resulted in a stop of the project. In contrast to the traditional technical solution, we will, based on lessons learned from organization theories, show that the logic of bricolage (a mental model of handcraft) is an adequate metaphor for describing and maybe even for planning design processes.

The Project

The project started with the idea to offer all relevant information services for Business Education students via the internet with a 3-D interface (Baumgartner & Wydra 1999). This idea was motivated by four basic cognitive principles:

- **Linking and remembering relevant study information:** Empirical studies in Cognitive Science demonstrated that information embedded in space or linked with spacial structures is easier to remember and learn (eg Günther 1998). The prototype of this idea can be explored at: http://iol1.uibk.ac.at/wipaed/.

- **Building up mental models of the study organization procedures:** Moving around in a 3-D virtual representation helps to build up mental models of the correlated and interconnected information which is relevant for mastering the situations in question. From the constructionist point of view, it is important to interact with the (virtual) environment in order to reach viable solutions for problems. Instead of passively looking up study problems like “what do I have to do to register my thesis” in a database of Frequently Asked Questions (FAQs) we could implement a robot avatar which guides the students around and shows them where to pick up the relevant information, forms etc.

- **Building up social virtual communities:** In our faculty we have a lot of students who spend many hours travelling to and from Innsbruck. For this reason we want to provide our students with an online service where they can get relevant information without having to come to the university in person. Clearly for faster access we have implemented this information in normal 2-D HTML. Due to a 3-D multi-user world our students cannot only communicate in real-time to exchange their views, but this also leads to closer contacts among the students. Tools like the avatar studio by blaxxun (http://www.blaxxun.de) can provide the necessary personal information to facilitate the process of building a community of students.
In contrast to the original idea our system developed from a student information system to an overall system not only for students but also for lecturers and secretaries. What went wrong? To understand this organizational trajectory we firstly have to examine in detail the different changes in the design process and secondly to generalize this process in the light of organizational theory.

History of the project

February 1998: The new professor (Peter), who is scheduled to get his professorship in Business Education in the winter term 98/99 is launching the idea of a 3-D student information system. An external graphic designer (Detlef, http://www.wydra.de) has been contracted. Additionally another lecturer brought in the context of the Business Education program. During this early stage it was realized that for the planned project different departments had to work together. Impossible! – There is simply nobody who has got the time, who is willing and/or has enough power to bring the different departments together (former efforts already failed). So the project was changed from a Business Education program to a department project.

March 1998: The department planned to merge with another department. Lecturers requested to discuss the quite different business processes at department level. But at this level the secretaries opposed to it. Therefore: nothing happened, but the usage of a database, developed from a lecturer from the other department, to provide the administration of the department, was at this point envisioned.

April 1998: The development of the homepage was assigned to a lecturer (Stefan), an external designer (http://www.ampuls.at) was contracted. A coordinating meeting (3 involved lecturers and the homepage designer) should clarify the relation between the 3-D student information system, the homepage, the database and an existing central www-database of course information implemented by and fitted to the requirements of the central EDP-department.

The following was decided withing two hours:

- to connect the administration database with the central course database and to use the database with small changes for the whole department.
- to use the central course database to provide the homepage with data of the courses. Because of financial reasons, we decided to connect these two systems with cgi-scripts. It was a general agreement that a database solution would be more efficient for the whole system, but there was no budget available.
- that the 3-D information system should be based on the existing administration database, on the homepage and course database. Only additional data should be captured in a separately linked database.

Finally, in a short discussion all existing, prospective and isolated planned systems were canned. Only small corrections were discussed, interfaces were defined on an abstract level. The 3-D information system should build on a various mixed systems.

September 99: The homepage is finished, the graphic designer and a lecturer meet to make a detailed plan for the info system. 3 points were discussed: 1. A lot of data from different systems must be imported in the database, because we need them for different inquiries from the database. 2. Secretaries and lecturers would not be able to see where to put in the data, due to a lack of a logic system. 3. Through a simple database important data for administration (eg marks) have to be brought in the system via different sets of www-forms (from the homepage, eg consultation hours, from the central database, eg schedule for the courses and from the 3-D info system, eg. information for a special course).

At the same time, the secretaries announced that they would not support the much less complex database for administration purposes.

Crisis hits: two days later it was clear financial support (more than the homepage budget!) was needed to develop an integrated system with one database, and the system had to meet the needs of secretaries and lecturers too.

November (plan!): 7 months after the first coordinating meeting a second one will take place. The secretaries and one professor will be in the meeting too. Business processes will be discussed and fixed in detail. In addition to the central course one integrated database for the department will be modelled. This database will be handled only via a...
www-surface. A new collaboration with another department and new budgeting rules make it possible to get a budget for this.

The result will be an integrated system with two databases (central and department) with two sets of www-forms. It is a system for a department and its students (some of them study Business Education) and not a system for the Business Education program, which would need a lot of information from other departments. Attention is not only drawn on students, but also on the lecturers and secretaries. The difference between 'outside' (infos for the students) and 'inside' (the administration at department and lecturer level) vanished.

the necessity of systematically analysing the business processes and the need of disobey the systemic approach

So what? In every text book (eg. Scheer 1998) we will find the recommendation that first of all we have to analyse systemic (on a gestalt level) and systematically all the different flows of the business process. This means you have to identify different entities (jobs, departments, ...) and their relations and describe in a very detailed and formal way the task-, performance and information flows. The description of the organization and the different flows should result in integrated, generalized business process models that do not depend on the actual human and incidental characteristics of the processes. When these tasks are finished the system engineer can generate a repository, a data-, function-, process-, organization-, performance and control system. For the purpose of analysis we will call this approach of system engineers the mental model of technical rationality.

No question - our strategy was stuporous. We developed isolated systems which became obsolete before they started. Specifically under the perspective of an engineer model it is, and really was, inefficient and expensive. The question is why didn't we follow this seemingly logical, obvious and coercive strategy? Already in our first meeting the question of the integration on gestalt level for the whole system raised, we failed to deal with it over 7 months.

Our anticipated conclusion: Until the day we are confident, that the project would have broken down, if we had had analysed the business processes and started to develop an integrated system at the first meeting. Why?

- At this time, the three departments were still two different institutions with quite different business processes. Especially the secretaries felt uncertain about the results of the merging process. At that time efficient and systematical clarification of the business processes would have resulted in a highly explosive atmosphere in the departments.
- Due to its time consuming aspects none of the staff members wanted to chair the project.
- It would have been difficult to raise additional financing.
- Designing one integrated system would have resulted in difficulties in sharing work responsibilities on the part of the agency and the graphic designer.
- Planning the entire project from scratch would have caused a major delay in starting the homepage.

The arguments mentioned above do not defeat the potential usefulness of a system design process based on a systemic and systemically analyses of the business processes. Strictly speaking they even do not refute the standard textbook procedure. But a common discursive reflection in retrospect showed convincingly that the financial shortcoming as well as the motivation of all the participants opposed a “cleaner” and more general approach. This assessment accepted, we were lucky that persons involved had not been practiced the engineer model: According to this model the design process would have to be interrupted when the pre-established goals could not be reached.

So what? - as Weik (1985, 242) noted, a reasonable question in organizations. We continued and succeeded. In order to explore the logic (!) behind the success of our case, we now refer to some concepts from the organization theory which give us valuable insights in the process of (the) organisation (of System Design).

Lessons learned from organization theory
Lesson 1: In the mental model of technical rationality you need to find solutions for existing clearly defined problems. In the garbage can model (Cohen/March/Olsen 1972; March/Olson 1976) problems, solutions, participants and choice opportunities are independent streams of events that flow into and through organizations, much like a random selection of waste gets mixed together in a garbage can.

As in our case study demonstrated problems followed envisioned solutions. The starting point was the vision of a solution (Schön 1983 and 1987): The perspective of an interactive 3-D virtual multiuser world. A fascinating idea and, as you can see, a good research object. Of course much more fascinating than dull problems on both administration and technical level. A budget was there and a producer for the system was found. Participants, who were willing to invest a considerable part of her working time were difficult to find and at the beginning the choice opportunities simply didn't exist. Therefore a lot of interlocked smaller (homepage, administration database) and larger (central course database) solutions exist, which are partly claimed to solve the information problems of the students and partly to solve other problems, eg from lecturers and secretaries. At the beginning nobody saw the ability to actualize a more systemic and systematical process and/or nobody was willing to invest more time than developing her/his small solution. As a consequence (eg with the garbage can model) we ignored emerging problems without reflecting on them.

Lesson 2 and 3: Ortmann (1990, 391ff) introduced the concept of a 'micropolitic bricolage' in the organization theory. The concept based on the bricolage-engineer concept from Lévi-Strauss lesson 2), enriched with micropolitics aspects of power and control (lesson 3)

The mental model of the engineer is described above. The mental model of the participants in this case was that of a 'Bricoleur' (a handicraft man). A Bricoleur looks a the actual situation and tries to find a solution with the tool box available. For her/him the result is not fixed established, it is accepted that the planned system is undergoing a continuous change depending on available resources. Even goals can be adapted and compromises are allowed. For a Bricoleur it is okay to accept limited budgets, to patch consisting systems together etc. And when he plans substantial changes in the system - like the two described movements - s/he will not ask wether the original goal is achieved, s/he will ask, whether the new solution is useful, even for another persons.

The bricoleur metaphor has got limited in scope when more Bricoleurs with different interests and world views have to work together or maybe work against each other (see Ortmann et al 1990, 395). Therefore you have to bring up the social process in mind. In the micropolitico approach of organization theory the developing and implementation of a service system can be interpreted as 'games of innovation' (Ortmann 1992), games which challenge the consisting 'routine games,' the existing regime of division of tasks, the negotiated arrangements etc. It is a meta-game, which defines interests, rules, structures, profits and losses and possible strategies of future games of routines. Hence, these games were played with high interests, in particular from those, who see the existing chances endangered.

In this view the implementation of a system is not only a technical process, but has also his social characteristics. In the model of technical rationality this is only another problem ("to raise the level of acceptance", "to reduce the resistance") to be solved by participation and information. In the model of a 'micropolitic bricolage' the technical and social process can't be divided. The social process will influence the technical solution and vice versa.

Lesson 4: In the mental model of technical rationality one has to follow a certain procedure to get to the solution. The goal is optimization of different variables for the purpose of efficient functionality. The "know how" of these procedures provides the professional knowledge of the specialist. In the mental model of bricolage knowing how is replaced by "to be able to" the usable skill in an actual situation. To know how to change a spare tire is not the same as to be able to do it. If someone confuses "knowing how" with "to be able to do" then there is the intrinsic fundamental rise of failure (Baumgartner 1993, 76).

Supplements of two logics: dream and reality

As you can see in the time-table, we are in an ongoing process and we are actually dreaming to change from the bricolage to the engineer model. The possibilities to change the project from bricolage to technical rationality (eg to the engineer model) are quite good. It appears, that there is now one of these seldom lucky chances, when solutions,
problems, participants and choice opportunities come together and results in a problem solution on a system level. Our minds are full of rational concepts, nonetheless we are sure, that the ongoing social process and (not) available resources will jumble our concepts and will influence the database, respectively the information system.

In this sense, the two different logics as summarized in the table below are not only excluding each other, but are supplements (Derrida) in the process of organization.

<table>

ray.land@ed.ac.uk

Abstract: The media through which academic discourses are conducted are rapidly shifting from the printed text and face to face dialogue, to the new electronic forms enabled by web-based hypertext, hypermedia and computer mediated conferencing. These new forms can be seen to embody and make explicit many of the key principles emerging from recent critical theory. Such theory, by radically challenging traditional notions of textual stability and the nature of language, also draw into question the possibility of stable meaning and systems of knowledge, the pursuit of which lie at the basis of traditional, positivist academic thought. This paper draws on such theory to consider not only how, by ‘de-stabilising’ the academic text, the new educational media are enabling new forms of academic discourse to emerge, but also how such changes in discourse have the potential fundamentally to alter the roles of instructor and learner, and the nature of the academic institution itself.

The Printed Text and the University

As learners and teachers in higher education, we work from within a scholarly paradigm predicated on print technology. Where the early manifestation of scholarly activity in the copying and annotating of manuscripts necessarily involved textual drift and idiosyncratic intervention – making each manuscript a unique artefact – print allowed us to apparently ‘fix’ text, to create for ourselves the possibility of a static, unitary, reproducible and ‘true’ version in which academic knowledge could be inscribed and disseminated. Commentators on the impact of print technology on our culture have shown how it has informed contemporary notions of scholarship (McLuhan 1962), while historians draw our attention to the involvement of the university with the very origins of the book trade (Haskins 1957). The crests and logos of countless academic institutions which are, or wish to appear, ancient and eminent repeatedly show the image of the printed and bound book, sitting at the very heart of the university’s symbolic representation of itself.

This central position of the printed text occurs because the notion of textual fixity, or stability, which print technology both symbolises and perpetuates is intrinsically bound up with what has traditionally been seen as the fundamental basis of scholarly activity – the pursuit of truth, authority, objectivity and stable systems of knowledge which characterise ‘traditional’ academic thought. During the latter half of this century, such ideas have been under sustained attack from literary, cultural, political and scientific theorists and philosophers, but it is only since the advent of hypertext, hypermedia and other manifestations of the new communication technologies that a material and explicit alternative to print has been available to us to question the formulations of meaning and knowledge inherited from print technology.

As Landow reminds us:

We so tend to take print and print-based culture for granted that...we have 'naturalized' the book by assuming that habits of mind and manners of working associated with it have naturally and inevitably always existed. (Landow 1997)
Electronic texts – in the form of hypertext and hypermedia-based learning materials, web-based and hyperlinked computer-mediated conferencing exchanges, and even simple email – are rapidly gaining ground in universities as means of generating and sharing academic knowledge. While we must take care not to subscribe blindly to what Duguid (1996) describes as a preoccupation with technological 'supersession' (the idea that each new technological type vanquishes or subsumes its predecessors), or to other forms of technological determinism, we might reasonably predict that such technologies will in time displace print as the primary, 'naturalized' medium through which academic discourses are conducted. As this occurs, we face fundamental changes in every area of the academy, from the ways in which the relations between instructor and learner are formulated, through the discourses and structures of our institutions and ultimately to our very perceptions of the nature of the 'scholarly' and what it means to pursue academic knowledge. The university, an essentially modernist institution (Bloland 1995), is being driven towards postmodernity by the postmodern artefacts of hypermedia.

The Electronic Text and the Transformed Role of the Reader

Such fundamental changes are predicated on the fact that hypertext and hypermedia force us to change both the way we read and our ideas about what constitutes 'text'. Hypertext theory teaches us that texts created in the electronic writing space do not conform to the Aristotelian notion that texts should have a beginning, middle and end, and be structured and read sequentially. Readers of hypertext enter the textual world at any point (in the case of web-based hypertext this world is almost infinite), determine for themselves a path through that world by following links in an order not determined by an author or instructor but by their own inclination, and emerge not when a text is 'finished', but when they feel ready to abandon it. Hypertext challenges traditional models of sequential progression, based on centuries of print-based technology, and presents a multi-linear, reader-defined model of interaction with text. The text does not exist in singular, static form but varies with each reading.

Hypertext theory emerges from critical theories of the last three or four decades, in particular those of post-structuralism. The latter have fundamentally altered our conception of the nature of text (regardless of what media it is presented in) and strikingly anticipate the emergence of hypertext and hypermedia, and the new ways of reading necessitated by these forms. It will be useful at this point briefly to outline such theories, and the ways in which they alter the relationships – forged in the context of the dominance of print technology – between author, reader and text. We will then consider how these new relationships are extended into the learning context and what the implications might be for institutions of higher education.

'Traditional' theory, or that which has its roots in the Romantic movement of the nineteenth century, assumes a fundamentally hierarchical relationship between the writer of a text and its reader. The writer is seen as the originator of the text, as the owner or inventor of the text's meaning (the word 'author' itself clearly implies this authoritative position). The author is, in the Romantic view, the possessor of a superior creative soul, one capable of communion with higher truths with which they enlighten the rest of the world through the medium of the written word. The reader in this scheme is the lowly recipient of the writer's vision (it is his or her duty to attempt to extract from the text its true meaning, i.e. that which the author has put into it).

This assumption was much questioned by twentieth century theorists. In particular, those of the reader-response school articulated theories which stressed the primary role of the reader in the construction of meaning. Iser claims that the literary work is not simply the text itself, but a synthesis of the text and its 'realization' in the mind of the reader (Iser 1972), while Fish goes further, suggesting that there is no meaning inherent in the text itself. A work is only ever a product of the reader's interpretive processes, and has no objective existence independent of the reading experience (the reader is the writer) (Fish 1980). Barthes distinguishes between the lisible ('readerly') classic text which places the reader in the position of passive consumer of narrative and meaning controlled by the author, and the scriptible ('writery') modern work which forces its readers to be active in the construction of meanings which are multiple and inexhaustible (Barthes 1970).

Though none of these theorists refers explicitly to hypertext or other forms of electronic writing, the connection is clear. Hypertext forces the reader to take control of his or her own experience of the text by requiring choices to be made about how and in what order connections between blocks of text, or units of meaning, are made. With certain forms of electronic text, including that generated in hyperlinked computer-mediated conferencing environments, the vision of the author as the single originator of the text and possessor of its meaning is submerged completely (the
reader quite literally is the writer). The reader, figuratively of central importance to the reader response theorists, is made materially central in the electronic medium. As Bolter puts it:

The computer makes concrete the act of reading (or misreading) as interpretation and challenges the reader to engage the author for control of the writing space. The computer makes visible the contest between author and reader that in previous technologies has gone on out of sight, 'behind' the page. (Bolter 1991)

Alongside such theories of reader response, we must also consider the ideas of the post-structuralist theorists (the philosopher Derrida, the historian Foucault and the psychoanalyst Lacan), and their focus on the indeterminacy or instability of meaning, the fragmentation of individual identity, and the centrality of discourse (Land & Bayne 1998). Post-structuralist thought emphasizes that language does not provide us with a set of terms or labels which we use to name entities which already exist independently in the world. Rather, language precedes the existence of these entities, enabling us to make the world intelligible by differentiating between concepts in a way which is particular to our own cultural context. The way in which we formulate meaning cannot be fixed and pinned down—language operates as a system of signs in which the relationship between signifiers (words, written or spoken) and signifieds (the concept or meaning referred to) is constantly shifting, always in a state of flux. Meaning cannot be nailed down, it is inherently unstable, 'never fully present in any one sign alone, but rather a kind of constant flickering of presence and absence together' (Eagleton 1983).

Ideas about the nature of text itself are radically affected by the ideas of the post-structuralists. Texts are no longer seen as closed, stable entities, holding within them definite meanings which the reader is required to decipher. Rather, they become a temporary arena for the endless play of signifiers—they cannot be tied down to any one meaning, but remain open and pluralistic, subject to multiple interpretation. All texts are woven out of other texts in that every element of them refers to other writings which surround, precede or follow, much as the sign itself is composed of traces of every other sign. This is broadly referred to as 'inter-textuality'.

What is more, the traditional hierarchical relationship between texts is undermined. Where traditionally a so-called central or 'primary' text takes a prime position, providing a focus for discussion and interpretation in the form of marginal or 'secondary' texts, Derridean deconstructionists would claim not only that the central can become marginal (and vice versa) but that the very difference between the two can be brought into question. Since both are subject to infinite play of meaning and interpretation, we cannot say where one ends and the other begins. The text is 'a differential network, a fabric of traces referring endlessly to something other than itself, to other differential traces. Thus the text overruns all the limits assigned to it so far' (Derrida 1991).

The relevance of all this to the study of electronic text is implied in a passage from Eagleton's *Literary Theory* which describes the post-structuralist vision of language:

Instead of being a well-defined, clearly demarcated structure containing symmetrical units of signifiers and signifieds, [language] now begins to look much more like a sprawling limitless web where there is a constant interchange and circulation of elements, where none of the elements is absolutely definable and where everything is caught up and traced through by everything else.

(Eagleton 1983)

Web-based hypertext and hypermedia can be seen as materialising the concepts of post-structuralist theory. The world wide web, sprawling, limitless, consisting of endless, unstable, changing elements, each one potentially linked to each other and therefore bearing within it infinite traces or connective possibilities, embodies the characteristics the post-structuralists see in language systems. Hypertext is endlessly recenterable. As a reader moves through a hypertext construct, or as a student moves through a virtual learning environment, he or she continually shifts centre or focus, is continually active in creating new possibilities for meaning. Such environments are also explicitly intertextual, stressing connectivity rather than what Bolter calls 'textual independence'—the electronic space permits us to visualize intertextuality as no previous medium has done' (Bolter 1991).

This intertextuality enables hypertext, in both art and pedagogy, to break through traditional generic and disciplinary boundaries, in the process violating the hierarchy of centre/margin (primary text/secondary text) identified by deconstructionist theory. Just as a hypertext poem might contain within it links to prose sites, to critical analyses, biographies, video and sound, so a section of online learning material might link to news clips, cartoon animation and discussion fora as well as to pedagogical material drawn from other related subject areas and disciplines. Just as
the work itself is not constrained to a single medium, neither does it contain a fixed centre. The centre is where the reader or learner is at any given moment; the marginal becomes central at the click of a mouse button.

Teaching and Learning in the Hypertextual University

How will academic study be affected as electronic text (which as we have seen embodies and makes ‘obvious’ some radical theoretical principles) begins to replace print-based text as the ‘norm’?

One chief effect of electronic hypertext has been the way it challenges now-conventional assumptions about teachers, learners, and the institutions they inhabit. It changes the roles of teacher and student in much the same way it changes those of writer and reader. Its emphasis upon the active, empowered reader, which fundamentally calls into question general assumptions about reading, writing and texts, similarly calls into question our assumptions about the nature and institutions of education that so depend upon these texts. (Landow 1997)

The transformational implications of hypertext for teaching and learning, and for the academy more generally, can be identified at a number of levels. We have already seen how at the textual level it implies a shift to openness, inconclusivity, infinite recenterability and the empowerment of the reader; the final section of this paper will show how such potential for transformation is extendable to the roles of instructor and learner, to the formulations and boundaries of disciplines, to the possibility for new forms of academic discourse, and finally to the nature of the higher education institution and community.

The Role of the Learner

Landow describes ways in which working with hypertext transforms the student learning experience. Because, within hypertextual space, students gain both information and habits of thinking critically in terms of ‘multiple approaches or causes’, hypertext can be seen to orient students towards developing a habit of ‘making connections’. This fosters ‘a participatory reading-and-writing environment’ which empowers students ‘by placing them within – rather than outside – the world of research and scholarly debate’. It thus enables students to explore and create new modes of discourse suited to modes of reading and writing increasingly used in e-space. (Landow 1997)

A clear implication for the role of the learner in such environments is the requirement that they adopt an active approach. Hypertextual systems, argue Jonassen and Grabinger ‘place more responsibility on the learner for accessing, sequencing and deriving meaning from the information’ (Jonassen & Grabinger 1990). In this regard hypertext is probably best considered as a learning rather than teaching environment in which an exploratory, ‘research’ approach to learning may flourish. By disposing students towards multilinear and multisquential patterns of thinking, and immersing them in environments of multivocality, hypertextual systems may also stimulate processes of ‘integration and contextualization’ – high order cognitive skills – in ways not achievable by linear presentation techniques (Mayes et al 1990). This accords with Landow’s interpretation of conceptual skill as ‘chiefly making connections’, a capacity eminently endorsed by hypertext’s defining characteristic of connectivity.

The Death of the Tutor?

Barthes once famously proclaimed the ‘death of the Author’ (Barthes 1977) – announcements of the death of the Tutor may be premature but the pedagogical application of hypertext does alter the role of instructors by shifting some of their authority and function to the learner. As we have seen, engagement with hypertext necessarily empowers the reader or learner so that a transmissive theory of knowledge which characterises teachers as ‘the ones who know’ and their task as ‘to channel what they know into the students’ is increasingly difficult to sustain (Spender 1995).

Such shifts in authority imply a transference of power to learners, which imposes upon them a duty of responsibility for autonomy, critical judgement, and a higher degree of tolerance of complexity and ambiguity. This in turn might be seen to have an emancipatory effect upon the role of the teacher, who is freed from the traditional status-oriented informative, didactive and confrontational interventions of traditional practice in favour of more supportive and guidance-oriented cathartic, catalytic and facilitative interventions.
Entwistle, Thomson and Tait (Entwistle et al 1992) argue that encouraging a ‘deep approach’ as opposed to a ‘surface approach’ in learners requires both an active approach and interaction with peers and tutors. Hypertext, as Landow shows (Landow 1992) affords excellent opportunity for collaborative learning, whereas such activity, as Ede and Lunsford (Ede & Lunsford 1990) demonstrate, tends to be mistrusted in closed text environments, where ‘the pervasive commonsense assumption’ is ‘that writing is inherently and necessarily a solitary, individual act.’ Entwistle and colleagues also show the need both for a ‘well-structured learning environment’ – a tall order in the hypertextual labyrinth but nonetheless crucial to pre-empt learner disorientation and intimidation – and for ‘a motivational base’, the support and encouragement needed by all learners. Assessment, too, Landow reminds us, must seek evidence of the connectivity and contextualisation hypertext affords, if it is to have validity. So a rich but challenging role remains for the instructor – one that is hypertextually transformed into that of facilitator-moderator.

Interdisciplinarity

It is no longer possible, Spender argues, for teachers to appear as experts in a computer-based world. ‘There is just too much information for any one individual to master’ (Spender 1995). Within the print-based university – the society of the closed, static text – knowledge was in short supply, a special commodity. This empowered the gatekeepers, the initiators into disciplines, to determine intellectual boundaries, to regulate entry to the next level of information, and, as the ambivalence of the Latin root of ‘discipline’ suggests, to control and to teach simultaneously. Lyman talks of an ‘ecology of knowledge’ in which, when knowledge is scarce, centralisation and conservation take precedence. In an information-saturated environment, however, ‘our distinctive information problem is one of selection, as much as conservation’ (Lyman 1994). There is no entry test, Spender reminds us, for TV viewing. The logic of hypertext, a postmodern phenomenon, is to erode the controlling boundaries of the discipline, which, in its unifying and totalizing tendency, is a modernist concept. The impetus of hypertext is inexorably towards interdisciplinary connection. The learner is no longer dominated by the dominus.

Democratic Publishing and Contextualised Debate

New hypertextual environments have the potential to transform the way in which scholarly publishing and debate operates. Buckingham Shum and Sumner (Buckingham Shum & Sumner 1998), for example, discuss how hypermedia might enable academic authors to break free of some of the constraints of traditional, paper-based scholarly publishing (its expense, long publication timescales, restriction to static text and image and generally non-existent facility for subsequent debate and discussion). Even the majority of web-based e-journals, they argue, remain ‘papyrocentric’, using technology to replicate traditional publishing approaches rather than to make meaningful advances on current forms of academic discourse.

Their toolkit for the publishing and discussion of web documents – the ‘Digital Document Discourse Environment’ (D3E), operates from the premise that ‘the intellectual cut and thrust of discussion and debate between peers as they contest the ideas proposed in a document’ is a key academic activity. It automates the procedures around publishing a document to the web and integrates the document (which may be in a variety of media) with a discussion environment which opens it up to clearly contextualised debate. Readers’ comments link back to the text and vice versa, and authors are able easily to revise and update documents as their research develops or ideas change. The traditional, static, closed, paper-based academic text becomes an accessible dynamic entity, potentially open to immediate input from a worldwide academic community. The toolkit also assists the creation of innovatory student assignments, with modes of student writing mirroring those of their instructor-publishers. This represents another manifestation of hypertext’s functioning, in Galegher and Kraut’s phrase, as a ‘permissive technology’, fostering new forms of academic discourse, and allowing ‘current practices to be extended into new realms in which they had previously been impracticable’. (Galegher & Kraut 1990)

Boundariless Anxiety, Widened Community

Hypertextual environments, in their protean boundarilessness, pose daunting dilemmas for the university as modernist institution. As Bergquist argues, in modern organisations ‘boundaries (and identities defined by roles and rules) serve as “containers” of anxiety’ (Bergquist 1995). We can see the function of disciplines, modularisation, academic management and reward structures in this regard. However in the postmodern condition these boundaries are eroded and there is a ‘spilling out of anxiety’, a ‘sense of living on the edge’. Another container of anxiety has traditionally been admission criteria and the division of individuals into those allowed in and those kept out.
But in the fully ‘technology-normalized’ institution, access becomes virtual and community easily widened, undermining the difference between centre and margin, what is inside the academy and what (or who) must remain outside. Deleuze has used the term ‘enclosed environments’ to describe territories which are circumscribed within organisations ‘to concentrate; to distribute space; to order time; to compose a productive force within the dimension of space-time whose effect will be greater than the sum of its component forces’ (Deleuze 1992), while Taylor suggests that terms such as ‘boundaries’ and ‘sites of enclosure’ are used ‘to describe attempts by institutions to create contexts — enclosed territories — in which only the occupants define the particular rules and practices which govern internal operations’ (Taylor 1999). But the educational institution now has the potential to develop as an unbounded environment, with all its anxieties and its emancipatory promise — an environment into which hypertext, in the guise of some neo-Promethean tool, beckons us.

A Study of the Influences and Barriers to Faculty Use of Instructional Technology in Higher Education

Thomas A. Beggs
Director of Learning Resources
State University of West Georgia
Carrollton, GA 30118 USA
tbeggs@westga.edu

Abstract: As instructional technology becomes ubiquitous in classrooms, faculty will be asked to utilize new technologies in their pedagogy. Some will accept new ways to teach with technology while others resist. What are factors that influence faculty to adopt this technology and find effective pedagogy to utilize it? The Department of Learning Resources at the State University of West Georgia asked its faculty about influences to technology adoption while creating a plan to tackle technology resistance. The resulting data showed the faculty recognized common barriers to instructional technology as well as influences that helped them overcome the barriers.

As higher education faculty adopt new instructional technologies, it will be important for influencing factors and barriers to their adoption of instructional technology to be addressed. The success of our faculty in utilizing technology will impact our students' education and ultimately success in their careers. In this technology age, higher education must prepare students to integrate technology in their learning if our institutions expect to continue to be viable avenues for students to prepare for life in the workforce.

Literature

The definition of instructional technology used in this study is one that refers to the use of technology to achieve an instructional objective (Spotts & Bowman, 1995). This technology includes computer hardware and software, networks, email, multimedia, and computer peripherals such as CD players. Traditional media such as video and audio are also defined as instructional technology.

Albright (1996) said in a keynote address to the Southern Regional Faculty and Instructional Development Consortium that so many barriers have existed in higher education to the adoption of instructional technology that faculty use of technology has been accomplished in spite of the campus environment. He notes that education may be the only business that actually discusses that there are barriers to its employees' adoption of technology. Albright also points out that higher education faculty have a conservative approach to its institution and a commitment to the traditional means of teaching—a barrier to innovation and technology in instruction. Approximately 80% of higher education instruction is delivered by lecture, a form in which instructional technology can be utilized, but only in rudimentary ways. Research suggests that lecture is not the best method for developing problem solving and critical thinking, often desired skills in the workplace (Oblinger & Rush, 1997).

Change in higher education has traditionally been slow. In the literature there is a reference to an anonymous quote apparently uttered by a frustrated instructional technologist:

The pace of academe is perhaps best measured by the 25 years it took to get the overhead projectors out of the bowling alley and into the classroom (in Gilbert & Green, 1997, p. 25).

The time span does not matter, but the heart of the issue remains. When faculty began adopting the new instructional technology there were issues that affected its acceptance and slowed its adoption.

The fear of failure in using the technology is a factor that has been cited as an initial barrier (Hannafin & Savenye, 1993). While faculty members are experts in their content area, they are not experts in the use of technology. They are also concerned about instructional technology operating consistently in the classroom (Byron, 1995). When the technology is difficult to use, the faculty would often have problems and refuse to use the technology again (Albright, 1996).
The availability of technical support staff to assist when in-class problems arise is important for faculty if they are going to tackle instructional technology (Nantz & Lundgren, 1998). Improved classroom designs will also alleviate concerns about difficult to use technology. Another anxiety that faculty face in adopting instructional technology is the devaluation of their profession and, consequently, the elimination of their jobs (Novek, 1996). As technologies are promoted as the next best way to reach more students, such as through distance learning, faculty worry about the role of the traditional campus and their possibly diminished place in the education system (Oblinger & Rush, 1997).

Novek (1996) also said faculty were concerned about the dehumanizing potential of technology. These instructors were concerned that students and teachers would become alienated by technologies such as distance learning. Oblinger and Rush (1997) suggest that some professorial functions such as simple transmission of facts may be replaced, but more important functions will continue to be essential. Leading discussions, helping students make sense of the whole, and suggesting resources are among the aspects that will create an improved learning environment. Research in asynchronous learning environments reported students have more access to their professors than in traditional lectures (Oblinger & Rush, 1997).

Whether the use of instructional technology in the classroom is effective for teaching is also an issue which faculty consider important (Byron, 1995). Faculty question whether students’ performance will be improved with the use of technology. Research has shown that it is not the technology itself but how the technology is used that improves learning and increases student interest (Albright, 1996; Charp, 1998).

Though students have said that faculty are not ready to make the paradigm shift to use multimedia and instructional technology in the classroom (DeLoughry, 1995), instructional technologists have evangelized for years that there are proven ways to encourage faculty to adopt and develop instructional technology (Albright, 1996). For example, the availability of instructional technology is an influence to its adoption by faculty. Faculty also welcome an effective support system. In a series of faculty focus groups at the University of North Texas, Byron (1995) found that knowledgeable, friendly technical support staff who respond in a timely manner are among the top factors for technology adoption.

Faculty members say it takes time to learn the technology and it takes even more time to develop instructional technology materials (Hirschbuhl & Faseyitan, 1994; Nantz & Lundgren, 1998). Green (1998) says that institutions have not been prepared for the sustained investment in time and support and financial resources needed to develop quality instructional resources. One of the most important support issues influencing faculty to adopt technology is training (Armstrong, 1996). In the Campus Computing Project 1998 National Survey of Information Technology in Higher Education, Green (1998) stated that “assisting faculty integrate technology into instruction” as the single most important issue reported and providing adequate user support as the second (p.1).

As faculty adapt technology to their pedagogy and grow in its use, they deserve recognition for their efforts. There must be a reward system that recognizes the adoption of technology through promotion and tenure (Nantz & Lundgren, 1998). It has become even more important as the adoption of technology has increased, but Green finds the majority of universities and colleges have not addressed this issue (Green, 1997). Technology support centers and faculty mini-grants are needed as well, but failing to recognize and promote faculty who are integrating technology "sends a chilling message about institution commitment," Green says (p. 2). Growth in the adoption of instructional technology requires a continuing investment of time, personnel, and funding (Green, 1996). Administrative commitment is required for this long-term development because only the institution can provide these resources.

Innovative teachers can be adopters or non-adopters of technology, but innovative adopters found significant advantages in the use of technology (Reimers, Rathbun & Goodrum, 1999). Innovative technology adopters discovered instructional technology gave them flexibility in designing course materials (Reimers, Rathbun & Goodrum, 1999).

One of the keys to the success of instructional technology may be the change in pedagogy from students being passive recipients of knowledge to becoming active participants in the instructional process. If students are to become more active learners, faculty must establish more communication and student-centered learning. When faculty are encouraged to utilize instructional technology their pedagogy evolves. In the project at Hofstra University, as faculty adopted multimedia technology they changed teaching styles to focus on guiding and facilitating instead of just lecturing about the material (Haile, 1998).

Interaction between faculty and student has been enhanced with the increased usage of email to transmit class assignments and make faculty available outside of class hours to answer questions (Reimers, Rathbun & Goodrum, 1999). Students can access courses anytime and anywhere by the use of the web and Internet.
During the 1990s, Kenneth Green has tracked the changes in the adoption of technology by surveying college and university computing officials. He reports that faculty technology adoption had reached a self-sustaining point based on Everett Rogers’ diffusion of innovation (Green, 1996). Rogers described this point as when 15-20% of individuals have adopted an innovation (Rogers, 1995).

Data from the 1998 National Survey of Information Technology shows there has been a jump from 8.4% in 1997 to 22.5% in 1998 in the use of web pages for class materials and resources (Green, 1998). Email use in support of courses has jumped from 32.8 percent in 1997 to 44 percent in 1998.

Until as late as the mid-1990s, there had not been significant research on the use of instructional technology by faculty in higher education. Green has annually reported since 1990 the results of Campus Computing Project annual National Survey of Information Technology in higher education. However, the survey information is provided by officials at some 500-600 two- and four-year colleges and universities and not directly from faculty members.

The purpose of this study is to examine the aforementioned barriers and influences to faculty adoption of instructional technology as well as to consider the technology that faculty are using in the classroom and the faculty’s perceived knowledge of technology.

Methodology

This research studies the influences on faculty adoption of instructional technology and the integration technology into instruction at a state university with 348 full-time faculty and about 8,800 students. A survey with 61 questions was adapted from an instrument previously used by Groves & Zemel (1999). Questions were designed to determine the faculty’s self-reported knowledge and use of technology, factors influencing their use of technology, and perceived barriers to the use of technology in the classroom. Faculty were also asked about the importance of instructional technology to their teaching and if they would continue to adopt new technology (Groves & Zemel, 1999). They were also asked about department, home computer use, rank and years in education.

The study was performed in April, 1999. There were 348 surveys sent by campus mail to all full-time faculty members along with a cover letter explaining its purpose and informing respondents they would remain anonymous. There were 156 surveys returned by campus mail for a return of just over 44%.

Results and Conclusions

This study considers questions that technology support personnel have debated for some time. What are the factors that influence faculty in their adoption of instructional technology and what are barriers that restrict faculty from utilizing technology? Closely tied to these factors are the technologies the faculty have adopted in their instruction and their perceived level of knowledge.

The factors that influence faculty to adopt technology in this were rated and ranked. The top two influences to the adoption of instructional technology in this survey are instructional issues - improved student learning (96.8% important to critically important), and clear advantages over traditional methods (96.1% important to critically important). Equipment availability (94.9% important to critically important) ranked third in this study. Increased student interest (93.6% important to critically important) was ranked fourth. This suggests that the faculty perceive that technology must have a significant impact on instruction for faculty to adopt its use even though the technology must be available.

Equipment factors that ranked high were ease of use (93% important to critically important), time to learn technology (91% important to critically important), and training (86.6% important to critically important). The high rankings also reflect critical factors for faculty, which perceive that time to learn technology and training in technology are essential. Personal comfort level (78.2% important to critically important), even though above a majority, does not seem to have a major impact compared to pedagogy and hardware issues.

The second lowest rated influence with positive ranking was administrative support with 80.1% rating it important to critically important. As an influence, faculty perceive administrative support technology as necessary to instructional technology but not necessarily critical. Least important of the influences to adoption in this study was technology use by colleagues. It seems the technology that a colleague is utilizing in class does not sway the respondents to adopt similar technologies. This was the only influence that faculty rated negatively with 36.5% reporting that it was not important and another 26.9% saying it was only somewhat important (Table 1).

* very importantly to critically important

Issues of influences and barriers are not only linked but in many cases are opposite sides to the certain factors. The top three barriers were equipment-oriented issues that also ranked high as influences - lack of time (87.4% important to critically important), lack of equipment (76% important to critically important), and lack of training (75.8% important to critically important). These factors reflected their comparable influences in their importance to faculty. Even if technology can have a positive impact on student learning, the faculty member must overcome these personal barriers in order to integrate instructional technology into their instructional processes.

Three factors that received strong negative ratings as barriers were lack of interest in technology (70.4% not important to somewhat important), lack of relevance to the discipline (65% not important to somewhat important), and, surprisingly, lack of contribution to professional development (61.4% not important to somewhat important). With pedagogical issues ranking as such strong influences, faculty seem to be saying that the student is the focus and not the teacher.

Influences and barriers are also linked to knowledge of technology. Not surprisingly, this study showed word processing is known almost universally. Ninety-three percent of the respondents ranked their knowledge good to expert. Email ranked second in this study (88.4%). Internet use for research and content support also was strong in third rank with 70.1% good to expert knowledge. Presentation software and multimedia use ranked near the bottom in this survey. In this survey presentation software rated 37.5% good to expert and multimedia rated 35.1%. Since multimedia/presentation equipment is being installed rapidly, the lower ranking of this knowledge creates a challenge for technology trainers.

A disappointing lack of knowledge in distance learning and computer conferencing is not unexpected but causes concern in the current environment that has state-wide projects focused on the development of distance learning. While 23.5% in this study said their knowledge is good to expert, another 58.8% said they know little to nothing about distance learning. Computer conferencing, which could be defined as a part of distance learning, was ranked last in this study with 21.6% good to expert and 58.6% none to a little. (Table 2).
The faculty's knowledge of technology is reflected by its use of technology in the classroom. Just as word processing and email were ranked at the top in knowledge, they were also ranked at the top in usage. Word processing was frequently used by 93%. Email communication with colleagues ranked second at 86.6% followed by email communication with students at 61.8%. Presentation software and multimedia usage also mirrored its knowledge ratings. Thirty-eight percent said they use presentation software weekly to almost every class. Multimedia usage was 30.7%.

Sixty-one percent of respondents said they used the Internet weekly to almost every class. For this institution and the state university system, this reflects the importance that has been placed on the development of virtual libraries and a continued development of on-line resources by the state of Georgia. The National Survey of Information Technology in Higher Education showed 33% of classes used the Internet as an aspect of the syllabus (Green, 1998).

Just as in a similar survey by Groves and Zemel, distance learning use is ranked low. Just over 10% used it almost every class, but 68.8% said they never use distance learning. Because email with students can be an aspect of distance learning, it may be that faculty have a limited definition of distance learning. Questions on future surveys should be designed differently to reflect use of the components of distance learning and if those components are for distance learning or on-campus classes.

When asked what technologies they use in class, faculty included word processing, email and Internet as the top ranked technologies. When asked what technology they would like to use, faculty in this study said multimedia (27%) and presentation software (13%). When asked if they would adopt a new technology in the coming year, 61% (n = 92) of the faculty respondents said it was very likely to highly likely. Only 6% of the respondents said it was not at all likely that they would adopt a new technology. Spotts and Bowman (1995) reported 22% were very likely to highly likely to adopt new technology and 26% said it was not likely that they would adopt a new technology. This seems to reflect the growth of technology in society as a whole.

How significant is instructional technology perceived to be? More than half of faculty in this survey (53.2%) said technology is essential to instruction with 83 respondents noting it is very important or critically important. Another 24.4% (n = 38) said it is, at the least, important. These results were higher than reported by Grove and Zemel who found that 46% said it was very important or critically important. Spotts and Bowman (1995) reported 38% rated instructional technology very important or critically important. A majority of the faculty also said there were incentives to the adoption of technology (65.9%), but it seems they have a variety of ideas about the definition of incentives.

In conclusion, the higher knowledge and use results in this survey as compared to previous surveys could be explained in various ways. The environment at this state university has become more conducive to the adoption of technology. An Associate Professor in the Library stated in the survey, "It is obvious that the climate on this campus rewards those who appear, at least, to be innovative." There is strong administrative support for technology. The President and Vice President of Academic Affairs are active in the use of new instructional technology, supportive of technology through funding and have encouraged the adoption of a technology plan which has been created by a faculty/technology staff committee. Faculty have stated that equipment availability is important and there has been an on-going development of campus networks as well as video and multimedia development in the classrooms. Two deans have committed significant funds to the development of multimedia. One college's classrooms are all multimedia and the other has almost all multimedia classrooms. Faculty have said training is important and there have been extensive training programs. There is a strong distance learning department and recent development of fully on-line programs.

When this survey is next administered, there are a number of elements that need to be redesigned to fit this institution, its technology, and its programs. Technologies will be defined to reflect more accurately what is being utilized. The extensive use of WebCT is not mentioned in this survey. Distance learning needs to be more appropriately defined for the university. Several additional factors also need to be explored such as the technology environment, availability of technology and training, and administrative support.

The influences and barriers to technology adoption define its use and possible incentives. As the administration and technology support staff continue to improve the environment by funding new technology, and training teachers, faculty will adopt, adapt, and integrate new technology. The faculty at this institution is young and most have technology in their homes. Technology will continue to evolve and become easier to use. Faculty and students will accept and adapt new technology to instruction and learning as they have the overhead projector. But this adoption won't take the 25 years it took to bring the overhead projector from the bowling alley to the classroom (Gilbert & Green, 1997) because the technology wave has already swept across the private sector and our society. Students will expect instructional technology when they attend post secondary education and it must delivered or else they will go to an institution that will provide the technology.

Multimedia/Multiliteracy: The multimedia arts education program

J. David Betts, University of Arizona, USA

Introduction

At the heart of the Multimedia Arts Education Program (MAEC) is a strong mix of literacy activities from the several arts disciplines and techniques. This is a descriptive study of this after school arts technology program for middle school youth. This paper describes the first year of an on-going longitudinal research project that will examine the effects of on high school success, graduation, and career aspirations. Data gathered in this phase will serve as part of the base-line data for that extended study.

MAEC is an intensive computer-mediated arts technology program begun in 1996 by the Tucson Pima Arts Council (TPAC). Middle school youth, targeted as being at risk from disadvantaged families, participate in a series of semester-long after school classes. The program is based on several literacies. Central to all the activities are written output from students consisting of journals, proposals, and descriptive abstracts, as well as poems and stories that are realized in video, computer-mediated animation or graphics. Students work in labs with professionals in computer graphics and publishing, language arts and word processing, computer animation, and video production. A final, fifth semester portfolio class capitalizes on cumulative skills and yields a home page a newsletter and a multimedia presentation. This study examines student development of literacies and computer skills as they effect school performance and prepare them for the electronic arts workplace.

Population

Approximately 8 - 10 middle school students were enrolled in each of the five labs each semester. Most were Hispanic and bilingual in Spanish to some extent. Most started the program during their 6th or 7th grade. A balance of male and female students was maintained by selection. Families must qualify for the free or reduced lunch program at their school and not already have a computer in the home. Students are not auditioned for this program.

MAEC youth who were selected based on factors contributing to high-drop out rates. Of the 44 students in the Spring1998 program, all but two were on free or reduced lunch programs at their school. 54% were bilingual Spanish, 79% Hispanic, 7% Native American, 7% African American and 7% Anglo. There is now a waiting list of interested students and families. Most live in neighborhoods near downtown Tucson with low graduation rates. Students are required to maintain a “c” average in school in order to continue in MAEP.

Theory

The integration of art into education facilitates the construction of new knowledge by young people based on this mediation. New facts are engaged with new skills in new media. These skills call forth new ideas and the transmediation of those ideas in a reciprocating spiral of learning (Salomon, 1990). The artistic content of the
actions and operations of the MAEC provides a parallel means of connection or engagement for the learner.

Leland and Harste (1994) define literacy in terms of transmediation, or "movement between and among communication systems" (p. 340). MAEC provides many opportunities for students to transmediate between sign systems, such as placing the words of a poem onto an illustration, or animating drawn characters from a storyboard. The computer mediates the artistic expression of the student's new ideas.

Those new ideas can come from any area of a child's life, including, as Moll (1992) writes, the "funds of knowledge" that are in family and neighborhood. The infusion of technology into the students' lives at the MAEC, and ultimately into their families' lives has an effect that ricochets among the several domains including school. Eisner (1994) acknowledges the importance of connections between school knowledge and students' lives outside of the academic environment. Transfer of learning will occur, Eisner asserts, when students encounter tasks and relationships similar to those outside of school.

We can see that the MAEC activities are complex, and as they are in transition into adolescence, their influence on their home and community is changing. In many cases we see evidence of their new learning having an effect on their family.

The Multimedia Arts Education Center

The MAEC views the arts as a critical factor in the mastery of computer and media technology. The MAEC teachers are professionals in their area of art technology, each with several years teaching experience. The large TPAC building, with several computer labs, also includes an art gallery. Many local artists pass through and influence the culture of the facility.

The curricula used in the labs each include art and design, technology, and literacy components. Students learn several professional level application programs and tools. They learn to make aesthetic considerations in design, to develop a critical eye and to revise. They keep journals and write proposals for their projects and create storyboards, video logs and scripts, as well as poems and stories.

The Language Arts lab students do word processing and basic desktop publishing. There is an emphasis on basic English grammar and composition. The Computer Graphics lab students learn to do computer photo-manipulation, drawing and printing. Various projects such as letterhead, calendars and logos involve integration of many electronic arts tools. The Animation students develop narrative storyboards and two-dimensional computer animations. The Video lab has several camera kits with lights and microphones, editors, and a special effects generator. Students learn to use this equipment and basic production techniques as they work through group and individual projects. The Portfolio lab emphasis is on developing multimedia presentations based on their work from previous semesters.

The students receive a small stipend ($25) twice each semester upon attaining the required skill level benchmarks and completion of their individual projects. When they complete of the program, each student receives a desktop computer of his or her own. This has been a very motivating aspect of the program, as most of the families involved are not able to have a computer at home.
Methodology

This longitudinal study of the MAEC activity utilizes several strands of data for analysis of the program in its context, taking into account its history and the history of its stakeholders, the students, faculty and staff. A coordination of qualitative and quantitative data gathering techniques will yield a picture of the nature and dynamics of this program. When we know how the students did finally in their high school careers, hopefully we will also know something of what they brought to the program and what they took from it, what their family lives were like and how it was related to the individual and group story. We know now that all the program graduates are still in school, the first will graduate next year (2000). This study should contribute to the program’s continuance because it represents an effort to monitor and be accountable for its continued improvement and ability to adapt to new needs and affordances.

Research questions

This longitudinal study is designed to track: a) students’ success in high school; b) the impact of the program on extended families; and c) the impact of the program on students’ college and/or career goals.

In addition, the study will look at a) the development of the MAEC, its curricula and management; b) the development of students’ perceived self-efficacy and attitudes about art technology; c) literacy skills development; d) evidence of aesthetic response; and e) school-to-work skills acquisition.

Exit interviews

At the end of each semester, this investigator interviewed the students who were about to graduate. They were each asked the following questions, among others: “Are you feeling like you accomplished something here in five semesters?” “What project do you remember the best, the most, what stands out?” “How is your family with this whole activity? Do you get a lot of support?”

It seemed that the students we have interviewed so far, who have all completed five semesters of the MAEC, were pleased to have made it, to be graduating. They were proud of what they had accomplished and each had some aspect of their multimedia work that they were pleased to recall and describe. They saw it as having been substantially different from their school experience. Most felt that the language arts lab was the most helpful in their schoolwork. There was a wide range of plans for after high school. All saw high school graduation as a clear and attainable goal. They had few complaints or suggestions, other than the snacks. A few of the more technologically advanced wished there had been more computer hardware and software for their use. They often reported that their family was proud of their accomplishment. The new computer that they were anticipating would have a place in their home and they were already fielding questions as to access by family members. The goals they had for themselves and the program were generally similar and related to new computer abilities and arts experiences. They were somewhat motivated by the educational incentive payments, several put these checks away for software or a printer to use with their new computer.

Parent interviews
These interviews were conducted shortly after the students graduated. Parents will be interviewed again before their child graduates from high school. Some of the questions asked in these interviews were: "What do you think was the most important thing in your child's participation in MAEC?" "What did the program mean to you, as a parent?"

At the end of each interview, parents were asked to respond to some scaled questions that helped them assign values to various aspects of the program. Such as, "How much did the multimedia program help your child with his/her self-esteem?" And "How much did the multimedia program help your child with his/her writing skill?"

Results from these interviews showed a high degree of satisfaction and parental involvement the program. Parents played an important role in helping their children meet the long-term commitment to MAEP. Parents said that the fact that their child completed the program was the most important aspect for them. Many said that it helped them grow up. Several parents remarked about the job-related skills that were required. Most were unfamiliar with the art technology that lies at the heart of the program, but appreciated the computer skills the students acquired.

Participant observation

Over first school year of the study, university students worked as teaching assistants in the labs. They were asked to record and submit their observations of the activities randomly twice a week. Their duties were to assist the artist/teachers with their teaching and help the students with their projects. They also worked with the teachers in formalizing the learning objectives and curriculum for each lab.

Skill tests

These brief tests, given at the beginning and end of each semester in each lab, were instituted to help the artist-teachers develop a scope and sequence for their arts technology lab. Basically, each teacher developed a series of questions based on what the students will need to learn to meet the requirements of the lab.

Questionnaires

Perceived self-efficacy and attitude questionnaires were administered several times over the course of the first few years of the program. These were designed to elicit student attitudes and perceived self-efficacy. Five of the items were language arts skills designed to determine if any individuals were coming into the program with serious deficits in language. The questionnaires were given several times during the course of each individual’s program.

Perceived self-efficacy

The perceived self-efficacy (Bandura, 1993) items covered a variety of activities in literacy, art, technology, and design, as well as social abilities such as collaboration and communication. Items addressed:

1. Technology-based applications
2. Creativity and design
3. Communication
4. Writing
5. Arts awareness
6. Reading

Attitudes
Another group of items on the questionnaire dealt with student attitudes regarding work, school, art, community, and the program. Items addressed:
1. Sense of community
2. Personal goals
3. Real world perceptions

Two of the items were more or less open-ended responses about their expectations for the program and their plans for after high school. Preliminary results indicate that the majority had goals of college and a successful career in mind and they felt that the program would help them attain those goals. These responses will be tabulated and further analyzed for language use.

The Essen Learning Model
A Step Towards a Standard Model of Learning Processes

Heimo H. Adelsberger, Markus Bick, Jan M. Pawlowski

Information Systems for Production and Operations Management
University of Essen, Germany
{H.Adelsberger|Bick|Jan.Pawlowski}@wi-inf.uni-essen.de

Abstract: Several standards like the Learning Technology Systems Architecture (LTSA) or the Instructional Management Systems Project (IMS) provide a format to interchange, reuse, and combine learning contents. They do not cover didactical methods in detail. Therefore we developed an approach to specify methods as a part of the description of learning sequences. This representation and selection of learning and teaching methods is an integral part of the Essen Learning Model (ELM), a generic development model supporting developers, educators, and users on different levels of educational activities. We show how to use structured teaching processes as a guideline to implement learning environments.

Introduction
Due to the enormous amount of developments in the field of educational technologies, a variety of approaches, architectures, and systems have emerged in the last decades. Recent educational concepts like Virtual Universities changed the research focus from single user, local architectures, to a multi-user, globally distributed architecture. The need to combine and integrate different systems has led to several standardization projects, determining standard architectures and formats for learning environments, such as Learning Technology Systems Architecture (Farance, Tonkel, 99) or Instructional Management Systems Project (EDUCAUSE, 99). One of the main issues is to standardize learning contents in order to make those contents available for integration, e.g., in a Virtual University. Less attention has been devoted to the standardization of learning and teaching methods. When choosing a course for the integration into a curriculum, the decision depends on the one hand on the content, on the other hand, the educator has to consider the teaching method used for a certain content. Therefore we focused on the representation of learning and teaching methods in order to develop a generic description. First of all, this description acts as a decision tool when integrating courses, secondly it guides the author implementing a course or a unit.

The representation and selection of learning and teaching methods is an integral part of the Essen Learning Model, a generic development model supporting developers, educator, and users on different levels of educational activities (Pawlowski, 2000).

In the following we point out the need of a standard representation of methods. The representation of learning processes was modeled in ARIS (Scheer, 98a), a standard modeling tool. Our implementation used this representation, but other process modeling tools could be used as well. We briefly describe ARIS, the implemented methods, the method selection process in the Essen Learning Model, and present a sample implementation from our university.

Essen Learning Model (ELM)
The Essen Learning Model was developed at the University of Essen. It is currently being evaluated to be used in different departments of our university. We will describe the design principles and the general flow of the approach.
The Essen Learning Model is a modular system (Fig. 1), supporting development processes as well as the system's use system on different levels: The support of curriculum design (C-level), the development of learning sequences (D-level), and the development of learning units (E-level). We distinguish between three abstraction levels: the generic development model provides knowledge for a variety of contexts. This generic model is customized depending on the user's needs and preferences, and transformed into a specific process model for each project. The process model provides a framework for educational technology projects. The third level is the result of the development process in form of certain implementations for each module. The result of ELM-C is a detailed network of learning objectives and goals. The structure and
Fig. 1: The Essen Learning Model

Each module. The result of ELM-C is a detailed network of learning objectives and goals. The structure and relations of learning sequences (courses) are determined. Based on these results, learning sequences are developed in ELM-D. The focus of this phase is to find an adequate didactical method including the right technology depending on learning objectives and user group. The selection of teaching methods which is supported in ELM-D is modeled in ARIS in this approach. Finally, single learning units are designed and implemented in ELM-E.

Modeling Techniques: ARIS

Modeling of processes is very complex. One approach is to use the Architecture of Integrated Information Systems (ARIS). This architecture is applicable for every type of (business) process: in manufacturing, in the service industry, and in the public services (Scheer, 98a). We will show that teaching methods, respectively teaching/learning processes, can be described as process models as well.

ARIS is a frame concept for a global description (modeling) of computer supported information systems covering the whole life-cycle range: from business process design to information technology deployment (Scheer, 98b). In order to reduce the complexity, the process model is divided into individual views that represent discrete design aspects and can be handled (largely) independently which simplifies the task. The ARIS concept distinguishes four views: organization view, data view, function view, and control view, the latter is used to establish the relationships between the components (Scheer, 98a).

The processes are modeled using the ARIS-Toolset, supporting the user in modeling, analyzing, and navigating through the business processes. It utilizes the event-driven process chain method (EPC). The model of event-driven process chains (EPCM) can be described as a model based on graphs which consist of vertices and edges. Furthermore it is possible to add several attributes to an EPC, like, e.g., the duration of a process, etc. (Keller, Teufel, 97). A detailed presentation of the elements of an event-driven process chain is described in (Keller, Teufel, 97).

Standardized Representation and Selection of Methods

Learning sequences are typically described by certain attributes, characterizing the contents, learning objectives, and sometimes learning materials. These definitions are being standardized in the Learning Object Metadata Model by the Learning Technology Standards Committee of IEEE (LTSC) (Farance, Tonkel, 99) and the Instructional Management Systems Project (EDUCAUSE, 99). The goal of this standardization is to develop a format for interchange, reuse, and combination of learning contents. An important criteria for choosing an alternative from a variety of learning sequences is the didactical method used for specific learning contents. The above-mentioned standard approaches do not cover a detailed description of didactical methods. Usually only informal information is added, which does not cover all aspects of a method and its usability for certain contents.

Therefore, we developed an approach to specify methods as a part of the description of learning sequences. Learning sequences are represented as process models using ARIS. These models cover the main activities, interactions, information systems, and persons involved. Besides the specification aspect, it helps the author, teacher, and learner to navigate through a learning sequence. It also provides the opportunity to easily combine and reuse learning sequences or parts of a sequence. The approach is not limited to ARIS as a modeling tool. Other specifications like IDEF (Adelsberger, Körner, 95) or UML (Booch, Jacobson,
Rumbaugh, 98) can be integrated easily. A further benefit is the option to integrate business processes and learning processes in order to close the traditional gap between operations and education (Adelsberger, Körner, Pawlowski, 98a, Adelsberger, Körner, Pawlowski, 98b). In the following, we will present the representation and selection of didactical methods. Furthermore, we will show a sample implementation. A learning sequence on “Simulation in SIMAN” was developed for students of Business Computing, following the Essen Learning Model. The Learning processes were modeled using ARIS, the learning environment was implemented in XML (W3C, 98).

**Representation**

Within the scope of our research activities (Adelsberger, Bick, Kraus, Pawlowski, 99) we developed and implemented a computer supported simulation game at the University of Essen for a learning sequence on “Simulation in SIMAN”. Using the phase model of Kolb, the modeling of this teaching method was implemented as an EPC. Thus the EPC can serve as a guideline for creating simulation games. A simulation game is an active teaching method for processing and solving practical problems by one or more teams. It allows experimental, competitive learning (action learning). The essential pedagogical goal of the simulation game method is to increase the students’ thinking flexibility (Geuting, 89).

![Fig. 2: Kolb’s learning cycle and the phases of simulation games (Ruohomäki, 95)](image)

The learning cycle, based on the theory of experiential learning, is commonly accepted for simulation games (Graf, 89, Ruohomäki, 95, Adelsberger, Bick, Kraus, Pawlowski, 99) and has four related stages (Fig. 2): Concrete Experiences, Reflective Observation, Abstract Conceptualization, and Active Experimentation.

Learning is understood as a continuous process whereby knowledge is created from experience. The cyclical model is best to be used in simulation games for education and training since they are a type of “controlled experience” which introduces the process mentioned above (Ruohomäki, 95). It is common to view playing simulation games as a three-phase process, involving Briefing, Activity, and Debriefing. These phases of the simulation game and the experiential learning cycle are closely linked. The learning cycle starts with a Briefing. The participants are generally introduced in the game and its surroundings, followed by activities and Concrete Experiences. The next phase of the learning cycle offers an opportunity to reflect and observe experiences from many perspectives, e.g., by sharing reactions and observations in discussion with other participants. Abstract Conceptualization is the process in which the participants create concepts that transform observations into logical theories. The following Active Experimentation could be used to develop hypotheses of reality and to test them during the game. Different kinds of solutions can be tested and probable consequences can be seen. These solutions can then be corrected, modified and retested. Debriefing is the process which examines and discusses the experience of the simulation game and thus turns it into learning.

**Selection**

The selection of a teaching method is supported by a generic process (Fig. 3). It starts with the event New Course, ends with the event Well Trained Student, and has the processes Select Method, Activity and Evaluation in between.
Process: Select Method

Process: Evaluation

Example Process: Simulation Game

Fig. 4: Processes
The process Select Method (Fig. 4) describes the sequence of selecting a method focus, as well as the selection of a teaching method. The selection of the teaching method is being controlled by attributes of the function Select Teaching Method.

After choosing the teaching method, the process Activity is initiated (Fig. 4). In this approach an exemplary description of the process Activity for a simulation game is shown.

After that an evaluation of the learning process follows, both the moderator and the students are participating. The evaluation method’s selection is supported by the Knowledge Base and the User Model.

The development process, supported by ELM, is based on an Architecture of Computer Supported Learning Environments (Adelsberger, Körner, Pawlowski, 98a, Adelsberger, Körner, Pawlowski, 98b). This architecture consists of the components: Learning Engine, Knowledge Base, Presentation Component, Communication Component, User Model, Evaluation Component, and Methods Base.

The Methods Base, used for a method’s selection, contains different didactical methods and concepts which have been modeled with ARIS. The moderator/author can use these structured EPC concepts to teach different kinds of learning contents. Traditional static learning environments are usually based on a single learning concept. Recent developments adapt methods depending on user and content characteristics.

Furthermore, the above-mentioned process of selection is supported by the components Knowledge Base and User Model (Fig. 5). The Knowledge Base contains learning objectives and contents, conceptual modeled in ARIS. The knowledge representation is implemented in XML. The User Model contains attributes, characteristics, and knowledge of a user. Ideally, the knowledge is represented adequately, based on the User Model, regarding individual learning pace, preferred learning method, and preferred presentation format.

![Fig. 5: Methods Base](image)

The attributes contained in the Knowledge Base and the User Model offer the author a selection of teaching methods by means of an inference mechanism enabling to choose a method according to his preferences. The author is supported by the structured EPCs of the specific methods, the given teaching materials, and the User Model.

The developed sample implementation of a learning sequence on “Simulation in SIMAN” follows the Essen Learning Model (Fig. 6). We have decided to use the simulation game teaching method, because of the learning goals in simulation are so complex, the students have to be trained to be able to work in teams, and our department focuses on application-oriented education.
The Activity process is used as a guideline for the implementation of the simulation game. During the development process, the Presentation Component, the Communication Component, and the Evaluation Component were specified. The complete implementation of this example is modeled in XML.

Abstract: This paper discusses some issues and research findings of the project we call UNIBASE. In order to improve the learning processes through hypermedia technology, we investigated the role of cognitive mapping and the application of certain cognitive ambiguities and breakdowns. The addition of clear learning goals, explicitly expressed through cognitive mapping tools, allowed students to acquire the right knowledge and helped them adopt a pro ductive strategy. Complementary to this elicitation process, video information embedded in hypermedia learning environments was used to increase the levels of attention and motivation, using devices such as movement, novelty and appeal. Our aims were to explore and develop the application of innovative hypermedia artefacts.

1. Introduction

The challenges ahead are usually identified with changes in how the learning experience is delivered, changes in who is delivering the learning experience, and changes in the role of the learner as part of a target population. Radical changes have already taken place in the latter and it seems reasonable to acknowledge that a new pedagogical approach is needed to cope with the arrival of a new generation of potential students. We can describe this change as a shift from a “drill generation” to a “play generation”. Somebody already called this new target group the “playstation” generation.

To cope with these radical changes, digital technology is being increasingly used to create new learning artefacts. At the heart of this technology is the "system" perspective, as proposed by Davenport (1997). Input and output devices serve as surrogate extensions of our senses, providing connectivity to the world. Computers and networks bear some correspondence to our own brains and nervous systems. When connected together into a system, these devices enable the digital creation of systemic worlds and scenarios. The learner’s involvement becomes active and conversational, rather than passively receptive, and leads to the co-construction of meaning.

The UNIBASE project aims were to explore and develop the application of innovative hypermedia artefacts. This paper discusses some issues and research findings of the project. The research activities and design experiments have been carried out with a group of 16 students, whose task was to prepare conceptual maps and hyperspaces, using a particular type of mapping software with editing and

1 Designed and carried out by Universidade Aberta (Open University in Portugal) and the Informatics Department of the University of Lisbon, Portugal.
2 MindManager™ (www.mindman.com)
communication tools. A group of instructional designers also participated in the design of an experimental prototype for the Web, using knowledge mapping in the same way as the students did. These activities were embedded in realistic and relevant contexts with rich audio-visual representations and real-world data.

2. Facing the Problem

What learning activities can be supported by hypermedia artefacts? What are the actual cognitive and affective strengths of hypermedia? How do we design for this medium? Much has been said about the potential for interactive learning sustained by the "right" design of hypermedia in systems such as the World Wide Web. But when designers attempt to give choices to the user, as to how to proceed, options seem often to be unengaging and ineffective. A clear sense of the experiential and reflective modes (Norman, 1993) that should support such design efforts is not attained by the users/learners. However, the human mind seems to work like the World Wide Web, in a dynamic, creative, fractal and unpredictable way.

The problem we want to address can be summarised as follows: which combination(s) of interaction processes, authoring functionality and synergy between complementary elements of multimedia information can improve learning in a learner-centred educational environment? Once an author or designer abandons the notion of total control over the learning material and, instead, engages the audience in a process of co-construction, he discovers that a more fundamental question surfaces: can the learning material become organic, adaptive, and generative?

Our approach has favoured the mapping of knowledge and the application of certain cognitive ambiguities and breakdowns, in order to improve the learning processes. The addition of clear learning goals, explicitly expressed through cognitive mapping tools, allowed students to acquire the right knowledge and helped them adopt a productive strategy. Complementary to this elicitation process, video information embedded in hypermedia learning environments was used to increase the levels of attention and motivation, using devices such as movement, novelty and appeal.

3. The use of Reference Models

An adequate usage of reference or mental models, for instance as concept maps or mind maps, stimulates and facilitates the recognition and transfer of information. Basically, we strive to develop mental reference models that are meaningful organisations of information in our brains. Adequate usage of these reference models suggests that we use, for example, meaningful sounds, pictures and graphics to express ideas.

Schadé, cited by Hoogeven (1997), argues that if reference images are added to text, the understanding of a story is about 75% faster than if we are confronted with a text only story. He also hypothesises that by using reference models, innate or acquired in our early childhood, text and picture stories are stored faster and more efficiently in our long-term memory than text-only stories. He states that people tend to remember 25-35% more of a text and pictures story than of a text only story.

The use of reference models is not exclusive to educational practice; it is a well-accepted marketing technique to use basic reference pictures and sounds to improve advertisements and commercials. Often family scenes, romantic environments, status symbols, attractive women and responsible men are weaned into the marketing material. We assume that an adequate use of reference models is an important variable with regard to an effective learner-centred design process.

4. The Role of Audio-Video

The integration of "raw" audio-visual information with the learner's knowledge structure may facilitate retention and retrieval. Training learners "to transform complex visual images (i.e., to analyse, describe, categorise them) can provide an important link between visual and verbal storage and retrieval." (Kozma, 1986, p.16). This has been implemented in UNIBASE by means of cognitive mapping devices that
support the integration of audio-video segments. The final result could be easily published as a hypermedia structure.

Hyperlinks could be mouse-clicked by the learner to play short narrative explanations or video clips. It was recognised by students and designers participating in our experiments that one of video's greatest strengths is the power to generate attitudes and emotions as no other medium can. According to Anderson (1983, p.72): “It is an excellent tool for displaying affective information.” The affective domain is concerned with the learner's reception and responses to the stimuli presented. Furthering this idea Azarnsa (1996, p. 39) identifies five categories that describe the levels of this domain: (a) receiving, (b) responding, (c) valuing, (d) organisation of values, and (e) internalisation, which is characterised by the learner holding a particular value or set of values.

To enhance the learner involvement in the initial stages, we had to find means to engage the learner in novel and interesting ways. Rather than just trying to simulate existing reality on the computer screen, or trying to create a “virtual reality”, we found that it is far more sustainable to create a new experience for the viewer with simple means. In the past, microworlds have been created to provide an entirely new framework for the learner to explore, but today the Web can already provide plenty of worlds to interact with. According to cognitive flexibility theory (Spiro and Jengh, 1990), learners are able to spontaneously restructure their knowledge in many ways as they chart their courses through the hypermedia material. So, we constructed artefacts - designated knowledge hyperscapes (Bidarra and Guimarães, 1999) initiated by the instructor and further developed by the students in an organic, adaptive and generative manner (see figure 1).

Figure 1. Map representing the hypermedia structure of the site produced.
5. Hypervideo Mechanisms as Authoring and Learning Tools

Constructivists have argued strongly for the need of authentic learning experiences and video is an appropriate tool to support this. Video clips can greatly enhance the authenticity of a computer based learning environment (Boyle, 1997). However, for a system to allow learner reflection, it must have a compositional and representational medium that affords adding new representations, modifying and manipulating old ones, and perform comparisons (Norman, 1993). Reflection also requires the time and ability to elaborate upon and compare ideas. The medium must afford the time for reflection. In this sense, broadcast television cannot augment human reflection, it does not afford composition or the time to reflect. However, television and video, when properly constructed, can be a powerful tool for reflection. If the user can select what is to be seen and control the pace of the material, and it is easy to go back and forth, to stop, to make annotations, to compare and to relate to other materials.

Effective reflection requires some structure and organisation (Norman, 1993). Structuring and organisation of information is the main issue in hypermedia. However, being multimedia is not enough for a system to be truly hypermedia. Different media can be used purely as illustration in a system where links are restricted to text. Hypervideo refers to the integration of video in truly hypermedia documents. True integration of video requires a more powerful hypermedia model, taking into account its spatial and temporal dimensions, defining the semantic structures and mechanisms for linking video, finding new concepts of navigational support, and taking into account the aesthetic and rhetoric aspects of integrating several media in hypermedia (Chambel, 1999a).

The design rationale we adopted for the educational artefacts being developed, in the context of the UNIBASE project, is based on the notion that the integration of basic elements of information must explore the cognitive bias of the different materials and create added value through adequate bridges between those elements. Effective integration must be sought by allowing the learner to exercise the "natural" cognitive attitude, while inducing proactive "breakdowns" (Winograd, 1986) that trigger reflection processes (Norman, 1993). On a video based material, such as the one we are proposing, this means letting the user enjoy and absorb the video information in very much the same way as it is currently "consumed" in the television type of interaction. On the other hand, as this type of information processing is essentially experiential, the hypervideo environment must be designed to involve the user in such a way that he is led to "stop, think, and correlate" different types of information.

Hypervideo mechanisms are therefore the basic tools for the purposeful and directed integration of video information in learning environments (Chambel, 1999b). In this context, we developed a model and some tools for hypervideo support on the Web (Chambel, 1999a), as extensions to HTML and existing Web tools, that are being used to integrate video in the UNIBASE hypermedia learning environment.

6. Experience with Learners

It is assumed that technologies like interactive multimedia help students to form rich representations of learning events and promote deeper understandings. However, this does not happen by simply adding more information and more (rich) media. We also assume that students learn in very different ways and we expect them to be able to recognise relevant domain information and be able to process it at some depth.

In our experiments, learners used their natural language to argue, question, and make connections to other subjects, other units of study, and their own experience. Many explained the course of the learned events and worked out a knowledge map. Some learners also displayed their understandings by means other than words. They also created new situations, produced images and short videos and represented the theme as a hypermedia production. Finally, they published their work on the World Wide Web (see http://www.univ-ab.pt/~bidarra/hyperscapes).

The experimental set-up was based on a group of 16 students following a course on video pedagogy and technology in a master's programme on multimedia communication. Their previous experience included teaching for at least one year and Internet common usage skills. They were given a basic conceptual map, with relevant knowledge for the course, which they had to explore and develop further, both in class and online. They were encouraged to proceed from (non-linear) thinking to (non-linear) authoring of knowledge hyperscapes.
Our experimental goals were:

- to examine the use of hypermedia and communication tools in their work;
- to investigate the effectiveness of the hypermedia/Web environment that we set up;
- to find ways of improving the usability of hypermedia learning interfaces.

Data on the interactions was gathered by means of direct observation, video recordings, screen capture. These were later interpreted and checked against the evaluation of individual portfolios. Final assessment of the students was accomplished via work portfolios and a final (individual or group) project. Overall, the results were very encouraging when compared with previous years.

7. Conclusions

The approach to build an effective learner-centered system was to collect descriptive, qualitative information on complex real work settings. This required research tools that were capable of examining interaction with the hypermedia environment and also interaction within the surrounding social system. The gathered data was to be later interpreted and integrated into the design process.

Our findings suggest that:

- User control and interactivity are very important. Students appreciated the freedom to access and integrate different resources, to build new materials as hypermedia productions, and to respond to challenges, creating new situations and working out their own knowledge maps.

- The ability to integrate video in hyperdocuments was also an important feature, especially in the context of the video pedagogy and technology course, where it could be used to illustrate and demonstrate the concepts being taught and learned, in an integrated manner.

- Constructivist activities were very motivating to the majority of students and MindManager™ software was easily mastered. Precise focus on the objectives was attained by workgroups without wasting time “playing around” with the software.

- We found that user acceptance increases, if tools for interaction, problem formulation, design and system building are supported by reliable information about the needs and desires of potential users and the setting in which systems are to be used.

- However, students are not prepared to contribute themselves and reflect on the main issues, if there is no previous experience with the software tools that enable it. Introductory information, preparation classes or online help are necessary.

- Guidance on the thematic criss-crossing of the subject domain is a must. Students get easily lost if there is no tutor or expert support, no matter the access they have to the Internet and external knowledge bases.

The formal features of our instructional program, especially the video component, could be seen to exert a great influence on the affective domain of the learners. However, we assumed that it was the responsibility of the instructional developer to stimulate the learner to such a degree that higher levels of involvement were reached. We think that the powerful affective attribute of video needs to be explored further.

When frames collide: adapting cognitive frame analysis to a child’s comprehension of narrative video

jblatt@po-box.mcgill.ca

Abstract: This proposal outlines research on the comprehension of narrative dynamic multimedia such as video. I describe an approach to investigating comprehension based on a synthesis of methods and models developed in classical cognitive studies (Kintsch, 1998; Frederiksen, Donin, and Bracewell, 1987; Bracewell and Breuleux, 1994) with theoretical work in cognitive film analysis (Bordwell, 1989) and film semiotics (Metz, 1968). This approach provides a principled argument for constructing a filmic text-base (Kintsch, 1998) that serves as the basis for studying the situation and frame models used by viewers to understand narrative content in dynamic multimedia. The paper applies this approach in a child’s recall task. Discrepancies between the child’s protocol and a text derived from a shot script of the viewed video are discussed in light of the situation knowledge needed to adequately construct a “problem/plot frame”. This work has implication for assessing instructional design modules that include video.

Introduction

Video, whether stand alone or embedded in interactive multimedia has become a powerful resource in many classroom settings. There is considerable research assessing the learning occurring with video delivered course content, such as Vanderbilt’s Jasper series. However, research on how students comprehend dynamic multimedia narratives needs more attention. Movies and video are such a pervasive part of K-12 culture that their comprehension seems almost a naturally acquired skill. The mimetic, iconic illusions in most films and videos children view lead to a perspective of movie viewing as being a simple mapping from world reality to screen diegesis. But, on closer look, understanding a “moving narrative” is a cognitively demanding task.

The purpose of this paper is 2-fold: to gain insight into the cognitive processes of film comprehension in recall; to provide a principled basis for applying discourse and propositional analysis to the inherently non-natural language of dynamic multimedia. My research is based on a recall task in which a 10 year- old is asked to “tell me what the movie was about”. The movie was a 20- minute stop-action animation, “Wallace and Gromit: a Grand Day Out”. Based on theories of comprehension and film semiotics, I show how a text base of film may be constructed and accommodate the kind of scrutiny for comprehension strategies successfully undertaken in classical cognitive accounts in text and discourse. Using propositional and frame analysis, I show how the child’s construction of meaning may be represented as structured around narrative and plot frames. Two text bases are provided: the child’s recall and a shot script derived from repeated viewing of the video. I compare the propositions and plot frames derived from an episode in the two text bases and discuss the results in light of summarizing strategies and situation knowledge.

Narrative film comprehension is generally under researched. Chafe’s (1980) discourse analysis of film recall production in children and adults yielded interesting insights into comprehension. However, his research failed to account for the filmic units of analysis; his work failed to articulate on what basis imagery and time were conflated into declarative knowledge. In the field of cognitive film studies, Bordwell (1989) has used script-based knowledge representation to develop his own model of film interpretation. Bordwell theorizes that critics adopt particular scripts or schemas and apply them to understand the connotations in film. As Bordwell states, however, there may be different mechanisms involved in the expert critic’s interpretation of a film than in the casual viewer’s more immediate comprehension process.

This study is based on Kintsch’s model (1998) of the comprehension process as constructed in a loosely structured, bottom up process which only gradually integrates knowledge into a more stable set or mental
representation. Kintsch differentiates comprehension knowledge into a text base and situation model with the text base representing the knowledge constructed from the text itself and the situation model representing the frames, scripts, or models derived from the readers/listener knowledge of similar texts, situations, and world knowledge. Kintsch has applied his model to many comprehension tasks yet admits that most of his work in narrative discourse focused on single situation problems. Frederiksen, based on a similar comprehension model, has explicitly probed texts and discourse for multiple situations or, in his model, multiple frame construction. Frederiksen’s model focuses on the representation of comprehension in both text (1987) and discourse (1998), as well as being applied to text production situations (Bracewell, and Breuleux, 1994). The model identifies three types of representational units: natural language units (e.g. clauses, words); units of propositional meaning (e.g., events, states, processes); units of conceptual meaning (related structures in which concepts are associated to form conceptual knowledge as in frames and situation models. The basic unit in these studies has been the proposition.

Current cognitive inquiry into comprehension is based on a fundamental, if not entirely uncontroversial assumption that comprehension knowledge may be represented at the semantic level as propositions. Kintsch points out the alternative views that point to the non-linguistic representation of mental imagery (Kosslyn, 1994). But even Kosslyn used spatial predicates to represent the deep knowledge level of surface pictorial forms. Without attempting to finalize the debate between linguistic, spatial, or symbolic representation of visual media such as movies, I proceed cautiously with Kintsch's basic assumption. In order to find an analogous representational structure to language, I looked to film semiotics, specifically as developed by Metz (1968).

Metz is adamant that while film has expressive and communicative features, it cannot be considered as having a syntactical system. As in art, there is a tight coupling between sign and signified. Film comprehension proceeds from “blocks of reality” which are actualized with their total meaning in discourse or in the filmic presentation. According to Metz, these blocks are shots, either individual (“autonomous”) or in sequence, which semantically relate to one another. Metz’s ambitious “Grand Syntagma” constructs a hierarchical film structure organized around shots and sequences.

Agreeing with Kintch that propositions may adequately represent comprehension knowledge even in non-linguistic phenomenon, the syntegematic framework suggests that comprehension may proceed from the autonomous or simple sequence. A main idea or event is presented in these syntegemes, and associated with subsequent syntegemes into a hierarchical structure of sequences and episodes. In essence, the shot or simple sequence may function as a clause in comprehension. Individual syntegemes cohere similarly to Kintch’s microrules, whereas macrorules relate events to sequences to episodes. With this assumption, a propositional representation may be derived from a filmic ‘text’.

Method

This study is based on the recall protocol of a 10 year-old girl who was asked to “tell me what the movie was about”. The purpose of the research was to see what summarizing strategies she used, and to compare her understanding to a text-base derived from a shot script constructed from the researcher’s viewing of the film.

The movie was a 20-minute, stop animation video by Nick Park, “Wallace and Gromit, A Grand Day Out”. The child had seen the film previously as well as his other animations in the series. She was therefore exposed to his filmic style, the characters, and the narrative genre. The researcher’s protocol was derived from constructing a “shooting script” while viewing and reviewing the movie. Both texts were segmented into clauses analyzed using propositional analysis as similarly developed and applied in Frederiksen, Donin-Frederiksen, and Bracewell (1987). A narrative frame and plot frame is mapped on to the respective propositions to reveal the conceptual structures present in the child’s and researcher’s knowledge. The study focuses on a particular episode in the final act of the movie, in which the main characters are discovered by a robot on the moon and rush to return home.

Findings

The frames were compared for frame completeness and accuracy, particularly on the marking of events, themes, temporal ordering, and causal and conditional links. The child correctly and completely recalled the plot structure but had difficulty in identifying and ordering the plot themes and events.
Discussion

Deviations between the child’s and researcher’s comprehension as compared in their respective construction of the narrative and plot frames are discussed in light of summarizing strategies and situation knowledge. According to Kintsch, summarizing is a form of recall which, like other types of comprehension, is governed by macrorules. These rules stipulate the selection of key events or objects, the generalization to a more abstract version, and the construction of a new ‘text’ (vanDijk and Kintsch, 1983). Thus, while the child had little problem in identifying this sub-plot as being significant to the main characters - and correctly selecting this in her recall - and subsequently generalizing to a global problem-goal-plan-action-response structure, her accounting of the events reveal gaps which would have required more knowledge of the technology depicted in the film. As an example of multi-situation comprehension, this study suggests that developers and users of narrative dynamic multimedia must identify frame knowledge needed to comprehend the content and relate it to the knowledge of their viewers.

Conclusion

Understanding how students comprehend narrative dynamic visual media was the direct objective of this paper. Providing a rationale for inferring a ‘text’ from dynamic visual media became necessary in order to apply comprehension theories and methods successfully used in text and verbal discourse. A synthesis between comprehension models and methods and film semiotics furnished a basis in which to approach the topic. This approach may be useful in assessing and developing multimedia projects for children.

Integrating ARCS Motivational Strategies into CALL Courseware for Holistic Practice: A Study

Abstract: This study investigated the effects on writing performance of three levels of integration (basic, medium, full) of ARCS motivational conditions (Attention, Relevance, Confidence, and Satisfaction) into a CALL (Computer-Assisted Language Learning) program for holistic foreign language practice. It also addressed the effects of two degrees of relevance (low, high) of the learning tasks. Forty-eight undergraduate students, randomly assigned to six treatments, accomplished two writing activities using one of the six versions of the program. The ARCS full integration groups performed significantly better than did the medium and basic groups. The degree of task relevance did not affect significantly performance. Students felt that the program gave them, in this order, confidence, attention, relevance, and satisfaction. Motivational strategy and task relevance impacted significantly the intensity and persistence of students' learning effort, as revealed by five sets of data traced by the program's tracking tools: Intro Time, Activity Time, Help Time, Help Frequency, and Overall Frequency of Access. Writing draft analysis uncovered the effects of three writing-fostering features of the program on subjects' use of "practice," "resourcing" and "output structuring" strategies.

Introduction
Motivational factors are an important mediator of performance and are considered instrumental in the expenditure of cognitive effort (Bandura, 1977, Salomon, 1983). An instructional design model that addresses motivation is the ARCS model (Keller, 1987). The model, which has been applied to courseware design (Keller and Suzuki, 1987), includes subcategories of motivational characteristics and examples of strategies that stimulate or sustain each motivational condition "Attention," "Relevance," "Confidence" and "Satisfaction."

Instructional technology (IT) research has addressed, with mixed results, the ways different ARCS strategies embedded in instructional materials affect learner's motivation and performance. Some studies have found that confidence-enhanced materials augment learner's assuredness (Naime-Diefenbanch, 1991) or that relevance-enhancing strategies result in enhanced motivation and performance (Means, Jonassen, and Dwyer, 1997). Other studies, however, have indicated no effects of confidence-enhanced materials on learners' achievement or confidence (Moller, 1993). Means et al. (1997) contend that this imparity of effects is due to the fact that the ARCS conditions are interdependent and that it is not clear how motivational enhancement affect cognitive activity.

Motivation is also an issue in Second Language Acquisition (SLA). Ushioda (1993) sustains that motivational outcomes such as learner's participation, attentiveness, and enthusiasm should be viewed as significant by themselves, apart from their particular relevance to second language development. Spolsky (1989), in his theory of second language learning, asserts that language knowledge and skills in the future are the result of a number of factors including knowledge in the present, abilities, motivation/affect, and opportunity. Spolsky sustains that learner's acquisition depends on the various strengths of these conditions and that the greater the amount of each, the greater the learning. Research is needed to understand how to build up and combine the Spolsky's factors that allow intervention, motivation and opportunity, within language learning environments and, particularly, within those supported by technology.

On the other hand, IT and SLA have been equally interested in the learning and attitudinal effects of tasks that are inherently relevant to the learner. Research from both fields suggest that perceptions of learning task meaningfulness influence learner's "cognitive capacity usage" (Salomon, 1993; Pokay & Blumenfeld, 1990), and that perceptions of enjoyableness of language learning tasks correlate with learning effectiveness (Green, 1993). However, intentional cognition is not always based on the task's interest. Means, et al.'s (1997) assertion that "many learners in undergraduate courses are not intrinsically motivated to learn course content" (p. 15) is all the more true for learners in foreign language courses since cultural context and background may affect their perceived relevance of second language tasks (Green, 1993). Thus, research is also needed on how to design Computer-Assisted Language Learning (CALL) programs whose manipulated motivational strengths affect performance and attitude beyond, or regardless of, the inherent motivational value of the programs' instructional tasks.

Purpose of the Study
Within the above framework, this study investigated if the comprehensive integration of ARCS motivational strategies in CALL courseware for holistic practice (Wyatt, 1987), affected the writing performance in a foreign language of undergraduate college students.

The study equally explored the effects on writing performance of language tasks relevant to students' interest, the potential interactions between motivational strategy integration and task relevance, the effects of motivational strategy integration on attitudes, and the correlation between attitudes and performance.

Additionally, in accordance with "contextualized" research tenets (Salomon, 1991), the study investigated a number of issues with a potential impact on the main outcomes. These included the impact of courseware motivational strategy integration and task relevance on learner's intensity and persistency of effort (Keller, 1987) and the effects of courseware writing-fostering features on subjects' use of "practice," "resourcing" and "output structuring" cognitive strategies.

Method

Subjects

Forty-eight lower-division undergraduate students, 28 women and 20 men, enrolled in the various sections of an intermediate Spanish course during the spring semester at San Diego State University constituted the experimental sample. Students were randomly assigned to the six experimental treatments of the study, which involved completing two writing tasks in Spanish using a CALL program. The subjects had quite heterogeneous academic backgrounds and their academic skills were mostly limited to word-processing.

Variables

The main independent variables of this study were motivational strategy integration and task relevance. The motivational strategy variable consisted of the levels of integration, basic, medium and full, of the ARCS motivational strategies found in the six versions of an original courseware package Writing in Spanish: Two Practice Sessions (WS) developed for the study (Borrás, 1999).

[1] From the "leader of activity" viewpoint, CALL software is routinely classified as tutorial, holistic practice, and games. Basically, the holistic practice variety provides "higher-level, contextualized, practice activities," "idea processor" and "on-line thesaurus" (Wyatt, 1987: 87).

The WS versions featured different number of screens. To the five screens of the basic versions (Title, Menu, Introduction, Activity, and Credits), the medium versions added one (Help), and the full versions two (Help and Archives). Common to all versions, the Activity screen included a four-page notepad for writing the drafting and final renditions of the tasks, a toggling writing prompt, on-demand access to contextualized multimedia resources, and users' input locking capabilities. Tracking tools available in all versions allowed the self-saving of user's writing input and navigational paths data on to an automatically created folder located on the hard disks of the computers used in the study.

As shown in Figure 1, the basic level of strategy integration consisted of the message found in the Introduction screens of the six versions of WS. Elements of the message included a statement of the program's goal, three comments on the task's nature, benefits and resources, and a warming up expression. The elements, which fell into the motivational strategies categories, "Experience," "Present Worth," "Learning Requirements," and "Positive Outcomes" (Keller's, 1987), were aimed at reaching three ARCS' motivational conditions, relevance, confidence, and satisfaction.
The medium level of strategy integration included the introductory component and the contents of a Help screen common to four versions of WS. The screen included information on the function of the assigned task, and a number of macro-aides (samples for imitating, brainstorming, and/or organizing the task) and micro-aides (audio-visual monolingual vocabulary lists, and grammar reference). These contents embodied such motivational strategies as "Conflict," "Concreteness," "Variability," "Need Matching," and "Expectations" and targeted the motivational conditions attention, relevance, and confidence.

The high level of strategy integration comprised the introductory and help components together with the Archives screen common to two versions of WS. The screen, which provided access, through a metaphorical button, to the instructor's corrective feedback on the writing activities subjects accomplished during the first experimental session, addressed motivational strategies like "Unexpected Rewards" and "Positive Outcomes" in order to attain the motivational condition satisfaction.

The second independent variable, task relevance degree (high, little), was based on the subjects' higher or lower interest in the writing tasks of the WS program. Taking into account Crookes and Schmidt's (1991) assertion that "a program which appears to meet the students' own expressed needs ... will be more motivating, more efficient, and thus more successful." (p. 492), the selection of the tasks drew on the results of a survey conducted one month before the experiment with 119 students of Intermediate Spanish. Surveyees were asked to rank from 1 (least liked) to 10 (most liked) the ten authentic writing activities of a Task Relevance questionnaire. Based on the results of the survey, four activities, two of them "highly relevant" and two others "little relevant," were selected to support subjects' writing practice with WS during two experimental sessions.

The primary dependent variable of the study, writing communicative performance, was defined as achievement in conveying information in writing (narration, description, persuasion, and argumentation). The second dependent variable, attitudes, was aimed at measuring the reactions of subjects toward the computerized writing experience, and to find out which were the features of the WS package that according to subjects' perceptions contributed the most to the activation of the ARCS' motivational conditions.

Other variables including learner's intensity and persistency of effort, and learner's use of particular strategies during writing practice were also considered to better understand where and how WS was strong or weak in producing the desired motivational and cognitive outcomes.

### Treatments

Using a two-way 3 x 2 factorial design, subjects were randomly assigned to one of the six treatments resulting from the combination of the levels of motivational strategy integration (basic vs medium vs full) with the degree of relevance of the writing task (little vs high). The treatments included T1 (basic motivational strategy/little relevant task); T2 (basic motivational strategy/highly relevant task); T3 (medium motivational strategy/little relevant task); T4 (medium motivational strategy/highly relevant task); T5 (full motivational strategy/little relevant task); and T6 (full motivational strategy/highly relevant task). Depending on their assignment to a given treatment, subjects used one of the six versions of the Writing in Spanish package.
Instruments

The main dependent variable, writing performance, was computed by applying Gaudiani's Composition Analytical Scales (1981) to the writing samples produced by the subjects using the WS package. The Scales allow the separate scoring of four composition features including grammar/vocabulary, style, organization, and content.

To measure the secondary dependent variable, attitudes, three slightly modified versions of Keller's (1993) Instructional Materials Motivational Survey (IMMS) were used to collect attitudinal data from the subjects working with WS under the basic (T1-T2), medium (T3-T4) or full (T5-T6) treatments. The IMMS (Cronbach's alpha reliability coefficient = .96) asks the survey-takers to assess the degree of truthfulness of its 36 statements using a 5-point Likert scale (1= not true; 5 = very true). In the IMMS adaptations, A1, A2, and A3, statements 27 and 28 were replaced by two others targeting subjects' attitudes toward the motivational strategies embedded in the Introduction, Help, and Archives screens of WS. Also, statement 29 was removed because of its tangential pertinence.

Procedure

The WS program was aimed at providing, in varying degrees, Spolsky's (1989) "motivation" and "opportunity" conditions for language learning by exposing learners to a diversity of tasks and sources that promoted their use of receptive and productive language skills (Krashen & Terrell, 1983). Thus, using the six versions of WS, subjects in the different treatments performed the variety of tasks involved in the writing activities they completed during the two experimental sessions (thereafter, S1 and S2).

In S1, subjects working with the basic versions of WS accomplished a number of tasks including reading the message of the Introduction screen, reading the writing prompt and exploring the multimedia resources of the Activity screen, and writing the draft and final versions of the experimental activity. Furthermore, subjects in the medium and full motivational strategy integration treatments explored the macro-aides and micro-aides of the Help screen available in the WS versions they were using.

In S2, subjects accomplished a number of activities similar to the ones they did in the first session. In addition, subjects in the basic strategy integration treatments could revisit the Activity screen of the first session to explore its resources and what they had written in its notepad. Subjects in the medium strategy integration treatments could access both the Activity and the Help screens of the WS version they worked with in the first session. And subjects in the full strategy integration treatments were able to access not only the Activity and the Help screens of the version used in the previous session but also the Archives screen with the instructor's feedback on their first writing sample. At the end of S2, subjects filled in one of the three adaptations of the IMMS (A1, A2, or A3), depending on the treatment basic, medium, or full to which they were assigned.

Subjects were encouraged to accomplish the activities as well as possible. In order to keep performance's standards equally high in both sessions, it was not until that the experiment was concluded that students were told that the first of the sessions had just a training purpose. Implementation of the experiment extended over fourteen days and took about one hundred and forty hours.

Throughout the sessions, seven sets of data were unobtrusively traced by the WS' tracking tools for weighing the intensity and persistency of students' effort using the package. These included the overall time subjects spent on the entire program, the time they spent on the program's Intro, Activity, and Help sections, and the frequency with which they accessed the entire program and the Help and Intro sections.

Results

Performance Outcomes

The effects and interactions of the independent variables motivational strategy integration and task relevance were analyzed for the composite writing performance scores using analysis of variance (ANOVA). The means and standard deviations for performance scores for each treatment group in S2 showed that the highest mean score across treatments was obtained by the T5 subjects (3.19) --the maximum possible score being 4.00.

Statistically significant effects were found for the independent variable of primary interest, motivational strategy integration (F (2, 42) = 3.844, p < .05). Results of Tukey-Honestly Significant Difference (HSD) post-hoc tests demonstrated that in S2 the highly motivational strategy integration/highly and little relevant task combinations were statistically different from both the medium motivational strategy integration/highly and little relevant task conditions (HSD (3, 42) = 4.53, p < .05) and the low motivational strategy integration/highly and little relevant task conditions (HSD (3, 42) = 4.90, p < .05).

The full motivational strategy integration treatments seemed to be the most beneficial across time as indicated by the significant effects yielded by the ANOVA performed on the combined writing performance scores of S1 and S2 (F (2, 42) = 3.327, p < .05).
No significant effects were found for task relevance independent variable on the ANOVA performed on the writing scores of S2. The T5 group, which accomplished the little relevant tasks, obtained the highest mean score. Finally, analysis of S2 data also revealed that a variable interaction (motivational strategy integration x task relevance) occurred in the basic and medium strategy integration treatments. No interaction was detected for the full strategy integration treatment.

**Attitudinal Outcomes**

The one-way ANOVA performed on the data yielded by the three IMMS versions (A1, A2, and A3) indicated that the motivational strategy integration variable did not have a significant effect on attitudes. The three strategy integration groups, however, demonstrated a quite positive attitude toward the writing practice with the courseware.

The most motivated subjects appeared to be those in the basic strategy integration treatments (T1, T2) (mean = 3.63 out of a possible 1-5 range) followed by those in the full (T5, T6) (mean = 3.43) and medium features treatments (T3, T4) (mean = 3.29).

Pearson r of overall attitude ratings (A1, A2, A3) with overall writing performance mean scores (S1 and S2) indicated a correlation of .1704 (the P<.05 for two-tailed test α=.05 and 46 df's for the basic (T1-T2), medium (T3-T4) and full (T5-T6) strategy groups respectively showed correlations of .1778, .4631, and -.2778 (the P<.05 for two-tailed test α=.05 and df's performance for the basic and full integration treatments, and low positive correlation, but almost significant, for the medium features treatments.

**Additional Findings**

*Subject's Perception of WS Motivational Value.* Responses to the attitudinal surveys' statements grouped by the motivational condition they addressed indicated that subjects across the "high", medium and "low" strategy integration treatments found that the highest motivational value conveyed by WS was Confidence (mean = 3.56) followed by Attention (mean = 3.49), Relevance (mean = 3.22), and Satisfaction (mean = 3.12).

Four WS' attributes including appropriate level of difficulty of the activities, spare number of screen components, suitability of the audiovisual resources, and comments encouraging previous writing efforts, were viewed by the subjects as the main motivating components of the program.

The effect on student's confidence of the appropriateness of tasks in the WS package ratifies tenets of expectancy-value theory (Lewin, 1938) which assume that people are motivated to engage in an activity if they have a positive expectation for success. The impact on subjects' attention of the frugal use of media attributes by WS proves the validity of the interface design principles that were applied to the package to achieve visual clarity (Mayhew, 1992) or avoid cognitive overload (Miller, 1953). The effects of WS praising comments about previous writing efforts on subjects' satisfaction supports research findings which indicate that feedback on past successes can be a powerful mediator in improving self-efficacy (Schunk, 1989).

*Subject's Intensity and Persistency of Working Effort with WS.* The MANOVA performed on four sets of data gathered by the WS tracking tools in S2, Intro Time, Activity Time, Help Time, and Overall Working Time revealed that task relevance affected significantly the time subjects in the T3-T6 treatments spent on the Help screen (F (1, 28) = 8.961, p <.05), and the time subjects in the different treatments invested on the Activity screen (F (1, 42) = 4.098, p <.05).

On the other hand, the MANOVA performed on three other sets of data, Intro Frequency, Help Frequency, and Overall Frequency of Access on S2, showed that task relevance impacted significantly (F (1, 28) = 6.153, p <.05) the frequency with which subjects in the T3-T6 treatments accessed the Help screen. Both motivational strategy integration (F (2, 42) = 7.482, p <.05) and task relevance (F (2, 42) = 4.250, p <.05) affected significantly the overall frequency of subjects' access to the program.

These findings indicate that the strategy integration and, particularly, the task relevance variables affected significantly the persistency and intensity of the effort subjects invested on the WS program. The finding are consistent with those of previous SLA (Crookes & Schmidt, 1991) and IT (Ames & Ames, 1989) research showing that personal relevance of instructional content is a good determinant of selective learner attention and results in increased time-on task.

*Subject's Use of WS Writing Strategy-Fostering Features.* A descriptive source of data was used to explore the impact of the WS motivational enhancements on subjects' cognitive activity. Forty-eight draft versions of the writing activities, twenty-four per session and four per treatment, were analyzed according to four sets of criteria including length (number of words), nature (outline, vocabulary, or rough work), language (native or target), and quality (inclusiveness of activity's requested ideas). Drafts' analyses indicated the ways three WS writing-fostering features including dedicated drafting space, comprehensive yet discretely available help, and systematic activity directions, affected subjects' use of strategies such as "practice," "resourcing" and "output structuring," which are relevant to language learning in general (Oxford, 1990) and CALL (Liou, 1997) in particular.
Conclusion and Implication
This study investigated the effects of ARCS motivational strategies integration into the WS courseware package on the writing performance and attitudes of college students of Intermediate Spanish. Results indicated that subjects who worked with the full strategy integration versions of WS, which provided the highest number and recurrence of ARCS strategies, significantly outperformed subjects who worked with the basic and medium integration modalities. Strategy integration level resulted in greater performance gains than did the inherent interest of the learning task.

The study provides a working model on how to manipulate in combination two language learning conditions, motivation and opportunity, through the comprehensive application of ARCS motivational strategies to a CALL courseware holistic paradigm. More research is needed to consistently validate the effectiveness of such model.

Results of the study imply that with high levels of motivational strategy integration it is possible to boost the performance of learners of a foreign language not necessarily interested in the activities of a CALL package for holistic practice. Future tests of CALL packages of similar nature featuring longer treatment periods and greater number of participants may provide wider evidence of this possibility.

Abstract: The work presented in this paper focuses on software tools that act as video explorers and annotation platforms and more specifically as diary composers for younger children. Through such tools, children can have as their raw material video recordings from everyday life and they are given the opportunity to review this material, reflect upon it and annotate it, thus creating the stories of everyday life from their own perspective. The specific tool proposed, focuses on multi-perspective capture of events by one or more children and their cooperation during the annotation procedure.

Introduction

Current educational software rarely offers either the child or the adult facilitator options for 'deeper interaction'. By 'deeper interaction' we refer to a procedure where the child takes active control over the material presented to it, reflects upon this material, annotates it alone or in teams and creates his own version of reality. This work focuses on developing both at interface levels of interaction and within the software, features that could explore a number of dimensions of learning (Umaschi 1997). The software paradigm being proposed will aim at supporting stages of reflection, levels of abstraction and opportunities for cooperation in grounded context that are accessible to young children. The ultimate aim is to enhance children's development both at cognitive, physical and social communication level (Baecker & Posner 1998), (Umaschi 1996).

More specifically, interaction with the video material recorded previously is performed through a video explorer. This video explorer is essentially a platform for the first stages of reflection. These will include the software and interface's functionalities of location, navigation and individual or collaborative viewing/annotation. The video explorer must therefore provide tools for both navigating inside videos and annotating them, thus consisting a diary composer. Navigating features are suggested to be inherent to the diary composer through a control panel, while annotation features are organized in distinguished toolbox palettes accompanying the composer. Functionality of the
palettes could include traditional editing functions such as cut, paste, drag, drop, coupled with other levels of annotation such as sequence by time, event, emotion, people, object, movement.

The research and implementation leading to the tool proposed here, have taken place within the framework of project "Today's Stories", part of the Long Term Research Task 4.4, (i3 – ESE, Project Nr. 29312, URL: http://stories.starlab.org/). The Today's Stories project is evolving a wearable technology facilitated approach to learning for young children (4 to 8 years old) that is aimed at supporting the development of social, communicative and emotional skills of children in the context of the everyday activities. In this paper, a thorough reference is being made to those requirements that must be met by an innovative diary composing tool, such as the one already outlined (see Druin 1998), (see Norman 1990). Consecutively, a list of the functional specifications of the proposed implementation is given. Based on the above, the diary composer prototype environment is described, escorted by implementation and usage details.

Related Work

Within the framework of the work presented in this paper, a thorough evaluation of the respectful number of current commercial and research activities in the field of multimedia editing and storyboarding for younger children has been performed (see Buckleitner et al. 1999). Among the commercial products taken under consideration, the most outstanding ones were:

- Kid Pix Studio Deluxe from Broderbund Software, California
- Magic Theatre from Instinct Corporation, Silicon Valley
- Stanley's Sticker Stories from Edmark Corporation, an IBM company
- The Multimedia Workshop from Davidson
- Kid Works(TM) Deluxe from Davidson
- ClarisWorks for Kids from Apple Computer, Inc

These products were evaluated with respect to the proposed tool and a summary of their features is given in (Tab. 1).

Table 1: A collection of features from commercial diary composing tools for younger children

An interesting research activity in the field of storyboarding consists 'The Fabula project: Interactive children's storybooks to promote bilingual literacy' ('Fabula' Project 1998). Fabula was a two-year project in which partners in Ireland, Spain, the Netherlands and the United Kingdom worked together to develop an easy to use multimedia software kit for schools. An authoring tool was developed, to enable teachers to create illustrated bilingual multimedia story books to help primary school children learn a second language (and gain a deeper understanding of their first) through the written word, supported by pictures, sound, animation and interactive graphics. As children read the 'pages' of those storybooks, using the specially developed Fabula viewer software, they were able to exploit the unique opportunities provided by a multimedia environment.
Requirements

In this section a more detailed set of requirements for stimulating reflection through the confrontation of viewpoints and perspectives is proposed. The design approach of the video explorer tool, given in the following sections, is entirely based on this set of requirements. The diary composer environment should be essentially shared (as opposed to single user). Although it must be possible for children to reflect on their own material alone, we expect the most productive sessions to be based on collaborative confrontation of children's interpretations. The diary composer should be as much as possible language neutral. We do not assume literacy so we do not propose the use of text. We also envisage that the spoken word is a powerful means of annotation, allowing the children for example to narrate, in their own language and words, an interpretation of an episode.

The tool should be open to include arbitrary libraries of annotations, including those that have been created by children (symbols from scanned drawings for instance). It should allow making explicit interpretations. The core of interpretation is by annotation with symbols that children can select from a given repository. The collaborative aspect is essential here. The design choice followed is to use a single repository of annotations, also when different video frames are rolling. This does not mean that there is only one consistent interpretation of the events but will foster mutual understanding of them. The tool should finally act as a self-organizing memory support, avoiding file naming and saving operations. The different recorded episodes will be organized on a time line reflecting the times of their occurrence e.g. throughout the day.

Functional specifications

Storing and Indexing

The structure of the database of video recordings is proposed to be based on a time line indexing, with a time span of e.g. one day. Functions to be performed on this database are:
- Adding a new recording
- Erasing a recording: Children should be allowed to delete recordings and preserve for editing and annotation only those considered to be more interesting

Annotating

Functions to be provided here include:
- Interaction with the video player: Either by using pause, forward, backward buttons or by a mechanism that translates movement of the mouse over the video screen
- Preview of the meaning of an annotation icon by clicking on it
- Insertion of new annotations, either verbal or graphical ones
- Implementation of a wizard acting as a guide throughout the annotation procedure

Archiving

This set of functions aims at maintaining a database of the annotated versions in addition or as a replacement of the original video recordings. The two alternatives are either to delete the previous annotated version of a recording if re-editing is desirable or to perform re-editing over an existent annotated version by removing old and adding new annotations. In both cases saving an annotated video is done automatically. In cases where the original video needs to be destroyed for privacy reasons, the better approach is to automatically delete a video after an expiry date.

Worthwhile Features

Based on our research in the field of commercial diary composing environments, we have ended up with a set of features that such a tool as the one proposed should try to inherit. Some of the most important features are:
- Possibility to send a "story" (annotated video) to a friend, parent, etc.
- Easy-to-use icon based User Interface.
A general description of the diary composer prototype environment

The prototype environment proposed for development consists of two modules: the ‘Timeline’ display and the ‘Annotation’ display. In (Fig. 1), those two displays are presented simultaneously. However, this is not obligatory. It is proposed that the ‘Timeline’ display is permanent on screen, while the ‘Annotation’ display appears only when it is required: during the procedure of video annotation.

The ‘Timeline’ display expands to the whole screen displaying one curved line for each child using the diary composer. Each one of the curved lines in (Fig. 1) represents a day for one child. One thumbnail for each video recording is placed on a child’s timeline. In (Fig. 1), three such thumbnails are created in the first timeline and two thumbnails are placed on the second timeline. Thumbnails are placed on the timelines in such a way that the time of recording is reflected, thus the distance of two thumbnails on a certain timeline is proportional to the real time interval between the two recordings. The ‘Annotation’ display consists of two groups of annotation icons, one group of icons symbolizing sounds and another group of icons symbolizing emotions and any other kind of annotation. Each group consists a tool bar placed at the screen edges (the placement of the ‘Sounds’ icon bar on the top left part of the screen and the ‘Annotations’ icon bar on the bottom right of the screen in (Fig. 1) is indicative).

The ‘Annotation’ display provides children with the tools for annotating the videos. The icons representing sounds can be either buttons, which when pressed allow for the playback of the correspondent sound, or drag and drop items, which the children will be able to drop on a video frame in order to annotate the instance displayed with the correspondent sound. The icons for the rest of the annotations (showing expressions, feelings etc.) can only be drag and drop icons, dragged by the children on certain video frames, during the annotation procedure.

Both the icon bars of the ‘Annotation’ display will be global in the diary composer environment. In other words, the annotation tool bars will always be visible during the annotation procedure of different videos, instead of appearing each time an annotation procedure is initiated and being imminently related to the current video under annotation. This will allow children to treat the diary composer as a homogeneous tool that provides the same layout and options regardless of the current thumbnails and video processing procedures.

The annotation procedure
When one or more children decide to annotate a video of an incident they have already recorded, they have to simply 'click' on this video's thumbnail, for the annotation procedure to begin. Immediately, the thumbnail is transformed to an enlarged video display, extending to a large part of the screen (see Fig. 2). The dimensions of the video display will be customizable but it is definite that they will not extend to the whole of the screen. Space on the screen must be preserved for the 'Annotation' display and the timeline(s) will remain at the background for the children to return to them and select another thumbnail, if needed.

Navigation in a video recording for the purposes of annotation will be made either by the buttons appearing on the bottom of the video (right arrow for 'Forward', left arrow for 'Backward' and the hand icon for 'Stop' or 'Slow Motion' playback) or by imminently clicking on the video itself. The latest feature will allow children to move forwards in the video by placing their mouse at the right hand-side of the video display, move backwards in the video by placing their mouse at the left hand-side of the video display and pausing/resuming playback of the video by clicking on the video display.

Once the child has successfully acquired the navigation techniques, it can then playback the video and pause/stop playback at any moment in order to annotate it. In the case where both sound and expression/emotion annotations are of a drag and drop nature, the diary composer screen will look like that of (Fig. 2). Two annotations, one sound and one expression/emotion annotation are added to the particular video frame and can appear as small icons, dropped on the top right corner of it. Of course, the placement of annotations will not be restricted.

During the annotation procedure, any annotations and changes on the current video will be automatically saved. However, when a child wishes to make a modification, it will be able to locate the annotated video frame it wishes to edit and remove or add annotations with the drag and drop fashion. Removing an annotation from a video frame will be achieved by dragging and dropping it out of the space where the video is displayed. Removing all annotations added to a video recording and restart annotating the pure video will be achieved by clicking on the thumbnail of the video recording, which remains on the timeline in the background. Clicking on the 'Timeline' display, which during the annotation procedure comprises the diary composer's background, will terminate an annotation procedure, saving automatically all annotations in the current video.

**Specific features of the Diary Composer**

An interesting feature that is proposed for the 'Timeline' display is that of dynamic behavior. Although the diary composer will allow a child to reflect only on his own material, by watching only his own timeline and thumbnails on the 'Timeline' display, it will also allow collaborative confrontation of children's interpretations. This feature will be supported by the dynamic the timelines. It is proposed that in cases where two children have recorded the same incident (from different points of view) and wish to annotate their recordings cooperatively, the two different thumbnails of this same incident will be associated. This association will be visualized by the two children's timelines 'approaching', as shown for the first thumbnails of the two timelines in (Fig. 3). This metaphor will initiate the procedure on collaborative annotation of the videos.
Conclusions and Future Work

It is evident by the nature and design of the tool proposed here that a lot of its implementation choices consist open issues with regard to their pedagogical value. The tool seems to succeed in acquiring collaboration of its young users, by presenting simultaneously video recordings on the same event and provoking small groups of children to comment upon them and annotate them. It, therefore, distinguishes itself among relevant existent tools.

The issue is here, how to stimulate the children’s involvement in the editing and annotating procedure as much as possible. On this goal, should future work on the diary composer focus. The issues to be dealt with are the improvement of the controls for loading, editing and annotating the videos as well as the library of annotations, so that they will approach as much as possible the children’s perception.

References

Abstract: Design Principles for Collaborative Telelearning have been extracted from design experiments and validated by instructional designers. The design approach integrates individual learning, teamwork and group/class instruction, and links on-site and on-line learning situations in a coherent instructional continuum. The challenge was to build scenarios that integrate a three-level set of learning activities: individual, team and group activities and to support collaboration in action.

Introduction

Telelearning represents a new educational opportunity that offers many of the same features as distance learning, but is different in some ways as well. Telelearning provides opportunities not available in traditional distance learning, such as highly interactive and media-enhanced peer collaboration. The potential for mediated social interactions raises a number of issues. Our research focuses on two of these issues: 1) What is the nature of collaboration in collaborative telelearning?; 2) What principles guide the design of collaborative telelearning scenarios and software environments?

Our definition of telelearning is as follows: “The term telelearning is used to designate new forms of distance or of computer mediated learning, where the distance is not only distance in terms of space or time as in traditional distance learning, but the mediation in learning activities served by media, such as multimedia-based shared workspaces, multimedia communication, or multimedia servers” (Bourdeau & Wasson, 1997). The definition of collaborative learning by Salomon (1991) contains three major components: sharing, interdependencies and involvement. Ohlson & Ohlson (1993) see collaboration in the context of computer-supported collaborative work as a combination of communication and coordination. Coordination science defines coordination as managing interdependencies, which can apply to interdependencies between actors (Bourdeau & Wasson, 1997). In order to develop design principles for collaborative telelearning, existing learning situations needed to be analyzed and new ones created. The purpose was to extract and elicit principles, then determine whether these principles could be implemented in the scenario or whether some roles could be played by a software agent. The general type of learning situation selected is called a distributed simulation lab, which consists of a scenario plus a software environment.

Starting from general instructional design principles for distance learning, (Bourdeau & Bates, 1996), the challenge was to extend or specify existing principles, add new ones, and validate the new set. The starting set of principles
was as follows: 1) Select media based on access for students; 2) Develop fully readable, understandable and feasible material and guidance; 3) Plan both synchronous and asynchronous two-way communication; 4) Design a variety of learning activities; 5) Design a structured interactive student support system; 6) Plan opportunities for peer collaboration; 7) Provide appropriate feedback to students; 8) Anticipate errors by students, both in terms of content and process; 9) Set clear evaluation standards for learning outcomes to compensate for the high distribution of students and tutors and to ensure equity; 10) Plan for the evaluation of instructional materials and student support.

Project 6.2.3 of the Telelearning Network of Centres of Excellence (www.telelearn.ca) focused on the development of Instructional Design principles for collaborative telelearning. The design approach is far more inclusive than existing ones in that it integrates individual learning (self-directed learning and self-tutoring), teamwork and group/class instruction. It also links on-site and on-line learning situations in a coherent instructional continuum. The challenge was to build scenarios that integrate a three-level set of learning activities: individual, team and group activities based on the belief that learning is maximized when the three situations are used appropriately (in alternation or combined). An additional challenge arose from the desire to support collaboration in action, not just in discourse, in the context of multimodal scenarios that integrate synchronous multimedia interactions with textual asynchronous communication.

Method

Design principles are the prescriptive knowledge produced in the field of instructional technology, based on instructional and learning theory (Gagné, 1992; Merrill, 1994; Reigeluth, 1983, 1997, 1998; Lebow, 1995) that serve a community of practice (Tessmer & Wedman, 1995). Their use and validity are strongly related to the field of practice. The methodological approach adopted here respected requirements of rigor and validity, while working within the constraints of technological innovation. The following principles will be revised as technological environments and our understanding of how people learn within them evolve.

A series of different methods was employed to develop and validate principles: a) Field testing to extract knowledge about collaborative telelearning in a distributed simulation lab for management students; b) Design experimentation to test a new design for a distributed simulation lab in physics; c) Modelling to analyze interdependencies and the potential roles of a coordination agent; d) Focus group to validate principles.

The field test for extracting knowledge about collaborative telelearning in a distributed simulation lab in the strategic management field consisted in a series of structured observations in various on-campus learning sessions. The central element of the learning environment is a business simulation (www.cetai.ca/netstrat) that is run as a game. Several teams can participate at a distance within a predetermined timeframe set by the gamemaster (Bourdeau & Winer, 1997). Participants were students in various business administration programs at the École des HEC (School of Commerce) in Montreal.

The scenarios involved students in a mix of face-to-face, distributed group, as well as inter- and intra-team activities. Researchers observed and analyzed interaction within and among the teams, between the students and the professor, and between the students and the computer simulation environment. Observations covered the briefing, action rounds, report writing and debriefing. Particular attention was paid to the following questions: a) What means of communication did the students use and to what end? (Communication); b) Which activities or methods encouraged the creation of interdependencies? (Interdependencies); c) Did all team members participate in the decision-making process? (Involvement); d) Which coordination strategies did the various teams develop? (Coordination)

Data sources included a structured journal and semi-structured comments from each participant, structured observations during group sessions, as well as copies of messages, decisions and reports. Results from the analysis of the field test showed that the processes involved in working and learning in a collaborative way need to be improved. The processes of information-sharing, fostering relationships among participants, participating in the decision-making process, and building specific coordination strategies among team members all need to be supported by implicit and explicit tools.
A design experiment was conducted to test a new distributed science lab in physics (Winer, Chomienne & Vázquez-Abad, 1999). The scenario consisted of three experiments: Experiment 1 was a qualitative exploration of the behaviour of simple electric circuits. It involved handling common electrical materials, such as bulbs, batteries, connecting wires, etc... Experimentation and data measurements were conducted using real instruments. The data analysis was carried out on an individual basis. Results were interpreted and conclusions were drawn as a team. Experiment 2 was on Ohm's Law. The experiment consisted of working with a computer simulation. Measurements were automated, data analysis was carried out on an individual basis, and interpretations/conclusions were drawn as a team. Experiment 3 was on Kirchhoff's Law on the distribution of current in a circuit. The experiment was again conducted with a simulator and measurements were automated. Data analysis, interpretations and conclusions were carried out as a team.

A software environment was developed and implemented at a distance learning college to test the learning scenario under distance learning conditions (i.e., students in different locations interacting in a software environment with their peers). See (http://crosemont.qc.ca/ccfd/soci/contenu/203-FPF-03/Section2/laboratoires/lab3/electrik.html).

Data sources included observations, student productions, and team interviews. Results enabled researchers to establish the following guidelines: a) Provide a workspace for the individual, not just a shared space for the team; b) Conduct a group-based formative evaluative of learning materials with different learners to ensure that the instructions and vocabulary are not only internally consistent, but also subject to the same interpretation; c) Offer a variety of learning activities; d) Error analysis must distinguish between productive and non-productive errors so as to permit the former and block the latter; e) The technology should enhance the learning experience; f) Each learner's contribution must be necessary but not sufficient for both the individual and the group to succeed in the learning activity.

The modelling conducted to analyze interdependencies and the potential roles of a coordination agent was based on both Salomon's framework for CL (Salomon, 1991) and the Crowston & Malone framework for coordination (Crowston & Malone, 1994) using a modelling tool called MOT (www.liceu teluq.quebec.ca). Several learning scenarios in the strategic management course were modelled and analyzed to identify interdependencies, and extract coordination principles (Bourdeau & Wasson, 1997; Wasson, 1998). The following observations were made: "Actors in a collaborative telelearning situation must or need to: 1) share goals to complete activities; 2) share activities to achieve goals; 3) share resources to complete activities; 4) share activities to produce resources (Bourdeau & Wasson, 1997). Interdependencies can be either collaborative or competitive. They differ in the coordination processes required to manage them. Coordination software agents can be designed to manage interdependencies. Preliminary work on identifying roles to be played by agents indicates that agents can either serve as coordination managers or coordination facilitators. Other roles they could play include: team-building agent, group decision-making assistant, scheduling manager, synchronization manager, competition manager, and competition monitor (Wasson, 1999).

The Focus group was conducted to validate principles. Preliminary principles derived from the steps above were developed as follows:

1. Select media based on their ability to support collaboration in learning activities (i.e., by being multidirectional, interactive and sharing).
2. Ensure shared understanding of learning materials--text, graphics, audio, video--by conducting formative evaluations in a team setting.
3. Create meaningful and balanced opportunities for synchronous--face-to-face or mediated--and asynchronous interactions among students, between distributed teams and the system, as well as between distributed teams and the instructor.
4. Provide specific support tools and structures for the team-building phase of the activity, whether teams are formed by participants or course leaders.
5. Introduce collaboration gradually. Ensure that students are familiar with the learning environment before requiring intensive collaboration.
6. Implement coordination mechanisms when designing each learning activity.
7. Design a student support system capable of supporting distributed teamwork.
8. Create authentic and feasible collaborative learning activities with built-in interdependencies.
9. Provide multidirectional feedback channels from student to student, team to team, and system to team.
10. Anticipate possible technical and conceptual errors. Eliminate non-productive errors by stronger guidance and/or interface design. Use productive errors as input for team discussions, to provoke cognitive conflict among team members, and to stimulate individual reflection.

11. Design an assessment method for both individual and team achievements by tracking individual contributions, and by asking individuals to reflect on teamwork processes and/or performance.

13. Provide strong guidance for learning how to use the tools, as well as support for teamwork and a design for active learning to develop skills.

A group of eight (8) instructional designers were selected based on their professional experience and interest in new ideas. Participants were asked to attend a one-day seminar with a course design of their own. Each participant completed a profile to answer the following questions: How many years' experience do you have in instructional design? Have you received formal training in instructional design? Have you designed or participated in the design or evaluation of "traditional" distance education or training involving computer-based learning? How often do you refer to ID references when designing instructional methods? If and when you consult references, what are you looking for?

Each principle was presented to the group with illustrative examples. The group was then divided into teams and asked the following questions: Are the principles easy to understand? Is there any terminology that is confusing? Do the principles apply to your design situation? Were the principles useful in the design process? Do you have instructional design questions specific to Web-based learning that were not addressed by the principles? Is there an order of presentation that would be useful? Are the principles independent, or does it make sense to look at them in a specific order? Do you have any other comments or questions?

After the teams had answered the questions, a group session was organized to discuss teamwork results, summarize the most important comments and suggestions, both on the wording and order of the principles.

**Results**

The preliminary principles were revised and reordered by design phase (analysis, 1-5; design/development, 6-11; evaluation, 12; delivery and management, 13) as presented below:

1. Identify opportunities for authentic and feasible collaborative learning activities.
2. Select media, channels and tools based on their ability to support collaboration in learning activities (i.e., by being multidirectional, interactive and sharing).
3. Provide feedback channels from student to student, team to team, and student support system to team.
4. Anticipate possible technical and conceptual learner errors. Use productive errors as input for team discussions, to provoke cognitive conflict among team members, and stimulate individual reflection. Eliminate non-productive errors by providing stronger guidance and/or interface design.
5. Use a structured learning approach for learning how to use tools and an active learning approach for developing skills.
6. Design meaningful and balanced opportunities for synchronous--face-to-face or mediated--and asynchronous interactions among team members, between distributed teams and the system, as well as between distributed teams and the instructor.
7. Design an assessment method for both individual and team achievements by tracking individual contributions, and by asking individuals to reflect on teamwork processes and/or performance.
8. Provide specific support tools and structures for the life span of the team. For example, during the team-building phase of the activity, whether teams are formed by participants or course leaders.
9. Introduce collaboration gradually. Ensure that students are familiar with the learning environment before requiring intensive collaboration.
10. Implement coordination mechanisms when designing each learning activity.
11. Design a student and tutor support system capable of supporting distributed teamwork.
12. Conduct formative evaluations in a team setting to ensure shared understanding of learning materials--text, graphics, audio, video—and coordination mechanisms.
As a by-product of the Telelearning project (6.2.3), a learning product and the profile for a software coordination agent were also developed. The design experiment in Step 2 was used to build and implement a learning scenario and environment. The product is called a distributed collaborative science learning lab: DCSLL (Winer et al., 1999). The modelling exercise in Step 3 served to complete the analysis of the roles of a coordination agent (Wasson, 1998b).

Conclusions and Outlook for the Future

The results of this project provide an in-depth understanding of collaborative telelearning scenarios distributed over both time and space. The groundwork has been laid to coordinate actors in collaborative telelearning scenarios. As a result, the design of pedagogical agents for collaborative telelearning has been further advanced.

The foundations for collaborative science telelearning laboratories have also been established and tested. More specifically, a scenario in a Web-based environment for a physics lab has been developed, implemented and tested. Collaborative telelearning scenarios were modelled using the MOT knowledge editor in order to extract instructional design principles.

Instructional designers and consultants have validated preliminary principles. Design principles, based both on theoretical foundations and training practices, should ideally provide instructional designers with the knowledge they need for innovative teletraining, while maintaining high-quality standards.

Until now, work has been carried out using “bridges” to develop and test training solutions: Management training was tested in a higher education environment at the École des Hautes Études Commerciales (HEC), and technical training was tested at the collegiate continuing education level – Centre Collégial de Formation à Distance (CCFD). This made it possible to test preliminary solutions in situations that were realistic enough for a formative evaluation of scenarios and technological environments.

Future work in the Telelearning Network of Centres of Excellence should include: 1) Creation of a Workplace Training portfolio, consisting of a collection of basic learning scenarios, as well as a methodology for adapting scenarios to specific learning situations or needs (DelaTeja et al., submitted to EDMEDIA’2000); 2) Design of a coordination agent able to play the roles identified above (Wasson, 1998b); 3) Implementation of the coordination agent in a virtual campus environment, such as LICEP’s Explora (Paquette et al., submitted to EDMEDIA’2000).

Abstract: The discipline of learning environment design has expanded greatly in the past decade. The need for effective methods to capture, represent and communicate design knowledge remains pressing. High level principles, such as those provided by constructivism, are not sufficient in themselves. This paper provides an exposition of the concept of PALs (Patterns for Learning). These are re-usable design patterns that can be applied in the development of computer supported learning environments. The paper discusses how PALs may be extracted to capture and represent design knowledge. It is argued that these re-usable design patterns provide a productive currency for metadesign, the theoretical discourse about design.

Introduction

There has been a rapid expansion of learning technology in the past decade. This expansion has involved not just an increase in the size of the community but also a burgeoning of design innovations. Many of these innovations are linked with the increasing influence of constructivist conceptions of the learning process (Cunningham et al. 1993, Jonassen et al. 1993). There remains, however, a considerable fragmentation in the representation of design knowledge, and often a considerable gap between exhortation and implementation. There is a need to develop a systematic conceptual representation of design knowledge.

There are different ways of capturing and representing design knowledge. Constructivism has presented design guidance at two main levels: principles and tactics. Constructivist principles include an emphasis on authentic learning tasks which evoke a high degree of interaction and collaboration to engage the learner in the knowledge construction process. These principles, emphasizing authentic tasks, interaction, engagement, collaboration and ownership of the learning process, have a high heuristic value for the designer. However, there is considerable freedom of interpretation in how they should be implemented. These principles may be realized through various methods. These methods range from constructionism with a very strong emphasis on learner freedom in constructing artifacts (Papert 1993) through to structured guided-discovery methods such as CORE (Boyle et al 1994). These methods may include refinement and expansion of constructivist principles and/or some degree of structured method for doing design.

These representations of design knowledge are both valuable. However, there remain a number of problems. This becomes particularly manifest when teaching learning environment design. There is often, for example, a marked gap between exhortation and implementation. For novice designers the principles are quite abstract. How do they relate these principles to the specific problem situation? In software engineering the re-use and tailibility of software components has been a very important issue in design. However, support for tailibility and re-use in learning environment design is weak. Constructivism provides reusable principles but at a very high level. The designer may struggle to extract re-usable components from examples of constructivist systems. Constructivist oriented methods for learning environment design, such as Cognitive Apprenticeship, does not fully solve this problem. Some features still remain at a high level of representation. How do modeling
and scaffolding apply at the level of detail, for example, of developing a learning environment for program
design? How do you apply the concepts when dealing with issues such as the complexity and abstraction of the
material to be learned? The concepts provide good starting principles. But how you progress from these starting
principles to develop successful systems is often not clear.

There is thus often a marked gap between principles and design practice. A central issue is: how do you capture
design insights in a form that provides re-usable techniques that can be applied to create a bridge from
principles into practice?

Design patterns

There is considerable research work that indicates that much expert knowledge is represented at the level of
'patterns'. These are abstract representations relating problem space characteristics to solution frames that can be
applied to a range of concrete problem situations. Patterns have been identified as a key presentation of expert
knowledge in domains such as chess, programming (Hohmann et al. 1992, Clancy and Linn 1999) and
hypermedia design (Lyardet, Rossi and Swabe 1998). In modern object oriented design 'design patterns' has
become recognized as a key way of capturing and disseminating high level design expertise (Gamma et al.
1995). These patterns capture expert knowledge. They are the 'chunks' that enable experts to deal at a much
higher level of representation in solving problems. They fit in with the classical psychological theory of how
people overcome the limitations of working memory - 7 plus or minus 2 bits of information (Miller 1956).
Experts deal with chunks or patterns of information (sometimes at a very high level) not isolated elements. The
development of expertise involves building up these patterns of information together with the skills to apply
them effectively.

Work has started in the area of object oriented design on the concept of pedagogical patterns as a way of
The work in this area has begun to tackle some important issues, such as developing formats for the
representation of pedagogical patterns (see http://www-lifia.info.unlp.edu.ar/ppp/format.htm). However, this
work has tended to be focused mainly on the domain of object-oriented programming and design. The
importance of the concept of re-usable design patterns as a way of capturing re-usable 'domain free' pedagogical
techniques has made little impact on the wider learning environment community. The concept of design patterns
should provide a powerful tool for analysis and synthesis. It should provide a tool to analyze existing
approaches, extract re-usable design patterns and support the use of these design patterns in new creative
systems or learning architectures. These are the objectives of the approach advocated in this paper.

PALs for designers

The aim is to develop an approach that will help extract, represent and apply the high level knowledge that is
possessed by expert designers of computer based learning environments. The term used in the paper for these
re-usable design patterns is PALs (Patterns for Learning). This explicated knowledge, in turn, should provide a
currency for productive dialogue among designers. It should facilitate a real debate, a dialectic of development
in furthering the explication and adaptation of design knowledge.

There are two main sources for extracting re-usable design patterns:

* Abstraction from examples of good practice

* Analysis of existing methods

This discussion will focus on the second source. This provides a very direct and productive way of extracting
re-usable design patterns. It supports the creation of a level of design knowledge at a level of granularity below
that of methods or tactical frameworks. It complements and extends traditional ways of representing design
knowledge.
Analysis of existing methods

There have been a number of methods proposed for the design and development of learning environments, such as Cognitive Apprenticeship (Collins et al. 1989), CORE (Boyle et al. 1994) and CaBLE (Feifer and Allender 1994). However, there is a limit to the theoretical utility of having a number of design methods presented as alternative choices. There ought to be common techniques for the analysis of these methods into smaller, re-usable design components that can be adaptively used by creative instructional designers. Where can we find PALs in these methods that can be used as design entities independently of the 'macro' methods in which they were originally embedded? Applying this approach should free up knowledge embedded in these larger methods and provide a more flexible currency for the exchange and re-use of creative design insights.

The extraction of PALs from these larger methods may be illustrated using the CORE Approach. This is a constructivist method for designing learning environments for complex skills or highly structured knowledge. It was first applied to the domain of programming (Boyle and Margetts 1992, Boyle and Davies 1996). It has subsequently been applied to a range of domains ranging from the formal recording of animal behaviour (Boyle et al. 1996) to nuclear medicine (Hogg et al. 1999). The CORE method involves structuring learning blocks based on a sequence of Context, Objects, Refinement and Expression. Each learning block commences by setting the context. This presents the new skill embedded in a larger working environment. This is followed by the provision of examples of the learning target disembedded from the working context. A refinement section follows. This is based on a series of carefully chosen questions with feedback. This dialogue of questions and answers enables the learners to construct their knowledge of the target domain rather than this knowledge being transmitted didactically. Each learning block terminates in an 'expression' phase where the student applies the new skill acquired. At the curriculum level, each of these learning blocks is organized around a target competence, with later learning blocks building on the accomplishments of earlier blocks.

A designer might wish to use certain features of this approach combined with features of other methods such as Cognitive Apprenticeship. How can this selective use of specific pedagogical features be achieved? Here we use the CORE approach as an example. A similar analysis could be applied to other methods such as CaBLE or Cognitive Apprenticeship to yield re-usable PALs. The 'Refinement' aspect of CORE, for example, provides pedagogical techniques that might be extracted and used independently of the full CORE approach. An examination of the 'Refinement' reveals that it has a link and chain structure phase. Two main design patterns can be extracted - the link PAL, and the chain level PAL which provides a higher level organization of the link components. In this discussion we may focus on the 'link' pattern.

The CORE 'link' pattern is based on a microproblem-response-feedback structure. In its simplest realization this is a structured variation on a 'question-answer-feedback' exchange. CORE uses example-based learning. Each link involves the presentation of an example. This example is an instantiation of some underlying structure, e.g. a construct in a programming language. The learner has to form a hypothesis or guess about the underlying pattern based on this example. This underlying hypothesis, or guess, informs the learner's response. When students answer the questions they receive feedback. This feedback provides the mature user's response with a short explication of this response. For example, if the learner is presented with a yes/no question the feedback will always give the reason for the expert's yes/no answer. This is the most important part of the feedback. It allows the learner to compare their response with the experts and use the feedback to elaborate or 'refine' their hypothesis, or idea, about the underlying structure. It is important to note that the feedback provided by the software does not require any AI type parsing. The information is provided as a knowledgeable response. The method encourages the learner to compare their response with the expert's response and actively refine their understanding as a result. The feedback also adds new formative knowledge that the user may apply to solve the next example-based question. In this way a didactic exposition of knowledge can be replaced by a highly constructivist 'example-infer-feedback' chain. The structure of the CORE link PAL is set out in Figure 1.

The 'link pattern in CORE may be extracted as a PAL entity in its own right. In the CORE method these links are organized in a dialogue 'chain' that has its own structural properties. However, systematically applying the full method is very time consuming. Pure example-based learning, as in CORE, is very demanding to develop. A learning environment designer might wish to employ smaller sets of 'CORE links' combined with direct exposition - as in 'modeling' espoused by Cognitive Apprenticeship. The separation of the 'CORE link' PAL
supports this creative and adaptive re-use. The designer may wish to break down a complex area into episodes of exposition followed by short sets of CORE links (e.g. three to five links). In this way the designer may wish to attain a balance between economy in development time with the use of example-based constructive learning. The analysis of CORE and Cognitive Apprenticeship into re-usable PALs would actively supports this creative 're-purposing' by the designer.

**Towards metadesign - discourse about design**

One of the learning objectives of constructivist theory is to encourage metacognition - thinking about thinking. Learners should not only learn about the domain and skills in problem solving, they should also be able to reflect on how they solve problems and how they think about the domain. This is a high level skill. If this is a skill that should encouraged in learners it is certainly a target that we as designers should doubly strive for. It is not enough to do good design - we need to reflect, analyze, explicate and communicate about design expertise. We need a disciple of 'metadesign' - a way of representing and communicating about the process of design. This is not 'doing' design; it is reflecting, explicating and developing dialogues about the doing of design. A dialogue about design requires a currency in which communication and exchange can be expressed. The idea of PALs and design patterns should make a significant contribution to this currency of exchange. It can provide a significant contribution to the language in which we can communicate, think and solve problems in the domain of learning environment design.
Conclusion

As a community we need to pay greater attention to the nature and development of design knowledge. The idea of PALs or re-usable design patterns provides a productive contribution to this debate. The concept of re-usable PALs points to a number of key activities for the design community. These activities include:

* the analysis of existing 'macro' methods into flexible, re-usable design patterns;
* the synthesis of new knowledge based on the combination and adaptation of existing PALs;
* developing a knowledge base to capture and provide access to these design patterns

More broadly we need to expand our theoretical discourse about design. The concept of PALs and re-usable design patterns provides a useful 'currency' for the exchange of ideas about design in a form that is directly related to the needs of designers. It is non-prescriptive. Design patterns from different and even ideologically opposed methods can be extracted and re-used. The assessment of a PAL is its utility in solving problems in the design of pedagogically sound learning environments.

The Forgotten Partner: the Role of Visual, Graphic and Design Principles in Educational Multi-media Course Instruction.

Ian Brown  
Faculty of Education  
University of Wollongong  
Australia  
ian_brown@uow.edu.au

Abstract  
As educational media becomes more interactive, there has been a proliferation of, and renewed interest in, courses relating to multi-media construction. On-line course and web page construction now occupy countless development hours within educational institutions. But in the ‘real’ world of media and software development, computer programmers and graphic designers now work in partnership to produce the final product. The question is posed: when educating and training teachers to develop new media for the classroom are we providing them with the visual, graphic and design skills necessary to produce quality products?

This paper will argue the case for greater inclusion of the basic visual, graphic and design principles to be included in educational multi-media courses. A number of core skills and principles will be outlined which should be developed and included for successful course implementation.

Advocacy. This paper unashamedly advocates a greater role for visual, graphic and design principles to be included in all educational multi-media courses. In 1996 the Australian Good Universities Guide listed three specialisations in information technology (IT). By 1999 there were over fourteen specialisations with dozens of connected courses. This is just one example of the dramatic increase or mini explosion of course development in the area of information technology and multi-media in Australia. The presumption that learning can be enhanced through technology, including on-line courses has been debated and supported through recent studies.new technologies, such as Web based delivery, promises superior classroom instruction in relation to traditional instructional delivery. (Turoff, 1995). As more and more courses go on-line and instruction moves from the traditional method educators are expected to develop skills to cope with this paradigm shift. Universities have been charged with the responsibility to play a major role in this shift.

Questions arise to what is appropriate for inclusion in a multi-media course instruction. What content is needed? What skills should educators develop? What course components should be categorised mandatory or elective? The problem of content selection could be (and should be) as problematic as the delivery of the course.

This paper has been motivated by ‘apologies’. The researcher has observed a number of educational multi-media conference presentations where authors have prefaced their talks by apologising for the ‘look’ of their products, be they packages, on-line courses or web page design. It was obvious, through their own admission, that considerable time and effort had been given to such areas as research, problem design, navigation, design solutions, metaphor choice, prototype construction, usability testing, choosing the appropriate cognitive processing tools but little effort had been given to the ‘look’ of their product.

Informal investigations eluded to the possibility that multi-media course instruction minimises the importance of visual design in their instructional courses. This paper proposes two notions:

- Visual design is an integral mandatory component of all educational multi-media courses
- Connections between learning cognitive theory and visualisation should be made more explicit
Visual Design is an Integral Mandatory Component of all Educational Multi-media Courses
According to Lynch (1994), highly interactive multimedia electronic documents pose unique graphic design problems. Visual design skills affect virtually every aspect of software interface design. Students need to develop skills in the following areas: spatial relations or layout, perceptual or aesthetic principles (such as, proximity, similarity, continuity, closure etc), designing for computer screens, graphic interface design, visual design conventions (such as, typography, or colour), animation, sound. There are many principles relating to interface design that should also be developed and included in course content but this paper is mainly dealing with visual design skills.

Traditional graphic design principles must be adapted to work successfully with new technologies. There needs to be a paradigm shift for working specifically with digital media. According to Heller and Drennan (1997), that although a high level of traditional design expertise is imperative students must develop a new way of 'reading' and 'seeing'.

Students need to be aware of the role of visual communication and the impact on the learner. A successful online course, web page or educational multi-media package needs to bring together all the elements of successful interface including the visual design component.

Connections Between Learning Cognitive Theory and Visualisation Should be Made More Explicit
The recent move to constructivist theory allows educators to reinforce the ways in which the learner's derive meaning and review the learning process. Traditional theories, such as Gestalt, combine with recent work by Herle (1996), concluding that the brain works by making patterns, making connections and deriving meaning. Metacognition has allowed educators to see how individuals can problem solve and reflect on their own thinking processes. Within multi-media, visualisation allows the user to participate in the learning process. In reality, the majority of educational multi-media produced today is highly relevant on visual design to help the learner make important connections for meaning. Tools such as visual mapping tools are contributing to teaching and learning in a constructivist-cognitive paradigm.

The role of multi-media education is to encourage interconnectedness of knowledge while allowing accessibility to visually supported information (Hyerle, 1996). Educators using new technologies are now confronted with a new set of problems. How will problems be represented? How do students control and access information? And for developers of educational multi-media specifically: how do you visually present and design the information?

The structure, choice and visual design is imperative for learning. (Tufte, 1990). According to Tufte (1990), effective and efficient visual displays are borne of the necessity to escape the endless flatlands of the bland tabulated mass of predigested data. Designers of educational multi-media need skill in visual design and an understanding of how visuals can provide meaning and context for the learner.

Often educational institutions spend energy and resources trying to improve interface and navigation for multimedia packages, on-line subjects, web page construction, while neglecting the visual impact of the product. Visually they look uninviting, inappropriate and often gives the user the impression that visual quality has little importance. Although products are often well organised, clear and easy to navigate, they can at times, be visually unappealing.

Course designers are charged with the task of developing a course for students which tries to pull all the elements together: content, organisation, navigation, interaction and visual design. On examination of many educational multi-media courses, the final component is either minimally represented or totally lacking. If this is the case, it raises a number of questions. What design principles should be included in a multi-media instructional course to allow students to develop a design aesthetic? What design rules and techniques need to be employed? What skills should be developed by students for greater success? How much time should be devoted to the components of visual, graphic and design principles within a course?
What is important is that visual design should not be just an added component, but instead an integrative, integral part of the total design process. Designers have acknowledged cognitive recognition is central to the process of interface design... then an added basic understanding of visual elements and their employment in the design projects would only enhance the process. For successful interface designers must have a well rounded understanding of perceptual elements and the affect on the user. Often we find that design fundamental rhetoric outlined for effective interface, focuses merely on the functional characteristics of the design. (Hobart 1997, Mullet 1994, Mountford 1990, Laurel 1990, Apple 1988). That is, visual structures are identified, such as, buttons, icons, metaphors, text fields, windows without recognising the importance of visual elements in the design (colour, shape, size, direction, texture). (Salomon 1990, Black 1997)

Visual design skills affect virtually every aspect of the multi-media construction. According to Lynch, visual design skills affect every component from simple generic objects like windows to the animated illustration of interactive three-dimensional structures within electronic documents. (Lynch 1994; Marcus 1992; Schneiderman 1992; Tognazzini 1992,).

Students enrolled in educational multi-media construction courses do not need to be qualified graphic designers or artists, but they do need fundamental skills and exposure to principles of graphical user interface, including visual design principles.

The following principles, skills or knowledge, (in relation to the visual, graphic and design area), should be included in all multi-media construction courses. This is not an exhaustive list but instead provides a basis for initial scholarly debate and a review of existing course content.

Students need to
- be exposed to visual design conventions;
- be able to develop a consistent visual structure;
- understand and employ visual design elements;
- understand and apply robust graphics;
- employ discretion concerning typography;
- understand the need for clear graphic layout;
- be able to identify and apply visual layering;
- be aware of spatial relationships;
- see the relationship between visual and functional goals;
- be aware of the positive use of the visual elements.

As Lynch (1994) contends, elements within the design must appear in a stable, intuitive and predictable relationship. This paper argues the notion that this will not occur by chance... it must be developed, nurtured and taught. The author challenges course designers to review course content, re-evaluate time allocation and include a visual, graphic and design component in your courses.

Interaction: The Key to Successful Distance Learning

Albert S. Byers
Virginia Tech
2812 Wellsley Court
Blacksburg, VA 24060
Abyers@vt.edu

Abstract: The purpose of this paper is to discuss the impediments to distance education (DE) programs and the critical value of interaction and dialog in DE learning environments. Many specific types of interaction like student-student and student-content will be presented. Examples showcasing distance delivered k-12 support curriculum projects from the National Aeronautics and Space Administration (NASA) will then be discussed with respect to their interaction and collaboration. The NASA examples provided will be tied back to the pedagogy surrounding distance education interaction.

Impediments to Distance Education

Distance education (DE) has usually been defined as the separation between instructor and student, whether temporally or by spatial distance. While this physical and temporal distance is a fact, it erroneously limits the factors affecting learning at a distance. Transactional distance more aptly describes the relational separation between learner and instructor and is based on the interplay between the environment, patterns of behavior or dialog between the learner and teacher and the autonomy of the learner (Moore, 1996).

With the physical separation of the learner and instructor there are psychological and sociological implications that limit communication (Wolcott, 1996). In effect the psychological distance may generate a feeling of isolation for the student and hinder the development of rapport between the learner and teacher. Wolcott (1996) states that it is this rapport that allows the learning discourse between teacher-student and student-student relationships to occur. Social presence or acceptance as perceived by the distance learner is a significant factor for consideration (McIsaac & Blocher, 1998) and should be included in the design process.

Distance education programs malfunction due to their lack of consideration for the human dimension (Spitzer, 1998). While tremendous strides have been made in telecommunication hardware, Spitzer (1998) states that it is the social interaction level between humans that will determine if a DE program fails or succeeds.

Necessity of Interaction

Moore (1997) describes the necessity of a purposeful instructional dialog, which facilitates and increases the interaction between student-student and teacher-student communication. In a purposeful dialog environment all learners are active participants, listening and building upon the contributions of other individuals. Moore continues on that dialog is also influenced by teacher and learner personality and content. Thus, intentionally designed collaborative opportunities should be incorporated into the instruction for distance learning environments to be most effective. As dialog and learner control increase transactional distance decreases (Saba & shearer, 1994). For learning is not an objective search for prescribed knowledge, but one that is experienced and formulated based on how we interact with our environment and others (Duffy & Jonassen, 1991).

Equally effecting the exchange of dialog or interaction between participants is the way a distance learning program is structured. Selecting the right instructional strategy, such as that of interaction facilitates learning of the higher levels of cognition such as: analysis, synthesis, and evaluation (Weston & Cranton, 1998).
Programs that are extremely rigid and that do not allow flexibility for student contributions, interactions or discussions are detrimental to the learning outcomes desired (Moore, 1996). Several forms of interaction are possible in a DE environment, all of which should be considered during the instructional design phase of a course. Interaction occurs between the following categories: learner-instructor, learner-learner, and learner-content (Wagner, 1997). A fourth dimension of interaction was added in 1994, that between the learner and the interface (Hillman, Willis, & Gunawardena, 1994). When designing instruction one should first should look at the intended instructional outcomes desired for a learning experience, analyzing the type of learning that is desired (verbal or intellectual skills, psychomotor skills or attitude changes), then select the appropriate type of interaction that will facilitate this type of learning (Wagner, 1997). A brief list of the types of interaction possible will finish this section.

Types of Interaction:

Interaction of the following types should be considered when designing a DE program (Wagner, 1997):
1. Interaction to increase learning
2. Interaction to increase participation
3. Interaction to develop communication
4. Interaction to receive feedback
5. Interaction to enhance elaboration and retention
6. Interaction to support learner control/self-regulation
7. Interaction to increase motivation
8. Interaction for negotiation and understanding
9. Interaction for team building
10. Interaction for discovery
11. Interaction for exploration
12. Interaction for clarification of understanding
13. Interaction for closure

With the impediments to distance education and the necessity of interaction in DE environments discussed, a look at several instructional examples from NASA's k-12 education program will next be presented. The first NASA program discussed below takes advantage of the interaction between teacher-student and student-student to increase learning, participation, team building, motivation, negotiation and understanding.

NASA Online Interactive Projects: NASA Quest/Sharing NASA (http://quest.arc.nasa.gov)

Senator Al Gore originally funded this project in 1991 as part of the NASA High Performance Computing and Communications (HPCC) program. Capitalizing on the motivational aspects of collaborating/communicating with NASA individuals, teachers have expressed the value of the "Sharing NASA" supplementary support curricula aligned with the National Science Education Standards (NSES). Sharing NASA provides "real-world" authentic contexts and situated learning opportunities that connect the science content and process skills currently taught in the classroom, transcending the physical and temporal classroom limitations.

At the link above you'll find a listing of online collaborative NASA projects where one may participate in a variety of conferencing opportunities with NASA scientists, engineers, researchers and support personnel via email, synchronous chats, asynchronous threaded discussions, and streaming video. In addition to the interaction opportunities, online activities, project background information, mission updates, and biographies are available.

A combination of software solutions and "Smartfilter" designates (volunteer teachers, paid employees) manage the enormous influx of inquiries, aggregating common questions and facilitating the asynchronous
interaction between the limited time of the NASA employee participants and the classrooms across the nation.

Past examples of "Sharing NASA" projects are archived and available online. One example will now be discussed.

Live From Mars: July 1996-December 1997 (http://quest.arc.nasa.gov/Ifm/index.html)

Created in conjunction with the "Passport to Knowledge-Live From" series, the "Live From Mars" Sharing NASA project had a host support curriculum with the following programmatic categories: featured events, live video, photo galleries, questions, chat, kids corner, teacher's lounge, background, Mars team (biographies, images), and what's new.

One featured event Weather Worlds challenged student classrooms from around the country to debate what key weather measurements and instruments they thought were most important to gather here on Earth (similar to decisions the NASA Mars Pathfinder scientists had to decide for the surface of Mars). Classroom submitted their proposals online with justifications for debate. For example, if a classroom felt temperature was a worthy measurement, they then had to figure out protocols and procedures on how, when and within what range and frequency they should collect temperature data.

Electronic individual class results were collected by the "Sharing NASA" personnel, placed in a spreadsheet, and responses aggregated and debated online. From these collective results, final instruments and protocols were tallied and presented.

Ironically, this type of interaction doesn't necessitate high bandwidth connectivity or a computer lab. The learning is done in the classroom facilitated by the teacher, then submitted via email for presentation and debate. Current "Sharing NASA" projects include:

1. Space Scientists Online
2. Aero Design Team Online
3. Women of NASA

The next NASA educational curriculum support area that will be discussed focuses on the interaction between the learner and the content, and learner-interface while also integrating teacher-student and student-student interactions to facilitate learning, exploration, feedback, and elaboration and retention.

NASA's Learning Technologies Project: (http://learn.ivv.nasa.gov)

Here you'll find the entry page to approximately 50 NASA funded Internet projects focusing on interaction between the learner and content. NASA is supporting the development of projects in disciplines like Agriculture, Aeronautics, Aquatics, Earth Science, Tourism, and Space Science. At this site one may search for projects by discipline or state. One project from NASA's LTP will be referenced below.

NASA Glen Research Center:
FoilSim (Basic Aerodynamics Software)

FoilSim is simulation software that allows students to interact and control the parameters of airflow around a wing or baseball by varying the airspeed, altitude, thickness, camber, and area. Students also have learner control over the placement of the probe gathering aerodynamic data, and receive immediate feedback via a Plotter View Panel that depicts graphical changes in surface pressure, speed at surface and lift. The student can also visually see how far a curve ball would "break" across homeplate for various elevations (Cleveland, Denver, Mt. Everest). This Java applet (Mac or PC) when used in conjunction with guided questions and the necessary content background facilitates the learning of the factors that influence lift.
The final NASA educational project that will be discussed concerns the interactions between learner-interface, learner content, and learner-learner while enhancing learning, communication, feedback, team building, exploration and discovery.

EarthKAM (http://www.earthkam.ucsd.edu/)

EarthKAM is an opportunity for students to investigate Earth from the unique perspective of space via digital photographs they request during live space flights and from previous mission image archives. Piloted on 4 previous space shuttle missions, EarthKAM will be the first operational payload on the International Space Station.

In essence, students plan investigations that can in part be answered from examination and manipulation of remotely sensed images. For example EarthKAM can be used to answer questions involving real world problems like deforestation, beach erosion, urban crawl, etc.

Uniquely designed web interfaces allow students to search from images either visually by geographic location, by image index number, by mission, by school, or by geographic name (China, Nile River, etc.). Once a particular image is selected, students can then examine the image by zooming in/out or panning left, right, up, and down. To place the image in the "big picture" a student can overlay the digital photograph onto a composite map showing the elevations and contours of the surrounding areas or a Jet Navigation Map (JNM) displaying the location and names of major geographic reference points (rivers, cities, etc.).

Also available is the ability to view the map against the animated cloud cover that was present (within 3 hours) on the day the image was taken using weather satellite remote sensing image overlays. Finally, with the use of a VRML browser plug-in, the student can take a composite map (image overlaid against surrounding colored contour map or JNM) and visualize the image in a 3-D environment. This environment allows the student to fly by, fly over, fly under, or fly around the image with the elevations literally portrayed with vertical depth as well as 2-D color. Finally, using free image editing software (NIH image), student can label their photographs and make measurements like scale distances, area, and perimeter.

This environment provides complete learner control and higher learner-interface, learner-content interaction. It should be said that while this program is extremely technologically savvy, without proper instruction and ancillary reference documents to facilitate worthy investigative questions, image manipulation alone merely becomes a novelty toy.

Summation:

For distance education to be effective design efforts must consider the impediments that hinder effective learning such as: transactional, psychological and sociological distance (Moore, 1996; Wolcott, 1996). Intentionally designed programs that foster interaction and dialog between the student-teacher and student-student enhance learning and emphasize specific learning skills if properly facilitated (Wagner, 1997). Several NASA education support curriculum projects seem to emphasize interaction and were described herein.

Abstract
The building of collaborative online communities raises questions about the nature of discourse in these environments: Underlying these questions are fundamental notions about the social construction of knowledge. CMC has the potential to even out social/technology-related gender issues. However, a body of literature has emerged from various domains that describes the presence of gendered discourse patterns in online communities. Would these gendered patterns extend to the discourse patterns among conference facilitators and conference participants? What effect would these patterns have on the conversation, especially for women participants? This exploratory study analyzes the CMC transcripts of two junior undergraduate courses employing a conference forum as part of the learning design. A framework integrating several theories of online discourse contextualizes findings.

The 1980's saw a large-scale post-secondary technology infrastructure project supporting the use of productivity tools such as word processors and spreadsheets in numerous computer labs across campus. The IT field focused on the creation of optimal blueprint models of computer-based instruction in which learners worked alone, often on tasks that were procedural and criterion-based, with little interaction among themselves, with their instructors, or even with the authentic content of the domain (Ewing, Dowling, & Coutts, 1998). The nature of the technology itself maintained a hierarchical relationship between instructors and students in which the instructor was regarded as the Intellectual Authority; the source of all knowledge in the classroom.

However, with increasing access to other sources of knowledge, and new constructivist approaches, learning designs now focus on social interaction among communities of learners. The building and maintenance of online communities as forums in which to construct and share knowledge naturally raises questions about the nature of discourse in these communities: What counts as knowledge? Whose knowledge counts? And how is it valued in computer-mediated conversation (CMC)? Underlying these questions are fundamental notions about the social construction of knowledge through language, and especially through computer-mediated language in virtual, asynchronous, online communities in which the traditional and taken-for-granted cues of social discourse are mostly absent. Sherry Turkle describes a new social construction of computers, in which a "new set of intellectual and emotional values more like those applied to harpsichords than hammers" prevails (p.280, in Kirkup, 1992). Here, groups that have been traditionally excluded by an epistemological value set, such as women, will find a learning environment that distributes "authority to bring everyone into an educational process extending beyond time and physical space and sociopolitical boundaries" (Slatin, 1992, p 50). CMC goes beyond a technological tool to provide a pedagogical framework that can encourage active learning in a context of "constant collaborative conversation" (Hollingsworth, in Elliot & Woloshyn, 1997).

Much has been written about the potential of CMC to even out the gender inequities described in educational technology studies over the past 30 years. Equally, however, a body of literature has emerged from sociolinguistics, discourse analysis, feminist theory, and educational computing research that describes the presence of gendered discourse patterns in online communities. We were curious to know whether that
gendered pattern extended to the discourse patterns of online facilitators. As a first step towards understanding the problem, we have analyzed two junior undergraduate courses in which a conference forum was an integral part of the learning design. One facilitator was male; the other female. In the first phase, reported here, we intended to develop a rubric from which to examine and describe any gender-related differences. The next step will explore their effects on the conversation of the learning community.

Theoretical Framework

This study is embedded in four intersecting research strands. Taken together from a feminist perspective, they form an epistemological framework for investigating the design and implementation of technology-based learning environments in the post-secondary setting. These strands are: the exploration of technology as a social construct; the seminal, yet controversial, work characterized by the phrase women’s ways of knowing (WWK); and the emerging research base in gender characteristics of online discourse. The promise of CMC for constructivist learning is the fourth strand that weaves them all together.

Technology as Social Construct

Women’s relationships with technology have been aptly summed up by the admonishment, ‘Don’t touch it, you’ll get a shock’ (Turkle in Spender, 1995, p. 173). Computer culture may reproduce and reinforce sexist gender ideologies (deCastell in Luba, 1997, p.23) represented by technological innovations such as individualized computer-based learning software, used in contexts (such as computer labs) that are isolated and unappealing to women. An established body of work in the social sciences has emphasized that innovations reflect social constructs (Cockburn & Ormond, 1993, p. 7). Therefore, technology is a culture out of which artifacts are created.

If men have been the creators and designers of technological artifacts (the thinking goes), men’s social domination of the technological culture is extended. Technology relations, then, ultimately become gender relations (Cockburn & Ormond, 1993, p. 155). On the political face of it, technological solutions to power over women and the contexts in which they live, work, and learn are global issues of knowledge creation and representation, language use, and access, and could be condemned. However, if culture is socially negotiated rather than imposed, CMC can be used as a critical pedagogy; an agent of change in the real world.

Beardon and Worden (1995) describe a collaboratively constructed learning environment in which we see, "the value of a broad experience of possible applications; (and) the advantages of students setting their own agendas" (p. 65). Implementing electronic communications in the classroom is a decision to build an active community for learning that is grounded in conversation.

In its role in sustaining relationships with others, Bruffee (1993) characterizes conversation as connected knowing and the site for constructing knowledge. This aspect of conversation reflects its centrality in the constructivist environment, because dialogue is a cognitive process in which students work together to decenter, moving beyond personally held views to construct new and expanded representations (Fosnot, 1996), and transforming classroom relationships (Slatin, 1992, p.30). However, teachers may have trouble re-conceptualizing their roles in these active, participatory, and democratic environments (Ewing, Dowling & Coutts, 1998, p 6). We wondered if the difficulty in this process is inherently gender-related.

In the virtual classroom CMC provides both a pedagogical framework and a strategy for collaborative knowing. Pedagogically, CMC emphasizes extensive and sustained interaction that is more student-centered, than teacher-controlled (Kearsley, Lynch, & Wizer, 1994). Strategically, the asynchronous nature of CMC expands user control because learners can control the timing, amount, and pace of their contributions since opportunities to speak are not limited or constrained by time or turn-taking concerns, or to social position and language ability.

Women’s ways of knowing

Women may be socialized to process information in concrete, relational, and associative ways (Elliot & Woloshyn, 1997), as opposed to the abstract, systematic ways required by androcentric designs (c.f. Shade, 1993; Winkelman, 1997). This view has informed feminist criticism of traditional learning design for two
decades. Articulated by Carol Gilligan in 1982, and elaborated in the work of Belenky, Clinchy, Goldberger, and Tarule (1986, 1996), women’s ways of knowing (WWK) describes an alternate view of cognitive development in which the received knowing of Western intellectualism is contrasted with the relational position of connected knowing. The criticism of mainstream technology design is exemplified by Margaret Wylie’s (1995) observation that "the Internet is male territory. Considering its roots are sunk deep in academia and the military-industrial complex, that’s hardly surprising" (p. 3). The WWK framework suggests that knowledge can be socially constructed in ways that include intuition, emotion, and experience; and shared through relationship and conversation. Therefore, much of the work of WWK continues to have a critical, activist stance.

The adult learning literature suggests different learning styles that are somewhat gender-related. Theorists in this field suggest two developmental paths (Table 1): the autonomous, separate, or independent path, typifying most men (and some women); and the relational, connected, or interdependent path, typifying most women (and some men). Virtual learning designs based on relational concepts may accommodate learners who are autonomous or separate as well as connected learners, but not vice versa (MacKeracher, 1996).

Table 1: Paths of Knowing

Gender and online discourse

Much has been written, and expected of, the virtual community of CMC as social barriers of sex, age, race, physical appearance, and facility in face-to-face, real-time discourse are apparently eliminated (or at least mediated). CMC provides an opportunity to solve the problem of inequitable distribution of dialogue space, reflected in gender inequalities in language use (Spender, 1995). However, Kirkup (1995) suggests that the style of talk that CMC participants are required to engage in is very dialogue-oriented, which privileges the expository style of men. These communicative styles, or cultures, are described by Deborah Tannen (1990), a sociolinguist, whose work has been extended to include data from a study of men and women communicating in the workplace (1994a) and online (1994b). Herring (1996), for example, described women’s tendency to attenuate (Tannen’s rapport talk) online, whereas men tended to adopt an aggressive and adversarial stance, challenging the ideas of others (Tannen’s report talk). Tarule (1996) points out a gendered discourse style that emphasizes a game and privileges a separate knowing approach to understanding and analyzing dialogues (p. 279). Dialogue as debate defeats a constructivist learning design, and does not reflect women’s ways of knowing. Do we see this gendered style in facilitator talk? Table 2 identifies several gender-related styles of discourse noted in online forums (Herring, 1996; Hiltz & Turoff, 1993; Taylor and others, 1993):

<table>

<td>* Directness, task-orientation</td>
</tr>
<tr>
<td></td>
<td>* Control of cross-gender conversations</td>
</tr>
</tbody>
</table>
Table 2: Styles of Discourse

Accepting the view that knowledge is a product of social interchange, the nature of that exchange through electronic conversation is pivotal in the experience of meaning-making (Bohan, 1993). And, if the nature of conversation in these environments is gendered, the social construction of knowledge is more likely to reflect a gendered worldview. Learners (especially younger and/or novice learners) may expect an online experience resembling traditional classroom discourse in which the instructor is the Intellectual Authority, knowledge is received, and peer perspectives are not welcomed or valued (Magolda, 1992). The expectations of both learners and instructors are quite likely gendered in this regard. We believe it evident that facilitator talk, which represents and supports a particular view of knowledge representation, is pivotal in developing learning environments that reflect either received or connected knowing.

The Study

To help make sense of the many relevant theories and models related to the four strands elucidated above, we constructed a research rubric that attempts to weave the main ideas together along three (of many possible) dimensions of the facilitator's online discourse patterns, and their potential underlying epistemologies, shown in Table 3, below.

Table 3: Research Rubric

Preliminary Results: Table 4
Both first-year undergraduate courses, from two different Faculties, each had a face-to-face (F2F) component supported by an online conference. The male facilitator’s (MF) class size was 1/3 that of the female facilitator’s (6 to 18, respectively); he also had a student participating by videoconference. The MF’s students were less active which may be reflected in his level of direct participation. The FF replaced some F2F sessions with CMC, while the MF did not. The MF teaches in a bilingual Faculty, i.e. he is a language teacher as well as a content expert. The FF teaches in the Humanities; the MF in a science-based domain. These contexts are important as facilitator talk is embedded in social constructs related to academic disciplines as well as gender.

The Hypermedia Conversation: Reflecting Upon, Building And Communicating Ill-Defined Arguments

Milton N. Campos
Département de communication
Université de Montréal
Montréal, QC, Canada
Milton.Campos@umontreal.ca

Abstract: This paper shows how reasoning upon questions and hypotheses built collaboratively can lead to knowledge-building and conceptual change in hypermedia conferencing systems. It is a qualitative study of the conditional reasoning process carried on in a biology mixed-mode undergraduate course on mammals delivered in the fall semester of 1998. The professor applied Socratic maieutic by posing online questions to the students, and then reasoning upon the answers and raising new questions in face-to-face encounters. We applied the meaning implication analysis to study the role of production systems in the conditional reasoning activity, taken in their logical (procedural) and referential (declarative) dimensions altogether. Results show qualitative circumscribed evidence of high order reasoning and conceptual change, and indication that high order learning had been achieved through collaborative knowledge building. The study discusses implications for course and conferencing systems design, and gives directions for new forms of representation in asynchronous conferencing systems.

Introduction

This paper shows how reasoning upon questions and hypotheses built collaboratively can lead to knowledge building and conceptual change in hypermedia conferencing systems. We studied one sub-conference of a biology mixed-mode undergraduate course on mammals delivered in the fall semester of 1998 in a French speaking Canadian university. The professor applied Socratic maieutic by posing online questions to the students, and then reasoning upon the answers and raising new questions in face-to-face encounters.

Results show the knowledge building process that led some of the participating students to achieve high order reasoning and conceptual change in the part of the conference chosen for study. We understand high order reasoning as the ability to logically operate the modules of content, and conceptual change as the ability to rebuild a conceptual (logical) based on the assumption that the previous construction had premises that were inconsistent with the conclusion of the argument. Conceptual change suggests that high order learning was achieved, i.e., that the content was retrieved and stored in the memory. The circumscribed collaborative knowledge building found in the students’ learning processes, reified by the transcripts as objects of knowledge (Popper, 1994; Bereiter, 1994; Scardamalia, & Bereiter, 1996), was assessed by transcript analysis. The meaning implication transcript analysis technique was applied to identify the chains of interconnected meaning implications, and how collaborative conditional reasoning and hypotheses formulation evolved in the hypermedia conversation (Campos, 1998).

Theory and Method

Learning is the process of acquiring expertise (Bereiter, & Scardamalia, 1993; Bruer, 1994) by storing mental objects as memory traces (Changeux, 1997). Assessing expertise acquisition in conceptual specific domains is usually done by applying the traditional comparison of the way novices and experts solve problems, like in physics (Larkin, 1981; Larkin, McDermott, Simon, & Simon, 1980), and how the schemas of the procedures are accommodated (Piaget, 1976a). Methods of assessing how novices and experts solve well-defined problems in conceptual domains, in which axiomatization allows necessity and sufficiency (Grize, 1990), cannot be simply transposed to ill-defined domains, in which the degree of the subjective referencing of natural language impeaches the occurrence of logical necessity and sufficiency (Grize, 1990). Indeed, the natural, social and human sciences, in different degrees, all suffer the lack of relative and provisional certainty provided by the hard sciences.
To allow assessing reasoning in ill-defined domains, in which classic problem solving is not possible due to the constraints of the referential function of natural language, we developed a method in which both the logical and referential dimensions were taken into account (Campos, 1998). This method looks at the way we reason through natural language and the conditional operations subjacent to the inferences we make. The inferential capacity, expressed by conscious or unconscious conditional reasoning, is at the core of the cognitive process and can be considered its gist (Piaget, 1976c).

To apply our method to hypermedia learning environments we developed a technique of analyzing transcripts of online conversation. The analysis allows the study of production systems in the conditional reasoning activity, taken in their logical (procedural) and referential (declarative) dimensions altogether. This technique allows the identification of implications among meanings in online discourse (Campos, 1998).

The classical definition of meaning implication is that it is the source of necessary relations (Piaget, 1976b, 1977), and that if part of a meaning C is embedded in B and a part of a meaning B is embedded in A, then A implies C in terms of meaning (Piaget, 1991): a backtracking process, though. This definition applies strictly to the level of actions and the abstract logical concepts (mainly procedural, logical propositions, knowledge construction) and loosely to that of statements (mainly declarative, referred enunciates, knowledge building). Statements are referred notions whose referencing depends on the subjective social-cultural-psychological symbolic universe of the individual (Campos, 1998; Ramozzi-Chiarottino, 1998). The notion of meaning implication, a late development in genetic epistemology, allows the inclusion of pragmatics in Piaget’s syntactic-semantic model of knowledge. It enhances the classic Piagetian theory to the domain of psychosocial linguistic processes allowing the establishment of consistent links with Vygotsky’s pragmatic psychological model (Z. Ramozzi-Chiarottino, personal communication, August 1999) and the classic model of cognitive architecture.

Applied to statements, meaning implications are notional conditional enunciates in which subjacent If-Then operations do not have the logical consistency of propositional argumentation. They are encountered in ill-defined knowledge domains in which the validity of the notions is given by the act of signifying through natural language. These symbolic operations are analogous and complementary to those found in action implication. Action implications are If-Then operations encountered in physical actions independently of the use of natural language to express them (Ex: if I run then I am able to cross the field before that mad cow reaches me, given that I really run to cross the field before that mad cow reaches me).

Meaning implications are as varied as the possibilities of natural language. Generally, they are tautological because from the psychological point of view of the individual who writes or talks, the argumentation is always correct. Nonetheless, in a hypermedia conversation, the participants can check the tautological character given by individuals through refutation, making knowledge building possible. When the content coincides with logical rules, inductive validity results from the agreement between logic and reality (Ex: if I step on a banana it is likely that I will fall), although necessity and sufficiency might not be achieved. When the content does not coincide with logical rules, inductive validity results from strict psychological subjectivity (Ex: if all mammals develop two breasts as human beings then they will all also look sexy). There is, though, a scale: the closer the content comes to the agreement between logic and objective reality, the more plausible is the reasoning and the further it is from subjective judgment. This scale is also applicable to the sciences: from the closest to pure form (propositional logic, mathematics) to the closest to pure content (history, the social sciences) (Granger, 1994, 1992).

The Study

Our goal was to show circumscribed qualitative evidence of collaborative learning in a hypermedia asynchronous conversation triggered by the process of interrogation and reasoning about scientific dilemmas as a teaching method.

The following instruments were used in the research: Transcript analysis, in-depth interview with the professor and the teaching assistant, and the analysis of the comments written and the marks given to the messages published by the students in the online learning environment (comments and marks were provided by the professor).

We studied a biology mixed-mode undergraduate course on mammals delivered in the fall semester of 1998 in a French speaking Canadian university. Seventy-three persons took part of the course, including students, the professor and the teaching assistant. A root conference was opened from which eight sub-conferences were created. The root conference aimed to provide all needed information, including hypermedia navigation manuals to help the students, and also hyperlinks to a number of mammalogy web sites. Each sub-conference had a different topic: Introduction (in which general notions applied to the field were discussed), Characters, Constructive criticism (in
which students could discuss the use of hypermedia conferencing for learning mammalogy), Origins and evolution, Reproduction, Domestication, Dentition, and Locomotion.

The online teaching strategy applied by the professor was that of triggering discussion through questions related to unsolved scientific dilemmas in mammalogy. Different hypotheses explaining those dilemmas formulated by biology theorists were presented to the students by the professor through traditional face-to-face lecturing. The students were then encouraged to propose alternative solutions for the dilemmas in the hypermedia conferences by applying the knowledge about mammals and biology they had already acquired. No readings or literature research were required for the course, although the students were encouraged to do so. To guide their reasoning, the students had primarily access to black and white drawings and graphics provided by the professor, in addition to the notes they were able to take during the lectures.

The instructor is a full professor who teaches this course without significant changes for more than 20 years. The professor was not knowledgeable about technology, did not want to get involved in learning how to use computers, and did not participate directly in the hypermedia part of the course. According to the professor, the hypermedia component was chosen as a tool that would, eventually, enhance the learning process and allow discussions that would never take place in the classroom due to the way the course is taught.

A graduate student, expert in educational technology, worked as an exclusive online teaching assistant, responsible for posting the questions and providing instructions to the students on how to participate. No facilitator or moderator was assigned to mediate the conferences. The students were left free to take charge of the discussions. Participation was not mandatory.

After each of the sequential hypermedia conferences was over, the professor marked the messages according to the level of plausibility of the hypotheses formulated and the quality of argumentation. Together with the marks, there were sometimes, written comments. The marks did not count for evaluation purposes. Marks given were:

- Zero – no meaningful contribution,
- ¼ - minor contribution,
- ½ - reasonable contribution, and
- 1 – outstanding contribution (plausible hypothesis and argumentation).

Later, the comments (marks were not made available to the students) and the messages were discussed in class. The professor commented on the most plausible solutions presented, raised further questions, and discussed the state of the dilemmas.

We hypothesized that if implications among meanings were found in arguments present in different messages, then the quality of the arguments marked “1” could be explained by the conditional contribution given by others. In addition, it would indicate that high order learning (attributed by the professor through the marks) in the knowledge building process was achieved through collaboration. Furthermore, such predicted result would provide qualitative evidence that the process of interrogation and reasoning about scientific dilemmas would be a consistent method for teaching evolutionary biology.

Results

After reading the texts of all conferences and identifying meaning implications sustaining the arguments, we have chosen the conference on characters of mammals because it was the most interactive both in terms of implications among meanings and in terms of a reasonable (although poor) use of the threading feature of the conferencing system used (Virtual-U). This feature allows users to sort messages by threads, as shown in Figure 1.

Five questions were posed to the students in the sub-conference about characters. We chose the chain of thought of question 2 for this study by following the meaning implications built. The reason for the choice of question 2 was that two messages related to this question were marked “1” by the professor (outstanding contributions). In three of the four remaining questions only one single message was marked “1” by the professor.

To study the meaning implication chain of question 2, we focused on backtracking the meaning implications between the arguments and hypotheses marked “1” in order to understand how they were built (identify knowledge building), and to examine whether they had been gestated in other arguments written by other students in previous messages (identify collaboration). Messages that were published after the last contribution marked “1”, all isolated from threads, were ignored. We studied six messages in which we identified 12 meaning implications. Four students participated in this part of the discussion.
It is remarkable that only one of the six messages was a reply, although all meaning implications found were linked to each other, be in a message or among different messages. Meaning linking was not related to the built-in threads.

Figure 1 – In the studied hypermedia conference, knowledge was built through collaboration but meaning linking was not necessarily related to the built-in threads.

In addition, qualitative analysis shows that in both messages marked “1”, hypotheses were built upon non-plausible hypotheses formulated in previous messages. Two different students wrote these messages. The plausibility of the formulated hypotheses, assessed by the professor’s expert marking, indicates that high order learning was achieved. In addition, one of the students whose message was marked 1 passed through a process of conceptual change when he/she realized that his/her previous analysis was a misinterpretation of the evidence (highlighted by the professor in a comment) and decided to re-build his/her own argument. This student, thus, accommodated his/her own learning and changed the previous conceptualization of the problem, adjusting it to the evidence. In addition, the analysis indicates that all participating students built knowledge through collaboration. In other words, built their arguments by discussing the premises formulated by the colleagues.

Implications
For course design

The study suggests that the teaching strategy might be strongly related to the results. The Socratic maieutic was applied by posing questions to the students, reflecting upon the answers provided, building and communicating arguments both in the hypermedia environment and in face-to-face encounters. Questions were challenging, and they are still to be answered by evolutionary biology. This aspect seems to be specifically attractive for the students because, as novices, they were given the opportunity to exercise their own sense of how to apply background knowledge to scientific dilemmas, given the chance to solve ill-defined problems that scientists had still not done, and had the opportunity to provide meaningful contribution to the discipline. The importance of questioning in educational processes is common sense. In Socrates, it is a teaching method (Mondolfo, 1972) through which problems about the empirical world could be responded inductively (Jaeger, 1987). Questioning seems to be an appropriate teaching method for exploring scientific dilemmas in online written conferencing. The depth of argumentation triggered by questioning would be difficult to achieve in a face-to-face conversation because writing demands deeper reflection and allows thought refining.
For conferencing systems design

Data indicate that the agreement of threads and meanings in hypermedia conversation does not emerge by itself. The analysis of the way the students linked their chain of thoughts shows that the threading feature is neither necessary nor sufficient for knowledge building through collaboration. Most messages were not threaded although they were linked by meaning. This finding is consistent with that of a previous study and is a strong indicator that hypermedia conferencing systems still need further development and increased flexibility. Their underlying formal structure should adapt to the way we use natural language, mold our symbol systems to assimilate what the others have to say, and accommodate knowledge. Advance of conferencing systems depends on representations closer to the functioning of our neural systems. A reply-to-many feature would be a first step to allow more interaction (Campos, 1998). A pop up help tool to guide conference participants in the use of threads would be another important feature to be added.

Conclusion

We discussed in this paper how we assessed qualitative circumscribed evidence of high order reasoning and conceptual change, achieved through collaborative knowledge building. The meaning implication transcript analysis allowed us to assess this circumscribed evidence in the studied online written conversation. The analysis shows how conditional reasoning governed the inferences students made upon the contribution of their colleagues. In addition, it presents hypothesis formulation and argument building as a likely result of memory retrieval of both information presented in face-to-face lecturing and the study of drawings provided by the professor (Changeux, 1997), of acquisition of scientific reasoning expertise (Bruer, 1994; Bereiter, & Scardamalia, 1993) and of in-depth reflection upon contributions provided by others (Scardamalia, & Bereiter, 1994).

The analysis of the way the students built their chain of thoughts shows that the threading feature, as it is today, is neither necessary nor sufficient for meaning linking. This finding is consistent with a previous study (Campos, 1998) and is a strong indicator that hypermedia conferencing systems still need further development to make their underlying formal structure more flexible in order to be adapted to the way we use natural language, to the way we converse and mold our symbol systems to assimilate what the others have to say, and to accommodate this knowledge into our mental semiotic configurations. Furthermore, the study suggests that the Socratic maieutic, as a teaching strategy, might be strongly related to the results.

These reasons, altogether, might explain why such a level of collaborative knowledge building was achieved in a situation in which the students were left free to take charge of their own learning processes without any of the award systems found in pedagogical behaviorism. The fact that the professor did not participate at all is additional indication of the inner learning possibilities of hypermedia conferencing. Another fact, not unimportant, is that the studied course was mixed-mode. The use of this teaching hypermedia modality suggests that mixing face-to-face encounters with the use of the conferencing component provided specific opportunities that enriched experiences leading to social interaction and learning (Laferrière, Breuleux, & Campos, 1999). The teaching and the learning processes of this mixed-mode course seem to show that when proper teaching strategies are present, knowledge building and collaboration are achieved (Campos, & Harasim, 1999).

Abstract: In 1998 The University of Iowa Libraries was the recipient of a grant from the Library of Congress/Ameritech National Digital Library Competition in support of a project to digitize a portion of its unique and extensive Redpath Chautauqua Collection. Although the staff of the Information Arcade at the University of Iowa Libraries has extensive experience in instructional technology, this was the first opportunity for them to engage in the digitization of a large text collection of rare materials. This article describes the processes undertaken in the project as well as the challenges when the theory of how to approach a digitization project of significant scope clashed with the realities faced by the project team.

Introduction

In 1998 The University of Iowa Libraries was the recipient of a grant from the Library of Congress/Ameritech National Digital Library Competition in support of a project to digitize a portion of its unique Redpath Chautauqua Collection. The competition, which was funded for three years by a $2-million partnership between the Library of Congress and the Ameritech Corporation, has made awards to a total of 29 institutions with the aim of supporting the digitization of a range of materials of significance to the social and cultural history of the United States.

One of the goals of the competition was to encourage U.S. libraries, archives, museums, and historical societies to assist in the development of the American Memory electronic collections of the Library of Congress. But in making the awards, the LC/Ameritech program also offered many institutions that would not otherwise have had sufficient institutional resources to learn by "getting their hands dirty" about the sometimes confounding issues involved in planning and carrying out a complex digitization project. Although the staff of the Information Arcade at The University of Iowa Libraries has extensive experience in instructional technology, this was the first opportunity for them to engage in the digitization of a large text collection. This article will describe the processes undertaken in the project as well as the challenges faced by the project team when the theory of how to approach a digitization project of significant scope clashed with the realities faced by the project team.

The Redpath Chautauqua Collection

The University Libraries collection chosen for the award is a series of talent flyers in its distinguished Redpath Chautauqua Collection and the project was named: "Traveling Culture: Circuit Chautauqua in the Twentieth Century." The circuit Chautauqua Movement represents an early embodiment of the American drive for self-realization and self-improvement. Its importance as a manifestation of the "American spirit" and as a dominant influence on American culture has been well documented in both scholarly and general works. By the mid-1920s there were twenty-one circuits of traveling performers providing seven-day programs in more than 10,000 rural communities in 45 states to an estimated 40 million people. Programs included discussions on political, literary, scientific, and moral topics, music (from accordionists to yodelers), and entertainment for all ages of both high and popular culture.
Comprising some 648 linear feet of materials dating between 1890 and 1940, the Redpath collection is considered to be the most extensive holding of circuit Chautauqua materials in existence. Its particular strength lies in the breadth of coverage and length of time over which the Redpath Bureau conducted business as the premier booking agency in the U.S.A.

The talent portion is the largest series in the collection consisting of nearly 8,000 flyers promoting the talents of nearly 4,600 performers. At the beginning of the project the flyers were housed in folders arranged alphabetically by performer’s name in 279 manuscript containers in which flyers, correspondence, and contracts were intermingled. The series comprised 139 linear feet of primary research materials especially rich in contemporary information by and about notable people of the period. Selection of this collection for digitization was not the difficult part of this project. The talent flyers were a natural resource to select for presentation to the widest possible audience via the web.

The spirited language and vivid art work used in the promotional flyers reflect the emotions and ideals of the Chautauqua movement. Presenting the flyers in digital form makes the possibly dry topic of U.S. history come alive to the casual and serious researcher alike. For instance, young students are able to discover that the public’s fascination with pet tricks did not begin with David Letterman. Rather, they would be able to see that Pamahasika’s 50 Highly Educated Pets were an amazing and popular source of entertainment in the early part of the century. Secondary school students could learn that outrageous expenditure of federal funds is not a new concern. Judson King’s lecture on how a "certain state government recently paid $10 each wholesale for some jack-knives which were worth $2.50 each retail” would point out that government reformers have long had their work cut out for them. The general public of today would be just as curious as their great-grandparents about tales of hardship and misfortune, such as the experiences of Mrs. Florence E. Maybrick. Unjustly convicted of poisoning her husband, she was sentenced by a judge who went insane shortly thereafter. Yet she served 14 1/2 years of her punishment and then went on the circuit to lecture on prison life and the need for judicial and prison reform.

Initial Plan for Workflow

Both the text and the graphic layout of the flyers are highly valuable for the study of American popular culture so the digitization strategy had to include adequate access to both the textual information on the flyers and the graphic representation of the flyers. As with most advertising material, there was no standard presentation or design to any of the flyers, although it was very rare that a flyer would be more than four pages in length. Moreover the physical state of the flyers and correspondence was such that a preservation effort simultaneous to the digitization effort was essential. Therefore the project had four distinct workflows that had to be managed separately within a timeframe of 18 months (a stipulation of the award) with an eye toward re-assembling all the pieces in both physical and digital form in the final phase. The workflows include: preservation, keying/encoding the textual information on the flyers for full text searching, providing intellectual access to the individual flyers, and imaging of the flyers.

Because the flyers are rare, no consideration was given to outsourcing the imaging of the flyers. Iowa City is not near enough to a major urban area to allow a vendor to come on-site to perform outsourced tasks. Therefore the budget and workflow plan had to accommodate student staff for the imaging workflow. The planning team estimated that full-time staff would be needed to train, supervise, and provide quality control for the student workers doing the imaging. There would be no possibility of including in the grant budget additional full-time staff for the training, supervision, and quality control for students who might be doing OCR/re-keying and SGML encoding - especially considering the timeframe in which the project was to be completed. Therefore the task of keying and "light" SGML encoding (based on a TEI-Lite DTD) was outsourced to a vendor through a bid-process managed by the University of Iowa’s Purchasing Department.

Over the years flyers have been used by researchers and staff who were not uniformly attentive to replacing materials in strict order. It was anticipated that some reorganization would be needed to ensure that all flyers were in the correct folders. The number of flyers in the collection and the number of unique performers was estimated by a random sampling one folder in each of the 256 boxes. This process indicated that there were 9,600 flyers representing 7,600 performers and those figures were the basis for estimating the number of page images to be scanned for purposes of writing the grant proposal. However early in the project it was discovered that there were fewer performers (about 4,600) represented by about 8,400 flyers. Lesson: Know the
dimensions of the project you are undertaking and then add in sufficient time to accommodate the unexpected - especially if one is working in a special collection of substantial size and variety.

Preservation

Although the flyers were in satisfactory condition to withstand the rigors of digitization, the accompanying materials had badly deteriorated. Those materials are letters and news clippings on acidic paper, or even onionskin, or carbon copies of original documents in other files.

To ensure that the folders containing the flyers and correspondence would be handled only once, a plan was developed comprised of the following steps: a folder is removed from its container, the brochures and correspondence are separated, a preservation photocopy of the correspondence is made on archival bond paper, and returned to the collection. These preservation activities are not funded as part of the LC/Ameritech grant so the tracking of staff time and the costs involved in handling the preservation of these materials has to be accounted for separately.

A photocopy surrogate of the entire flyer is made for use by the vendor in keying/encoding the text and a second photocopy of the flyer's first page is made for use by the catalogers. At this juncture a unique identifier, which is the directory/file structure for the electronic file, is written on both copies of the first page. This identifier is the common bond that links the cataloging record to the digitized image. After the flyer is cataloged, the title page photocopy and the original flyer in a new acid-free folder are sent to the in-house imaging process. After imaging is completed, talent flyers are re-united with the correspondence related to that performer, each in separate acid-free folders, and replaced in alphabetical order in archival boxes.

Keying/Encoding

As mentioned above, the initial estimate of the number of flyers and the number of performers involved was lower than expected based on initial samples. Unfortunately, this was not the case with the keying/SGML encoding estimates.

The Library of Congress encourages SGML encoding of textual materials in the American Memory project in support of full-text searching and to serve as the basis for more sophisticated search and discovery strategies that might be available in the future. Although the talent flyers are highly graphical and the nature of a promotional flyer might not seem to warrant full text searching, the quality of the text and the richness it provides as context to the images led the project team to concur with a plan for encoded full text. However the team also decided that deep encoding was not necessary and only nineteen elements were identified for the vendor's tagging work. The elements selected were primarily structural, like <figure> and <cell>. Other elements focused on the types of text that might be likely to provide special insight into contemporary culture and style, like citations, quotes from verse, and quotations. It was reasoned that if use of the collection warranted more encoding it could be inserted at a later date when more money was available for such activities.

Initial estimates of a character count of 28 million characters for purposes of the grant proposal were based on counting the number of characters (including spaces) in a relatively small sample of flyers during the grant-writing process. Unfortunately the sample proved to be skewed and the number of characters required for keying and encoding was underestimated by about 100%, even considering the fact that there were fewer flyers than was first assumed. Part of the under-estimation was due to inexperience in estimating the number of keystrokes that would be involved in the insertion of the SGML tagging. This miscalculation was compounded with the discovery that there were quite a few flyers that had unexpectedly substantial textual material. Taken together the team severely underestimated the number of characters to be keyed which led in turn to an underestimation in the budget required to support this dimension of the project. Lesson: Take the time to do a substantial sample of the textual materials to ensure that one has a solid sense of the amount of text to be keyed - and then add at least 25% for tagging character strokes.

Fortunately, the commitment of the University Libraries administration to this project is strong and the commitment of the vendor to the project was equally deep. Together a negotiation of the fee to finish the keying was achieved which resulted in both sides accommodating some of the extra cost. Lesson: Find a vendor who considers the venture to be a partnership and with whom you can communicate frequently. Also, be very diligent about reviewing initial encoding samples for quality.
One other unanticipated wrinkle in the workflow occurred during the keying process. The quality of the photocopies to be used by the vendor in the keying and encoding process was often difficult to decipher. The flyers make great use of shading for background effect and the text is artistically displayed in a variety of fonts around and across multiple images. (This was one reason that OCR was not considered for the keying process - another reason is the poor quality of affordable OCR software which requires a great deal of proofreading and correction.) Photocopies of text printed in black font on a gray or colored background were in many instances illegible to the keying staff. It is especially important to have absolutely legible photocopies for keying staff who may not be proficient enough in the language of the text to decipher poor reproductions. Lesson: The quality control procedures employed to ensure adequate photocopying were sufficient for the preservation photocopying, but we did not employ the same procedures for photocopies to be used by the vendor. Now the team needs to devise a method for filling in the <gap> and <illegible> tags from the source originals.

**Intellectual Access**

Intellectual access to "Traveling Culture" is provided through a number of avenues. The finding aid for the collection, which has been encoded in both HTML and SGML according to the EAD DTD, provides a box list of performer names. Part of the agreement for the grant was the development of a scholarly historical essay. Charlotte Canning, University of Texas at Austin Department of Theatre and Dance, a frequent user of the collection, has agreed to provide the historical essay for "Traveling Culture."

Each flyer is individually cataloged according to USMARC compatible standards. Strict adherence to USMARC standards was not feasible in determining the title of many of the brochures. In those instances, the decision was arbitrarily based on such factors as font size, placement on the page, or other dominant characteristics. Bibliographic data are included in the TEI Header and will also reside in a Library of Congress USMARC database. The homepage for "Traveling Culture" will provide both full text searching and access to flyers through a browse list of subject terms based on Library of Congress Subject Headings, Thesaurus for Graphic Materials I : Topical Terms for Subject Access (LCTGM 1), and Thesaurus for Graphic Materials II: Genre and Physical Terms (LCTGM 2). Subject analysis has been applied for the context of the piece as well as to its content. Uncontrolled subject terms have also been applied when appropriate. For example, we have yet to find a controlled vocabulary term for bird imitators or cymbolomists.

The Redpath Collection has been cataloged at the collection level for quite a while, but cataloging at the flyer level was a requirement of the grant. Workstation based packages for simple MARC cataloging did not suit our needs. We wanted to catalog the item once and then automatically export a MARC file for both the Library of Congress and our local online catalog, as well as a TEI header with the bibliographic data inserted in the correct elements. Finally our project team developed a FileMaker Pro database that could manage both the MARC and TEI header export. The FileMaker Pro database has been easy for our student catalogers to use and flexible to adapt. We have added special fields that contain the file names (see below) and the identifying numbers for the archival CDs that contain the images for that flyer so the database record contains all the information necessary to provide full access to any given flyer. Moreover it now provides a fully functional database in support of interim subject access to the "Traveling Culture" collection until such time as full-text SGML searching is available.

After cataloging each flyer staff have an additional task that provides the lynch-pin for the entire process--assigning the file naming structure to be used as the unique identifier for linking together the TEI headers with the text files and the page images of the flyers. The basic directories are based first upon file type, i.e. "sgm" for the text, "gif" for the thumbnail image, "jpg" for the JPEG images, etc. The second level of the directory indicates the series, performer, sequential number of unique flyer in the collection by that performer, and the individual page image. An example: ssrc/traveling-culture/chaul/img/stagg/3/5.gif indicates the Traveling Culture collection, talent flyer series, the performer named Alonso Stagg, the third unique talent flyer in the box, and the gif image of page 5 of that flyer.

Requiring that the file naming structure reflect the flyers of a particular performer has both advantages and drawbacks. One advantage is that it reflects the traditional structure of the collection, which has always been based upon performer name. The naming procedure makes sense to human beings which assists in the construction of the unique identifier for the files and may assist humans in quality control when linking the page image, text and header files together. However, as more flyers by the same performer are found or as more flyers by performers with similar name stems are discovered, the system begins to be subject to transcription
errors. No change in the file structure naming process is planned, but these considerations will inform our choices in the next project. Lesson: Plan for as much extensibility in file structures as possible, even when dealing with collections that are no longer growing in size. It may be the case that machine-assigned/random components to file names provide the most flexibility in the long run for large text collections that are intended to grow and expand in coverage.

Imaging

The imaging for the project has been accomplished in-house by student staff with equipment provided by the Office of the Vice-President for Research. Special attention to simplifying and automating procedures as much as possible has been a goal of the project team to minimize training time and error rate.

The general procedure is as follows: the original flyers arrive from the catalogers with the photocopied title page indicating the unique identifier/file name for the flyer. Students scan the flyer pages creating 600dpi 32-bit color TIFF images (a much slower process than had been originally estimated) that are saved to Jaz disks. The Jaz disks are used to burn archival CDs so no more than 650 megabytes of data are saved to each disk. Each CD is labeled sequentially with a note indicating which performer's flyers/pages are included. The color TIFF files are so large that each CD averages only 6 images.

An automated program creates a 300dpi 32-bit color file on the workstation desktop from the 600dpi TIFF image after it is saved to the Jaz disk. The 300dpi file is again downsampled into one 300dpi 1-bit black/white PDF file, one 150dpi 32-bit color JPEG, one 72dpi 8-bit color GIF image and one 6dpi 8-bit color GIF image. All images for a flyer are saved in one folder on the server. The color 300dpi file is then discarded. We originally tried to use Debabelizer for the downsampling, but that software could not rename the files as they were downsampled according to our file naming scheme. So we use a semi-automated procedure based on Photoscrtipter. There is an as-yet-unidentified "waffle-effect" that sometimes appears with GIF images, but not in the JPEGs. Quality control on the imaging will be the primary focus of post-production image processing. The results of the review of image quality will inform our production workflow for the next project.

GIF images at 6dpi are used as thumbnail navigational aids in the search interface; GIFs at 72dpi are the default display images. The JPEG image is an option that may be selected by the user who wishes to view or download a higher quality image than the GIF image provides. PDF images are provided for ease of printing.

Many talent flyers contain images that span two pages, or even three. The project team made a strategic decision that images that span pages should be presented to the public as coherent whole images. This requires that the images be "stitched together" after they are downsampled - a job that requires patience, time, and a keen artistic eye. Sometimes the colors of each scan are slightly different for the respective image halves due to unpredictable (and undefinable) equipment problems that require extensive staff time to correct. This is a task for the team member who supervises the students and the scanning process. Lesson: Consider carefully whether and how much one can create automated routines to prevent the need for extensive training and lots of "handwork" on the part of project staff. The budget impact of the need for special handling can be substantial.

Putting It All Together

The strategy for presenting the collection to the public was the subject of much discussion during the grant writing phase. Should "live" SGML be presented to the public? That would involve customized scripting to convert SGML to HTML for display purposes which is entirely possible, but requires staff expertise that The University Libraries does not normally have on hand. Monies available through the grant were quite limited and although the Libraries administration was prepared for a substantial cost-share there was a limit to what we thought we should attempt. After some debate it was decided that the highly visual nature of the flyers would be equally well served by presenting only page images of the flyers and using the encoded text as the basis for full-text searching behind the scene, but not for display purposes. Lesson: This was the right decision! As the project progressed there were substantial other issues to address. The time required to test and perfect the SGML encoding and to write the scripts to translate text on the fly to HTML would have been over-burdensome and too costly.
The prototype website for the collection is now available and it includes a facility for basic searching on bibliographic data in the FileMaker Pro database. The next technical step is to begin to export the TEI header, pre-pond it to the text files that have arrived from the vendor, begin the process of linking text to page images, and develop full-text searching with LiveLink software.

The next policy step was to develop a copyright statement for the site. The Head of Special Collections drafted a statement indicating support of unfettered use by researchers of all ages, but requiring that permission be sought by commercial entities that might want to use the images. A fee schedule for high-quality reproductions was developed, with the copyright/use statement, had to be reviewed by the university's lawyers and administration. The statement as well as an updated method for ordering high quality reproductions is now on the website.

General Lessons Learned: Although hiring and training student staff is time consuming, the quality of the work of students and their facility with the technology has been wonderful. Equipment and scheduling "hiccups" have occasionally delayed work, but the scanners and the server have been robust. We could use more students, more equipment, and more hours in the day, but the experience gained in this project has been invaluable as a staff development and enrichment activity. Nothing replaces the opportunity to "get one's hands dirty."

In August 1999 the project staff gave a presentation to the University of Iowa Libraries staff about the project. Our colleagues were impressed with the complexity and scope of the project and were glad to learn more about exactly what is involved with the workflow. But what impressed us was their equal conviction that the Redpath Chautauqua Collection is indeed a treasure that should be available to the world. We share that conviction and look forward to offering "Traveling Culture" to people around the world.

Abstract: The capacity of computer technology to support cognitive and learning processes is illustrated in the Quality in Learning and Teaching Project (QuILT), a case and problem-based multimedia resource which presents critical aspects of classroom practice in order to scaffold critical inquiry, observation and reflection. QuILT is an interactive CD ROM program that provides teacher education students with a range of examples of authentic scenarios where they can observe, analyse, reflect and evaluate actions, pedagogies and decision-making through immersion and engagement in virtual classrooms. QuILT is now being used extensively within the Faculty of Education, University of Melbourne, Australia as part of the teacher education program. The software provides an enabling environment in which student teachers can develop the skills of analysis, prediction, inference and interpretation. This integration of technology into professional education extends the range of experiences available to teacher educators and applies multimedia technology into new areas of learning support. This paper analyses and demonstrates the elements that have made QuILT a successful technological tool in the professional education of teachers. The key design elements are identified as the integration of authentic classroom scenarios with opportunities for reflection and articulation of beliefs, the involvement of students in new mediator roles and the provision of a powerful technology supported environment to create contexts for students' professional development.

Aim of the study

The aim of this paper is to demonstrate the capacity of interactive multimedia to scaffold teacher practices, inquiry and decision making in order to develop the skills and competencies required in professional practice. Information technology has not yet achieved a great deal of recognition in the professional education of teachers (Schrum & Dehoney, 1998; Davis, 1997, Collis, 1994). However, there are increasingly greater constraints on education faculties in terms of resources and staff-student ratios with the consequent problems of developing teaching and diagnostic skills that are transferable into actual classroom settings. It is important that professional development for teacher continues to be embedded in contexts and practices for which the skills are intended. Technology support for professional development through the interactive multimedia resource of QuILT enables novice teachers to interact, reflect and learn collaboratively in scalable and sustainable ways in authentic settings.

The design features of QuILT are analysed in terms of a cognitive apprenticeship model of teaching, constructivist learning principles and scaffolded learning processes (eg, Levin & Waugh, 1998; Guzdial & Keogh, 1998; Hmelo & Day, 1999). On the basis of their immersion in, and interaction with a range of authentic classroom situations, student teachers are supported in extending and modifying their understandings of teaching processes, decision-making and interpretation of classroom events.
Rationale for technology supported scaffolding in teacher education

The incorporation of experiential learning tasks to cultivate reflective thinking in teacher preparation programs at university is widely acknowledged in the literature (Stuhlman, 1998; Collis, 1998). Through experience, teachers learn how different learning outcomes can be achieved and what skills are required in particular situations. In addition to teaching skills, teachers need to consider how different school settings, events and resources can impact on their teaching. Individual teachers working in isolation in schools do not have opportunities to share experience or to examine different perspectives on teaching, and to test their own developing skills against established criteria. According to Shulman (1987: 19), teaching requires reflective practice that develops through experience and sharing of information with peers and mentors. According to Shulman, reflection is:

...what a teacher does when she or he looks back at the teaching and learning that has occurred, and reconstructs, reenacts, and/or recaptures the events, the emotions, and the accomplishments. It is that set of processes through which a person learns from experience.

For the development of critical reflection, student teachers need to undergo a period of self-evaluation and reflection based on their own observations of teaching, their existing belief systems and their experience. This stage in the development of professional expertise has dominated the discussion of teacher education provision in recent years (Bright, 1995). Student teachers have been observed to undergo a steep learning curve at the beginning of their teaching career, when they abandon strongly held beliefs regarding pedagogy and educational values. This is the critical period of reflection when teachers learn from others, question and analyse their own experiences and develop the capacity for principled knowledge of teaching. For this to occur, there needs to be time, encouragement, monitoring and feedback in a context where critical reflection can unfold.

While teacher education programs advocate the adoption of 'reflective approaches' to their own practice, constraints imposed by the resource implications are impinging on the provision of opportunities and time for development of reflective teaching practice. In the current climate of decreasing staff-student ratios in many education faculties, and the reality that school placements of teachers are widely dispersed, the opportunities and tasks that foster reflection are very limited. New frameworks and instructional strategies for learning are called for, and technology offers both cognitive tools and resources to enhance learning for professional development (Robson, 1999).

Using technology to scaffold teacher reflection: The QuILT metaphor

Communications technology and multimedia can contribute to the range of tools that contribute to experiences of teachers and foster critical thinking. For example, electronic networks and e-mail contribute to reflective practice by enabling teachers to communicate and to share ideas and experiences (Wu & Lee, 1999; Pearson, 1999). In order to enhance the skills of teachers before they enter a real school setting, it is possible to use a variety of technological supports as facilitation. QuILT provides a complete multimedia experiential environment where teachers can engage in problem solving and diagnostic teaching. Through the scenarios presented in QuILT, teachers are scaffolded through a range of interpersonal, diagnostic and decision-making tasks. Through technological scaffolding, teachers encounter a broad range of experiences and also have the opportunity to learn skills in a safe environment, with feedback provided by peers, technology and mentors.

Four specific organisational devices have been designed to provide a visual and conceptual structure to assist users as they work through the program. The QuILT program allows the user to view and re-view authentic video recordings of teaching episodes (which reflect problem situations) from four major lenses:

1. What is the teacher doing?
2. What is the teacher thinking and feeling?
3. What are the students doing?
4. What are the students thinking and feeling?
Each of these lenses is signalled through colour coding and the use of icons that draw from aspects of weaving involved in quilt making. In addition, the lenses show patterns of how the four elements interrelate in and between teaching sequences. These interrelationships demonstrate that learning and teaching are complex, multiple and strongly dependent on personal, interpersonal, and physical contextual features. Research perspectives attest that the nature of quality learning and teaching is clearly pluralist and relativist in nature (Alexander, 1996) and this is integrated into the design of the multimedia environment of QuILT. Metaphorically, each of the four lenses are the fibres (colour coded to teacher-related lenses 1 and 2, and student-related lenses 3 and 4) that, through weaving, form the material's warp and weft. The Quilt is an intricate, complex web of teacher beliefs, understanding conceptual knowledge and action, that is woven from experience and reflection.

For learners engaging with this virtual classroom environment, an adequate interpretation of each of the episodes and consequent decisions regarding future personal teaching actions can only be achieved by consideration of the episode through many or all of these lenses. Encounters with multiple perspectives, decision-making and inquiry into action are the learning processes scaffolded the multimedia environment on QuILT, which is informed by constructivist learning theory.

**Using multimedia technology as scaffolding: QuILT environment**

The major purpose of QuILT is to create a multimedia environment whereby novice teachers achieve particular goals related to effective teaching. In presenting critical aspects of classroom practice the intended learning outcomes are that users:

1. critically observe sequences of teaching that present classroom based-problem situations and then respond to these by considering, determining and undertaking planned actions;
2. develop or modify their conceptions, values and beliefs in ways that indicate enhanced understandings of quality through a process of guided reflection involved in the performance of particular tasks;
3. make decisions, record these and then defend their choices within and outside the program. Some feedback will be within the program design, other feedback will come from other users and from the teaching staff; and
4. solve case-based problems in ways similar to the problem presented on the CD ROM applying strategies and thinking employed by effective teachers.

Task design is based on the pedagogy of problem and case-based learning (Savery & Duffy, 1995; McLoughlin & Oliver, 1999). Problem and case-based learning reflects conceptions of learning, knowledge and understanding that are very different from conventional ideas on learning. For example, content or subject experts know a lot about a subjects and their expertise is judged on the amount of content known, or on the display of propositional knowledge (to know that such and such is the case). In professional areas it is also important to have procedural knowledge (to know how to do something). It is this alternative understanding of expertise that characterises problem-based learning. According to Margetson (1997: 38) “Expertise is the ability to make sound judgements as to what is problematic about a situation, to identify the most important problems and to know how to go about solving or at least ameliorating them”.

In the professions and in the teaching world, the skills of identifying problems, managing solutions or improving problem-situations are considered to be important competencies that need to be scaffolded or assisted in novice learners. More recent work in technology-supported environments illustrates how the concept of scaffolding has expanded to include many innovative forms of support, increased responsibility for students and a fading of the directive of asymmetrical aspect of earlier work on scaffolding. Theoretical models of scaffolding in technology-supported environments have been elaborated by Winnips (1998) and McLoughlin (1999). In QuILT, the multimedia environment enables learners to engage critically with authentic cases and develop professional knowledge and awareness.

**Employing the Technology: The Quilt metaphor as an architecture for design**

The conceptual and procedural frames for the QuILT program are organised through the metaphor of a quilt. The construction of a patchwork quilt involves a number of processes: the weaving of the fibres to produce material from
which the patches are made, the construction of the patches, the arranging and stitching together of these and their possible fashioning through embroidery. Each of these stages of construction is referred to iconographically as the program proceeds. For instance, the finished quilt is a metaphoric construction of the nature and practice of quality in classroom learning and teaching. This construction requires the user to create patches (one for each of nine major areas for study), and then arrange and cohere these patches to make a unified conceptual and methodological frame for professional thought and action. When constructing the patches, the user is guided by utilisation of four different 'lenses' with which to explore lesson activities and contexts. These lenses are teacher action, thinking and motivation, and student action, thinking and motivation.

This metaphor provides an integrated architecture for the design of the program. Continuous social interactions, a sequence of patterns and relationships, and a resultant creative harmony are necessary for successful crafting of a quilt. The social meanings inherent in quilt production vary according to the cultural setting, the materials and the technology available. Similar qualities and features are evident in quality learning and teaching.

**Student Tasks: Action, inquiry and reflection interwoven**

Progress through the program is framed according to nine professional focus areas that include planning units for learning, teaching individuals and groups, student and classroom management and evaluating learning. Users analyse teaching segments to interpret classroom activities, predict what actions will follow certain key points in teaching and learning, propose and justify actions they would take themselves in such a teaching situation and draw inferences and conclusions about feasible and appropriate teaching strategies to foster quality classroom practices. All segments are presented in a way that requires the user to induce, through a process of guided reflection, substantiated insights regarding effective and productive teaching and learning. In addition, users have access to numerous interviews with the classroom teachers and students. These interviews provide perspectives, feelings, explanations and interpretations of classroom interaction that are normally not available to observers.

Interactivity is manifested in various ways. The design of some sequences within the program prompts users to pursue alternative pathways and assess the quality of teacher action and decision making. As each pathway is enacted, the journey provides immediate feedback to the user who has chosen that particular pathway and then justified and recorded that decision. Other prompts within the program require users to record their individual observations, predictions, justifications and reflections. Thus, by providing support for inquiry, participants are scaffolded in developing their own understandings through active participation in a learning event. Each participant has the opportunity to learn within his/her own zone of development, and support is given to enable student to perform the task according to the level of their competence (Vygotsky, 1978). Offering choices of pathways, multiple perspectives and individual feedback combined with reflective action fosters self-regulation. In addition by scaffolding metacognitive processes through personal reflection and subsequent group dialogue, self directed-inquiry and decision making are intended learning outcomes (Boekaerts, 1995; Shin, 1998; Winne, 1995).

**Reflection through an electronic notepad**

Two software in QuILT tools allow for systematic staged reflection. An electronic notepad is available to users at all times and is saved to file server or local disk for further refinement. This notepad allows users to record their predictions, observations, inferences and analyses of classroom episodes and teacher and student interviews and to take a personal position. The second tool, known as an action planner, requires users to reshape and refine data from the notepad. This is achieved through a variety of devices that enable the user to summarise and synthesise, compare and contrast, signify and prioritise, review their positions and frame their teaching. Printouts of these files are brought to scheduled class workshops for sharing, reflection, analysis and synthesis. The classroom becomes a space for shared discourse where learners can negotiate and construct new understandings. Technology offers the initial support for learners when they encounter new experiences, and provides a facilitating structure and tools that enables them to make maximum use of their own knowledge and experience. This form of scaffolding has been referred to as procedural facilitation (Scardamalia & Bereiter, 1994; Scardamalia & Bereiter, 1989).
Summary: Categorising the range of scaffolds in QuILT

An overview of the forms of scaffolding provided in QuILT shows the diverse ways in which knowledge building and professional skills are developed. Conceptual scaffolding is provided when the problem under study is delineated, contextualised and defined so as to focus the learner towards central issues and concepts where there may be multiple interpretations. This is achieved in QuILT through the presentation of classroom scenarios and problems. Metacognitive scaffolding supports the underlying processes associated with learning management and reflection. It provides support for thinking through enabling tool (an electronic notepad) to enable students to record their thinking while engaging with the classroom scenarios. Metacognitive support is also provided by promoting and questioning learners to relate incidents to personal belief systems. In addition, QuILT fosters thinking processes by encouraging users to link cases with prior knowledge and experience. Procedural scaffolding supports learners in using available tools and resources. In QuILT, classroom scenarios are viewed from different angles, or lenses (teacher action and motivation, student action and motivation). Each of these lenses is signalled through colour coding and use of icons that use the metaphor of weaving, as in quilt making. Visual and conceptual forms of scaffolding are thus interwoven. Strategic scaffolding is afforded by emphasising alternative courses of actions and events that might be applied in classroom contexts. The presentation of multiple scenarios, events and perspectives in QuILT supports analysis, planning and decision making, which are valued skills in teaching.

Conclusion: QuILT as a cognitive tool

Initial assessment of user responses to QuILT have been positive. For novice teachers, the CDROM is an innovative and powerful cognitive tool, a multimedia resource that supports higher order thinking, decision-making and the development of critical reflective practice among student teachers. This resource provides experiential learning environment that fosters the reflective skills needed to become a professional educator.

Abstract: This paper discusses the potentials and limitations of web-based Virtual Reality (VR) in operating slide projector. A VR-based interactive and simulated environment on web for immersively learning slide projector operation has been designed, developed, and evaluated. The framework and functionality of the system described in this study are also presented. The evaluation results report that this learning material has positive effects on students' learning outcomes. Finally some indication of further researches to be done will be given based on using the material developed in this study.

Introduction
It has been reported that many students fail to easily understand the manipulation activity that occurs at a psychomotor level during the production and presentation of slides, and the operation of slide projector. Students usually do not have enough time to physically practice the operation of slide projector after the class due to insufficient equipment of slide projectors provided by the school. Students are therefore not well motivated to learn this subject and have difficulty grasping these complex procedures. Without sufficient simulation and visualized demonstration, students argued that transfer of skills and retention of knowledge for producing slides and operating slide projector would not effectively work.

VR-based learning environment on the Web could provide alternative to make presentation of learning materials more visualized and enables their demonstration dynamically. Students would be more motivated to actively learn, and able to highly visualize the complex process of producing slides and operating slide projector. Additionally, students could then manipulate the VR-based system dynamically and learn by their own hands-on experiences how slides are produced and a slide projector is operated that is impossible to observe in real situation. The application of distributed VR to online simulation for the hands-on experiences of operating slide projector on World Wide Web (WWW) are worthwhile creating for reasons of equipment, safety, expense, time, and distance. VR-based learning environment on the Web to learn slides projector operation (WebVR) would be very helpful for students to acquire and construct the needed knowledge in the social and active sense.

Application of VR to Psychomotor Learning
Virtual Reality are drawing more and more attention in skill training and psychomotor learning due to its capabilities of real-time interactivity, three dimensional animation, situated simulation, dynamic mediated environment, immersive sense of presence and so forth. In such a artificial 3D simulated learning environment based on VR technologies, students can highly interact with the virtual world, move around within it at will, highly control over their self-paced navigation through it, freely manipulate virtual objects insides, and immediately have a immersive sense of really being there. Additional, it allows students to visualize abstract concepts, and to observe events at atomic scales that cost, distance, time, and safety factors make unavailable (Youngblut, 1997).

Repair to the Hubble Space Telescope were simulated in VR environment to enable the technicians to familiarize themselves with the dangerous manipulations they would experience before the actual repairs were done (Traub, 1994). Safe space and situation to practice skills of repair was provided in the virtual environment that was risky to do so in real situation. Skills learned in the virtual environment could transfer successfully to the telescope repair ability of real world. VR via the Internet and World Wide Web (WWW) may offer the possibilities of enabling students being able to collaboratively create their online virtual worlds or contribute to those created by others (Moore, 1995). The types of activities supported by VR capability facilitate current educational application that students are better able to acquire, master, retain, transfer, and generalized new knowledge whenever they are actively engaged constructing their knowledge in a learning-by-doing situation (Youngblut, 1997).

Design and Development of Learning Environment
Environmental Framework and Functionality
Students can easily move around within and freely navigate through the virtual worlds and do all kinds of
actions, such as freely manipulating virtual objects in any degrees of freedom. Additional, students immersively existing in the 3D environment of WebVR may experience several degrees of freedom, including full freedom in navigation, the access to information through multiple interactions, and the capability to figure their own learning process.

Figure 1 Main menu of the WebVR

Designing Instructional Strategies

The constructivist principles of learning in the design of WebVR are proper approaches to the work of our instructional strategies. The main learning approaches to implementing the constructivist principles in the 3D virtual worlds are exploration, discovery, problem-solving, and learning by doing. Using web-based VR browser capabilities, students are able to freely explore the virtual objects, discover phenomenon, practice skills, move around and navigate through the 3D virtual worlds composed of simulated equipment and tools. The manipulation of an object in a virtual world supports the practice of constructivism. According to Salis & Pantelidis (1997), object manipulation in the virtual worlds is a powerful learning strategy frequently used for constructing a knowledge framework that presents concrete components for associating some superior knowledge. Additionally, transformation and rotation of the objects enable students clearly to observe their various situations that can be rarely observed in traditional situation. The attributes of virtual objects can be explored through direct interaction with them. In this study the WebVR was using these strategy to develop psychomotor skills for high level of human interaction and knowledge association from a motor answer to a stimulus which students received in the virtual worlds.

A self-space learning navigation system is employed in the WebVR to increase the opportunities for exploration, manipulation of objects, discovery, movements, and senses of real or not real by using visualized controlling elements within virtual worlds. The self-spaced learning navigation system for users through the virtual worlds was designed and used as a learning tool in search for information and objects so as to highly take control over their exploration and manipulation. In a virtual world students may use the navigation system to freely determine to select and manipulate the objects that might be of interest and for the observation at convenience. Visualization, navigation, and manipulation tools was developed in the WebVR to allow students to move around within a virtual world and to discover the attributes of an object.

Designing Learning Content and Activities

The content of this WebVR material for the VR simulation part (operating slide projector) was divided into four essential parts based on the results from a content analysis and task analysis, they are individually Set Up, Operate, Disassemble, Maintain, and Troubleshooting. The VR-based learning world contains many virtual objects such as slide, focus button, lens barrel, slide tray, lock ring, elevation leg, remote controller, forward button, reverse button, and selection button that are the components of a slide projector. Each object is made from many models and attributes. Models describe it outside appearance, while attributes present its interactivity and actions. Students are allowed to reinforce their experiences of operating slide projector through manipulating the virtual objects and exploring the virtual worlds.

When students pick up a virtual object, they may execute the actions predefined inside by clicking the mouse button such as rotation or deflection. Students can pick up and move the objects, as well as observe them and their behaviors from various directions. The scenes in the virtual worlds have viewpoint so that students can quickly
view the virtual objects from the front, back, left, right, top, and bottom. Object names are shown when students move the cursor on them using mouse, while the names disappear when the cursor is moved away. By this way, students may observe the various components of the slide projector, and learn the names, appearances, and attributes of the virtual objects. In other words, students must actively manipulate, explore, and interact with the virtual objects, otherwise they could not be able to learn their attributes.

In the VR-based learning world of operating slide projector, the functionality and simulated actions are as follows (Heinich, Molenda, Russell, & Smaldino, 1996):

1. Slides could be load into tray and locking ring could be tightened as users pick up the slides and place them into the tray, and adjust the locking ring on the tray by clicking mouse button and moving the mouse.
2. The slide would be pop up as users push and hold selection button by clicking mouse button.
3. Slide tray would rotate clockwise or counterclockwise as the users press forward or reverse button on slide projector or remote controller to project slides by clicking mouse button.
4. Lock ring could be locked on slide tray as users tighten it by clicking and moving mouse button. If it is not locked, system would present a warning message that "slides would drop out."
5. Lens barrel would move out or in as users adjust focus knob or move lens barrel to focus image, position it on screen, make it smaller or larger by clicking mouse button and moving the mouse.
6. User could remove slide tray and remove slides from the slide tray buy clicking mouse button and moving the mouse.
7. Slide projector could be viewed from different directions by clicking mouse button and moving the mouse.
8. Names of virtual objects such as button, lens barrel, slide tray, lock ring, elevation leg, remote controller, forward button, reverse button, and selection button would be shown up when users place cursor on them by moving mouse.
9. Slide's image would upside down or backwards as users remove the slide and reverse it by clicking mouse button and moving the mouse.

**Development Platforms and Tools**

Due to the factors of cost and convenience, a desktop virtual environment with less immersion was developed in this study rather than using a head-mounted display with higher immersion. In order to make interfacing uses as friendly as possible and keep the cost as low as possible in cases of educational institutions' using our system, we chose a standard mouse rather than a data glove or a 3D mouse. In addition, data glove and 3D mouse art still not popular to the public at large was taken into consideration for not using them. WebVR in the study may therefore support direct dynamic interaction with the virtual worlds and objects with a standard and regular mouse.

Recent advanced technology in WWW platform have provided with tools and browsers for the capability of A desktop Virtual Reality known as the Virtual Reality Modeling Language (VRML). 3D Webmaster, the ultimate software tool for designing interactive 3D WebVR worlds in the study, allows developers to create rich, interactive, real-time 3D worlds quickly and efficiently, as well as lets developers add interactive 3D virtual worlds to flat 2D Web pages. 3D Webmaster not only may support VRML and 3D web producing but also can integrate with HTML and JavaScript commands. In addition to hundreds of ready made components and Virtual Clip Art objects, there is a fully functional 3D Shape and World Modeller as well as Sound and Image Editors included in 3D Webmaster. This also includes the powerful VR control language SCL (Superscape Control Language) for assigning behaviors to virtual world objects (see http://www.superscape.com/). 3D Webmaster provide users interactions and offer a natural way for extending the practice environment to a virtual 3D practice world. This extension provides with more advanced simulation and enable learning transfer from a virtual situation to a real situation.

Prototyping WebVR materials including interface was first developed by using Frontpage, and then completed environments were further established on the WWW by using 3D Webmaster to create the 3D virtual worlds and objects relevant to slides production and slide projector operation. Superscape Viscape, the fastest 3D browser plugin, enables users to view the product developed by 3D Webmaster and lets users experience interactive 3D virtual worlds on Web. It is therefore needed to install for viewing the WebVR materials in the study.

**Evaluation Methodologies and Results**

We evaluated the quality of the WebVR through doing qualitative study for mainly examining the functions, interface, content, and learning experiences by means of questionnaires that embrace specific questions. The results from the survey of students' feedback on the satisfactions for the WebVR reported that the system interface is easily accessible and usable to users. They also indicated that there are many learning materials that can be delivered more effectively by video and audio media that are not provided in the WebVR materials. Students reported that they liked having hands-on experiences with the virtual worlds, and they felt comfortable with the simulated capabilities.
provided by the WebVR material.

In summary, the conclusions drawn from the evaluation study are as follows:
1. The majority of students had a very positive response in the functionality, usability, interface, and content of WebVR.
2. Students commonly enjoyed learning within the virtual worlds, and their learning process was highly motivated.
3. Students were not tolerant of the low running space that sometime occurred.
4. The use of WebVR could encourage students self-directed learning.
5. The use of WebVR could captivate students' attention and foster active involvement in their learning process.
6. The test scores of students had higher learning performances than those of traditional instructions in classroom based upon the comparisons with last few semesters.

As a result of the evaluation study, the WebVR provides a promising platform for exposing students to actively learn in the domain of "Slides Projector Operation", draw a high attraction to students and can be employed for a wide variety of instructional purposes. A claim can be derived from observation study that identified a fact that WebVR does support the learning process, reception of information, and active participation. WebVR acts as an experience facilitator who allows students observe and explore phenomenon via their various senses. In short, our key insight to the evaluation results of the WebVR material is the verification of its successful design, creation and use experiences.

Conclusions and Summary

A VR-based learning environment on the Web was developed to examine the feasibility of applying VR to media education. However, the material does not want to replace the teacher, but only wants to be a teacher-assistant or student-assistant to help guide the student during the learning process. This means that if students experience difficulties learning, they may attempt to solve the problem in collaboration with their peers under the support of web-based VR technologies. Evaluation results of WebVR indicate that it is a helpful tool both for students and teachers in the learning process. This is concerned about the experiences students gained from the free navigation and high interaction afforded to them, and from the exploration of basic skills of operating slide projector. In summary, this study not only refines the content of distributed VR-based learning materials on the Web developed to learning slides production and slide projector operation, but also help us verify a methodology for instructional designing uses.

We do believe that the application of VR on web not only highly encourage the creative design of learning environments, methods, and tools, but also bring us into the new instructional strategies and tactics. It is hopeful that more studies on the web-based VR learning environment will be conducted to benefit all students in teacher preparation program.

Suggestions and Future Work

The WebVR is currently a stand-alone application not associated with the learning support tools such as chat room, conferencing and discussion board on the Web. It would be greater to be integrated into a web-based instructional environment so that the high level of collaborative learning activities can more profoundly be developed and relative issues can more deeply be investigated. In this study, we experienced difficulties in displaying a large amount textual information, however some textual information is indispensable for learning slide projector operation. Therefore, how to display large amounts of textual information using current VR techniques is still a big problem that needs to solve. An experimental research to examine the real learning performance by comparing the classical classroom situation with the WebVR through statistically controlled group and experimental group is recommended being conducted in the future. (This research was supported by NSC Project No.88-2520-S-032-003 of Taiwan)

A Concept-Mapping Methodology to Eliminate Dangling Questions in Asynchronous Learning Forum

Chih-Kai Chang
Department of Management Information Science
Da Yeh University
Da-Tsuen, Chang-Hwa 51505 Taiwan, R.O.C.
E-mail: chihkai@aries.dyu.edu.tw

Abstract: After an instructor had used the Web-based forum in a course for years, the system database will contain an accumulation of discussion articles from different classes, which may be of similar topics. Furthermore, the discussion processes of some classes may be very heuristic for other learners in the same course. In general, the Web-based forum serves as an additional discussion channel for learners in the absence of an instructor. However, an instructor may want to guide learners to read the meaningful discussion articles in portfolios of previous learners when a similar question is asked. Hence, it is necessary to model the relationships between discussion articles of different classes. Furthermore, an instructor desires no unanswered question, called dangling question, in the Web-based forum because of the possible negative influence, such as discouraging learners to raise questions. This paper proposes a concept-mapping method for representing the relations between learners’ questions and accumulated discussion articles, which enable a learner to find easily the set of discussion articles from the system database with conceptual similarity to his/her question.

Introduction

Many researches use portfolios for learning assessment, supporting instructors’ decision making, or planning instruction (Wiggins, 1993; Chang and Chen, 1998; Chang, Chen, and Ou, 1998). Such usage of portfolio is only from an instructor’s perspective. From a learner’s points of views, portfolio means learning efforts of previous learners. For instance, portfolio of a previous learner may include the previous learner’s discussion, project, and homework so on. The portfolios of a Web-based learning environment can be reused as recommended readings to eliminate dangling questions by filtering, encoding, and indexing previous learners’ portfolios into a concept similarity representation. This paper proposes a methodology for reusing the discussion articles in portfolios to answer dangling questions by the concept similarity between dangling questions and discussion articles.

Most of the existing asynchronous discussion styles is thread-based on the Web. This means that an initial article was first posted, which followed by articles of the same subject. Discussion articles can be presented in different ways, for instance, by time order, author order, or subject order. However, most learners will use subject order because they need to know others’ response to the subject before posting an article. Sometimes, a prior learner will use “please see a specific article posted before” as an answer to a question raised. Furthermore, new learners are very interested in the experience of the prior learners. For instance, new learners may want to know whether a specific topic had been discussed or not. Hence, it is necessary to find a method for reusing prior learners’ discussion articles.

Very often, some questions are never answered in the discussion activity of the distance learning system. These unanswered questions are called as dangling questions. The dangling questions may occur for different reasons. For instance, the dangling question is so easy that other learners ignore it. Sometimes, other learners may not be discussing the topics related to the dangling question. Dangling questions are important both to the learners and the discussion group. If a dangling question is noticed and answered, the discussion that follows may be very abundant in some cases. Furthermore, some studies have indicated the positive effects of reducing the turnaround time of learners’ question (Rekkedal, 1983). However, there is still no mechanism for triggering learners to review dangling questions.

There are many advantages for dangling questions to be answered by prior learners’ discussion articles in the discussion process of a Web-based forum. First, the participation of the discussion activity will be enhanced because every learner may feel that there are responses to his/her question. Second, the group discussion will be more efficient because prior learners’ articles will answer some types of questions, for instance, the frequently asked questions. Third, all learners will get an additional chance to reflect more
Portfolios can also be used for active dialogue scaffolding. Discussion articles may contain any topic, for instance, discussing a misconception, exchanging notes, sharing an article, and even checking on the deadline for homework. If there is a prior learner in the new class, he/she will often use previous discussion articles to answer questions for the new classmates. The types of questions, answered by prior learners' discussion articles, varied from frequently asked questions for novices to very specific questions for experts; depending on whether the prior learners' discussion articles contain the topic of the new question or not. Hence, it is very difficult to reuse previous discussion articles without a prior learner in the new class. The issue is referred to as the reusability problem.

Learners do not know whether a specific topic in a course has been discussed or not. In general, learners will use the keyword search method to probe whether there are related discussion articles in prior learners' portfolios or not. However, the results of keyword search may be too much to handle. Hence, learners will use the Boolean system to improve the keyword search results. Using the Boolean system to retrieve answers from discussion portfolios, learners have to provide sufficient syntactical restrictions in their query to limit the number of articles retrieved. Worse still, these retrieved articles are not ranked in any relationship to learners' query. However, learners may not be familiar with the terminology of the specific domain, which could be used in the discussion articles. Furthermore, learners find it difficult to get consistently good results because they lack the training for expressing the complex query syntax required by the Boolean system. Consequently, some models for retrieving answers easily from prior learners' discussion portfolios should be constructed. This issue is denoted as the recognizability problem.

Prior learners' discussion portfolios are not meant for use by novices. Its organization is difficult for a novice to absorb prior learners' learning experience. Hence, it is necessary to reorganize prior learners' Web-based discussion portfolios so that even new learners can benefit from using them. Although learners can retrieve prior learners' discussion articles by asking questions, they may want to know why prior learners discussed this topic. There should be a mechanism not only for answering dangling questions, but for also providing a hyperlink to the beginning of the thread leading to the answer (the discussion article) of the dangling question. Furthermore, a thread of prior learners' discussion articles may contain a reference to other portfolios. Hence, the prior learners' portfolios should be more readable for novices to reuse and benefit from them. The issue is called the readability problem.

This paper presents a ranking method of retrieving discussion articles and detailed instructions on using ranking technology to answering dangling questions of a Web-based forum by the support of prior learners' portfolios in a distance learning system. First, we solve the reusability problem by answering learners' questions with retrieved articles from prior learners' discussion articles. Then, a concept-based mapping method is used to reorganize prior learners' portfolios so that learners can benefit from them without the readability problem. Finally, the relevance ranking in concept vector space is used to retrieve articles from portfolios for answering questions. Learners need not know whether there is any related discussion articles in prior learners' discussion articles before asking questions. Hence, the vector space model will solve the recognizability problem. The following table illustrates the relationships between the aforementioned problems, requirements and proposed methodology.

Table 1: Relations between problems and methods.

Illustrative Example and Article Retrieval

We assume that there are seven vocabularies in a specific domain, including “factors”, “distance”, “human”, “portfolio”, “collaboration”, “learning”, and “system”. If a learner asks “Please tell me about collaboration in distance learning systems”, the question will be transferred to the 7-dimensional vector as follows:

$$ q = [0 \ 1 \ 0 \ 0 \ 1 \ 1 \ 1] $$

where $q$ denotes the question. The terms in $q$ are determined by whether the vocabularies appear in $q$ or not. The question will become a dangling question if there is no answer to the question after a few days.

Suppose there are three learners' discussion articles, denoted as $d_1$, $d_2$, and $d_3$. Discussion article $d_1$ contains “distance”, “portfolio”, “collaboration”, “learning”, and “system” vocabularies. Hence, the 7-
dimensional vector for \( d_1 \) is as follows:

\[
d_1 = [0 \ 1 \ 0 \ 1 \ 1 \ 1 \ 1]
\]

Suppose discussion article \( d_2 \) contains "factors", "distance", "human", "learning", and "system"; while discussion article \( d_3 \) contains "factors", "human", and "collaboration". Similarly, these two discussion articles are denoted as follows:

\[
d_2 = [1 \ 1 \ 1 \ 0 \ 0 \ 1 \ 1]
\]

\[
d_3 = [1 \ 0 \ 1 \ 0 \ 1 \ 0 \ 0]
\]

To determine whether an article is a suitable answer to a dangling question, a dot product of the dangling question vector and each document vector is made. The document, with the highest result number, will be the answer to the dangling question. The \( q^T d_i \) of \( d_1, d_2, d_3 \) is 4, 3, 2 respectively. Consequently, discussion article \( d_1 \) is retrieved to answer the dangling question.

The above method, though feasible, also causes some difficulty. First, the matching process may cost expensively because there are many accumulated discussion articles. An alternative is to cluster the discussion articles with the same concept into the same category. Second, the previous method determines the relevance degrees between a question and accumulated discussion articles by shared words. However, there is a vocabulary gap problem in retrieving discussion articles. The vocabulary gap problem means that two discussion articles may be related in concept but there may be no shared words. Consequently, a concept-based methodology is crucial for solving the vocabulary gap problem by vocabulary transformation.

### Concept-Based Mapping Method

The goal of answer retrieval is to post a discussion article in prior learners' portfolios to a learner's question. The basic problem is how to determine the relevance of a discussion article in portfolios to a learner's question. In other words, this is a problem of relevance ranking of the discussion articles in portfolios. Once the discussion articles are retrieved with respect to a question, they can be ranked according to a relevance score. However, the vector representation of a discussion article does not indicate how the discussion articles can be arranged by a relevance score. In other words, the vector representation of a discussion article does not consider the learning requirements of a novice, which depends on the learning domain and concept.

To determine the relevance score of discussion articles to a learner's question, there should be a ranking method that is based on the conceptual similarity, rather than on words shared by the question and the retrieved answer. This method cannot assume that there is any shared vocabulary between the learners' questions and the discussion articles. Figure 1 illustrates an example of representing the discussion articles as a matrix. We use four discussion articles, each with its own set of concepts. There are two matrices, \( A \) and \( B \), used to represent the concept mapping process. A row in matrix \( A \) means a discussion article and the words contained in the discussion article. The rows of matrix \( B \) are sets of concepts for each discussion article. We use \( w_i \) to denote the weight of a word because there are many methods for determining the weight of each word, for instance, binary weight, within-document word frequency, and inverse document frequency (Salton, 1989).

set2 & 1 & 0 & 0 & \\
set3 & 0 & 0 & 1 & \\
set4 & 0 & 1 & 0 & \\
\end{bmatrix}
\]

representing the concepts of a discussion article.

**Figure 1:** The matrix representation for the concept-mapping process.

Figure 1 depicts how to represent a discussion article with vocabulary (words) by matrix A and the concepts of a discussion article by matrix B. Hence, the concept-based mapping method can be implemented without shared words if the "magic" matrix F can be computed to transfer matrix A to matrix B. Now we are ready to find a matrix F that can be used to determine the relevance scores between the question and discussion articles by concept similarity. Theoretically, the problem is exactly like finding the Linear Least Squares Fits (LLSF) between matrix B and matrix FA. Under this assumption, the LLSF method can provide a conceptual-based transformation of the original words of a question into the vocabulary of discussion articles in portfolios (Yang and Chute, 1993).

**Definition:** The LLSF problem is to find a matrix \(F_{kn}\) that minimizes the sum of residual squares

\[
\sum_{i=1}^{m} \left\| F \tilde{a}_i^T - \tilde{b}_i^T \right\|^2_2 = \left\| FA^T - B^T \right\|^2_F
\]

where

- \(A_{nxm}\) and \(B_{nxm}\) are given matrices representing the training pairs;
- \(A^T\) and \(B^T\) are the transposes;
- \(\tilde{a}_i\) and \(\tilde{b}_i\) are the \(i\)th pair in the training set;

\[
\left\| \cdot \right\|_2 = \sqrt{\sum_{j=1}^{l} v_j^2} \quad \text{is a vector 2-norm of an } l \times 1 \text{ vector, and}
\]

\[
\left\| \cdot \right\|_F = \sqrt{\sum_{i=1}^{m} \sum_{j=1}^{l} M_{ij}^2} \quad \text{is the Frobenius matrix norm of an } l \times m \text{ matrix.}
\]

The LLSF problem was proven to have at least one solution. The singular value decomposition (SVD) method is often used to solve the LLSF problem. (Lawson and Hanson, 1974; Golub and Van Loan, 1989)

The intuitive meaning of the solution of the LLSF problem is to find an matrix \(F\) that can be used to measure the "distance" between a learner's question and a discussion article in previous learners' portfolios. Because the matrix \(F\) is derived from discussion articles of some classes, the matrix \(F\) is trained to assign properly a question to a set of discussion articles. The scenario may be as follows. A learner asks a question a few days ago and no one answers or follows his/her question. Then, the system uses the matrix \(F\) to find some related discussion articles from prior learners' portfolios as answers to the learner's question. Finally, the system asks the learner whether he/she is satisfied with the retrieved discussion articles or not. If he/she is satisfied with the retrieved discussion articles, the methodology works. If not, the system will notify a teaching assistant of the case. The teaching assistant will answer the learner's question or manually seek for some related discussion articles. Then, the system will retrain/derive the matrix \(F\) so that it can solve a similar case in future.

Hence, the system or the agent can reorganize the discussion articles according to the similarity between the transformed question and the concepts of discussion articles for a relevance order to choose a most suitable article in a suitable concept as the retrieved answer. Then, we can solve the *readability*
problem by reorganizing the prior learners' discussion articles in a concept-based style.

The Relevance Ranking in Concept Vector Space

As the illustrative example demonstrates, every discussion article is viewed as an n-dimensional vector space in the concept vector space. Hence, a dangling question should be represented as an n-dimensional vector in the concept vector space before the system begins to find the suitable article. Then, an n-dimensional vector matching operation can be used to compute the similarity between a discussion article and a dangling question. Let $d_j$ denote the j-th discussion article and $q$ refer to the dangling question in concept vector space, $\vec{q} = (Fx^T)^T$. The system uses the following formula to compute the similarity in the concept vector space.

$$similarity(d_j, q) = \frac{\sum_{i=1}^{n} (td_{ij} \cdot tq_i)}{\sqrt{\sum_{i=1}^{n} td_{ij}^2 \cdot \sum_{i=1}^{n} tq_i^2}}$$

where

- $td_{ij}$ means the i-th vocabulary in the vector for the discussion article $d_j$,
- $tq_i$ means the i-th vocabulary in the vector for the dangling question, and
- $n$ means the number of vocabularies in the learning domain.

The vector space model has been proved useful in many experiments at Harvard University and Cornell University (Salton and McGill, 1983; Salton and Buckley, 1988). Learners' question will not be dangling any more if there is any prior learners' discussion articles related to the concepts of his/her question by the similarity in the concept vector space. Figure 2 illustrates the framework of our methodology.

![Figure 2: The framework of the concept-based transformation to answer dangling question.](image)

Conclusion

This paper proposes a methodology for reusing the discussion articles of learners' portfolio by a vector space model. Since the Web-based forum has accumulated many discussion articles after years, an instructor may expect all learners in a new class to benefit from prior learners' discussion articles. Because an instructor providing a Web-based, asynchronized forum for his/her course becomes continual, the "concept-based" text retrieval methodology to quick search topics and scaffold learners by prior learners' learning experience becomes crucial. Consequently, the relations between the discussion articles of
different class (with the same course) should be constructed.

This paper uses the information retrieval technology to retrieve a most suitable discussion article as the answer of a learner's dangling question. Consequently, a learner need not review all prior learners' discussion articles but can still benefit from the prior learners' discussion articles. Most important of all, the Web-based discussion portfolios not only can play the passive role in the Web-based distance learning research, but can also serve an active role by answering dangling questions. Hence, the forum will be full of suggestions that answers dangling questions from the perspective based on the prior learners' Web-based discussion portfolios.

Abstract: In recent years, there has been a worldwide trend toward greater integration of technology use in teaching and learning. There has also been a concomitant shift away from traditional teacher-centered instruction towards interactive, peer tutoring, collaborative group learning, and global education. By leveraging off the dissemination of technology, we have developed a system that allows multiple geographically remote learners to participate simultaneously in a simulation-oriented VR-based collaborative learning environment. Virtual environments allow users to participate in experientially-grounded simulation environments and support the exploration of activities that may be impractical to perform in real life. Moreover, users can benefit from mutual tutoring and interactions with experts.

Our system development work is based entirely upon open standards. For this reason, the system is called VirtUOS (Virtual Reality Learning Environment Using Open Standards). Adherence to open standards ensures that the system is portable across hardware platforms thus benefiting a wide range of users.

Introduction

The use of desktop virtual reality (VR) to support learning presents educational technologists with exciting opportunities as well as significant challenges that need to be overcome. Desktop VR is ideally suited to use in domains that benefit from the use of simulation, experientially-grounded learning, and socialized learning. However, desktop VR systems have traditionally been realized by various commercial organizations using their own proprietary technologies and file formats. In view of this, we have developed a desktop VR learning system directed at supporting collaborative learning in a simulation-oriented environment. The objective is to allow learners to learn collaboratively in real time by sharing learning experiences as well as by articulating and refining conceptual ideas related to these learning experiences. In line with developments in the VR field, our system moves beyond the first generation of navigation-oriented VR to the development of interactive VR, where interactions with virtual world objects give users richer learning experiences.

Theoretical Underpinnings

Constructivist theory is perhaps the most widely accepted pedagogical standpoint adopted by teachers today. Constructivism views the student "as one who acts on objects and events within his or her environment and thereby gains some understanding of the features held by the objects and events" (Boger-Mehall). Constructivism suggests that people make significant progress when they collaborate. Moreover, mutual tutoring, shared visions, and collaboration produce substantial impetus to learning. The Internet makes this collaboration process convenient and viable. However, as McKenzie (1997) points out, technology does not remove the need for traditional sources of knowledge. Studies by Strommen (1992) also show that technology is a completing augmentation rather than a competing aggravation.

A constructivist orientation requires the adoption of a fresh perspective on technology. Instead of viewing computers as a knowledge presentation device, we should view them as tools for supporting a pedagogical focus on communications in collaborative learning.
ventures (Koschmann et al., 1993). If we are able to bring a group of people together to interact in a model of a real environment, then we also have a tool for constructivist learning. Imagine a music composition class where the students can compose music and present their individual works to the rest of their class in a virtual mode. Or perhaps a chemistry class where students can mix chemicals and test chemical reactions in the safety of a virtual chemistry laboratory.

Gagnon and Collay (1996) posit that a successful Constructivist Learning Design (CLD) should provide familiar environments that reflect the thinking processes of the participants; in such environments there must be trust and public sharing of knowledge in this environment. Moreover, the Across-Schools Pedagogy Issues group (Koschmann et al., 1993) endorses the “necessity of large-area networks for particular contexts, instructional goals, and learner characteristics.” Injecting constructivism into the educational system culminates in a revolution, from planning for teaching to designing for learning (Gagnon and Collay, 1996). Fosnot (1996) rightly asserts that the “key to reinventing our educational system... lies in what our teachers believe about the nature of knowing.”

Working within the constructivist paradigm, we have developed a system that creates virtual environments where users can perform experiments and experience simulations in support of collaborative on-line learning. In such environments, users can engage in experiments that may be expensive or even dangerous to perform in real life. Our system supports user interactions that facilitate mutual tutoring and knowledge sharing. The system can be used by academic institutions that offer courses through distance learning, or it may be used as a complementary form of on-line collaborative learning in on-campus education. In particular, such institutions can conduct laboratory classes with visual demonstrations and presentations in real-time. The system can also be used to give guided tours of museums, art galleries, and show rooms of new houses.

Research Focus

There have been several attempts to create similar VR environments. We reviewed four representative systems among these applications. The first system, VR for Learning (Lim, 1997), is limited in that it does not store its world data in a database. Moreover, avatars are static and non-standard, and they float in virtual worlds rather than walk. The second system that we reviewed is Active Worlds. This proprietary-standard virtual world browser has a remarkably fast response time. However, this fast response time is achieved at the price of only supporting avatars that are more coarsely defined. The third system, Community Place, is designed to be scalable to support many “geographically dispersed users, interconnected through low bandwidth, high latency communication links”. However, Community Place separates the chat and whiteboard windows from the virtual world navigation window. This separation increases the semantic distance between the different components of the system. The final system, blaccun, has the advantage of using Humanoid Animation 1.0 (HANIM, Roehl, 1997) compliant avatars. However, blaccun’s avatars float instead of walk. While the avatars move very quickly, realism is compromised.

In order for our system to benefit as many users as possible, we implemented our work using open standards. Our system uses a third-party virtual world browser, Cosmo Player. The other components of the system are implemented in Java. Hence our system is portable to hardware platforms that support the virtual world browser. Moreover, the system is designed to support a large number of users while maintaining reasonable performance.

Given that we wanted to help users participate in learning environments and not in learning how to use the system, considerable attention was given to designing an engaging interface that would make the system pleasurable to use. A pleasant experience will attract users back to the virtual learning worlds, resulting in more experiential learning and familiarity with the learning context.

Our system moves away from traditional navigation-oriented VR to interactive VR that enriches users’ learning experiences. In VirtUOS, virtual object states are modified by manipulating components of these virtual models directly. Each object has unique behaviors and properties, or is able share behaviors and properties with other similar objects. This concept is similar to Object Oriented Programming where each object has its own variables and methods. VirtUOS processes new object states and updates virtual worlds accordingly. By storing object states, users can collaborate in discussions that span several login sessions. Moreover, VirtUOS models avatars realistically in that they no longer float around virtual worlds. Instead, the avatars perform life-like walking motions as users navigate in virtual worlds. Avatars are instrumental for promoting user interactions because they allow users to establish presence in virtual worlds by simulating the sense of “being there.”

System Design

Our design considers the database, avatar animation, object interaction, and user interface aspects of the system. A database is needed to provide storage and retrieval of virtual world states. Avatar animation is desirable because it increases the realism of virtual
Given that VirtUOS is targeted at Internet users, we use VRML to model our virtual worlds and objects. In a traditional VRML environment, the states of virtual worlds are not maintained. Hence, objects appear at their same default locations every time users log in afresh. Users also always enter a world at the same location regardless of where they were when they last logged off. Lim's system (Lim, 1997) simulates a database using Java but the database does not exist on a persistent medium or in a form that can be queried and updated using standard commands (such as SQL statements). Furthermore, Lim's system has to explicitly consider concurrency control issues that are inherently taken care of in a database environment. As we believe that there is no reason to re-code a SQL database, we make use of the comprehensive set of functions provided by Java that standardizes database access.

The design of our world objects to provide object behaviors requires our system to be able to encapsulate avatar (and any virtual object in general) animations, behaviors, and properties as though they are Object Oriented classes. Hence, it is necessary to have a standard structure for representing an avatar. VirtUOS uses the Humanoid Animation 1.0 (HANIM) standard (Roehl, 1997). HANIM 1.0 is an extension of the VRML 2.0 standard that defines the scene graph of any humanoid VRML model. Standard avatar structures allow animations, behaviors, and properties to be reused by all other avatars. Each avatar has its own instantiation of the animations, behaviors, and properties. Moreover, shared animations need to be downloaded only once from the web because Internet browsers cache downloaded documents. Subsequent accesses (within the same browser session) are read from cache.

The plethora of possible objects in a virtual world makes it impossible to define a rigid structure for the VRML representations of arbitrary objects. However, it is possible to characterise the common attributes (e.g. position and orientation) while letting the other attributes be object specific. For example, batteries, resistors, and bulbs have position, orientation, and resistance attributes (and associated “methods” to get and set the attributes). But only batteries have a voltage attribute, and only bulbs have a power attribute and a set method. The power attribute indicates the power that the bulb is designed for, and the set method is used to tell the bulb the amount of power that the circuit is supplying it with.

The design of the user interface must ensure that the system is engaging and pleasurable to use. Moreover, the interface should be simple enough for users to use without any prior training or instruction. It is difficult to provide users with an extended user interface, e.g. popup menus for interacting with virtual objects, because the system makes use of a third-party application, such as Cosmo Player or Cortona, as the VRML browser. Consequently, there are no easy means of extending the user interface of the browser to support interactions between users and virtual objects. In our system, Cosmo Player is chosen as the browser for VirtUOS because it is better established than newer browsers such as Cortona.

Functional and Performance Requirements

In this section, we set out the functional and performance requirements that our system is designed to support. Most of the functional requirements that we propose are desirable for enhancing the realism of virtual worlds and providing a rich learning experience. On the other hand, the performance requirements are directed at supporting virtual world interactions realistically with minimal latency.

Functional Requirements

Our system has been designed to support the following functions:

- Allow users to change their avatar representations and to reflect these changes on all other clients.
- Allow the storage of virtual world states and the restoration of these states when users log in afresh. This feature facilitates the building of complex virtual structures spanning several sessions.
- Allow animated avatars that walk instead of float. The system also allows users to walk in arbitrary step sizes and directions. Users need not walk in full steps, nor is the walking restricted to moving forward.
- Allow users to navigate by using the cursor keys/mouse to interact with a virtual world browser. The system should not use navigation controls outside of the virtual world because users may have difficulty mapping such controls to the virtual world.
- Allow different actions to be associated with an avatar with minimal changes to the system. This would free us from making significant modifications to the system when we include experiments requiring new avatar behaviors.
- Ensure concurrency control over virtual objects that users can manipulate. The system should not allow two or more users to update an object at the same time in order to maintain consistency of virtual worlds across all users.
- Allow the alignment of virtual objects that users can manipulate by snapping to a grid. This “forcing function” frees users from having to manage minute details of object orientations and positions.

Provide a user interface to support object interaction. The interface provided by Cosmo Player allows only mouse clicks and dragging actions. However, some simulations need to support several actions that depend on users' choices. Hence, it is necessary to extend Cosmo Player's user interface to circumvent this restriction.

Allow users to hide the avatars of other users whom they do not wish to see. Users can also use this function to speed up the system when too many users are logged on simultaneously.

Performance Requirements

It is desirable for the system to meet the following performance requirements:

- Virtual world updates should be propagated fast enough to all clients so that users can interact with one another in real-time.
- The rendering process should take less time when avatars are hidden.
- The system is expected to run on Pentium II PCs with at least 32MB RAM.

System Description

This section is divided into two parts. First, we describe our system by means of a simulation-oriented virtual world model that we have created. In this description, we present a typical scenario of how users learn collaboratively using our system. Second, we discuss the technical innovations in the development of our system.

Simulation-oriented Collaborative Learning

VirtUOS is capable of supporting multiple virtual worlds. Each world has its own learning goals and users can teleport between these worlds. Figure 1 (Fig. 1) shows a screen snapshot of VirtUOS viewed through Netscape 4.5 and Cosmo Player 2.1. The Chat client and Multi-user client are displayed at the bottom left and bottom right of the virtual world respectively. The HTML display on the right hand side of the Netscape window explains the goals of the virtual world that Cosmo Player displays.

Figure 1: Screen capture of VirtUOS learning environment
One particular world in our implementation uses the flowing waters and teeming crowds analogies (Gentner and Gentner, 1983) and colliding billiard balls (Humphrey and Topping, 1949) to demonstrate the system’s ability to support collaborative learning. We built a virtual electrical circuit that contains several batteries, resistors, and a bulb in a virtual physics laboratory. The background information on the right of the virtual world describes the flowing waters and teeming crowds analogies. Users are asked to predict and compare the effects of the circuit using the analogies when batteries and resistors are placed in series and parallel on the circuit. In addition, users can use the virtual VCR (shown on the left side of the virtual circuit in Figure 1) to view MPEG movies that demonstrate the tasks that the experiments require them to perform. The virtual VCR plays any MPEG movie indicated by a URL input by the user into a system dialog when the VCR is clicked upon.

In order to make our virtual laboratory more engaging, the system plays soothing spatialized background music. Our system also provides audio feedback when users interact with the virtual circuit components and with the billiard balls.

Users can manipulate batteries and resistors of the virtual circuit directly by dragging and dropping the components using the mouse. Our system prompts users for the orientation of the components in the circuit by using a popup menu. The orientation is not set automatically because orientations of components serve as valid learning goals as well. Batteries that are placed in opposite directions cancel out the voltages of one another. On the other hand, resistors produce the same resistance even when they are placed in opposing directions. However, when either batteries or resistors are placed perpendicular to the wire of the circuit, they are disconnected from the circuit. Hence, they do not contribute to the overall voltage and resistance in the circuit.

While some users are performing these battery and resistor arrangements, other users can comment on their progress. Furthermore, users can collaborate in the circuit building process. Users who are more proficient can help others by sharing knowledge and understanding with the weaker users. The text chat facility allows participants to engage in collaborative knowledge building activities. Consequently, teaching becomes more participative and distributed across users.

The second simulation in this virtual world investigates impulsive forces using colliding billiard balls. VirtUOS allows users to modify the friction and restitution between billiard balls and the billiard table as well as the maximum initial force applied to a billiard ball. The ease with which users can change these environmental parameters is impossible in real life. For example, it is unlikely to find tables and billiard balls with zero frictional force. It is similarly difficult to find such a setup with zero restitution. Moreover, unless experimenters are expert billiard players, it is difficult to hit billiard balls squarely at the center of gravity all the time. Although hitting billiard balls off the center of gravity can be another modifiable parameter, uncontrolled variations of such parameters are likely to impede users’ investigations of simulations that they choose to focus on (such as the conservation of momentum).

Users can vary the initial force acting on a billiard ball by holding onto the ball. The length of time is used to estimate the initial force proportionately with respect to the maximum force. Hence, clicking (and holding) onto a ball for a longer period will cause the ball to have a higher initial speed compared to clicking (and holding) onto a ball for a shorter period.

We intend to conduct empirical evaluations on users in order to determine the usability and effectiveness of our system. These evaluations will include the time taken for users to be familiar with the system, the amount of knowledge retained from virtual world learning experiences, and the willingness of users to use our system repeatedly.

Technical Innovations

In supporting the shift from navigation-oriented to interaction-oriented VR, we achieved the following:

- Encapsulation of object behaviours in VRML. Object behaviours are created separately from the objects that use the behaviours. As a result, these behaviours can be shared among many objects at the same time. An example of shared behaviours is the walk animation. Avatars in VirtUOS walk instead of float in virtual worlds. All avatars share the same walk animation behaviour.

- User-interface support for object interactions. VirtUOS extends the user-interface of Cosmo Player 2.1 by adding popup menus. These menus are displayed as VRML objects rendered by Cosmo Player in virtual worlds.

- VirtUOS provides database access for VRML objects. VirtUOS uses the database to store and retrieve virtual world states. These states are updated as users interact with virtual worlds.

- VirtUOS provides network support for VRML objects. The system enables VRML events to be propagated to clients over the Internet hence allowing other clients to reflect changes to virtual world states.

- Concurrency control for object manipulations. VirtUOS uses a database to provide concurrency control so that only one user can update a virtual object at a time.
Conclusion

VirtUOS supports collaborative learning through simulated virtual environments. These virtual environments allow users to actively participate in collaborative activities. Users can accelerate their learning processes by engaging in mutual tutoring and knowledge sharing through the virtual environments that VirtUOS provides.

VirtUOS extends the existing user interface of Cosmo Player so that users can interact with virtual objects. For example, VirtUOS displays a popup menu that can be used to control the orientation of virtual objects. Because popup menus are not part of Cosmo Player's virtual world representation, we developed this functionality.

There are four possible future enhancements to our work. First, in order to increase system efficiency, we plan to partition virtual worlds so that only visible portions of the worlds are updated on every client computer. Second, it is desirable to exploit users' hearing as an alternative perception channel. Consequently, the system should be able to receive audio input from users and propagate that to other users. Third, VirtUOS does not currently indicate which user is moving a virtual object. Hence, there is a detached feeling when other users see non-living objects move on their own. The system should show users holding or pushing the objects that the users are moving. Fourth, the system should allow users to manipulate virtual world objects more directly. The current implementation of our system uses a popup menu for interactions between users and virtual objects.

In summary, our work deals with the synthesis of technology and learning by using desktop VR to facilitate experientially-grounded collaborative learning. Neither component replaces the other; rather, the two complement each other. The ongoing rapid evolution of various VRML standards such as DIS (Brutzman, 1998), HANIM, and External Authoring Interface (EAI), means that VirtUOS has to be maintained and updated constantly to be up-to-date with the open standards. Fortunately, the highly modular design of VirtUOS makes the system readily modifiable to conform to new standards. Using VirtUOS, we are attempting to reach out to a global community of learners to collaborate in the exciting new world of VR-based constructivist learning.

chou@hawaii.edu

Abstract: This study examines the different patterns of online interaction between asynchronous communication and synchronous communication networks. Discussion transcripts were analyzed and coded using Bale’s Interaction Process Analysis (IPA) model (revised and expanded version). The preliminary findings showed significant differences in the interaction between social-emotional and task-oriented contents. There was a higher percentage of social-emotional oriented interaction in synchronous communication. Whereas in asynchronous communication mode, a significantly higher percentage of online interaction were task-oriented. Furthermore, asynchronous discussion appeared to be mostly one-way communication and synchronous discussion showed evidence of two-way communication.

INTRODUCTION

Computer-mediated communication (CMC) systems have become an integral part of distance learning. Distance courses are conducted over CMC systems and learners interact with instructors or peers through computer conferencing. Studies on interaction over CMC networks have provided educators and researchers information on learners in terms of both intellectual growth and social development. Research findings on how interaction contributes to intellectual growth such as knowledge construction (Gunawardena, 1997), academic achievements (Hartman et al., 1995), and critical thinking (Newman, Webb, & Cochrane, 1995) indicates that cognitive development can be achieved over distance learning networks. Research on the social aspect of interaction also furthers the understanding of learner behaviors and dynamics in distance education (Johanson, 1996; McDonald & Gibson, 1998).

The majority of research on learner interaction was conducted over asynchronous computer networks which are the primary media for distance education (Lewis et al., 1999). Few studies have been done on learner interactions in a synchronous communication network and even fewer research projects have been designed to compare both synchronous and asynchronous communication. Factors such as difficulty in coordinating meeting time, high cost in good quality synchronous communication technology, and tool stability may explain the under-utilization of synchronous CMC systems. Nevertheless, with the improvement in CMC technology and more affordable tools available, synchronous conferencing systems have become more common in distance learning environments.

The problems of the previous research can be summarized as follow: a). lack of long-term study: most of the research uses previously unacquainted participants and short-lived group; b). lack of study on synchronous interaction: much emphasis has been placed on interaction over asynchronous communication networks; and c). lack of study on the comparison of asynchronous and synchronous interaction.

Moore (1989) defines three types of interactions in distance education: learner-content interaction, learner-instructor interaction, and learner-learner interaction. A comprehensive understanding of each type of interaction can help educators better plan learning activities and make use of the CMC technology for maximum effectiveness. Most of the research on online interaction draws conclusions from studies on asynchronous communication networks, e.g. electronic mail, listserv, web-based bulletin, BBS, etc. Little research has been conducted over synchronous networks. What are the nature and patterns of synchronous interactions? To what degree can learner interactions over synchronous learning networks contribute to learning? It is the purpose of this
proposed study to examine learner-learner interactions in a collaborative online learning environment. The objectives for this study are:

1. To identify the patterns and developments of learner interactions over time, especially on task-oriented versus social-emotional oriented content;
2. to determine if there is a difference in the interactions when learners assume the roles of moderators and participants; and
3. to compare learner-learner interactions between synchronous and asynchronous communication networks.

LITERATURE REVIEW

Learners’ abilities to interact with the instructor, the peers, and the content can affect their performance in distance learning. Acker and McCain (1993) state that "interaction is central to the social expectations of education in the broadest sense and is in itself a primary goal of the larger educational process and that feedback between learner and teacher is necessary for education to develop and improve" (p. 11). Online interactions take into consideration the characteristics of the learners as well as the communication technology. The interactive features of the current CMC systems, such as two-way video and instant feedback, have provided more options for learner interactions. Gunawardena (1998) interprets interaction as "the process through which negotiation of meaning and co-creation of knowledge occurs in a constructivist learning environment" (p. 141). Wagner (1998) argues that interaction can serve as a means to an end of enhancing learning and performance.

The design of the learning environments influences the results of learner-learner interactions. Scardamalia et al. (1992) found significant difference in the verbal scores from a Canadian standardized achievement test between elementary students who used Computer Supported Intentional Learning Environments (CSILE) to collaborate with teammates and those who used CSILE for individual study. CSILE is a multimedia learning environment that allows students to collaboratively contribute to one another’s learning through co-construction of a knowledge database. As suggested by Martens et al. (1997), interaction is "supported by the user interface that enables the learner to access and manipulate the objects in the knowledge base" (p. 46). Good interface design provides students the opportunities to learn by interaction with their peers.

One should not equate interaction with learning. It depends on whether the goal of an interaction task or activity is for the purpose of enhancing understanding of the subject matter or for improving interpersonal connections. Learner interactions require planning and structure in order to achieve the goal of active learning. Rohfeld and Hiemstra (1995) suggest tasks such as debates, guest lecturers/discussants, polling, brainstorming, or student-moderated discussions via CMC networks to increase student interactions for learning. The principles of student-centered discussion accord the students the responsibilities of facilitating online conversations. The process serves well for both cognitive and affective purposes. On the one hand, the process stimulates intellectual growth and enhances organizational skills; on the other hand, it improves the student connection at the interpersonal level (Paulsen, 1995). When the activities and tasks become an integral part of the learning process, learner interactions can be conducive to learning.

Bales’ Interaction Process Analysis (IPA) (1950) has been utilized to examine small group interactions in both face-to-face and CMC groups (Rice & Love, 1987; Sorensen & McCroskey, 1977). IPA consists of twelve categories which fall into two main areas: social-emotional oriented and task-oriented contents. IPA was first developed in 1950 as the result of studies of group processes, e.g. who did what, who spoke to whom, and how interactions developed and changed (Bales, 1950). Bales’ IPA describes well the process of interaction and the dynamic in small groups. The twelve categories were modified for this study in order to better described the nature of online interactions. More details will be described in the following section.

RESEARCH DESIGN

RESEARCH QUESTIONS
To further the understanding of online learner-learner interactions, the research questions will address learner interactions in the following areas: learning tasks, learning environments, learner characteristics, and the relationship with learning. The main questions are listed as follows:

A. Learner-learner interactions in social-emotional oriented contents versus task-oriented contents: How do online interactions develop over time in terms of social-emotional versus task-oriented content as outlined in Bales’ Interaction Process Analysis? Is this pattern of interaction different between asynchronous communication mode and synchronous communication mode?

B. Learning task: Will role-taking, such as assuming the role of a moderator or a participant, make a difference in online interactions?

C. Learner characteristics: Do learner characteristics such as gender, attitude toward computer networks, experience in using computer, confidence in computer skills, affect the way they interact online?

D. Learning environments: What are the similarities and differences in learner interactions via synchronous and asynchronous networks?

METHODOLOGY

This study used mainly qualitative methodology with the support of statistical analysis program. Content analysis was employed to examine learner-learner interactions and learning. Bales’ Interaction Process Analysis (IPA) with minor modifications was used as the basis of content analysis for learner interactions. The procedure was to systematically code student’s weekly postings and online seminar transcripts in order to detect the interaction patterns.

The research was carried out by surveying distance learners and analyzing student written data in a ten-week writing-intensive online course titled “Theory and Application of Computer-Mediated Communication.” This course was delivered via a courseware called WebCT at the University of Hawaii in 1998. The data include weekly postings in the bulletin board (asynchronous data) and transcripts from a weekly seminar (synchronous data). In the weekly seminar, students met in a chat room in real time to discuss course-related topics from any locations that they could access a computer. Students were divided into five three-member small groups. Each group took turns to moderate one online seminar throughout the whole semester. Two researchers who specialize in instructional design worked on the coding of the data. The software program QSR NUD*IST was used for the coding of online transcripts. The unit of analysis was the sentence. A total of 5,015 text units (sentences) from the random sample transcripts were coded. The phi coefficient for intercoder reliability was .80.

Bale’s IPA was expanded from 12 categories into a total of 16 categories as shown in table 1. The original 12 categories can be divided into two main areas and four sub-groups. The two main areas are social-emotional contents and task-oriented contents. The social-emotional area consists of two groups: positive reactions and negative reactions. The task-oriented area consists of two groups that are attempted answers and questions. These areas represent the domain of interactions in small group discussions. The categories may not be comprehensive enough to describe the patterns of online interactions but the overall scheme does address most online interaction patterns. In his study on social-emotion interaction over computer-mediated communication networks, Rice (1987) expanded category 6 and 7 into two sub-categories. Category 6 on “gives orientation, information, repeats, clarifies, confirms” was divided into “gives personal information” (socioemotional) and “gives professional information” (task). Category 7 was divided into “asks for professional information” (task) and “asks for personal information” (socioemotional). For this study, category 6 and 7 were furthered divided into three sub-categories: “gives/asks topic-related information” (task), “gives/asks personal information” (socioemotional), “gives/asks technical information” (task). After the initial round of coding, the researcher found that the original category 6 and category 7 were too broad to reflect the actual online interaction patterns from the samples used for this study. Technical questions, topic-specific discussions, and personal information exchanges were frequently seen in the synchronous discussions and yet they were missing from the original IPA model. The researcher decided to include these new categories in order to better reflect the patterns of online interactions.

DISCUSSIONS
Coding online transcripts is a time-consuming process. In order to meet the submission deadline of the conference proceedings, only the data for the first research question is available for this report. The author will report the results of the data analysis for the rest of the research questions during the EDMEDIA2000 conference. The revised and expanded version of Bale’s IPA is shown in table 1. There were significant differences in online interactions between asynchronous and synchronous communication modes using analysis of variances. In terms of each individual category, the differences were significant in the following categories: category 4 (gives suggestion, \( p < .01 \)), category 5 (gives opinion, \( p < .01 \)), category 7.2 (asks topic-related information, \( p < .05 \)), category 7.3 (asks personal information, \( p = .01 \)), and category 11 (shows tension, \( p < .05 \)). In terms of the four sub-areas, i.e. positive reactions (\( p = .05 \)), negative reactions (\( p < .05 \)), attempted answers (\( p < .01 \)), and questions (\( p < .01 \)), the differences were significant. In terms of the two main areas of interaction, both social-emotional oriented contents (\( p < .05 \)) and task-oriented content (\( p = .01 \)) indicate the significant difference between the synchronous and asynchronous communication networks (table 2).

A closer look in category 4, 5, 7.2, 7.3, and 11 will provide a better understanding in the different interaction patterns between the two communication modes. First, there was virtually no interaction in category 4 (giving suggestion or direction) in asynchronous discussion mode. The mean sentence in category 4 is 0 for asynchronous discussion and 9.36 (SD: 7.49) for synchronous discussion. Category 9 (asking suggestions) is the counterpart of category 4. The mean sentence for category 9 is 0 too. It is understandable that in asynchronous communication most interactions focus on task-specific discussion and less on social-emotional oriented contents since there was a lack of immediacy. Most students either internalized their attempts to ask for suggestions or email the instructor for advice. The time lag in asynchronous mode may have prevented students from asking or providing suggestions. Interestingly, the mean sentence in category 5 (giving opinions) is 247.33 (SD: 129.1) for asynchronous mode and 62 (SD: 42.05) in synchronous mode. It is a clear indication that in asynchronous mode, participants devoted most of the discussion to task-related discussion and less on social-emotional interaction. Although, there was no interaction in giving/asking suggestion (category 4 & 9), the interaction in giving/asking opinion (category 5 & 8) was not scarce in asynchronous mode.

Whereas in the synchronous communication mode, student felt it more imperative to ask and receive instruction or direction in order to participate fully. Synchronous communication mode also made it easier to provide immediate feedback to information seekers. The high standard deviation in synchronous interaction also reveals the unequal participation in online discussion. Some students were active in engaging in discussions and some students reserved most of their opinions until they were asked to say something. The researcher observed that when the students were divided into three-member small groups, the participation was more even among members of a small group. In addition, there were more social-emotional oriented discussions in synchronous mode that is indicated in the difference in category 7.3 and 11. In synchronous mode, participants asked more personal questions and revealed their frustration or needs for help without hesitation. Personal questions such as one’s occupation, schooling history, professional training were given more “air time” in synchronous discussion.

= .48

In comparison of the two main areas in social-emotional oriented content and task-oriented content as shown in table 2, the mean sentence for social-emotional content in synchronous mode (68.18) is significantly higher than that in asynchronous mode (28.67). Task-oriented content consists of category 4, 5, 6.2, 6.3, 7.1, 7.2, 8, and 9. Social-emotional content consists of category 1, 2, 3, 6.1, 7.3, 10, 11, and 12. The breakdown in category 1, 2, and 3 shows that the mean sentence in synchronous mode (40.73, 5.36, 9.64 respectively) is much higher than those in asynchronous mode (7.5, 1.0, 6.5). In synchronous communication mode, there were more interactions in greeting, providing help, joking, and showing agreement. Whereas the mean sentence of task-oriented content in asynchronous mode (307.33) in significantly higher than that in synchronous mode (139.18). Student tended to give their opinions without asking other's opinions. It was done mostly through one-way communication in asynchronous discussion. The mean sentence of category 5 is significantly higher in asynchronous mode (247.33) than in synchronous mode (62.00). The interaction in task-oriented content indicated that in synchronous mode most of the discussions were two-way communication through the acts of providing and asking opinions on course-related subjects.

CONCLUSIONS

Studying online interaction can further the understanding of how people communicate over the networks. The main difference between this study and other studies is the focus on the comparison of synchronous and asynchronous communication networks. The preliminary findings highlight the significant differences in both social-emotional oriented interaction and task-oriented interaction between the two communication modes. These differences indicate the very different nature of online interaction in both modes. Educators may want to design activities that will ensure a focused online discussion without diverting to only interpersonal exchanges in synchronous communication mode. Whereas in asynchronous mode, activity design to enhance interpersonal connection may facilitate more two-way communication.

Further analysis on the effects of learner characteristics and learning tasks on interactions and the relationship between interaction and learning will be conducted in the near future. The research findings will contribute to the knowledge base of learner interaction in both synchronous and asynchronous networks. Educators, researchers, and instructional designers working on distance education can all make use of the knowledge to maximize the effectiveness of distance learning.

ACKNOWLEDGEMENTS

The author would like to acknowledge Xun Ge, Kelly Yamashiro, and Jenifer Winter for their assistance in coding the online transcripts and suggestions for this study. Also the author would like to thank Stephen Philion for his support and correction of this report.

Abstract: An Electronic Performance Support System (EPSS), featuring an extensive knowledge base of learning science and theory, is discussed and demonstrated. The EPSS is designed for use by instructional designer-developers of computer-mediated instruction (CMI) to help in the application of contemporary learning science in the design and development of instructional materials. The EPSS addresses the problems faced by practicing designer-developers in trying to keep up with the rapidly developing literature of learning science, and the heavy cognitive loading inherent in the CMI design and development process. Implemented as a HTML document, the EPSS features concise, prescriptive, practical guidelines in an operationalized checklist format. Hyperlinks lead to expanded checklists, explanations, examples, and Internet resources.

Introduction

Instructional designers and developers often do not apply contemporary learning science in the creation of computer-mediated instruction (CMI) (Brown 1997; Cooper 1997). Instead, they rely primarily on craft and heuristics for guidance (Clark & Estes 1998). The resulting materials, without the benefit of a science basis, are less effective than would otherwise be possible (Fletcher 1996; Chadwick 1997; Luterbach 1997; Radwan 1997; Winn 1997; Schmidt 1997).

Applying learning science and theory in CMI design and development is a challenge for several reasons. First, many designer-developers have neither formal training in learning science nor the time to learn and stay current with the rapidly developing learning science literature. Also, the application of learning science dramatically increases the cognitive loading of the design task; using heuristics is quicker and easier. Finally, popular authoring tools offer no support for the application of leaning science, nor are practical reference tools available (Brown 1997). The EPSS developed in this project is an attempt to help overcome some of these challenges.

To help designer-developers in applying learning science and theory to CMI materials, this project developed a prototype Electronic Performance Support System (EPSS) for use as a real-time reference tool. The EPSS provides cognitive support and makes available for real-time reference a large amount of learning science information in the form of practical guidelines. This type of cognitive support can enable non-experts to perform their work tasks in a manner approaching the level of expertise demonstrated by expert performers (Gerry 1995).

The underlying knowledge base for this project distills a broad sampling of information from cognitive constructivism science and theory, and uses neural science research data to support and embellish
the cognitive materials. Access is provided by three indexes: an instructional process index, a learning theory taxonomy index, and an alphabetical index. Knowledge base contents are expressed as short, prescriptive guidelines in an operationalized checklist format. Implemented in HTML, the EPSS features a rich network of hyperlinks to access increasingly detailed levels of information, explanations, and examples, including numerous links to Internet resources.

Project Background

The body of science and theory selected for use in this project includes cognitive science and learning theory and the neural sciences. The EPSS is based primarily on cognitive science literature but draws from the neural science literature to support and, in some cases, to extend the cognitively based information. The two fields of cognitive science and neurological science have historically developed separately, but today they are rapidly merging to provide a combined physical and conceptual understanding of how human senses, perception, memory, and recall work as a system for learning.

The rationale for using the cognitive and neural sciences as the basis for this project is as follows:

1. Cognitive constructionism was selected as the learning theory basis for this project because: (a) it comprises the greatest amount of contemporary work in progress, (b) it is based on scientifically designed experiments involving objective observation, controls, and repeatability, (c) it subsumes a great deal of work accomplished over the past 50 or 60 years, and (d) it is supportable from the perspectives of many contemporary sciences including the neural sciences (Collins & Smith 1998; Osherson & Lasnik 1990; Posner 1989; Gardner 1985).

2. The learning models and theories of John Anderson (Anderson & Lebiere 1998), Jerome van Merriënboer (1998), Robert Gagné (Gagné & Medsker 1996), and Ruth Clark (1998) are used to represent contemporary cognitive learning theory because: (a) they are presented in newly published literature and represent the most recent thinking on the subject, (b) they are firmly based in scientifically designed research, (c) collectively they address a broad range of considerations within the human learning domain, and (d) collectively they comprise a complementary set of perspectives ranging from a broad treatment of human cognition in John Anderson's theory to specific instructional design features in Ruth Clark's work.

3. Neural science data were added to the above because: (a) they provide insight into sensory and perceptual processing events that are not addressed in cognitive theory, (b) they tend to affirm and complement cognitive theory, and (c) they point the direction for future cognitive research.

EPSS Design Considerations

Guidelines in the EPSS are provided in abbreviated, checklist format with prescriptive statements pertaining directly to design and development decisions. For experienced and knowledgeable professionals, the top-level indexes will provide sufficient support to assure that important considerations are not overlooked. For users who need additional support second- and third-tier indexes, definitions, explanations, and additional background materials are available by hyperlink connectivity.

Several means are provided to access information in the knowledge base including a process oriented index, a learning theory taxonomy index, and an alphabetical index. The process-oriented index is based on Gagné's 9 events of instruction (Gagné & Medsker, 1998) with one additional event added for this project. Each of the events is developed by using material from several sources. As an example, the first event, "Gain Learner's Attention," lists 5 categories of attention-gaining measures taken from both cognitive materials, especially Clark (1998), and neural data (Gazzaniga, Ivry, & Mangun 1998). The second event, "State the Learning Objectives," combines Mager's objective oriented instruction approach (Mager 1984) with Gagné's knowledge types (Gagné & Medsker, 1998) and Bloom's taxonomy of knowledge levels (Bloom, 1989). The third event, "Help the Learner to Recall (and Use) Prior Knowledge," is based largely on Gagné's material as supplemented by information from Ruth Clark's work on how to encourage recall and also neural data on why it is important to do so. The forth event, "Present the Instructional Content," draws heavily on both Gagné and Clark, but includes working memory data (Chandler & Sweller 1991; Mousavi, Low & Sweller 1995; Cooper 1997), and information from neural science as well. The remaining events, provide learning guidance, elicit performance, assess performance,
reinforce retention, and reinforce transfer to the workplace, each draw on Gagné and Clark as supplemented by the other sources mentioned.

The learning theory taxonomy index is based in part on the sequence of events that occurs in processing sensory inputs into learned information: sensing and perceiving, working memory (WM), long term memory (LTM), and transfer to the workplace. Additional categories include the following: types and levels of knowledge, supporting cognitive processes, and individual learner differences.

Implementation of the EPSS

The EPSS knowledge base is developed in HTML code to facilitate the use of many useful features available in this format such as hyperlinking. Also, the HTML format is usable in any standard web browser, with which all designer-developers are well familiar. Using a hyperlink format, additional explanatory information is readily available for designer-developers who need increased levels of support. Second- and third-tier data present expanded checklists and discussions including explanations and examples to support the checklists. Embedded in the expanded discussion are hyperlinks to sources of expanded presentations of the research and theory, including links to sources on the Internet when appropriate. This multi-level approach takes after Gerry's description of an effective EPSS (1995).

Example materials from the EPSS

The following excerpt from the instructional process index shows how hyperlinks are used to access increasingly detailed levels of guideline checklists. The arrow indicates the link selected by a user to access the next index list shown. The top-level index is based on Gagné's nine instructional events, with the addition of a tenth step borrowed from Clark (1998), to reinforce the transfer new knowledge to the workplace.

- Instructional Process Index
  - Gain Learner's Attention
    - Change stimuli suddenly - to gain involuntary sensory attention.  
  - State Learning Objectives
  - Help Learner to Recall (and Use) Prior Knowledge
  - Present Instructional Content
  - Provide Learning Guidance
  - Elicit Performance
  - Provide Feedback
  - Assess Performance
  - Reinforce Retention
  - Reinforce Transfer to the Workplace

The second-tier index, below, is hyperlinked from "Gain Learner's Attention," above, and expands on the concept by providing several specific ways to gain attention. Each of the methods listed should be considered.

- Gain Learner's Attention
  - Change stimuli suddenly - to gain involuntary sensory attention.  
  - Change topic, perspective, or approach - to gain voluntary cognitive attention.
  - Present the logical importance of the topic - to gain intellectual attention.
  - Present an emotionally impactful appeal - to gain motivated attention.
  - Regain and refocus the learner's attention at each instructional step.

A third-tier index in linked from "Change stimuli suddenly," above, and expands further on the concept by providing some specific ideas for implementing the guideline.

- Change stimulus suddenly - to gain involuntary sensory attention.
  - Change the screen contents or appearance where attention should be focused.
  - Momentarily flash a symbol, picture, word, or other visual stimulus.
• Use a momentary sound effect as a signal for the learner to be observant.
• Use a pointer that moves to, or flashes near, the item that should be attended to.
• Use stimulus changes to draw attention to content, not distract away from it.
• Stimulus changes that support content can increase continuity but do not necessarily increase learning.

An additional level of detail, in the form of explanations and examples, is available for many sections, and hyperlinks to Internet resources are provided for many topics as well.

Usability Evaluation and Project Conclusions

The EPSS prototype was field tested by a number of graduate students in instructional technology and professional instructional designer-developers of CMI materials. They responded to the following questions, which are patterned after Gloria Gerry's criteria for EPSS design (Gerry 1995). The purpose of the evaluation was to assess the perceived usefulness and usability of the EPSS tool:

• Aids ID task goal establishment?
• Structures work process and progression through tasks?
• Contains embedded knowledge in the interface and support resources?
• Uses language that capitalizes on users' prior learning?
• Is compatible with the natural ID work situation?
• Provides alternative views of the document interface and resources?
• Provides layers to accommodate various user knowledge levels?
• Provides access to underlying logic?
• Provides alternative knowledge search and navigation mechanisms?
• Allows customization?
• Provides obvious options, next steps, and resources?
• Employs consistent use of visual conventions, language, visual navigation, and other system behavior?

The usability and usefulness of the prototype EPSS was rated at about 80% - a mean rating of 4 on a Likert scale of 5 possible points. This result is interpreted as representing fairly strong support for this EPSS concept, especially since it was tested only in a prototype configuration. Overall conclusions from the project are as follows: (1) learning science literature contains a large amount of practical, usable data, (2) such data can be expressed in abbreviated, operationalized terms, and (3) field testing showed the EPSS document to be both useful and useable in presenting learning science knowledge for CMI designer-developers to use.

Future Directions

The current EPSS project provides a conceptual starting point for future development in several directions. Three principle areas being considered for future development are: (1) inclusion of additional relevant learning science information, (2) addition of material on accommodating to individual learner's capabilities and needs, and (3) providing automated links to instructional authoring tools.

The current project knowledge base was developed on a framework developed from cognitive learning theory literature. This procedure tended to focus the literature search on subjects addressed in this literature. Late in the project, however, neural science data pointed to the important effects of stress and emotion on the learning process that are not developed in the cognitive learning materials. Stress and emotion appear to be of such importance to the learning process that their inclusion is seen as essential in the future development of this EPSS.

Additionally, the neurological basis for individual differences among learners was explored in sufficient depth to understand clearly that the use of computer capabilities to make individualized accommodations is the way for CMI to bring a real revolution in training and education. Differences among learners are not small or subtle, they are large and have a significant impact on how each person
processes information. The inclusion of data on accommodating to individual learners will be an important addition to the present project.

Finally, this EPSS will achieve a great deal of additional usefulness when it is linked with popular instructional design authoring applications so that the learning science embodied in its knowledge base can more easily be included in the development of CMI materials of the future.

References

Abstract: The integration of Information technologies into the educational system has spurred the creation of new courses to effectively train teachers. Hypermedia environments are becoming essential tools for the enrichment of pedagogical values in the teaching area. WWW technology has made using these environments much easier since such hypermedia resources can be accessed via the Internet. Hypermedia environments, however, do not truly meet the needs of the teachers: Often, they are too far removed from teachers' true concerns and needs with regards to the integration of educational technologies. Furthermore, several MILE (Multimedia Interactive Learning Environments) designers are placing the focusing on the development of sophisticated functionalities which seldom make tasks easy for the user. This paper introduces a system called CINEMA which is committed to the design and integration of new multimedia learning environments. This system is ideally suited to the needs of teachers who are eager to know what to do with multimedia and how to develop their abilities using multimedia.

1. Introduction

Education professionals are called upon to integrate multimedia in their courses, thereby renewing the teaching/learning process (Tardif, 1998) by designing multimedia teaching materials. They are confronted with a teaching process that increasingly requires the use of Information technologies. Teachers are caught in an technico-educational paradox (IsaBelle, 1999): the general population demands that the educational community offer training which meets the needs of the today's society; yet, the majority of teachers receive little, if any, training. Much of the time, what little training they do get hardly emphasizes the importance of information and communication technologies in the classroom. While some interactive learning environments for distance education are available, there are relatively few teachers who use them. First and foremost, these environments present contents that are too far removed from teachers'actual concerns and needs with regards to the integration of Information technologies. Secondly, although the majority of methods used to design Multimedia Interactive Learning Environments (MILEs) involve more explicit reflections of the learning process (Rouet and de la Passardiere, 1998), several designers still emphasize the development of sophisticated functionalities which often do not facilitate the user's task (Nkambou, IsaBelle and Frasson, 1998; Barthe, 1995). This paper introduces CINEMA, a unique system for the design and integration of new multimedia learning environments, which is actually tailored to the real needs of teachers who are eager to know what to do with multimedia and how to develop their abilities.

2. Elements for effective learning

In order to support effective learning, the person learning must feel involved through:
- general knowledge and know-how (the cognitive dimension), (Giordan and de Vecchi, 1987)
- motivation (the emotional dimension)
- a relationship with his peers and/or the teacher, (Aumont and Mesnier, 1992).

---

1 CINEMA: Conception et Implantation de Nouveaux Environnements Multimédias d'Apprentissage.
Many MILE designers neglect the pedagogical dimension when developing their systems. The learning process must allow the user to work in a constructive environment. In fact, this environment must promote active, constructive, cooperative, authentic and intentional learning (Jonassen and al., 1999).

3. Designer Traps

The ergonomics of interfaces deal primarily with facilitating navigation as well as addressing the effects of the cognitive load (Rouet and Tricot, 1995; Dufresne, 1997). However, there are some traps which await MILE designers. The Technological trap provides the user with powerful, fast and visually attractive MILEs that often totally ignore the pedagogical aspects. The Ergonomic trap places the emphasis on the ergonomic aspects without taking into account the cognitive values of renewed pedagogy which result from the constructivism of Piaget (Choplin, Galisson and Lemarchand, 1998). On one hand, ergonomic experts emphasize the user in order to facilitate the system's use and decrease the complexity of the user's task. On the other, pedagogues may design tools that encourage the ideas of rupture, deconstruction, or dissonance, in order to facilitate the development of the learner's intellectual abilities (Giordan, 1996).

Therefore, ergonomic experts try, as much as possible, simplify and clarify the use of computer software. Didactic experts, on the other hand, prefer to create more difficulty, which is necessary to any learning (Choplin, Galisson and Lemarchand, 1998).

In any MILEs design, the task is complex because the designers must strive to balance the "user side" with the "learning side" of any subject. Can there truly be a system which succeeds in finding the perfect balance between the ergonomic and didactic entities while still granting important emphasis to each side of a subject?

4. The CINEMA system

The CINEMA system was conceived by a team made up of an educator, a designer and a computer scientist. Collectively, they have built, deconstructed and rebuilt a model (Gregori, 1999) of an effective interface, a relevant content, even a content presentation corresponding to the essential dimensions in a learning process that would allow the creation of pedagogical multimedia material. The CINEMA program is available on the Internet. It is easy to use yet still allows sufficient questioning during information processing. The primary objective of the site is to make it possible for users to create pedagogical material, in most cases an educational Web page.

CINEMA provides special attention to the application of constructivism where user commits him/herself to a process of "Learning how to learn" (Bordeleau, 1994). The system is made up of six modules: Learning, Storyboarding, Ergonomics, Production, System and Implantation (see figure 1). The first five modules are specific to the creation of multimedia and interactive learning materials. The sixth module details how to integrate this environment in a school context. In fact, it is important to plan for the integration of the developed environment early on in the design phase. Without addressing this concern, there is the risk of obtaining a MILE too far removed from the school needs, and therefore difficult to integrate into the school context (Depover and Strebele, 1996).

![Figure 1: A view of the CINEMA system](image-url)
4.1. Educational content
In each module, the user is presented with the declarative and procedural knowledge involved. This is done through objectives and many interactive exercises provided for the learner.

Learning module
In this module (figure 2), the teaching/learning methods, the styles and the learner profile are detailed. The module also includes information about computer applications which promote the development of multiple intelligence (Forcier, 1999, Gardner, 1997).

Storyboarding module
In this module, the user discovers the logic which sustains the elaboration of a storyboard, adapted to the needs of "future designers", for the creation of a Web page. Specific guidelines, designed to help schools create their own web pages, are also included in this module.

Ergonomic module
This section is specifically devoted to understanding the human-machine interaction. Detailed theories about human information processing are provided. Ergonomic principles and the eight golden rules of interface design, according to Schneiderman (1998), are explained. These help future teacher-designers to create better Web pages as well as evaluate existing systems.

Production module
This module covers the basic elements of an Internet Site, such as tables, frames, etc. as well as ways to produce them. The basic and advanced feature of an authoring tool (Dreamweaver 3.0) which facilitates web-page creation and site organization is also covered.

System module
The System module introduces two interactive surveys to evaluate educational Web sites and CD-ROMs. The first questionnaire (IsaBelle and Zucchiati 1999) is made up of 60 criteria for evaluating the pedagogical aspects of a MILE. The second consists of 60 criteria, which allow the evaluation of interfaces on an ergonomic level. For briefer
evaluations of educational and ergonomic aspects, two "express" surveys of 15 criteria each are also available. Given the number of CD-ROMs and educational Web sites already on the market, there is a great demand for evaluation criteria within the teaching community as well as a need for systems already assessed by professionals. The System module of CINEMA allow users to evaluate educational CD-ROMs and web-sites using an interactive form. It is also possible for users to share the results of their evaluation with others.

**Implantation module**
This module outlines four conditions which ensure the quality of educational technologies:
1. Changing the beliefs and the attitudes of the whole educational community;
2. Incorporating technology into the pedagogical structure;
3. Supporting teachers and encouraging collaboration between educators;
4. Transforming teachers into agents for "change".

Beyond showing teachers a way to integrate educational technologies into the practice of renewed learning, this module outlines how to use the CINEMA system, further helping to enhance their multimedia knowledge.

The CINEMA system also offers the user more navigational freedom. Although the program's built-in suggests a specific browsing and reading order, the user is free to start with the module of their choice. By offering this freedom, CINEMA's creators wanted to allow the user to question him/herself about their learning process (Choplin, Galisson and Lemarchand, 1998).

4.2. Ergonomic aspects
The CINEMA system was designed to be easy to use, freeing the user to concentrate on content. Each icon was carefully selected for its significance, in order to represent all possible types of activities. For example, a hand giving a "thumbs up" indicates the presence of a positive example. The "muscular" arm symbolizes an exercise which must be performed by the learner.

All examples, exercises and tests are opened in a new, smaller window in order to communicate their context to the learner. To help the user navigate, the title of the current module is displayed above the work area while the menu on the left indicates sub-menus which have already been visited. Each module is also colour-coded with a specific colour for easier identification.

4.3. Collaborative learning: communication issues
Tardif (1998) addresses the importance of vertical and horizontal communication to support learning. In distance education, there are significant communication elements which are considered crucial to maintaining a students' motivation and encouraging them in their learning process. According to a study by Moore and Kearsley (1996), as many as 30% to 50% of all students who start a distance education course drop out before finishing it. In order to increase the students' success ratio, the study recommends: establishing a learning community between the students and the instructor, as well as providing teacher-feedback to the students. This learning community includes collaborative training and socio-affective exchanges between students. Studies (Bertrand, 1996) show that the socio-affective aspects of the student are very important.

Studies further suggest that collaboration between experts and other learners facilitates the acquisition of skills and knowledge. A Vygotsian perspective states that it is important for less skilled people to learn from an expert within the zone of proximal development (ZPD). Through this process, the learner gradually builds their own skills and knowledge with help from someone of greater ability (Vygotsky, 1978).

Thus CINEMA provides a complete and relevant discussion forum (Figure 3). This includes three distinct boards (contents, technique and café) allowing the learner to exchange according to the contents and technical aspects of a course, as well as according to more personal aspects (café).
4.4. Prototype Evaluation

It often seems that many systems are introduced without being fully evaluated and yet this stage remains as significant as the design phase itself. Espéret (1998) indicated the importance of generalizing evaluation and experimentation methods. Within the framework of this project, and in order to ensure a use which truly meets the needs of those concerned, four types of evaluation were proposed. These would be conducted by various groups: future teachers, students registered in a course on ergonomics, teachers studying educational technology and practicing teachers who want to create educational multimedia environments.

Right now, the evaluation by future teachers has taken place at the University of Moncton and at the University of Montreal. They specifically revised the contents as well as the interface. They also proposed new interactive examples and exercises. Furthermore, more than a hundred students registered in the "Interface et multimedia" course at the University of Sherbrooke are currently evaluating the system. This group, in particular, will evaluate the ergonomic aspects of the CINEMA using a heuristic evaluation technique.

As part of the "Training and the Information and Communication Technology" course, offered at the University of Moncton during the fall of 1999, teachers used the CINEMA system and had to share their comments and evaluations, especially concerning its pedagogical aspects (contents, examples, exercises, pedagogical strategies...). By the end of the course, each "teacher in training" involved had also created an educational Web page.

Finally, within the context of a research project relating to distance education and Web page creation, teachers at an elementary school showed great interest in the use of this system to develop their school and/or classroom Web sites. This use of the CINEMA program by the very users it targets will gather invaluable data concerning CINEMA's unique, symbiotic balance between the didactic and the ergonomic in the suggested learning environment.

5. Conclusion

The CINEMA system offers a unique blend of solid content and optimized functionalities ideally suited to the real needs of teachers, especially when it comes to information technology. While everyone can benefit this comprehensive program, regardless of their profession, the CINEMA system addresses the important need to adequately prepare and empower educators, involving them in the process of change to integrate Information technologies into the school system. It is hoped that other new designers of MILEs will be as eager to offer users such versatile contents and optimized functionalities.

6. References

Abstract: The paper presents a prototype that manages the reading paths in a set of multimedia documents. It allows to create the path while the user navigates not only on Web pages, but also on local documents or documents not necessarily on the Web. The system stores the references of the information fragments, allowing the user to save the created path, to review it, to replay the sequence and finally to distribute the path to students, thus avoiding (or limiting) the disorientation phenomenon. The prototype also supplies some simple but powerful methods for manipulating the paths and creating new ones. These primitives consist of a series of basic operations on paths, like the concatenation of two paths, the intersection of a series of paths in order to find common nodes, the difference of two paths and so on.

1. Introduction

Hypertext systems have been for long time the only software tools to produce non-linear organization of information chunks. Nowadays, we have a plethora of software tools that can produce hypermedia documents (word processors, presentation tools, graphic tools etc.), and we have a standard language to produce hypermedia and put them on the Web, i.e., HTML. The problem is that, generally, the integration of these different hypermedia documents into one unified hypermedia is difficult. Building a meta-hypertext of many different documents coming from different software sources is a task where technical skills are necessary. A good example of this difficulty is the relation between a hypertext system and another software data management system used to handle geo-referenced data, i.e., a Geographic Information System (GIS)[Colazzo et al. 97]. At the time of our experiments in this field, we had to choose the option of extending the functions of a commercially available hypertext system by adding primitives that handle maps, rather than adding hypertext functions to a commercially available GIS. In fact, GIS capabilities of performing hypertext functions have little similarity with the current standard of hypermedia systems.

Besides the problem of integrating information chunks coming from different sources, the organization of these chunks in different reading paths (as we usually do while building hypertexts) does not mean necessarily to cancel the linearity of the learning process. In most hypertexts, the reader does not proceed randomly in the navigation. The author guides the navigation by proposing some standard "routes" of comprehension. The paths built in this way are often the only reasonable way of navigation for the user, and can not be changed by him/her. However, these paths could not satisfy all the user needs, and in this case s/he should be able to create her/his own path, for example by taking information chunks from different hypermedia and by combining them in a new personalized path. The paper presents a prototype that allows the reader to build custom paths on hypermedia documents derived from different sources, and to review, cancel, modify and aggregate these paths by using some specialized primitives. Every path connects a potentially large number of information chunks deriving from different development tools, like word processors, HTML pages, Postscript or PDF files, presentation slides, technical sketches etc. The prototype creates generalized lists of chunks coming from these different sources, by allowing a virtual "sequence" among documents technically different but logically connected. This could be very useful in educational environments where the only availability of HTML pages for creating hypermedia limits the creativity of the author.

1.1 Relevant works

Hypertext paths, also called tours, are a concept as old as hypertext itself. Bush [Bush, 45] incorporated in Memex the paths to provide a personal means for organizing found information and to provide a means to communicate that information to other persons. Generally, the paths implemented to help to solve two major problem, namely "user disorientation" in hypertext networks and the additional "cognitive overhead" needed to create, manage and choose among links [Conklin, 87]. Paths appear in many implemented systems: for example, Textnet paths [Trigg et al., 86], HyperCard scripts [Goodman, 87], Guided tours in NoteCards [Halasaz et al., 87], Hammond & Allinson's guided tours [Hammond et al., 88], Petri nets in aTrellis [Stotts et al., 88], Scripted Documents [Zellweger, 89]. There have been several different implementations of paths in hypertext systems: the history trail, which automatically logs every location the reader visits, and the guided tour, which is a predetermined set of locations that can be stored and visited over and over, in the same order.
[Mylonas et al., 90]. Besides, generally, the hypertext systems are specialized mechanism built for their own customized environments: the published accounts suggest that they were intended for use by a sophisticated audience of hypertext authors and readers. In last time, the concept of hypertext paths is applied to the WWW. For example the Walden’s Paths [Furuta, 97]: the reason is the heterogeneity of the web and the desirability of supporting the teacher-student relationship. Walden’s Paths is designed to enable teachers to make use of materials available via Internet by creating directed paths over the World-Wide Web. The system consists of two main components: the Path Authoring and the Path Server. The first enables the teacher to create, modify, validate and reuse paths: especially, it supports the process of locating sites with relevant information, ordering and annotating those pages to form the path. The path server is the implementation means through which the students navigate the path: when it receives a request, it determines the path and page number of the request.

2. Different chunks from different tools

Our work starts from a simple consideration concerning the current state of the process of distributing educational material from producers (teachers) to consumers (students). The WWW has given a strong impetus to the concept of distance learning, but in part it has also distorted its meaning and limited the use of multimedia and technical documents, i.e., what is not easily adaptable to an HTML file or an GIF/JPEG image. In addition, it is difficult to recreate a full interaction with the user in Web pages: for example, a multimedia package is surely more suitable than a Java applet to build an animation simulating an industrial automation process. The idea presented here is to leave the educational material in the “best suited” format, i.e., the original format, having a meta-tool that manages the hypertext chunks by launching the specific viewer when the reader needs it. Moreover, some attributes can be assigned to the elements of these paths for subsequent retrieval, and a series of primitives can be performed of these lists of references. Here follow two examples that show how useful is to build generalized paths on different sources of information chunks. The considerations here explained are extensible to other fields, though both situations have the educational material as common background.

2.1 A hypermedia system used to project slides

The construction of a slide for a lecture is a time-consuming operation, and it is advisable to design slides so that they can be reused several times. A collection of slides to expound a set of arguments has an intrinsically linear structure: indeed, the arguments can only be presented in a temporally linear sequence. There is therefore close connection between the sequence of the arguments discussed and the fragments used during the lesson. However, it is obvious that not all the lessons have the same audience or the same communicative purpose. Moreover, an argument can be treated in different ways according to the level of the students’ knowledge. It follows that, even if the structure of the navigation among the slides is linear, the teacher must reorganize the slides with every new lesson. In principle, the lecturer could duplicate slides to construct a new sequence, but this work takes a certain amount of time and leads to the proliferation of copies of the same slide. If changes are made to one slide, these changes must be reproduced in all the lessons that use the modified slide. In some cases, the lecturer must make an impromptu change to his/her exposition in order to deal with an unexpected event during the lecture. The only thing that the lecturer can do is try to find the slides relating to the topic and navigate through the directories of the file system opening different collections of slides. If the paths among the slides are managed as objects endowed with their own behaviors and methods, it is no longer necessary to duplicate the slides: all that is required is to create several paths through the same slides and give different labels to them.

2.2. Reading paths in a CD for teaching purposes

Every path in a hypertext inevitably interweaves with many others. As a consequence, the same fragment may belong to several reading paths organized into difference sequences. The creation of reading paths is a crucial stage in the design of a hypertext. The designer must place him/herself in the shoes of the future user and create links among the various fragments according to a unitary and systematic logic, which prevents reader disorientation. In this way, as the reader follows a route, s/he must be able to grasp the meaning of that particular sequence.

The creation of personalized paths among hypermedia documents has been the subject of a joint project undertaken by the Department of Computer and Management Sciences of the University of Trento and IPRASE of Trento (an educational research center). The outcome of the project is a CD-ROM on medieval history, with particular reference to the Trentino area of Italy.

However, a teacher may want to deal with the material from a different point of view: for example, the teacher may decide to present a sequence of frescoes to be found in various medieval castles in the area, thus extracting this information from the medieval history CD. The teacher may also make it possible for the
students to upset this sequence by adding further information that they believe relevant to the topic. Moreover, the teacher may have another hypertext available, which presents, for example, a collection of medieval jewelry.

Another example is taken from a CD-ROM with educational content regarding botany and biology (see fig. 2). The hypermedia includes the navigation tool with some extensions and peculiarities. In particular:

- It is possible to recall the navigator while selecting a path, instead of starting the navigation with the tool;
- From a simple integration the tool has become the main navigation tool of the CD. The opera contains a huge number of different paths, which can be modified, added, deleted because they are stored on the disc. Moreover, the user can build new paths based on his/her own needs.
- The tool allows the creation of paths that include documents from tools other than the original (Asymetrix Toolbook), for example integrating Word documents with Toolbook hypermedia and HTML pages.

3. The prototype

The prototype is an application that enables the user, or group of users, to handle abstract objects called Paths. A path is defined as a class of objects called References. A Reference has the following attributes:

- **Application**: carries the name of the application that has generated the file. It may be absent in cases when the operating system is able to recognize the file from its extension, as happens in MS Windows;
- **File location**: gives the path which identifies the position of a file in the file system;
- **File name**: gives the name of the file with its extension;
- **relative address of the node**: fragment identifier allowing to position on a specific part of a document;
- **script**: a piece of code in the specific scripting language of the application for precise positioning at a certain fragment/page/node etc. of the document;
- **Comment**: optional, helps user during navigation by appearing in the title bar of the navigation tool.
- **Keyword 1, 2, 3**: descriptive fields in which the user can insert a keyword for subsequent search. This is useful, for example, when information chunks have a common attribute that characterizes them.

The references in a path are arranged into an order established by the creator of that particular path. As well as its ordered list of references, every path is given a number of attributes when it is first created (figure 3):

- **Title**: one for each path;
- **Author**: the name of the creator of the path;
- **Type of author**: student, teacher,
The application, which permits the creation and management of paths, is based on a stratified architecture comprising two distinct but linked components. The actions performed by the user at the FrontEnd are translated into actions based on data that constitute the BackEnd of the application.

3.1. Creating a path

Once activated in path creation mode, the prototype works in background and presents itself as an icon. Whenever the user decides that a particular file or node is of interest to the path that s/he wants to create, s/he clicks on the prototype’s icon. The prototype transparently stores the data relative to the information node chosen by the user in the BackEnd. We are working on some extensions of the creation step: in fact, it is possible to imagine the paths as being constructed by an automatic process (experiments have already been conducted). For example, in products constructed with multimedia authoring systems, it is possible to activate a process of automatic creation based on identification of objects endowed with specific properties. The process analyzes all the information nodes included in the list of inputs retrieved from the BackEnd and creates an order according to the values of the property selected. It finally translates the order obtained into a sequence of references.

3.2. Changing and combining paths

The prototype allows the user to inspect the paths produced and to act in two distinct ways: alter the references of individual paths or combine paths to produce new ones. In the former case, it is possible to: 1) change the characteristics of the path; 2) alter the sequence of links among the references; 3) remove certain references; 4) remove the path itself; 5) insert a new reference at an arbitrary point in the sequence.

In the latter case, composition functions can be applied to the references constituting two paths. These are automatic processes which, when applied to two or more paths, produce a further one (figure 4). The prototype in its current form comprises the following composition functions:

1. **Intersection of two paths A and B**: a path formed from references included in both A and B;
2. **Union of two paths A and B**: this is a path formed from all the references belonging to at least one of the paths A and B; duplicated references are eliminated;
3. **Difference of two paths A and B**: (in the order given) path A references which are not in B;
4. **Concatenation of two paths A and B**: a path with all the references in A followed by all the references in B;
5. **Specific nodes from two paths A and B**: a path consisting of nodes which are not shared by A and B, i.e., they are present in one of the two paths but not in both of them.

It is similarly possible to define the intersection, union, concatenation, etc. of more than two paths.

---

**Figure 3**: the attributes of a path

**Figure 4**: example of combining two paths
3.3. Following a path
When the prototype is used to follow an already-existing path, the reader works with an interface like the one in Fig. 5, reduced to the minimum so that it is as unobtrusive as possible. There are six buttons: one to close the program, four to navigate through the paths created, and one to consult the list of references that are in the path. After selecting the desired path, the reader uses the buttons to view the following pages: First reference: shows the first path reference; Next reference: shows the reference following the current one; Previous reference: shows the reference previous to the current one; Last reference: shows the last reference in the path; List references: shows a listbox with the references in the current paths and the current reference marked. This helps the user to understand where the path will lead next (figure 6). The reader can change path at any time, by only choosing another path among those handled by the prototype. The reader may also explore paths starting from a specific location. S/he can obtain a list of all paths that traverse the current reference. For example, if the reader is at reference X (Figure 7), s/he can obtain a list of all possible paths which pass through that reference and continue to navigate by changing direction and following one of the alternative paths: for example, paths 1, 2 or 3.

![Figure 5. Main window of the prototype](image1)

![Figure 6. The list of nodes available with the current node highlighted](image2)

![Figure 7. Paths intersecting a reference X](image3)

![Figure 8: Architecture of the distributed version of the navigation tool](image4)

4. Extending the prototype: sharing paths among users
We are currently testing another extension of the prototype that regards the distribution of the created paths to a centralized database accessible through the Internet. This has some evident advantages:
- Teachers/students that are not currently on their computer can use the stored path wherever they are taking the lesson, thus allowing distributing not the material, but the sequence that constitutes the lesson. Under this perspective, we can think to the prototype as a "sequencer" of hypermedia
- the powerful primitives of the system can be applied not only to local paths, but also to educational paths that a community of teachers has decided to share. This could be interesting, for example, for a multinational corporate, where huge amounts of hypermedia presentations are created. Single teachers use them but share not only the slides, but also the sequence among them. It could be, for example, very useful to provide an "intersection" primitive on all path created for a presentation of a new product, in order to verify what the different salespersons have presented.
- The use of a centralized database as back-end (figure 8) for storing the paths has evident advantages of administration regarding the references contained in the corpus. We can imagine an institution / company that administer its educational material in a better way by providing a centralized administration not only of the paths but also of the physical documents and slides composing the educational material. On the market there are some products that provide centralized administration of educational material, but in terms of costs and complexity of the system we are moving towards a far simpler solution.
The architecture of the system is based on a proprietary though simple communication protocol that allows two remote instances of the prototype to exchange commands and data regarding the paths required by the user. The protocol is based on Tcp/ip, thus allowing the connection among computers connected to the Internet, but does not imply the sophisticated structure typical of client/server approaches, like DCOM or CORBA. The application is simply the same, it is only activated in server mode or client mode (Figure 9).

In the first case, it does not navigate by itself, but receives from the Internet requests of executing primitives on the database stored on the server computer. The content of the packets exchanged among the clients and the server is relatively simple and small, and so there are few issues regarding network performance.

### 5. Conclusions and future developments

We presented a software tool that abstracts from the software that manages digitized information. The tool integrates the path that an author creates on these different chunks of information, allowing connecting pieces of information coming from different applications in a hypertextual structure. The prototype manages these paths allowing: a) the transportability of the path without encapsulating the single chunks of information; b) the abstraction from the application that creates the document, thus allowing the integration of different types of digitized information in an unique hypertext; c) the management of multiple paths, thus sharing different hypertexts from different authors; d) some elementary operation on the paths, like intersection, union etc.

The prototype has been successfully used in some informative and educational CD-ROMs and has other undergoing projects in which it will be used as the main navigation mechanism. The current development is oriented to the integration of the prototype with a mechanism of remote archiving of the paths through Internet.

We believe that our prototype, even though it is experimental and simple in its approach, prompts reassessment of the role of 'rationalized sequences' in computer-mediated teaching. Good feedback from users who have consulted the CDs produced with the navigator demonstrates their natural but documentable 'familiarity' with the concept of sequence. It also demonstrates that teaching materials are more easily assimilated if they can be consulted: (A) along a path created by an author; (B) where the path corresponds exactly with the metaphor of sequence and the elementary navigation operations (first, last, next, previous); (C) it is possible, with the sufficient knowledge, to operate simultaneously on paths viewed as sets of links. Evaluation of these features with a complete benchmarking system is indispensable for clearer understanding of the issues involved in computer-supported learning.

### Acknowledgment

We would like to thank Romano Nesler for his helpful comments and valuable discussion on the implementing of the prototype.

The Design, Assessment, And Implementation of a Web-Based Course

Leon L. Combs, Ph.D.
Department of Chemistry
Kennesaw State University
Kennesaw, GA
Lcombs@kennesaw.edu

Abstract: The design of a web-based course is discussed based upon considerations of content, pedagogy, learning styles, and assessment. The learning styles are examined as primary considerations and indeed dictate needed elements in a web-based course. Assessment is also considered in the initial planning of such a course. These design elements are discussed with particular web elements given for each design element. Further illustration of the design procedure will be demonstrated by an application to a freshman chemistry course. All considerations may be used both for a web-enhanced course and a course taught totally online.

INTRODUCTION

To design a course for optimum impact, the following should be simultaneously considered: the course material; the students' learning styles; pedagogy, which includes methodologies of presentation; and assessment. These items then need to be considered as itemized below.

- Regarding course material, experienced educators know the needs of the customer regarding the content of the courses. The students (learners) need courses that are current and that are relevant to their career choices. Because most faculty members keep up with their disciplines and their relevance to other disciplines, they generally know what is needed in the lower-division courses and in the upper-division courses. Course content is not constant over the years, and all educators must work to keep up with subject advances. However, the area of course content is usually the most dependable part of course design. But read below for web implementation.

- Learning styles often vary significantly among a typical group of freshman students. However, most faculty members often omit consideration of the students' approach to the course. The teacher often will teach the course based upon his/her learning style and the way that he/she was taught. Certainly most faculty members usually don't plan their course presentations based upon the myriad learning styles of their students. Many students leave science partly because of our poor planning regarding these learning styles (1,2). This area is usually the weakest component of course design.

- Pedagogy appropriate for each particular course must drive the development of the course (3). Although course content may be well known, and the relevance of the subject matter to many disciplines well known, often not enough thought is given to the pedagogy required for the best development of student learning. Methods of effective presentation can vary widely among disciplines. The white board is still an excellent tool for presentation, but now we also have the smart board. The importance of small group work is also well known now. Student presentations are also an important component of educational methodology. Faculty members now have a wide choice of technology suitable for enhancing their teaching of the courses. Modern technology can considerably enhance their applications of good pedagogy. So we must consider how to incorporate these techniques into a web-based course.

- Course assessment must also be considered at the development stage of a course - note in the title that assessment is listed before implementation. Many books have been written about course assessment (4). At the beginning of the course, it is very important to know the beginning level of student understanding of the subject. It is also important that all of the students know their own learning styles, and the best way to approach learning based upon their individual learning styles. The student and professor must also understand their personality profiles to aid in a more proficient learning experience. Assessment will involve studies of content knowledge, before and after taking the course; learning styles; personality profiles; and environment.
WEB SITE CONSIDERATIONS

When we begin our course development/design considering the course material that needs to be mastered, pedagogy, the possible learning styles of our students, and assessment, a new paradigm of course design develops. What follows can be used for either on-campus or on-line courses. It can also be applied to any other area of learning (government, industry, etc).

We will assume that the gross course content is not an issue. For the first-year teaching faculty member, putting together the first set of course material can be quite a daunting task. Also every year the faculty member must fight against the tendency to use the "yellow notes" from previous years. It is very important for all faculty to keep their course content current, but we will assume that such a consideration is a given. However, putting the material on the web presents some additional considerations. We want to make the best use of the web medium to maximize the constructivist possibilities (5). There will be some elements of objectivism in the presentation because some material has to be memorized so that deeper understanding can be based upon that memorized base. This discussion is now overlapping between course content and pedagogy, but such an overlap is an essential part of the design process.

The pedagogy and the method of presentation have to be reconsidered every year by the faculty member. New technology for use by the educator is being developed every month. A good example of the use of modern technology is in the development of a web component to a course. The amount of web involvement for a course can vary considerably from a very minimal involvement of putting a course syllabus on the web to the considerable effort of developing a web-based course. Web-based courses are courses that have a major component of all aspects of the course on the web. These web-based courses can be used as course supplements for lectures or for totally on-line courses. Because they can be used in both venues, the development time is optimized for its effectiveness. As stated in the preceding paragraph, we want to maximize the constructivism that can occur based upon the design of the web site. In chemistry, we do want some objectivism in the design so we will have some drill exercises. However we will want to clearly use that memorized base to lead the students into a constructivist approach to their knowledge development. Abstract topics such as in chemistry and physics can be considerably enhanced by the use of simulations and animations. The simulations can also have a student interface allowing for students to change the operational parameters of the simulations and thus lead to a deeper understanding of the concepts.

The consideration of the learning styles of our students is usually the most often neglected item. Below are some learning styles and the course elements needed for those learners.

<table>

Active Learners

These learners need group work. We can make assignments to groups of students and require presentation of results over the web using a course management system such as WebCT. Case studies appropriate to the discipline can be used very effectively in this component. Reports of these assignments should be due often (every two weeks).

Reflective Learners

These learners need time to think over the material before trying it out. On-line quizzes that are taken at the time of their choosing appeals to these learners. A thorough assignment due at the end of the semester also appeals to these students.

Other authors have also examined utilizing some of the implications of learning theory and web-based instruction (6).

It is recommended that faculty begin work on designing the web site and how to include course material while considering assessment. The methods of assessment need to be in place well before the first semester of use begins, and a specialist in assessment should be part of the team. The assessment needs to include comparisons with an on-campus class covering the same subject, and the best arrangement is for the same professor to teach the on-campus and on-line class. Before the classes begin, both classes need to take a subject matter test, a personality profile test, the Learning and Study Strategies Inventory (LASSI) test, and at least two different kinds of learning styles tests. It is best if a standardized subject matter test can be found such as is offered by the American Chemical Society for chemistry tests. At the end of the class the students need to then take the subject matter test again. Studies of the student environment involve the actual class-related experiences of the student during the course. Obtaining student input on the environmental issues is very important. For a web-based course the environmental issues are ease of site navigation, usefulness of various sections, ease of use of audio/video components, ease of electronic correspondence with other students and faculty, etc. The assessment expert should help the faculty member choose the proper tests and opinion surveys, and aid in the analysis of the correlations.

WEB SITE CONSTRUCTION

For effective use of everyone's time, it is very important to use a team approach to the construction of the web site. It is unreasonable to expect one person to become an expert in all needed areas. The team should consist of a content expert, an instructional designer, a programmer, a web interface designer, a graphic designer, and an assessment expert. There are a number of good references for considerations in the web design process (7).

At this point we know the discipline material needed on the web site, how to design the web site for optimal use by the students, the methodologies of presentation, and the methods of assessment. Now we can begin to develop our web-based course by including all of the above elements in our design. From the above we see that we need: synchronous and asynchronous means of communication among the class members, video clips, sound bites, simulations and animations, photos with sound and text, access to a conference software package like Microsoft Net Meeting, short web pages, different web pages for different topics, drill routines for help in understanding and memorizing, animations with input, a good overview of each section and of the entire site, prepared method of progression through the site for those who need such, methods for inductive and deductive approaches, short-term and long-term group assignments, and on-line quizzes at appropriate locations to help students gauge their educational progress.

Now we are ready to design the web site for the course. From the above considerations, there are many needed components of the web site. Now the team must examine the course material and begin to storyboard it into needed segments, and requisite interactions among the segments. As also seen above, the overall site should be designed so that a student can be guided through it, or so that a student can choose his/her own path. At this point it is a good idea to use a hierarchy program and place the titles of all segments in the spaces and begin to determine the best arrangement and interactions. Because we are trying to maximize the constructivist element of the web site design, the placement of the course material must be done with that priority. It is very important to remember that the individual web pages need to be short, so a given chapter of material will need to be divided into appropriate small sections.
It is also time to begin to determine what animations and simulations will be placed with what sections and where to place drill exercises. Drills are to be placed at necessary points in the objectivist portion of the site (such as in the learning of significant figures). If a programmer is part of the team then he/she needs to begin developing the needed animations, simulations, and drills. Generous faculty members at many universities are also willing to share their work, which could save a lot of time. There are also a number of software packages that can help in constructing these portions of the site.

Once the design of the web site has been determined, the conversion to html coding begins. Much of this work can be done with word processors, although usually such conversions have to be considerably modified to appear as desired. Because most of us are never satisfied with the html conversion of word processors, it is advisable to just create all the code with an appropriate web page software suite. There are many software packages available for constructing web pages. We have found Dreamweaver 3 and Coursebuilder for Dreamweaver 3 (8) to be very good packages for this work. Coursebuilder can be used to add short quizzes at appropriate places in the sections of the web material.

The style of the writing needs to be different from that in a textbook. The writing should be friendlier and written like one would talk when tutoring a student in the office for that is what a good site is — an electronic tutor. A good method is to start with lecture notes and then fill in details and modify the tone of the writing. A good reference point for the writing is to think about explaining the material to your 15-year old child or grandchild. The entire course should begin with a broad overview; each "chapter", and each "section" of each chapter should have an overview and learning goals clearly stated. Each "section" should then be followed with a conceptual quiz to help the students assess their progress.

The learning style considerations revealed that one needed component was video, which presents some problems if students are accessing the material from off-campus, as most will be doing. The videos should be short, approximately ten minutes, and narrowly focussed in content. We produced short topical lectures on many topics in freshman chemistry and compressed them for Real Streaming video presentation over the web. However the pipeline to homes is still too narrow for the effective use of such video. We have decided that for the next few years, the best method for delivering such videos to students is via CD-ROM disks. The video on the disks can be assessed from the web course material, and it is easy for the students to then watch at their convenience. The videos should be produced in their original form with streaming video in mind (few motions, simple background, simple scenes, etc), so that they will compress into as small a file as possible. Later, when the technology improves for video delivery over the web, the same videos can probably still be used over the web.

The synchronous and asynchronous communications among the students can be accomplished by a course management software package such as WebCT, Blackboard, Web-Course-in-a-Box, or needed individual components may be used. We chose to use WebCT for the discussion forum, chat room, and mail aspects of the web course. We also use WebCT for on-line tests to be made available to the students a couple of days before each test. These on-line tests are of similar coverage and difficulty as the real tests. For some students who have the computer capability, we also make available a server for use with Microsoft Net Meeting. Using Net Meeting we can schedule on-line office hours and students can schedule group meetings.

A web site that has general information about the campus and specifics about on-line learning should also be available for the students. We constructed a site called "ChemNet" that contains links to the university homepage, campus resources, admissions, financial aid, the catalog, the bookstore, library resources, the university on-line registration site, and a site where the students can obtain free e-mail and web pages. The site also contains a link to a site that discusses on-line learning, that has links to needed software, and that has on-line learning style tests. This site also has links to information about all degrees offered on campus, and links to the on-line courses available from this campus. Such a site is essential to including the students of the on-line class into the on-campus scene.

IMPLEMENTATION

Now that the site is constructed, it is time for implementation. It is very important to have an on-campus meeting before the course begins. At this one mandated meeting, the students get to see the professor and each other, work
through some of the details of the class in a computer lab, and take some of the assessment tests. I also prepared a
web site that walks the students through the various aspects of the web-based course that is useful for those students
who can't attend the on-campus meeting and as a review for those who did attend the orientation.

Each chapter should have group assignments that are due every two weeks. Testing should be frequent. Optimally
the students should be given a test every two weeks and group assignments due every two weeks with the timing
such that something official happens every week. For a semester course, there will then be eight proctored tests,
eight on-line quizzes, the final exam, eight group assignments, short quizzes, and homework (due the day of the test)
all to be used in some combination to give a grade. It is preferable to require that the tests be proctored either on or
off campus. The validity of off-campus proctors must also be carefully checked. If this sounds like a lot of work for
the students and the professor, it is! An on-line course conducted in this manner forces the students to study as we
ideally want all students to study, but we know that probably only about ten percent study this intensely. Professors
and students must be warned about the extra work before the course starts. Our data show that students finishing
such a course in freshman chemistry scored 57% better on a standardized test, so for the serious student such an
approach is worth the effort.

The professor must check all possible student input at least daily. It is critical to keep the students involved in the
course and motivated to learn. Nothing turns off a student as much as a request for information to sit in a mail
hopper for days, or for a posted message to the discussion forum go totally unanswered for days. It is a good
procedure for the professor to enter himself/herself as a counterfeit student in the class so that the professor can pose
as a student, see the material from the student’s view, and discuss issues with the students from a different
perspective. Students will discuss concepts more openly with other students than they will with a faculty member.
Of course, usually someone begins to wonder who the kid is who seems to know all the answers! It is also a good
strategy to let the discussions continue on the bulletin board without intervention unless the students are getting
way off course on trying to understand some concept. Students learn more when they teach other rather than having
the professor answer all questions immediately. It is also a wise procedure to sometimes enter as the counterfeit
student and pose a question to try to get the discussions focused properly.

Assessment tests and surveys are also available on-line for ease of taking and analyzing.

Upon implementation the professor becomes the guide through the material. The web site must also be kept
updated, which includes checking all referenced links often, changing course content as needed, modifying and
adding new animations and simulations as needed, monitoring the use of synchronous and asynchronous
communication tools so that the most effective methods are used from the students’ perspective, modifying areas of
the site as needed to meet the needs of all learning styles, and continual use of assessment data to make the site
optimally effective.

CONCLUSIONS

Assembling a web-based course is not an easy task and requires a lot of time and commitment of the professor and
the team. After the initial implementation, the professor is forever in a continuous iterative process of assessment,
modification, learning modern techniques, and implementation. However, this iterative process has always been the
job of the professor. The web era has not introduced any new job description, just different details and a new
medium that can be used to develop constructivist learning in a more effective manner than ever before. This last
statement is a rather bold statement, but we believe that it is true, especially for rather abstract subjects. The use of
computer simulations with feedback loops, animations, drills for memorization, and computer models of molecules
and their interactions (again with feedback loops) afford a method for active learning that was not available until
recently. The web-based uses of these techniques all the students to be repeated as often as the student desires rather
than just once in class. The use of the electronic bulletin boards for discussions generally afford a deeper level of
discussion as students can think more about their comments than most do in person-to-person interactions.

A major benefit of a web-based site from the students’ perspective is that the students leave such a course with
better-developed abilities to be life-long learners. They will always have to be learning on their own, and the web is
a fantastic tool for education. They will also have learned how to approach the web cautiously regarding the validity
of information on the web. They will have developed skills in working with other individuals using various
technologies. Most corporations now use the web for training employees and keeping employees modernized in their knowledge relating to their jobs. The successful completion of a web-based course is then an excellent part of a student’s education and at least one such course should be required of all students.

The presentation will more completely discuss all the elements of design; the assessment results of four semesters of teaching General Chemistry, a chemistry course for science majors; and show some of the actual details of the web-based courses.

Evaluation of a support tool for musical problem-seeking

John Cook
University of North London,
School of Informatics and Multimedia Technology,
166-220 Holloway Road, London N7 8DB, UK
j.cook@unl.ac.uk

Abstract: MetaMuse is a pedagogical agent that supports the fast generation of musical ideas and which specializes in interactions that aim to foster learner problem-seeking (i.e. the first stages of creative problem-solving). This paper provides an overview of MetaMuse and then gives details of an evaluation of MetaMuse with teachers and learners. The evaluation results were favorable. In particular the evaluation participants rated highly the learning support approach taken by MetaMuse (i.e. getting students to learn how to make predictions about musical ideas and then encouraging reflection on what actually happened when the idea was played back).

Introduction

A pervasive musical education problem is that there is often no "correct" body of knowledge to teach (Johnstone, 1996, p. 247). In musical composition it is not just a question of solving a problem, it is more a question of seeking out the nature of the problem and then devising an approach to solving it. More generally, Lipman (1991) has suggested that in the humanities and arts, the subject matter itself is treated as essentially problematic and that it is more a question of problem-seeking than problem-solving (Lipman, 1991, p. 175). We have extended this notion (Cook, 1994) by proposing that when reflecting about creative problem-solving, the first stage is often to problem-seek, i.e. to define, formulate, find, invent, or create the problem before a method for arriving at a solution can be identified.

This paper first presents a pedagogical agent called MetaMuse. The agent is a learning support tool that has been developed to promote problem-seeking and problem-solving interactions in the area of undergraduate musical composition. We also report on an evaluation of MetaMuse with teachers and learners.

MetaMuse: A Support Tool for Problem-Seeking and Creative Reflection

In the empirical work reported in Cook (1998), the author of this paper describes a formal analysis of teacher-learner dialogues. One outcome of this analysis was prescriptive models of interactions described at the level of participants' goals and communicative acts (the latter being seen as a way of achieving goals). The prescriptive models generated by the analysis of empirical data were used in the design and implementation of a computer-based pedagogical agent called MetaMuse. The agent is able to engage in interactions that aim to promote problem-seeking.

MetaMuse can only deal with a small task revolving around the chromatic transposition of a four note phrase. Furthermore, MetaMuse can not understand natural language. The system is not able to engage in dialogue about the 'free text' inputs by the learner. As a result the system sometimes lets the user input some thoughts on what they are doing, stores these explanations and reflections in an Interaction History and then moves on to the next part of the session. Interactions with MetaMuse thus typically take the form of structured questioning by the system and menu and button selections by the learner. However, within certain limitations, the system is able to comment on a musical phrase input by the learner. MetaMuse also has various (empirically derived) prescriptive models of expected interaction patterns which it uses as the basis for problem-seeking interactions. An example of the MetaMuse interface is shown in Figure 1 (note that "phrase" in the text refers to a musical phrase).
MetaMuse has the ability to provide the student with a Learner Profile (a summary of the learner and teacher interactions) that can form the basis for further reflective engagement and dialogue with fellow students or with the teacher. This ties in with one approach to supporting reflection and speculation about music (Auker, 1991). Auker has suggested that students should be allowed to develop the appropriate spoken language by interacting with each other. They can then adapt and take ownership of this language as they begin to internalise and 'reflect' on creative opportunities, and hence build the appropriate mental structures of their creative intentions.

Figure 1: An example of the MetaMuse interface

MetaMuse attempts to engage in a 'mentoring' style of teaching. Mentoring is an approach to teaching that aims to support learners' creative, metacognitive and critical thinking, these being essential to musical composition and other open-ended, problem-seeking domains. Specifically, mentoring intends to promote learner 'creative reflection', which is a constrained type of metacognition. In the domain of musical composition, creative reflection would be defined as the ability of a learner to imagine musical opportunities in novel situations and to then make accurate predictions (verbally) about these opportunities. An example of 'imagining a musical opportunity' would be an utterance like: 'I don't want to repeat the same note twice in my phrase'. An example of creative reflection would be a learner first writing a phrase using musical notation, then predicting verbally how that phrase will sound, then playing the phrase back on a piano and finally evaluating if the prediction was accurate or not. To succeed at creative reflection there should be a correspondence between what a learner predicts will happen and what actually happens.

What the pedagogical agent 'knows' is very limited. The focus for the pedagogical agent is on the potential that the choice of musical intervals provides for musical material to be sectionalised into phrases. Heuristics on how this is taught have been taken from the interaction data (Cook, 1998) and augmented by some musical grouping constraints as proposed by Lerdahl (1988).

The pedagogical agent is capable of certain types of symbolic reasoning based on its knowledge. For example, the pedagogical agent 'knows' that 'an interval leap of 23 or more may indicate a musical phrase boundary'. The agent also knows some good teaching tactics; for example, a tactic called 'critical probing' involves an attempt to get the learner to imagine that they are playing their phrase on an instrument, as this can help the learner firm up their own perception of the purpose of the interval leap (in metacognitive terms 'go-above' and regulate their knowledge). This gives a good example of the challenge of mentoring in a problem-seeking domain, i.e. mentoring involves tutoring with non-absolute rules, where there is no right or wrong answer. Normally, if the MetaMuse detects a large leap then 'critical probing' would be selected as an appropriate intervention.

State Transition Networks, i.e. prescriptive models, derived from dialogue modeling (Cook, 1998) are used to plan interactions. Often, more than one exit was possible from a state node. Interactions are structured by offering all of these choices to a learner as 'Respond' menu options (these options would vary from one node to the next). Preferred options would, it was decided, sometimes be indicated to the learner if there was a strong basis
(empirically based) for the pedagogical agent making a suggestion to the learner. Thus, the State Transition Networks are used to give options for choice and provide expectations of answers. A measure of confidence in the degree of learner co-operation can be built up over time, based on the degree to which a learner fails to match the pedagogical agent's expectations (e.g. how often do they ignore advice given by the pedagogical agent?).

Evaluation of MetaMuse

The evaluation was in two parts. In part one five individuals evaluated MetaMuse. In part two six pairs of collaborating learners were used to help evaluate MetaMuse. Thus the total number of participants in the evaluation was 17. We will refer to the participants in part 1 of the evaluation as participant numbers 1 to 5. We will refer to the participants in part 2 of the evaluation as participant numbers 6 to 17.

The Evaluation Study Set-Up

The method that was used for the evaluation (parts 1 and 2) was questionnaire. The specific aim of the evaluation was to get initial feedback (by the use of questionnaires) from music teachers, educational technology researchers and students on six related questions:

1. Details of participants' current post, professional qualifications and experience with music teaching and educational technology.
2. How interesting participants found MetaMuse.
3. How useful participants found the way that MetaMuse promotes creative reflection about a musical phrase.
4. Participants' assessment of the potential that MetaMuse has for assisting in undergraduate composition classes.
5. Participants' assessment of how useful they found the guidance provided by MetaMuse.
6. Participants' assessment of how useful they thought the learning approach used by MetaMuse was for musical composition education (i.e. learning how to make predictions and reflecting on what actually happened).

There were various aims behind the above questions. The second question was used as a general question to catch user impressions of the pedagogical agent. Another aim of the questions was to see if users felt that the agent could reproduce, at the formal level, interaction that were similar in structure to a human pedagogical agent whose goal was 'creative reflection' (the third and sixth questions). The pedagogical agent, in its current implementation, has no natural language understanding; there is a lot of processing going on behind the scenes (although response time was very fast) and some interface activity. Given this limitation, the fourth question attempts to identify the applicability of the system, could it be used in the classroom with students? The fifth question attempted to ascertain how the participants evaluated the help screens and messages provided by the pedagogical agent.

Part 1 of the evaluation was conducted in London and at a Department of Music in a University College in the north-east of England in May and June, 1998. This part of the evaluation was conducted with one AI-Music-Education researcher/lecturer (in London) and with four musical teachers (at the Department of Music). Part 2 of the evaluation took place at a British University in the south-east of England in March 1999. In part 2, six pairs of learners worked with MetaMuse in each session. The twelve participants in part 2 of the evaluation ranged from undergraduate students, postgraduate students, research fellows and members of staff (teaching and support). The participants in Part 2 had varying levels of musical ability. For the whole evaluation eleven participants were male and six were female. Each session in both parts of the evaluation lasted between 30 and 50 minutes.

The evaluation subjects (one participant and one observer per session in Part 1; pairs of participants and two observers per session in Part 2) sat in front of a composer workstation, which consisted of a Macintosh Centris, with MetaMuse installed, attached to a midi-device and speakers. Each session involved the participant being asked to carry out a small composition task (10 minutes of the session were set aside for participants to read the notes and ask questions of clarification; in Part 2 the pairs were simply asked 'to work together on the task'). Briefly, the compositional task was for the participant to attempt, using MetaMuse, to create a phrase by the repeated chromatic transposition of an initial four note motive (C C# F# G). When using MetaMuse to compose a phrase, participants were asked, in the task sheet and by MetaMuse, to limit the approach used (when transposing the phrase) to repetition, contrast and trajectory. The reason for taking this constrained approach (of only allowing repetition, contrast and trajectory) was that MetaMuse knows more about how to interact than it does about music (later versions will improve on this lack of musical knowledge). Thus, constraining the types of activities that the
composer was allowed to undertake would, it was hoped, give MetaMuse a chance of being able to analyse what the participant was doing (and hence MetaMuse would have a reasonable basis for mentoring interactions).

Participants were informed that the current implementation of MetaMuse could only recognize the following approaches (which are based around the work of Lerdahl, 1988), and were asked to limit themselves to variations on one of these approaches when composing a phrase: octave leaps, descending trajectory, ascending trajectory, large leaps, repeated transposition and small phrase. Each evaluation participant individually filled in a questionnaire following a session. It is these questionnaires which are used as the basis for our evaluation. Following the very first evaluation session some minor changes were made to MetaMuse. Consequently, sessions 2 to 11 (i.e. with participants 2 to 17) were conducted with a slightly improved version of the pedagogical agent.

Results and discussion

Table 1 shows average response scores (out of possible maximum score of 5) to interview questions.

<table>
<thead>
<tr>
<th>q2</th>
<th>q3</th>
<th>q4</th>
<th>q5</th>
<th>q6</th>
</tr>
</thead>
<tbody>
<tr>
<td>Av.</td>
<td>4.06</td>
<td>3.35</td>
<td>3.65</td>
<td>2.76</td>
</tr>
</tbody>
</table>

Table 1: Average Response Scores (out of 5) to Interview Questions

The number of study participants, at 17, was small and so some caution is required when attaching significance to these results. Given this reservation, however, the results seem favorable: the total average response score for questions 2 to 6 was 3.63 (out of 5). We will now discuss the above results in the context of the underlying purpose of the questionnaire, which was outlined above.

**Impression of the Pedagogical Agent (q2)**

With an average score of 4.06 the overall impression of MetaMuse seems good. The comments made by participant 5 (a former head of department of music) were encouraging:

“Compositional value in teaching very useful. Patterns are quite limiting - which make a good test of both ‘learning’ and ‘ingenuity’. It would be further use in teaching to [be able to] play around with the pattern (invert, retrograde) and with tempo.” (Participant 5)

Participant 13, who has a degree in Music (and who specializes in musical performance) made the following comment:

“With the facet that we were looking at, it was interesting to hear what the transposed phrase sounded like ...” (Participant 13)

Comments against this question (q2) also tended to make some suggestions for improvement. Following the above comment, Participant 13 went on to make a suggestion:

“I would like to see it incorporate rhythm and volume of sound and a few musical variations like staccato and legato, varying tempi etc.” (Participant 13)

**Were the Interactions Able to Promote ‘Creative Reflection’? (q3 and q6)**

The average scores of 3.35 (for question 3), and 4.35 (for question 6) we feel are further indicators that MetaMuse is ‘on the right track’. However, one comment made against question 3 recognized the need for a more sophisticated analysis of what has already been said by the learner, in order to avoid repetition:
"It would probably be more helpful if it were able to pick up on key words in the responses and therefore not ask questions which have already been answered. However, the process of evaluation is useful, although I'd be interested to see how it coped with larger structures." (Participant 4)

The issue raised in the ending of participant 4's comment above ("I'd be interested to see how it coped with larger structures") was also picked up by participant 5 ("Needs to explore further how small components can contribute to a larger frame (structure : form)"). Indeed, in her comments with respect to question 3, participant 8 (who plays classical guitar) made the following useful suggestions about the way MetaMuse tutors phrases:

"Not always clear quite what was required — needed "tuition" element — e.g. we are now going to look at phrasing marks; the effect of phrasing marks on a particular sequence — now try it out. Difficult to say how would phrase if cannot try it out. Difficult (for me) to say how would play without seeing it written in standard notation." (Participant 8)

Future work could develop MetaMuse's ability to work with larger phrases and sections (i.e. structures). The question of musical notation is more problematic. In the design of MetaMuse we deliberately avoided the use of notation and opted for numerical transposition values. The reason for this was that we wanted learners with varying musical backgrounds to be able mentally image their musical ideas. Hence the use of the numbers would, we hoped, assist in this process of imaging (we could not assume that users were able to read music). However, future versions of MetaMuse could include the ability to handle musical notation. The impact of doing this on the types of interactions and reflections that would then take place is, however, unclear.

The responses to question 6 (which received the highest average score for any question, at 4.35) was very positive, and as such several selected comments are included below:

Participant 2: Except on a one to one basis, I cannot imagine any other way of achieving this experience. This does test and help develop memory and critical thinking in a relatively non-threatening manner.
Participant 3: Most undergraduates would be at too high a level. Better on Primary/Secondary.
Participant 4: Overall, I think this could be very useful in terms of a learning tool in encouraging students to think about both local events and (potentially) larger scale events; and the process of constructing events to create cohesive work.
Participant 5: Excellent introduction to awareness of sound.
Participant 8: Hearing rather than seeing a representation of the phrase is useful.
Participant 11: This is the basis for all my own compositions, and I am trying to encourage this approach in other subject areas by assessing reflections rather than task solution.
Participant 12: Would be useful to music education even at late primary/secondary level.
Participant 13: It is a good approach because encourages composition in the head without playing first, which is a very useful skill.
Participant 17: Quite a lot of potential.

Interestingly participant 3 (who was the only music teacher participant not to give question 6 a score of 5 out of 5) is not actually a composition lecturer, unlike participants 2, 4 and 5, who do teach composition at undergraduate level and who do see the 'full' potential for MetaMuse to teach creative reflection.

**Could MetaMuse be used in the Classroom with Students? (q4)**

As far as Part 1 of the evaluation went (i.e. participants 1 to 5), opinion on question 4 seemed to be split between those who do not teach composition (participants 1 and 3, who thought that MetaMuse may be appropriate in schools) and those who do teach composition (participants 2, 4 and 5, who thought it would be useful for first year undergraduates). Participant 12 (who is a research fellow in computing, but who plays the bagpipes) in his comments, quoted above in the context of question 6, appears to agree with participants 1 and 3. Subject 13 also added to the split decision on who MetaMuse should be aimed at:

"I would see this tool to be more appropriate at the secondary or 6th form level. I think it would be a bit basic for undergraduate level." (Participant 13)
If MetaMuse were given more domain knowledge then we feel that it would appear more convincing to non-composition teachers and undergraduate users. Improving MetaMuse's domain knowledge would provide an interesting project for future work. However, once again we should point out that the implications for MetaMuse (in terms of the type of interactions and reflective thinking that it would then encourage) of 'adding' more domain knowledge remains unclear. The approach taken in MetaMuse is to constrain what the composer is allowed to do. This is a perfectly valid compositional learning technique, often called a study or exercise.

**Evaluation of the Help Screens and Messages Provided by MetaMuse (q5)**

This question received the lowest average score (2.76). The help screens and the language used by MetaMuse clearly need improving. Participant 2 (when actually answering question 2) probably put his finger on the weakness of the help screens and messages:

"The language and display of text needs a radical rethink! A session with students on the language used would be essential - and a good thing to do anyway as this kind of formal language use is not (but should be) encouraged." (Participant 2)

The many responses to question 5 provided us with a useful source of user data on how to go about improving the usability of MetaMuse.

**Conclusions**

This paper has described the evaluation of MetaMuse, a pedagogical agent that aims to foster learner problem-seeking and creative-reflection. The questionnaire approach to evaluation provided us with a useful snapshot of user opinions about MetaMuse. However, the above evaluation of the teaching agent did not give us any insight into the following question: what are the interactive means by which learning agents engage in cooperative problem-seeking? Future work will focus on both answering this question (by undertaking detailed dialogue interaction analysis of part 2 of the evaluation) and on improving the learning support provided by MetaMuse by drawing on the evaluation results discussed above.

Abstract: A collective case study examined the change in pedagogy that occurred in a postgraduate Information Technology in Education subject that utilised World Wide Web technology. Two implementation cycles were examined. The model that surfaced from the first case correlates with a Radical Constructivist approach (von Glasersfeld 1995) and the model that emerged from the second case maps with the Beyond The Information Given (BIG) constructivist framework (Perkins 1991). This paper describes the parallels of theory to practice and raises implications for the design of web-based learning environments.

Introduction

This study examined the pedagogical change that occurred in a course that was delivered using network-based technologies. Using a collective case study method (Stake 1997), the researcher (primary author) was a participant observer in a postgraduate course offered by the Graduate School of Education at the University of Wollongong over two years. The research focus was to examine the interactions that occurred amongst the students and the instructor. In addition to participant observation, data was gathered from student and instructor interviews and via a collection of artifacts such as student work, computer-mediated communication transcripts and email messages. The model that emerged from each implementation parallels two theoretical constructivist frameworks. Case One parallels Radical Constructivism (von Glasersfeld 1995) whilst Case Two parallels a Beyond the Information Given (BIG) approach (Perkins 1991).

As part of the initiative by the Faculty of Education to investigate flexible delivery strategies, in 1996 the postgraduate course: Implementation and Evaluation of Technology-Based Learning was chosen as a pilot study to explore the use of internet and videoconferencing technologies. The introduction of these technologies enabled students to experience the use of technology whilst learning about its use in an educational context. Two different implementations were undertaken one in each year.

In the first case, there were two geographically separate classes. Eight students met on campus and six students met at another site 80 kilometres away. Both classes were held on the same evening for three hours over a semester of fourteen weeks. Videoconferencing, a subject Web site and computer-mediated communication tools facilitated interaction between the two sites. The instructor physically attended each site on alternate weeks. The content material was structured so that a new topic was addressed each week. The first five weeks were structured as instructor-led sessions delivered via videoconferencing and computer-mediated communication tools. The remaining nine weeks were structured as student-led sessions. Assessment requirements were based on individual work and consisted of three assignments. The first assignment was a seminar presentation that was to be conducted as a collaborative exercise between two students, one from each site. Seminar presentations began from Week Six of the course. Students had to facilitate a discussion for the entire evening and had to create a web page and provide online activities to engage both sites as one class. A grade was given based on a theoretical paper that accompanied the presentation. The last two assignments were due at the end of the semester. One involved developing a portfolio of resources that each student found relevant in terms of the content of the course and the other involved producing an evaluation report of the implementation...
of the course as a technology-based learning project or of an educational software package of the students’ choice.

The lessons learnt from this case were used to redesign the teaching and learning environment for the subject offering in the following year. For this second case, the subject was implemented using internet technology. There again were two geographically separate classes. Eleven students met on campus and six students met at the remote site. The two classes ran on different evenings for three hours. During the fourteen week semester, students attended eight class meetings, which were scheduled approximately every second week (Weeks 1, 2, 4, 6, 8, 10, 11 and 14), and participated in asynchronous and synchronous online discussions during the non-meeting weeks. A web site facilitated interaction among the students and instructor outside class time. The instructor physically attended every face-to-face meeting. The researcher attended the face-to-face classes held on campus.

Assessment was restructured and comprised four assignments. The first assignment was due in Week Four and involved writing a paper about evaluation theory and its relevance to technology-based learning. A Web page on an agreed topic was to be completed by Week Eight. Students then had to evaluate all the Web pages and produce an evaluation report by Week Eleven. The last assignment involved developing and presenting an evaluation proposal. It was due in the last week (Week Fourteen) and was completed and graded as a group project. These assessable tasks were structured so that the first three tasks could be used as resources for the final group project. Content material was provided to help with the completion of an assessment task. The concept of a Web page replaced the need for content to be presented in a weekly sequence in class time as the content was now available in electronic form and accessible at a time and place convenient to the students.

The instructor incorporated several online activities during the semester. The first online activity involved students working in small groups to discuss asynchronously, the content required for the first assignment. Each group worked on different content and posted a summary of their discussions to the subject web site. The intention was that students could use the summaries produced by the different groups as resources for the first assignment. Other online activities included synchronous and asynchronous discussions regarding particular content.

Constructivism—Its Application in Technology-Based Learning Environments

Jonassen, Mayes & McAleese (1993) argue that “constructivistic learning environments are most effective for an advanced knowledge acquisition stage of learning”, which is mostly required and promoted in university education. The underlying premise that purports a constructivist approach is the epistemological belief that knowledge is not an objective reality, that is, exists “outside the mind” but rather, it is internally constructed. “Knowledge is a function of how the individual creates meaning from his or her experiences; it is not a function of what someone else says is true” (Jonassen, Davidson, Collins, Campbell, & Haag 1995, p. 11). What constitutes a constructivist approach to teaching and learning, particularly within a technology-based learning environment? Much of the current educational technology literature is devoted to this issue and several frameworks have been presented (for example: Jonassen et al. 1993; Jonassen et al. 1995, p. 13-14; Duffy & Cunningham 1996, p. 177; Roblyer, Edwards & Havriluk 1997, pp. 70-72; Jonassen 1999, pp 2-7, 193-201). From a coalescence of this literature, four generic principles essentially characterise a constructivist learning environment:

1. **Learning is a process of construction.** Learners are provided the opportunity to actively create their own meaning from their current and past experiences and prior knowledge rather than passively learn the instructor’s interpretation of the content.
2. **Learning occurs through social negotiation of meaning.** Learners are able to collaborate with peers.
3. **Learning is contextually mediated.** Learners are immersed in authentic contexts.
4. **Reflective thinking is an ultimate goal.** Learners are encouraged to think about their own thinking processes.

The degree in which these generic principles are manipulated has given rise to various interpretations of constructivism ranging from “mild” (Boudourides 1998) or “trivial” (von Glasersfeld 1993 cited in Geelan 1997) constructivism to “radical constructivism” (von Glasersfeld 1995). Perkins (1991, p. 20) states: “Almost all educators and psychologists are constructivists of some stripe these days. But battles rage concerning just how constructive one should be.” Phillips (1995, p. 5) claims: “As in all living religions, constructivism has many sects...” Several frameworks for comparing the different forms of constructivism are presented in the literature (see Perkins 1991; Phillips 1995; Geelan 1997; Roblyer et al. 1997; Boudourides 1998). Perkins (1991) differentiates two forms of constructivism: Beyond the Information Given (BIG), and Without the Information Given (WIG). These two forms are based on the amount of intervention provided by the instructor. Phillips (1995) presents a complex comparison framework made up of three dimensions: (1) The individual construction of knowledge versus the construction of human knowledge in general (p. 7); (2) “Humans the creators versus nature the instructor” (p. 7). That is, ‘is individual knowledge created actively in the mind or imposed from the outside?’, (3) The active construction process can be described in terms of individual cognition or in terms of social and political process (p. 9). Geelan (1997) provides a synthesis of six different forms of constructivism.
based on a two-dimensional comparison model: (1) Individual versus social learning, (2) Epistemological belief, that is, objectivism versus relativism. Robyler et al. (1997, pp. 65-70) describes various degrees of constructivism in the form of different learning theories and the amount of intervention provided. For instance, they claim that cognitive flexibility theory is a form of radical constructivism as it suggests little direct instruction. Boudourides (1998) presents various “streams” of constructivism along a continuum from “mild” to “radical”. Petraglia (1998), however, presents a different argument with respect to the application, or as he states “misapplication”, of constructivism. Petraglia states: “educational technologists have fundamentally misunderstood the challenges posed by constructivism. This is seen in an approach to contextualising learning that I call preauthentication” (p. 58). He goes on to explain:

A problem with the goal of authenticating learning arises when we remember that constructivism argues that the world is not understood independently of our experiences, and that, therefore, any sense of authenticity can be neither predetermined nor preordained... educational technologists have responded to this epistemological dilemma by creating problems and environments that they have determined to be authentic; we might call this practice preauthentication. (p. 58-59)

A synthesis of the different conceptions of constructivism is provided in Figure 1. It is a somewhat simplistic view but merely serves as an illustration to situate the differences in constructivist approaches that surfaced from the collective case study.

| Beyond information given (BIG) (Perkins 1991) | Radical constructivism (von Glasersfeld 1995) |
| Without information given (WIG) (Perkins 1991) | Without information given (WIG) (Perkins 1991) |

More — Amount of intervention provided — Less
(Examples of interventions include: assistance/guidance from instructor; the nature and structure of tasks assigned to students)

Figure 1: Different conceptions of constructivism

Comparing the Two Cases

Interestingly, the model that emerged from each course implementation parallels with the characteristics of constructivism provided at the two extremes in Figure 1: Case One exemplifies a radical constructivist learning environment whilst Case Two is an example of the Beyond the Information Given approach. (See Hedberg & Corrent-Agostinho 1999 for a discussion of the themes that emerged from each case.) Both cases are described in terms of how the four generic constructivist principles identified above were implemented in practice and how the technology was incorporated.

1. Learning is a process of construction

The following description illustrates the difference in emphasis of the knowledge construction process in the two cases. Students in Case One experienced an ill-structured knowledge domain (Spiro et al. 1991) whereas students in Case Two were provided with learning scaffolds via the progressive nature of the assessment tasks.

**Case One:** Although the course content material was pre-determined, the pilot nature of the course delivery afforded students the opportunity to experience a “real-life” technology-based learning implementation, that is, an ill-structured knowledge domain. Different computer-mediated communication tools were introduced during the course and the entire class (instructor included) was learning about computer-mediated communication by experiencing it. The role that technology played was as much the message as the medium. Students were introduced to the technology to learn about it. As such, the technology was not transparent and integrated seamlessly in the course, it was as much the focus as the content material. The following example of student feedback highlights the significance of such a learning environment.

The subject was a valuable learning experience despite the technical glitches, periodic support problems and communication difficulties. We learnt as much about implementation of technology-based learning through the failed attempts to innovate as we did through the more traditional presentations and reading. There was a very heavy workload and a real danger of cognitive overload in this course. It challenged us to extend ourselves, perhaps unrealistically in terms of our part-time status and work commitments, but we mostly rose to the occasion.

Students experienced tolerance for ambiguity (Jonassen & Grabowski 1993). They had to manage their own learning experience and had to facilitate their own discussion when the instructor was not physically present. Whilst some students rose to the occasion, as exemplified in student comments such as: “There’s one thing about all these hiccups [referring to the use of the technology]. They make you think and you really learn how to cope with things that don’t work and strategies to try to make them work.” (Evaluation Report); others found the teaching and learning process challenging, for example: “I found the lecturer’s style...vague, loose and
unstructured. In some tutorials I really had no idea of what was going on, or what was expected of me. I feel I was not alone. I found this style frustrating and annoying." (Evaluation Report)

All assessment was based on individual work and was not used to scaffold the learning process. Specific assessment criteria were not provided. The assignments were open-ended and tailored to the individual. For example, the portfolio was based on individual student relevance. There was no set format for the evaluation report discussed. These two assessments were very individual in nature. It was left to the students to decide how to approach the task.

Case Two: The second implementation was structured so that the assessment tasks drove the learning process. The assessment tasks acted as scaffolds as each task informed the next subsequent task. Student feedback from the end-of-subject questionnaire (N=15) indicated that the majority of students thought the sequence of the assessment tasks was appropriate. There were several students that commented that the first assignment was "too much too soon" (4 students). For example, one student commented: "I felt the first assignment was too early to have formed any views in the subject".

The technology was integrated into the learning process. Computer-mediated communication tools were introduced at the beginning of the subject and students were given the opportunity to learn how to use the tools before online discussions took place. The technology was used as a vehicle for students to interact with each other. It became more transparent in this case than in Case One.

The themes that surfaced in this case suggest that students experienced a lesser degree of tolerance ambiguity than in Case One. The data suggests the following factors were influential: The scaffolding nature of the assessment tasks, the instructor being physically present with each class during meeting weeks, and more stringently defined assessment criteria than in Case One.

2. Learning occurs through social negotiation of meaning

The nature in which learners were able to discuss content issues with peers differed between the two cases. In Case One, the interaction amongst students was predominantly of a synchronous nature that occurred on a weekly basis. That is, interaction amongst students, both face-to-face and online, occurred mostly during class time. In addition, there was little opportunity for students to reflect and build on content discussions as discrete content "chunks" were discussed each week. In Case Two, the technology was used to encourage both synchronous and asynchronous discussions. The asynchronous online mode afforded students the opportunity to build on the discussion during the course. Also, the nature of the assessment tasks encouraged student collaboration. For example, collaboration was encouraged in the first online task as students discussed content in small groups and each group produced an online summary. Also, the final assignment was structured as group project.

3. Learners are immersed in authentic contexts

The degree of "authenticity" differed between the two implementations. The description below explains how students were afforded with an authentic context in Case One and a pre-authenticated context (Petraglia 1998) in Case Two.

Case One: The "real world" task was the course itself. Due to the pilot nature of the course delivery students experienced problems that were not pre-determined by the instructor. They were also able to evaluate the implementation as part of their assessment. Thus both students and the instructor were immersed in an authentic setting for the entire duration of the course. The following student feedback illustrates the perceived value of this learning context.

I guess one of my own observations about this course is that most of us spend a great deal of time discussing the technology and its use. This breaks us from the 'formal' side of discussion in the classroom and I think is a statement about the power of what we are doing. I'm not quite sure why this is happening though. I think this in itself is marvellous as we all seem to share the same concerns/thoughts etc....The other interesting observation from my conversation's with others is that everyone seems to be trying really hard to use the technology to its capacity. The last few seminars I think have been markedly different and successful in their own rights....We really seem to be gently pushing the boundaries and experimenting - great stuff!!...At the end of the day, I hope that the course and process ends up by being one huge experiment whereby we can reflect on VC, social interaction and learning. Perhaps we can also reflect on what technology really is capable of doing because we've been there. (Email message from student to researcher, Week 9)

Case Two: The instructor imposed more structure in the course via the four assessment tasks and the technology innovation was at a more routine form of use (Hall & Hord 1987). Thus the element of experimentation that students experienced in Case One was not as great. The "real world" context was confined within the assessment tasks particularly in the final group project. This assessment task was deemed an authentic task by the instructor. It was pre-determined before commencement of the course. Such a learning context is claimed by Petraglia (1998) to be preauthenticated.

4. Reflective thinking is an ultimate goal

The degree to which students exercised metacognition differed between the two cases. In Case One, reflective thinking was encouraged via the open-ended nature of the tasks and the recursive nature of the tasks. The evaluation assignment of the course itself enabled students to reflect on their experience during the course.
The student seminars also provided opportunity for reflection as students could refine their implementation strategy after reviewing other seminar strategies. In Case Two, the reflective thinking component was isolated within each task. The instructor encouraged students to reflect on their experience in completing each assignment during the face-to-face class discussions.

Conclusion and Implications

This study has demonstrated two different approaches that fall under the “constructivist” banner and the different emphasis in learning outcomes each approach can generate. The instructor contends that effective learning outcomes were achieved in both cases; however, there was a difference in their emphasis. Case One fostered exploration and afforded students to reflect on their own practice. As such, the learning outcomes were directly attributable to the amount of reflective thinking performed by the students. In Case Two, students were able to compartmentalize their learning into manageable “chunks” that were more clearly identifiable than in Case One and the sense of exploration was diminished.

The use of the technology in both cases from a “mechanical” form of use to a more “routine” form of use illustrates a consistency with the Concerns Based Adoption Model (Hall & Hord 1987). This study, however, highlights an added dimension to the change process advocated by CBAM. Unlike the change process being only confined to the instructor of the innovation, Case One demonstrated that students were also engaged in the change process. The experimental nature of Case One created a community of researchers that explored the nature of their own learning process and how lessons could be transferred in other web-based learning contexts.

This particular approach is not often attempted, possibly as the role of the instructor as a co-learner is not comfortable and can be seen as less disciplined. However, the resulting enthusiasm and learning growth of the students in this case demonstrated the potential gains from this approach. An implication for postgraduate education may be that instructors, rather than embarking on a solitary journey of innovation when teaching technology-based content, can invite students to experience the journey, thus producing a community of learners.

The maturity of each student cohort will greatly influence the outcome and the learning experience. The course content and the focus on change as being both a process and the content of the subject provide a powerful focus for learning. Unlike much of the change literature, if the concerns of the instructor are met, the radical view might achieve greater personal movement in the students. It also enables each student to address their own concerns and move from mechanical and routine use of technology in the learning process through to a renewal and reassessment of their own personal expertise to employ the technology as a professional educator.

Abstract: The use of the World Wide Web for education is increasing rapidly, but the usability and utility of instructional Web sites varies greatly. The difficulty experienced by designers in mapping instructional design activities onto instructional systems is a major cause of this. Thus there is a need for ways to make instructional design more accessible to non-instructional designers. Evolving standards in learning technology exacerbate this problem. Using patterns in instructional design may help. This paper reports on work in progress on developing an instructional design pattern language for Web-based learning materials and its planned use in the development of a post-graduate Human-Computer Interaction (HCI) course to be offered via distance education.

Usability Problems of Educational Web Sites

Many researchers and professionals realise that the usability and utility of World Wide Web sites varies greatly (Nielsen 1995). This observation also applies to educational Web sites, many of which are merely electronic page-turners. The use of the World Wide Web (WWW) as one of the delivery systems for asynchronous and semi-synchronous distance education and training is growing at an astonishing rate. Institutions of higher learning, government, business and industry will continue to rely ever more heavily on the WWW for this. Thus it is in the interests of progressive societies that the usability and utility of educational Web sites be improved, particularly those providing formal instruction. By “formal” is meant “in an institutional setting”. To improve these two qualities will require using some systematic way of reengineering existing educational Web sites (if this is feasible) and constructing new ones, that goes beyond mere layout aesthetics or page mechanics. What systematic ways of doing this are there? The next section will discuss one possible solution: instructional design.

The Need for Instructional Design

According to Berger and Kam, instructional design as a process is “the systematic development of instructional specifications using learning and instructional theory to ensure the quality of instruction. It is the entire process of analysis of learning needs and goals and the development of a delivery system to meet those needs. It includes development of instructional materials and activities; and tryout and evaluation of all instruction and learner activities.” (Ryder 1999)

The first task of instructional design is to choose an instructional design model. An instructional design model is an abstract perspective on how learners learn from others, and its choice will determine how the remaining activities of instructional design (described above) are carried out. There are about three dozen models (see the very good Instructional Design Models Web site at (Ryder 1999)). Fortunately, some instructional design models are more popular and well known than others. Two of the most popular models are Constructivism and Instructional Systems Design (ISD). Constructivism views learning as an active, personal construction of meaning about the world by
learners and is popular in the educational realm (schools and universities), although not universally so. ISD views learning as a matter of conditioning learners to provide the correct responses to stimuli, and is rooted in behaviourism. It still dominates in the training realm (government, business and industry).

An instructional delivery system presents learning content (instructional materials and activities) to learners, who interact with the content, giving feedback on their interaction. Hopefully the learners will emerge from the experience changed in a positive sense. The delivery system need not be computer-based. Good instructional design is a pre-requisite for producing a good instructional delivery system. But instructional design is more complex than the short list of activities shown above might suggest. It is a specialist field and is difficult to do well, requiring expert knowledge and a considerable investment of time and effort, usually by a team of developers rather than an individual. How can instructional design be made more accessible to those who develop instruction, most of whom are not professional instructional designers? The following section will discuss the concept of pattern languages and how they can be used to assist in the design process.

Patterns and Pattern Languages
Patterns and Why They Are Better

The most important property of modern computer software is the level of support that it provides for the underlying user activities. The interaction between software and users takes place through its user interface (UI), and thus a well-designed UI that properly supports the tasks of users is essential. Considerable empirical research has been done on designing usable UIs (Newman 1995). This research includes general UI design guidelines and domain-specific guidelines for the WWW and general hypermedia (Lowe 1999) (Nielsen 1995). Despite these guidelines, a large number of usability problems still occur (Wesson 1999). This is because design guidelines may be imprecise, have limited applicability and be contradictory.

Patterns may be a better way of designing UIs than guidelines (Tidwell 1999) (Wesson 1999). A pattern is a way of documenting a successful solution to a recurring problem in an application-independent, concrete manner, so that the solution can be applied in many contexts (reused). A pattern is generally derived from experience (by induction through a process called pattern mining, which is both tentative and collaborative) and is not the same as a stylistic rule. Its pre-scientific, humanistic approach runs contrary to the deductive approach of much of Computer Science and Software Engineering. Unlike guidelines, patterns are precise, are applicable in many contexts and harmonise with neighbouring patterns. Patterns can form a framework in which HCI knowledge can be structured, and be a communication tool within HCI and between other disciplines—like instructional design, for example.

A Short History of Patterns

Pattern languages were first proposed by Christopher Alexander et al. in building architecture (Alexander 1979) (Alexander 1987). They have proved useful and popular in object-oriented design (OOD) (Gamma 1995), and in a number of other areas of Software Engineering. Pattern languages as used in Software Engineering are also rooted in the literate programming movement started by Donald Knuth (Thompson 1997). Software Engineering patterns range in granularity from programming language-specific idioms to general design principles. There is an active online OOD community, exemplified by the Patterns Home Page (Sane 1999). There is also a small but growing patterns group in the HCI community (see e.g. (Erickson 1999), (Tidwell 1999) and (Wesson 2000)) and among those who model organisational structures.

Structure of Patterns and Pattern Languages

Patterns have a standardised format that is generally discipline-dependent. For example, the classical Alexandrian format for a building architecture pattern consists of a meaningful name for the pattern, examples of contexts in which the pattern is used, a description of the problem which the pattern solves and a listing of the external forces which act to shape a solution. The last two parts of an Alexandrian pattern are a solution that explains what must be done to solve the problem and the context in which one would use the pattern, plus any additional information required. The OOD pattern community uses a different format (Gamma 1995).
A pattern language (Salingeros 19--) is an interconnected group of patterns. A pattern language may be visualised as a graph, made up of nodes (individual patterns) and edges (the functional relationships between patterns). Good pattern languages have the properties of internal consistency and connectivity to other pattern languages at their applicability boundaries. Pattern languages are usually hierarchically structured in that a particular pattern’s applicability is limited to a certain level in the hierarchy, supporting larger-scale patterns and being supported by smaller-scale patterns (HCI pattern languages may be an exception (Tidwell 1999)). They provide superior ways of understanding and creating complex systems. The OOD pattern community does not make use of pattern languages, but rather of catalogues, which are lists of useful programming language-specific patterns.

The Case for an Instructional Design Pattern Language
Difficulties in Mapping Instructional Design Models onto Instructional Systems

A search of the Web reveals numerous general tutorials of varying quality on Web page design that deal with layout aesthetics, HTML, DHTML, XML, Java and JavaScript coding or the use of various Web authoring tools (e.g. http://www.taxpolicy.com/tutorial/httutor.htm). Tutorials and on-line documents that focus on practical issues connected with applying instructional design to educational Web sites, or hypermedia modelling (Lowe 1999) for educational Web sites, are far fewer in number. There are many good online resources on instructional design (e.g. (Kennedy 1997)), but the theoretical treatment of models like Cognitive Apprenticeship and Conversation Theory is difficult to translate into Web sites that work, particularly for those who are not instructional designers. What is needed is a way to map instructional design models onto design activities in a practical, straightforward way.

Evolving Instructional Technology Standards

A development which will also increase the need for a practical, straightforward way to perform instructional design tasks is the work being done by the IEEE 1484 Learning Technology Standards Committee (LTSC) on the Learning Technology Systems Architecture (LTSA) (Ryder 1999). This is being done in close collaboration with Educom's Instructional Management System (IMS) Project, the Aviation Industry CBT Committee (AICC), and the US Department of Defense's Advanced Distributed Learning (ADL) project. It includes specifying an architecture/reference model, and learning objects and their metadata.

Although the LTSA and its associated projects seem to have a slight training (ISD) emphasis, there seems little doubt that they will change and expand computer-assisted learning, especially via the Web. One of the changes will be a push towards harnessing the creativity of individuals, academic institutions and businesses in the production of large numbers of learning objects, each of which serves an educational objective (or a few objectives). These will be given away or more likely sold. Educational programmes will be produced by selecting the necessary learning objects and combining them by means of instructional management systems.

As more effort is put into producing instructional materials, the set of learner interactions is likely to become richer, compared to the rather impoverished interaction set generally now possible with the low-bandwidth WWW (server-side ASP pages, and client-side plug-ins, applets and scripts notwithstanding). XML and Java will play an important part in this. One can conceive of the production of families of learning objects that conform to a particular instructional design model, like Andragogy or Computer-Supported Collaborative Learning. As this push gains momentum, the need for instructional design knowledge by learning object developers will become greater, as the draft standards are all pedagogically neutral. In addition, knowledge of how to build highly usable systems that make use of the richer set of learner interactions will become more important.

Thus there is a need for very practical assistance for non-expert developers of Web-based learning materials in these two interwoven areas of instructional design and UI design, and this will increase as the Web (and the Internet) expands and becomes increasingly pervasive. An instructional design pattern language could be of assistance, particularly when one considers that the two major commercial instructional design (“pre-authoring”) software tools support ISD only. Such a language could be built into an electronic performance support system for the use of developers.
Related Research

There are a number of projects that are related to the work described in this paper and these may be studied with profit. (Bernstein 1998), (Nanard 1998) and (Lyardet 1998) are examples. The international Pedagogical Patterns Project of Manns et al. (Manns 1999), which focuses on patterns for teaching object technology (a special case of (probably) synchronous, non-distance, non-computer-assisted learning) and the pattern languages for instructional multimedia interface design project of Dimitrova (Dimitrova 1999) are further useful examples. This list is not exhaustive.

Examples of Instructional Design Patterns

At the INTERACT'99 HCI Patterns Workshop, a classification scheme for HCI patterns on the basis of scale was proposed (Borchers 1999). This scheme, in decreasing order of scale, consists of the following levels: Society (beyond systems), Multiple Users, Social Position, System, Application, User Interface Structure (dialog), Components (containers, windows, layout), Primitives (buttons and other simple widgets) and Physical Properties. Instructional design patterns (which are at least partially HCI patterns) map onto the System and Application levels. The greatest rate of change in real-world systems takes place between the System and Components levels, inclusive, and patterns that map onto these levels may become obsolete quite quickly. It is wise to be aware of this possibility for instructional design patterns.

To illustrate how instructional design patterns can assist in mapping models to implementations, two simple instructional design patterns for instructional Web pages follow. These are products of a broader research project that is described in the conclusion to this paper. These patterns were mined by considering two instructional design models, examples of Web-based instructional materials design practice and descriptions of best practice by developers. They deal with aspects of the models, not the entire models (there may be an entire pattern language for each model). Since mining patterns is a tentative process, it is customary to call a newly mined pattern a protopattern (Sane 1999) until sufficient empirical evidence through use cases has been accumulated to promote it to the ranks of patterns.

Example 1: Present Initial Knowledge

Present Initial Knowledge, the first protopattern presented, deals with an aspect of ISD: how to present initial knowledge about a topic to a novice learner.

Name: Present Initial Knowledge

Context: The learning activity supported is essential for grounding a novice learner in a new learning area.

Problem: How should initial knowledge about a topic be presented to a novice learner?

Forces: A novice learner learning the initial facts, definitions, procedures, etc. of some field must not be distracted by too many choices. The content must be presented in a logical sequence. It must be clear to the novice learner what the purpose of the lesson is, and how to control the display of, and interaction with, the content.

Solution: Create a linear structure made up of one or more relatively short pages/frames, limiting the links to those required for jumping forward and backward between adjacent pages/frames in the linear structure. This structure closely follows the model of conventional, linear text. Structure the content on the pages/frames into logical units that follow a sequence from elementary to more complex. Define all terms used and explain how new objects encountered fit into the overall content. Provide a consistent set of navigation interaction objects on each page/frame. If possible, embed assessment interaction objects in the sequence of pages/frames to allow the learner to practice mastery of the content. It may be desirable to control forward progress to make it conditional on content mastery (e.g. using ASPs or client-side scripts) if a Mastery Learning instructional design model is being used.

The Present Initial Knowledge pattern can be used to evaluate the Web-page shown in Figure 1, which exhibits both strengths and weaknesses. Its strengths are that it is short, its content is logically structured and that it does have...
some navigation interaction objects. Its weaknesses are that the linearity requirement of forward and backward links is not satisfied, and that terms presented are not defined.

![Figure 1: A Web-page to evaluate using the Present Initial Knowledge pattern](image)

**Example 2: Fade Out Scaffolding**

Fade Out Scaffolding, the second protopattern presented, deals with an aspect of the Cognitive Apprenticeship model. Cognitive Apprenticeship, based on the methods of traditional craft and trade apprenticeships (learning by doing), aims to initiate the novice into a community of expert practice. Scaffolding is support provided while a learner learns to carry out a task. Fading is the progressive reduction of support as the learner becomes more and more expert at executing the task. This pattern was synthesized from theory and practitioners' exposition of theory; it was not mined from Web-sites.

**Name:** Fade Out Scaffolding

**Examples:** A mechanic shows an apprentice how to change a tyre. The apprentice does it herself several times. The mechanic gives a lot of feedback during the first attempt by the apprentice, but as she becomes more proficient, intervenes less and less until at last he can say, "You've got it!"

**Context:** The learning activity supported by this structure is essential for grounding a novice learner in a new skill, using Cognitive Apprenticeship as a method.

**Problem:** How should scaffolding provided to the learner be progressively reduced?

**Forces:**
- The learning characteristics of the individual novice learner need to be catered for. The skills to be mastered need to be capable of being practised on a Web page (manual skills may be very difficult, but more computational skills are possible). There may be limits on the type of feedback possible.
- The level and frequency of scaffolding on each page/frame until expert performance is achieved, and then terminate the iteration. Provide a consistent set of navigation interaction objects on each page/frame.
Conclusions and Future Work

The instructional design pattern language proposed in this paper might make it easier for people who are not instructional designers to design educational Web sites of high usability and utility. The investigation of the potential of HCI design patterns for designing technology-supported distance learning programs, particularly those using the Internet, will continue. The project will involve an investigation into the design of several such systems. The goal of this investigation will be to assess the usability of these systems and to identify possible design patterns that have been used. This project also involves an investigation into the general area of HCI design patterns, and specifically those at the Application and Dialogue level that could be applied to the design of distance learning programs. The instructional design pattern language will be used to design a distance learning program for the postgraduate HCI course at the University of Port Elizabeth, that could be incorporated into a virtual classroom environment. The usability of this program will be evaluated in order to validate the pattern language and provide suggestions for improvement.

Abstract: The proposed Best Practices web-based tool is designed to help 4th grade California teachers integrate technology and constructivist learning into existing lessons. The tool guides teachers through the instructional development process to clarify, enhance, and reflect on their instructional practices. Throughout the process, teachers explore and build on specific instructional examples. The resulting instructional lessons use technology and constructivist approaches to engage students in active historical thinking.

Introduction

Technology use in a constructivist learning environment can enhance student learning, specifically, the development of higher order thinking skills. The Best Practices web-based instructional development tool will help teachers develop constructivist learning activities and revise existing instruction while integrating technology and higher order thinking skills simultaneously. Successful technology-integration not only teaches students to use the computer as a learning tool, but can actually improve the quality of instruction by encouraging teachers to apply constructivist principles. Furthermore, higher order thinking skills provide a necessary foundation for learning advanced subject matter.

Many teachers are uncomfortable with using computers for learning and are unsure how to integrate computers into their own lessons successfully. When technology-integration is unsuccessful, it is often because the teacher has not used the computer to enhance learning (Cuban, 1986). The Best Practices tool will provide structured support for 4th grade teachers to integrate technology and constructivism into their existing history lessons to support higher-order thinking. Because the Best Practices tool is designed for history teachers, higher-order thinking skills focus specifically on historical thinking and understanding.

This paper begins with a background on constructivist learning environments, higher order thinking skills and technology as they relate to learning and instruction. Then the challenges facing teachers in developing effective technology-integrated instruction will be explored. Finally, I will explain how the design and development of Best Practices provides this necessary support to teachers.

Constructivist Learning, Higher Order Thinking and Technology

The differences between behavioral and constructivist learning approaches stem from differing definitions of the teaching process (Willis & Mehlinger, 1996). These differing views directly affect the nature of student and teacher roles and the content, context and goals of the learning activities. In traditional instruction students tend to
act as recipients of information and the teachers as the deliverers (Brown, 1992). A constructivist learning environment provides more opportunities and motivation for learning through interactive, authentic and student-centered learning activities. In a Constructivist model, both teachers and students act as additional resources for testing and redirecting the student’s understandings. In a behavioral setting, activities are likely to be highly structured and geared towards learning a specific set of skills (Willis & Mehlinger, 1996). In a constructivist approach, skills are often developed because the learning activity requires the utilization of those skills.

Constructivist learning engages and supports higher order thinking skills in students. In fact, constructivist pedagogy places more importance on the development of higher-order thinking skills than on specific instructional content (Cadiero-Kaplan, 1999). Common learning goals of constructivist technology-integrated instruction include building on ideas, solving problems and creating research presentations (Cognition and Technology Group at Vanderbilt, 1996). As students build their own knowledge, they analyze, obtain, reconstruct and apply higher order thinking skills. The connection is evident in Honebein’s (1996) seven constructivist learning principles. In a constructivist learning environment, students become more responsible for determining the learning process while teachers act as facilitators to support them. In order to support students in being active learners, teachers’ roles change from “knowledge givers” to guides or “co-learners” (Resnick, 1996). The focus shifts from “transforming knowledge” to engaging students in acquiring learning skills (Minstrell & Stimpson, 1996). The content, context and goals of constructivist learning activities emphasize multiple perspectives and encourage multiple methods of communication, collaboration and student reflection on the learning process.

Higher order thinking skills specific to the content of history and social studies are well recognized by both National and California State History-Social Science Standards. These historical thinking skills are essential for students to be able to integrate, recount and analyze in the context of time and place, the social, political, scientific, technological, economic and cultural forces that have influenced history (National Center For History in the Schools, 1998). The National History-Social Science standards present five categories of historical thinking – chronological thinking, historical comprehension, historical analysis and interpretation, historical research, and historical issues-analysis and decision making. In other words, instead of simply memorizing information, students should create historical argument and narratives, explain the major events leading to a war or analyze their interrelationship.

In order for students to have the opportunity to develop and use historical thinking skills, they must be exposed to instruction that allows them the opportunity for substantial exploration (Cognition and Technology Group at Vanderbilt, 1996). One approach is to engage the students in authentic history activities (like those in which historians would engage) with historical thinking and strategies support provided (Bain, 1998). Another useful strategy for developing historical thinking skills involves asking students “what if” questions about a presented situation and having them explain their answer (Cognition and Technology Group at Vanderbilt, 1996). For example, history students might be asked what might have happened if the 49ers hadn’t discovered gold.

The successful integration of these strategies can be enhanced with technology (Cognition and Technology Group at Vanderbilt, 1996) Recently researchers have begun to explore the benefits that technology and constructivist learning environments bring to each other (Panel on Educational Technology, 1997). It appears that the combination of constructivist learning environments and technology both encourages students to construct their own knowledge and enhances teaching practices (Cadiero-Kaplan, 1999). In addition to supporting authentic and student-centered learning, increasing communication and improving the student’s ability to collect and analyze information (Nickerson, 1995; U.S. Government, 1996), technology is specifically useful when it is used to support and model higher order thinking skills for students.

The overall success of technology depends on how it is used (Cognition and Technology Group at Vanderbilt, 1996) and whether it involves any cognitive thinking (Salomon, 1993b, 1991). When technology is used to deliver information to a student, Rogers (1998) suggests that there is little or no increase in learning. If, instead, technology is thoughtfully integrated into the instructional design, curriculum goals, standards and assessment (Kahn, 1997), learning is enhanced “with” computers rather than “from” them (Salomon, 1988). Jonassen and Reeves (1996) determined that technology is most effective when it is integrated into a constructivist environment as a cognitive tool.

Many computer applications currently available in school classrooms can be used as cognitive tools. Applications commonly include communication, spreadsheets database, semantic networks and presentation software -- all of which support student learning processes such as collaborating (the Internet), calculating, organizing and analyzing data (spreadsheets, databases) and representing information (presentation and semantic
network software). Telecommunication tools provide students with new opportunities to discuss and collaborate on problem solving (Jonassen & Reeves, 1996). Spreadsheets also support student problem-solving by helping to reorganize and amplify student thinking (Jonassen & Reeves, 1996). Databases enable students to actively manage, categorize, search, and analyze data (Jonassen & Reeves, 1996). Semantic Networks (e.g. Timeliner, Inspiration and Learning Tool) support students’ organization and reorganization of information concepts and relationships (Jonassen & Reeves, 1996). Presentation applications allow students to analyze, construct and present knowledge in a nonlinear format (Cognition and Technology Group at Vanderbilt, 1996). Such tools also offer opportunities for students and teachers to develop their own instructional software (using authoring software such as HyperStudio), individualize student learning, and encourage team work and self-confidence (Office of Technology Assessment (OTA, 1995).

Teacher Challenges and the Best Practices Solution

Many researchers are beginning to see technology as a catalyst for changing teachers’ instructional practices to a more constructivist approach (Cadiero-Kaplan, 1999). The effective use of technology lends itself to student-centered instruction (Clark, 1991; Cognition and Technology Group at Vanderbilt, 1996), which is an important component of constructivist learning environments. Current research suggests that the effective integration of technology requires teachers to adjust instructional practices toward Constructivist models of teaching and learning (Cognition and Technology Group at Vanderbilt, 1996).

Best Practices addresses teachers’ instructional challenges by encouraging exploration, providing technology integration and supporting activity development with guiding prompts. The prompts provide a constructivist instructional development model and thus scaffold the development process. Additionally, because content relates to the teacher’s existing lessons and instructional standards, Best Practices is also flexible, efficient and relevant to the teacher.

The OTA report (1995) suggests that barriers to technology use include the lack of opportunities to experiment and share experiences, an understanding of how and why to use technology in the curriculum, good models and training and support. Best Practices provides teachers with opportunities to experiment through the technology matrix tool, which provides various technology solutions and activity examples. Sample lesson plans also allow teachers to share and learn from their colleagues’ experience. Through guiding prompts and constructivist-based examples, the tool offers teachers a model as well as rationale for integrating technology. Because technology integration focuses on existing lesson plans, it is both efficient and effective. Teachers are more likely to integrate this process into their teaching practice because they experience technology integration as relevant to them and their instructional needs. While Best Practices can’t provide in-person training, the tool models and supports teachers’ own learning process.

The Best Practices environment is modeled closely on a particular constructivist learning approach -- Problem-Based learning. Problem-Based learning uses constructivist principles to focus student learning around a specific problem. Once the problem is defined, the learner must find a way to solve the problem with support from peers, teachers and/or other resources. Throughout, learners reflect on their solutions and learning process. To be successful, the learner must have support in using and developing their cognitive skills (Savery & Duffy, 1996). Best Practices helps the teacher to identify and solve a specified instructional problem encountered in teaching historical thinking to students.

Best Practices also encourages exploration. Hughes (1998) suggested that such barriers might be overcome by encouraging technology exploration. The OTA report suggests that teachers “need visions of technology’s potential, opportunities to apply them, training, just-in-time support and time to experiment”. The OTA report found that the most effective technology training for new teachers includes watching videos of actual classroom teaching, practicing with case studies and participating in computer simulations and electronic networks (such as newsgroups and bulletin boards). Experienced teachers responded best to on-line access to new technology ideas, good teacher examples, and on-line contact with colleagues and technology use experts (OTA, 1996). Through exploration and reflection on their own teaching and learning processes, teachers with a more traditional teaching approach can explore learning from a constructivist approach. Because teachers often teach in the same way that they themselves were taught, teachers often need to have the experience of being a student in the same environment that they will create for their own students (Fosnot, 1989).

Because Best Practices will be available on the Internet access it is not limited by geography, time or personnel constraints. This tool could also be used within a group professional development context to help clarify
individual instructional goals and view examples. Although Best Practices currently focuses on instruction for 4th grade California history, it can be expanded to include multiple content areas and grade levels. This content and standards specific focus further ensures that the instructional development process is meaningful to the teacher’s instructional goals and practices. By revising an existing lesson, a teacher is more likely to develop a lesson he or she will feel comfortable teaching as well as be able to take ownership for the improvements in the lessons.

Best Practices also provides the teacher with support and a framework in which to reflect upon his or her solution and learning process. Using the Technology Matrix at the beginning of the Enhancement Process helps the teacher identify the specific goals (technology-integration and historical thinking engagement) at the beginning of the instructional development process. The teachers have the opportunity to explore technology-integrated activity examples that demonstrate the strengths of different software applications for engaging historical thinking skills. The examples also illustrate how multiple historical thinking skills can be addressed in a single activity.

The Technology Matrix can be used in several ways. Some teachers may want to explore all options — and view activities for all historical thinking skills and software. Other teachers may be interested in viewing the way different activities engage different historical thinking skills for each software program. The Technology Matrix also provides teachers with the opportunity to compare solutions to those of other teachers, broadening their perspective and resources for approaching an instructional problem. The Technology Matrix should help teachers see “how” to integrate technology to meet the content standards (historical thinking skills and content). The Technology Matrix’s flexibility allows the teacher to choose those areas (historical thinking skills and software applications) that fit his or her needs.

Program Components

Teachers are offered the tools to revise their lessons through a two-stage process: the Clarification Process and the Enhancement Process. In the Clarification stage, teachers identify and clarify the components of their existing lesson. In the Enhancement stage, teachers begin to revise their lesson and develop a technology-integrated activity. Teachers choose from a list of historical thinking skills and software applications. The resulting matrix provides activity ideas as well as teacher examples to match their preferences. From there, teachers develop technology-enhanced activities with the help of guiding prompts. The teacher’s responses to these prompts eventually inform the content of the revised lesson.

Clarification Process

With the support from specific prompts, teachers identify and enter the lesson components from their pre-existing lesson — such as student prior knowledge, goals and objectives, learning activities and assessment — into a specific format. This format helps teachers to identify the specific elements of their existing lesson and to recognize the implications of those choices. The prompts help engage the teacher in active reflection and response to the instructional development process. The teacher’s responses are automatically entered in the final Lesson Plan. These responses provide the teacher with a preliminary instruction plan on which to build and reflect on as they begin the Enhancement process.

Enhancement Process

The Enhancement process is the central focus of Best Practices — this is where the teacher’s existing lesson is revised to incorporate constructivist learning and technology in a way that supports historical thinking engagement. The Enhancement Process consists of (1) five sets of prompts that guide teachers toward developing the revised instruction and (2) the Technology Matrix tool, which provides resources to help the teacher respond to the prompts. The teacher begins the enhancement process by using the Tech Matrix tool to match computer software applications and specific historical thinking skills with appropriate instructional activities.

The Tech Matrix tool functions as a first step in the Enhancement process. The Tech Matrix tool allows teachers to choose historical thinking skills that they want to focus on and specific software that they want to use. The tool then creates a matrix offering descriptions and specific teacher examples of activities that meet both criteria. The matrix provides both general and content specific activity examples. Teachers will use these activity examples to begin developing their own technology-integrated activities with the support of development prompts.
The five sets of prompts -- technology integration, historical thinking skills, constructivist learning, assessment and final reflection -- provide support and structure as the teachers interact with the Technology Matrix tool and creates the content for the revised lesson. Each set of prompts supports the integration of a specific instructional goal into the developing activity. These prompts support teachers in integrating technology as a "cognitive tool" that promotes historical thinking skills, integrating constructivist principles and developing an authentic student assessment method for the created lesson. The reflection prompts provide a time for teachers to reflect and revise their lesson as a whole.

The prompts include questions about specific lesson plan components (e.g. instructional goals, activity, and student learning processes) as well as questions to encourage reflection on the teachers' teaching practices. A sample response and detailed description are offered for each prompt. The teachers reflect on their instruction throughout development to maintain or develop an awareness of their own design process as well as their solution. The teachers' responses are automatically entered into the lesson plan at the end of each set of prompts. The teachers can then reflect on their changes and additions as they relate to the lesson as a whole as well as make additional changes.

This Enhancement process guides the teachers through basic principles and examples for developing constructivist instruction and provides a final checklist to help teachers identify areas that need further development.

Conclusion

Since it is essential that teacher training programs model appropriate teaching methods, Best Practices integrates three important constructivist characteristics. First, the instructional development is centered around a teacher-determined problem (Technology Matrix). Second, the teacher has a role in determining the process for solving the problem. Third, the environment supports and challenges the teacher’s thinking.

Designing an On-Line Campus (OLC) from the Learners’ Perspective

Gary Culwick, Academic Development Group, University of Greenwich, UK  
G.Culwick@greenwich.ac.uk

Malcolm Ryan, School of Post Compulsory Education and Training, University of Greenwich, UK  
M.Ryan@greenwich.ac.uk

Ann Allen, Student Office, University of Greenwich, UK  
A.Allen@greenwich.ac.uk

Abstract: This paper examines the design of an On-Line Campus (OLC) and how it affects the learner. It describes the structure and analyses the thought processes that went into the design of the first OLC at the University of Greenwich. It states the importance of the students' perspectives when designing a virtual learning environment. The discussion is focused on the various elements that comprise the OLC, as well as speculating about future developments.

Background

In 1998 the University of Greenwich began piloting an On-Line Campus (OLC) accessed via the World Wide Web by students (gre-guns2.gre.ac.uk) and via Lotus Notes groupware by staff. Until this time the university had never attempted to co-ordinate teaching via the Internet, instead individual schools with appropriate expertise constructed their own web pages in isolation from other areas of the university. In the early stages, the OLC was used primarily for piloting the school of Post Compulsory Education & Training’s Computer Mediated Communication (CMC) related courses on the Internet, which had previously been delivered via Lotus Notes [Ryan, 1997]. Early in 1999 the OLC had progressed to a stage where the interface had been redesigned to facilitate easier access to core areas and more schools and departments were involved.

The Design – everything only ‘one-click’ away

When constructing the OLC we wanted to mirror the student experience of being on a physical campus, so that any department that existed on one of the university’s real campuses would be available to our on-line students. We wanted this virtual environment to be perceived as an extension to the university’s physical locations, so we designed it around the metaphor of a real campus (Gould, 1995). This differed from the university’s corporate web site philosophy, which was more of an advert - one big web-enabled prospectus.

The advantage of the OLC from the learner’s perspective is that it provides a 'one stop shop' for university learning and teaching materials and support. The use of Lotus Notes as the authoring tool and Domino as the web server provided a much greater degree of interactivity than many of the web-based materials found on the corporate site. The OLC was designed to be highly user friendly, particularly for learners studying at a distance, and consisted of mostly interactive, rather than static (dateable), material. Our philosophy of using Information and Communication Technology (ICT) to provide opportunities for interaction was based on our earlier work, using CMC to support adult distant learners engaged in Continuing Professional Development (Lewis et al, 1997; Jordan and Ryan, 1999)

There were threes core rules that we tried to apply when constructing the OLC:
1. ‘One click’ from useful information

In our view, so many web sites lose sight of their core function. Our function was, and is, to provide a learning environment where access to information should be quick and easy. We were conscious that many of our students were novice ICT users and when studying at a distance they were likely to have limited access to technical support and be easily discouraged if presented with a complex system. We felt it important that no matter where the student was in their individual school’s web pages that they should, with ‘one click’, be able to access many sources of information. To make this ‘one click’ approach possible we opted for a frame-based design with a navigation bar running down the left side of the screen, as can be seen in figure 1 (Brookes, 1993; McCormack and Jones, 1997; Latham, 1998).

![Figure 1: On-Line Campus web site layout with navigation side bar.](image)

This allows our students to work within their course on the right side of the screen and quickly move from one part of the OLC to another to access other resources. For example, if a student were reading a conference entry by a tutor or peer and a book was mentioned, with one click on the Student Resource Area on the navigation bar, they would have access to the university library’s search engines to see if the book was in stock. They could then email or submit a form requesting the book be held or sent to them.

2. No prospectus type materials to be included on school pages

Primarily, we wanted the OLC to be a learning and teaching site, so we discouraged the placing of large amounts of course documentation as this would duplicate the information held on the university’s corporate site. The problem was that pages could be authored easily using Lotus Notes with no prior knowledge of
HTML. Consequently, staff preferred to use Notes to place information on the OLC as opposed to the corporate web site that was still based around traditional HTML language and Unix command structures.

3. A fully featured environment experience

Often web sites tend to include materials that require plug-ins but with no link to download them. By providing a collection of plug-ins on the OLC this saved time and provided a convenient download site to many of the users, especially in the UK where even local phone calls are chargeable.

The Core Areas

The OLC Navigation bar contains links to core areas of the campus. We kept these to a minimum to make the OLC easy to use and by placing this navigation bar in its own frame, it provided an anchor for the students. Wherever they went (which always occurred in the right hand frame) in the OLC, or even if URL links took them away from the OLC, they would always be able to switch to a different OLC area with one click (Brookes, 1993).

The Faculty Area shows a list of schools and departments, which provide services for the students, this list is updated automatically whenever a new school or department home page is created. The Student Resource Area provides a central place for links that will be helpful to students; at the top of this area is the link to the Student Common Room. We decided there should be a single common room for all students, irrespective of course or school. This is more representative of a real campus where all students mingle in the canteen. The News and Helpdesk is where students can find all the latest information on the OLC as well as any web browser plug-in resources that they might require. This area also houses a helpdesk - a bespoke Lotus Notes database that accepts forms submitted by a web browser. Helpdesk personnel can email an answer to the user or compose a technical note that is added automatically to the Frequently Asked Questions (FAQ) list of the helpdesk. The special project area is where new OLC developments are tested prior to launch. Although students may view these, access is restricted to project participants and the final link is to the university’s corporate site.

The Student Office (SO), which is part of Central Registry, have worked with the OLC developers from the beginning. This has allowed a great many of the resources that are available for traditional on-site students to be repackaged for OLC users. They have converted many of the print-based, student-centred publications into a web format for the very first time. These include: regulation documents, advice leaflets, information regarding assessment and two important books that all new students receive when they first join the university; a Guide for New Students and a Skills for Learning Handbook.

With the Student Office taking such an active role in the development of the OLC, this has raised awareness throughout the university of the need to treat distance students as equals to their on-site counterparts. This is shown by the SO constructed, student satisfaction survey form, which is only available electronically via the web and makes no distinction between distance and local students.

The Educational Elements

From the tutor’s or institutional view, the OLC provides an integrated suite of virtual departments including; Library, Media Resources, Student Office and Registry, which gives the distance learner the sense of belonging to a real institution. At the same time it provides a single gateway into school-based materials which remain under the school’s control. Because of the non-html nature of the authoring system, even non-technical staff can maintain these pages, and they also benefit from the accumulated good practise being developed in other flexible learning initiatives employing the OLC.
Educational innovation has primarily come from use of the system by the School of Post Compulsory Education and Training who have developed a large area to:

a) support their current traditional courses  
b) to develop purely CMC based courses for continuing professional development [Jordan & Ryan, 1999].

With collaboration between the developers and tutors of the OLC it has been possible to add new features to the course areas [McCormack and Jones, 1997]. For instance, at the end of a course all students are required to complete an evaluation form. This is now done electronically and submitted and held within the respective course database. Using Lotus Notes workflow features the course database has the ability to allow the tutor to correlate these evaluation results into percentages for analysis. These can be emailed automatically to appropriate departments in the university for inclusion in a variety of reports.

In 1998 we developed our first validated programme to exploit the potential of the OLC. Designed by the Natural Resource Institute, this is a worldwide, distance master's programme in grain storage management that employs the OLC for tutor support and peer to peer interaction.

The Future

There are many ways we would like to extend the OLC in the future. One would be to include a template database for creating on-line exams with automatic results generation, which could be adapted easily by non-technical staff for any course.

Another would be to integrate more university facilities into the OLC, possibly in an on-line, 'multiplex' lecture theatre. The university's lecture theatres are geographically dispersed across many campuses. If they all had video cameras installed and were connected to computers, this would allow the lecture to be uploaded to the OLC for live transmission or archived for future presentation. The students entering the 'multiplex' would be able to choose which live lecture to attend or go to the archive and view an old lecture, although we have yet to find a way to simulate popcorn on the OLC!

Lastly, to integrate real-time collaboration via Lotus Sametime software (Lotus, 1999), which would allow students to see if their tutor is available on-line to interact with them synchronously, via a Chat based system. This would also allow the tutor to share computer applications with the student. Such a system would also greatly assist the helpdesk by allowing the personnel to demonstrate visually at a distance where the student is having a problem.

Whilst we attempt to introduce innovation into the university's learning and teaching processes via the OLC, we must never forget it must be focused on what students want and we need to be ever mindful of the vast range of technical abilities of these virtual students. We welcome constructive criticism from all our users in our endeavour to make the OLC an even better virtual experience.

Abstract

The purpose of the study was to examine how students (n = 14) participated in a web-based graduate course discussions. The focus of this examination was to analyze the interactions that occurred during synchronous (chat) and asynchronous (listserv) modes of discussions using a coding scheme developed by the researchers. During a one week period, students were randomly assigned to either a small group chat or threaded discussion. The next week, the two small groups switched forms of discussion and were given another topic question to discuss. The study is qualitative in nature in order to find out whether the students' participation were substantive (that is, directly related to the topic) or non-substantive (messages were not directly related to the content) in both types of discussions and these were compared by type of comment and quantified. In addition, the students were surveyed about their computer and Internet experience and skills as well as their attitudes toward the course content, its organization and delivery. Results indicated that overall students' discussions included all 8 types of substantive and non-substantive. However, the participants when in the chat showed greater numbers of responding and reacting statements (substantive types) in both weeks than when participating in the threaded discussion. Based on the survey results, some students found it difficult to follow the dialogue in the chat, but overall they enjoy this type of interaction. The students also enjoyed the threaded discussion, especially for its convenience.

Introduction

Although various forms of Distance Education have been in existence for a long time, the advent of the Internet and the World Wide Web (WWW) has brought changes to teaching and learning at the university level. A number of universities and colleges are adding or converting traditional courses and programs to web-based instruction (WBI) or online learning environments. These WBI courses require not only a different design and delivery of the instruction, but also a different form of engagement on the part of students with the course materials, other students, and the instructor. These learning environments require not only active, but interactive participation (Davidson-Shivers & Rasmussen, 1998 & 1999). Interactive learning includes an interchange of ideas with all participants; that is, the students and instructor exchange ideas in a flexible and dynamic environment (Rasmussen & Northrup, 1999).

This interchange of ideas may occur through a synchronous mode, which occurs at the same time but from different locations, or through an asynchronous mode, in that students and the instructor communicate to each other at differing times. The computer-mediated communication (CMC) literature documents the dynamics of online discussions by various forms of communication patterns, processes, and purposes (William & Merideth, 1996; Piburn & Middleton, 1998; Wojahn; 1994; Jeong, 1996; McCormick & McCormick, 1992; McConnell, 1997 Sherry, 1999; Hara, Bonk, & Angel (in press)). The CMC literature and the literature on Web-based instruction (WBI) identifies various online delivery formats (e-mail, listserv, chats, conferences, etc.) and how they might be used for discussions (Khan, 1997; Shotsberger, 1997; Driscoll, 1998). Developers of online learning environments often suggest that asynchronous communication may have advantages over synchronous.
For instance, Driscoll states that asynchronous methods allow students more time for reflection than do synchronous delivery formats; with one example shows only 20% of a web-based course to be in the synchronous format. In addition, Jeong argues that “most [not all] findings hail the use of asynchronous communication” but this author also “notes the absence of the evaluation of synchronous communication and their effects” (p. 51). His own findings suggest that synchronous online chats have an advantage of promoting highly interactive discussions with a disadvantage for the group to digress from the topic to another (p.62). However, there are mixed results based on the CMC research and there is a lack of evaluation on synchronous discussion, it seemed viable to compare and contrast how students participate in both types of discussions.

Methods

Subjects

Participants in the study were graduate students (n = 14) in a required course for their degree programs of study from a southeastern regional university in the USA. Approximately two-thirds of the students were female. Based on the survey results, the majority of students reported that they had computer experience with some having less experience with the Internet and WWW. Participation in the discussions was a course requirement. Confidentiality of information was maintained by having surveys collected and coded by someone other than the instructor and the analysis of the discussions occurred after final grades were posted.

Course content, organization, and requirements.

The course was an introductory course on trends and issues in instructional design. The course was organized by weekly topics with assignments and questions being posted to its website. Two or three questions were given with directions on how to post (either chat or threaded discussion) answers and replies. Students had a week to respond to any listserve question(s) and were also required to reply at least twice to other students’ responses during the week. Typically one question was scheduled for an hour and a half chat during the week. Chats were either large group (whole class) or small groups (half of the class per chat session). Students were also assigned particular readings as preparation for discussing the weekly topic. They were also encouraged to draw on their own experiences, knowledge and skills. Both threaded discussion and chat could be copied and all of the chats were distributed to all members of the class. After the fifth week of the term, students were assigned as discussion leaders to facilitate the weekly discussions in both chats and threaded discussions with guidance from the instructor. The instructor participated directly in the online chats; however, less so when another student was the discussion leader. With the threaded discussions, she added her comments to a summary at the end of the week rather than commenting during the week.

Procedures

The following procedures occurred for gathering the data.

C Using a Likert-type questionnaire, students were surveyed three times during the term in order to evaluate students’ reactions and attitudes toward the course. The survey also gathered information about the computer experiences and skills. Data was kept confidential by having someone other than the course instructor collect and code each set of questionnaires.

C For one question posted during the thirteenth and fourteenth week of the term, the students were randomly assigned to two groups. Half the students discussed the question (it was the third question posted for each week) using the online chat and the remaining students used the threaded discussion. The process was repeated the following week with a new topic and question, and the two groups switched discussion modes.

C Transcripts of the discussions for those two weeks were then coded using a coding scheme developed by the researchers based on the work of Piburn and Middleton (1998) and Williams and Meredith (1996). See Table 1 for the coding scheme. The coding and analyses of the discussions did not occur until after the final course grades were posted.

C The researchers were trained to use the coding scheme and then coded each discussion transcript independently. The transcripts were coded by each completed statement/thought made rather than
using a line-by-line method. Complete sentences, incomplete sentences, and short phrases were considered as a statement if a new or different thought was presented within them. Incomplete sentences or short phrases were often used within the chat due to the speed and interactive nature of this format.

C The researchers met together to reach agreement on each line coded. If any discrepancies were encountered their codings, the three researchers discussed the statement and then came to consensus. At that time, the researchers added another code type, supportive statements; it became number 9.

Table 1
Types of Discussion Participation Coding Scheme

<table>
<thead>
<tr>
<th>Code</th>
<th>Types of Discussion Participation Coding Scheme</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>SUBSTANTIVE: messages that relate to the discussion content or topic.</td>
</tr>
<tr>
<td></td>
<td>Structuring—Statements which initiate a discussion and focus attention on the topic of the discussion. These statements are often made by the discussion leader or instructor (i.e. “Today we are going to discuss . . .” or “This week’s discussion will focus on . . .”).</td>
</tr>
<tr>
<td>2.</td>
<td>Soliciting—Any content-related question, command or request which attempts to solicit a response or draw attention to something (i.e. “What do you think the author meant by . . .?” or “Give us some support for that assertion.”).</td>
</tr>
<tr>
<td>3.</td>
<td>Responding—A statement in direct response to a solicitation (i.e. answers to questions, commands, or requests). Generally these are the first response to a question by a given individual.</td>
</tr>
<tr>
<td>4.</td>
<td>Reacting—A reaction to either a structuring statement, to another person’s comments, but not a direct response to the question. (i.e. “Your earlier statement got me to thinking about . . .” or “I agree/disagree with Bob because . . .”).</td>
</tr>
<tr>
<td>5.</td>
<td>NONSUBSTANTIVE: messages that do not relate to the discussion topic or content.</td>
</tr>
<tr>
<td></td>
<td>Procedural—Scheduling information, announcements, logistics, listserv membership procedures, etc.</td>
</tr>
<tr>
<td>6.</td>
<td>Technical—Computer-related questions, content, suggestions of how to do something, not related to the topic directly.</td>
</tr>
<tr>
<td>7.</td>
<td>Chatting—Personal statements, jokes, introductions, greetings, etc.</td>
</tr>
<tr>
<td>8.</td>
<td>Uncodable—Statements that consist of too little information or unreadable to be coded meaningfully.</td>
</tr>
<tr>
<td>9.</td>
<td>Supportive—Statements that although similar to chatting, there is an underlying positive reinforcement to the comment! (i.e. “Good idea!” or “Excellent work!”). Note: This type was added when the researchers met for consensus of their coding of the transcripts.</td>
</tr>
</tbody>
</table>

Data Sources

Survey

Data were gathered by a questionnaire distributed three times to the group. The survey asked students to report their capabilities using technology, web-based technology in particular, experience with the discipline, and other demographic data. They were also asked to critique the course as it progressed through the term in
terms of technical difficulties, interest in topics, preferences to types of activities, instructional strategies used, and amount of work that this course in this format involved.

Coded Transcripts

Two threaded discussions and two chats were coded for types of participation that students made during online discussion. The coding scheme used two main categories of substantive, messages that related directly to the content or topic at hand and non-substantive, messages that did not relate to the discussion topic or content. The 4 subcategories for substantive were structuring, soliciting, responding, and reacting; the 5 subcategories for non-substantive were procedural, technical, chatting, supportive statements, and uncodable. Every statement or sentence was coded using one of these 9 subcategories. (See above Table 1.)

Discussion of Results

The analysis showed that participants' comments were made in all substantive and non-substantive categories in the chats and the listservs, except that there were no uncodable (albeit, unreadable by the researchers) in the threaded discussions and several in the chat transcripts. In addition, whether in a chat or threaded discussion for either week, students overall provided more substantive statements either by responding to a question or reacting to another's statements or comments than any of the other seven categories. By mere observation of the length of the responses by participants in a threaded discussion, it would seem that they would contain more substantive remarks than those in a chat discussion, especially since statements in the chat tended to be shorter in length and were often interrupted by others' comments. However, the chat discussions showed greater numbers of responding and reacting statements in both weeks over the substantive statements made in the threaded discussions. There were also greater amounts of non-substantive statements in the categories of chatting and supportive comments during the chats than in the threaded discussions. Overall there were a greater number of interchanges and interaction when participating in a chat than when involved in the threaded discussions. Thus, it appears that for these two weeks of a given course, the chat discussions were dynamic with a lot of interactive and interchanges among the participants.

The supportive data suggests that students liked both modes of delivery every time they were surveyed. In their comments, they stated the chat discussions were sometimes difficult to follow, but still enjoyed them. One student commented that they liked small group chats over large group ones. They enjoyed the convenience of the threaded discussion.

When reporting their computer experience level, most stated that they had experience using computers, although some stated that they had little experience using the Internet and WWW. It was noted that with the second survey, the reported level of computer experience was lowered slightly. But it returned to the same level as reported in the first by the end of the course (and in the third survey). The reported 'dip' in computer experience may be due, in part, to technical difficulties of online services. And once these were overcome, students may have regained their confidence in their computer abilities.

The importance in this study is not so much as to determine 'what group won', but rather to determine which form of discussion is preferred and which is most appropriate for the types of actions and interactions that students need to perform in order to be successful in such a learning community. It is also important to realize that these graduate students, for different reasons, enjoyed both forms of discussion. The use of chats provided a direct and interactive environment in which they reacted and responded to the topic at hand, chitchatted, and made supportive comments to each other. It involved a high degree of interchange and was a dynamic environment, although sometimes difficult for some students to follow the train(s) of thought. In contrast, threaded discussions provide an opportunity for students to provide reflective, thoughtful responses to posed questions, judging by the length and wording of any given single response. They were also able to provide insightful reactions to others' opinions and ideas presented perhaps because a threaded discussion's timeframe (of a week) allowed for that. Students enjoyed the chat because of the convenience factor. Both discussion modes—synchronous and asynchronous—have merit and may be used within online courses. They clearly can be used for different purposes and provide different, but useful, means for students to engage in learning. It is suggested that additional research into the use of chats and threaded discussions be conducted.

The Adaptation and Use of a WWW-Based Course Management System within Two Different Types of Faculties at the University of Twente

Wim De Boer and Betty Collis
Faculty of Educational Science and Technology
University of Twente
Enschede, The Netherlands
w.f.deboer@edte.utwente.nl, collis@edte.utwente.nl

Abstract: At the Faculty of Educational Science and Technology, University of Twente, in The Netherlands, the entire faculty is involved not only in the use of a new WWW-based course-management system (called TeleTOP) but more fundamentally in a new educational approach. In addition we are working with other faculties to support the same progression. How are we doing this? In this article, the TeleTOP Method and implementation model are (http://teletop.edte.utwente.nl) are described and the similarities and differences between the implementation, the adaptation, and the use of the TeleTOP course support environment in the Faculty of Educational Science and the Faculty of Telematics (computer science and networks) are analyzed.

Introduction: TeleTOP at the University of Twente

The University of Twente in The Netherlands has a national and international reputation in the field of telematics, the European name for the branch of computer science involving the combination of information and communication technologies (in particular, related to the Internet and the World Wide Web (WWW)). A focus is the application of telematics applications to the teaching and learning process, what we call "tele-learning". In our definition, tele-learning does not necessarily imply distance education but instead emphasizes the increased flexibility that can come to the teaching and learning process through the combination of the new possibilities offered by the WWW and new ways of teaching and learning. The most ambitious of the tele-learning initiatives at the University of Twente is the TeleTOP project in the Faculty of Educational Science and Technology. Our core ideas are extending the levels of activity and engagement of our students and extending the impact and influence of our good instructors (Collis, 1998).

The decision made by the Faculty of Educational Science and Technology in 1997 was to involve all courses in a re-design process, both pedagogically and including use of WWW tools and environments. This involves the challenge of working with a wide variety of courses and instructors. In the academic year 1997-98 we re-designed all the first-year courses, in 1998-99 all the second-year courses, and by approximately the end of the year 2000 all other courses (for more information, see http://teletop.edte.utwente.nl, through which a number of courses can be visited for inspection and many publications and presentations are available).

To support this new approach, we needed a technical platform and an implementation model that would fit a variety of different kinds of courses and instructors. We identified a core set of requirements for the WWW-based course-management system that we would need (Tielemans & Collis, 1999). In our analysis, no existing system met our requirements, so we capitalized on our own experience and in 1997 built our own system, based upon a Lotus Notes database. (This system is described in detail elsewhere; Collis & DeBoer, 1998; Tielemans & Collis, 1999). However, no matter how elegant a system is, instructors must use it, an administration must choose to support its use and thus must make resources available, the technical infrastructure already in the faculty must handle it, and soft- and hardware must be available. Thus an implementation model is necessary that integrates a variety of considerations and change entities.

After the first year and a half of implementing the WWW in our own faculty, we began in January of 1999 to respond to other faculties who also wanted to make use of our system and method. We chose as the next faculty to change its way of teaching and learning a faculty within our university with different types of courses, students, and instructors compared to our own faculty. This was the Faculty of Telematics, a technical faculty with many engineering and mathematics courses. The adaptation proceeded smoothly and we have now moved to the rest of the faculties in our own university as well as faculties in other universities. In this article, we describe the TeleTOP Implementation Model which underlies all this work. The Model indicates, based on literature and experiences, the change entities and areas which are of importance when an institution is going to implement the WWW in education in a wide-scale way. We also describe the transfer experiences with the Telematics Faculty.
The TeleTOP Implementation Model, Version 1

In an earlier study (see DeBoer & Collis, 1999) an implementation model of the change process was defined with the interrelationships among three phases of a time dimension, five change areas, and 12 change entities (see Figure 1).

Figure 1: The TeleTOP Implementation Model, Version 1

The Model is a direct reflection of the experiences within the Faculty of Educational science and Technology since 1997. Some aspects of the innovation have already reached the institutionalization phase (for example, all students and most faculty routinely going to their start pages generated by the TeleTOP system on a daily basis) while new aspects are being initiated (such as the capturing of instructor and student presentations on digital video for the reuse of segments of these presentations through course WWW environments as video-on-demand for a variety of learning purposes). The sizes of the circles and ovals reflect complexity in terms of the number of change areas involved. The importance of key figures in the initiation phase, including all of the members of the faculty administration, had an early impact on all change areas in the TeleTOP situation.

Experiences at the Faculty of Telematics

In January 1999 it was decided that the new Telematics Faculty at the University of Twente should also set up a WWW-based course-support environment as was done at the Faculty of Educational Science and Technology. A project group (including the first author) was set up which would be responsible for the technical and instructional implementation of TeleTOP in this new faculty. A key question was if the educational culture and approach in one faculty, as visualized by the TeleTOP Implementation Model (Figure 1) could map onto another faculty. The project group consisted of two TeleTOP team members and two members of the Telematics Faculty. The Telematics members became primarily responsible for the implementation, while the transfer of the TeleTOP method and course-management system was the responsibility of the TeleTOP team members.

Figure 2 gives an impression of how the TeleTOP team planned the steps for the transfer and adaptation of TeleTOP to another faculty (a process repeated in March-June 1999 for a faculty in another university). Figure 2 can be seen as an operational version of the TeleTOP Implementation Model shown in Figure 1.
The actual implementation steps visualized in Figure 2 will be summarized in the following section (Table 1). Comments will be given as to what was intended in the steps, and what actually occurred in the transfer process (see also Fisser, Kamp & Slot, 1999).

Table 1: The change entities used in the TeleTOP Implementation model, in terms of the experiences of the Telematics Faculty

<tbody>
<tr>
<td>1. Educational target</td>
<td>+/-</td>
<td>This is corresponding with: I. Defining the target group, context, goals and making a plan. In the Telematics Faculty situation, while most of these activities occurred, the goal of this innovation was not made explicitly clear to all involved. The Telematics faculty coordinator planned a start-up session with all who were involved at the start of the project, and indicated that the initiative was very important with regards to providing more flexibility for the students. There was not a real educational target; more focussed on flexibility towards students and the image of the new faculty.</td>
</tr>
<tr>
<td>2. Fit with instructional practices</td>
<td>+</td>
<td>The instructors indicated that they had to change their ways of teaching, but this was within reasonable boundaries. …</td>
</tr>
<tr>
<td>3. Quality hardware network</td>
<td>++</td>
<td>This is corresponding with: II. Setup the technical infrastructure. The operational model shown in Figure 2 indicates that the technical infrastructure for the WWW-based course-management system should be set up in Months 2 and 3. In the case of the Telematics Faculty, this was no problem. There was already a sophisticated technical infrastructure in place in the faculty, with an excellent network, and multi-media computers for all students and staff.</td>
</tr>
<tr>
<td>4. Key figures to initiate</td>
<td>++</td>
<td>The key figure to initiate the educational change was the faculty administrator. In this case a top-down approach initiated the process; some instructors already had used the WWW for their courses, but had to change to the new system.</td>
</tr>
<tr>
<td>5. Build/buy software/hardware</td>
<td>++</td>
<td>This is corresponding with: II. Setup the technical infrastructure. The only thing needed to be set-up was a Lotus Notes Domino server, and to guide the faculty Web masters in learning some new skills for maintaining it. The faculty invested a considerable sum of money to get the right hard- and software. They chose to buy/license the software from TeleTOP; not build it themselves, because it was available and had proven itself in practice.</td>
</tr>
<tr>
<td>6. Top down &amp; bottom-up</td>
<td>++</td>
<td>As already mentioned in #4 (Key figures to initiate) the administrator of the faculty followed a top-down approach introducing the change. The way instructors were encouraged to explore the possibilities of the system and were able to use it so they would maximally benefit from the system could be seen as bottom-up.</td>
</tr>
<tr>
<td>7. Embedding of use</td>
<td>+/-</td>
<td>As the initiation phase started in March 1999, the faculty is not at the point where embedding of use should start. This should happen in the future (within 1-2 years).</td>
</tr>
<tr>
<td>8. Innovative culture</td>
<td>+</td>
<td>An innovative culture should make it easier for an educational change. The faculty is still very young, so a characterization is difficult to give.</td>
</tr>
<tr>
<td>9. Budget</td>
<td>++</td>
<td>The commitment of the faculty management was evident, because extra money and resources were made available. The planning should indicate when the course-</td>
</tr>
</tbody>
</table>
management system should be operational for use. The faculty was willing to invest in human resources (support groups) and hard- and software. The instructors however did not get payment for their extra time investments.

<table>
<thead>
<tr>
<th>10. Initiation target</th>
<th>+</th>
<th>The initiation target in this case was the fact that the new faculty was just ready to start. This was a good time to set up new courses with the course-management system.</th>
</tr>
</thead>
<tbody>
<tr>
<td>11. Project team</td>
<td>++</td>
<td>This is corresponding with: <strong>III. Technical support, Helpdesk.</strong> The new supporters, already experienced in giving support, where educated in using the new software. The educational supporter also learned to work with the supportive educational tools, getting hands-on experiences. The project team played an important role in the implementation of the educational change. <strong>V &amp; VI. Instructor sessions &amp; Designing the course</strong> A series of sessions for the instructors were set up. The topics dealt with within the sessions were technical as well as instructional. After the first session, during which members of the administration introduced their plans, a technical session followed. The course-management system was demonstrated and instructors had the chance to try it out themselves. Two weeks later a personal session was arranged. In an one-hour interview examples of how the WWW could be used in support of technical courses. Every other week a two-hour hands-on sessions was held. Instructors used their own course-management environments, to try things out, and to exchange ideas. Most instructors attended these meetings, and thought they were worthwhile. The instructors used their time getting skilled in the using the course-management system at the same time as they were designing their own courses. Most work was done a few weeks before the starting date of a course. <strong>VII. Student session.</strong> The use of a course support-management system which is fully based on the WWW and does not make use of additional programs other than regular e-mail proved to be a very user-friendly system for the students. Students learned the basics of the system and were able to work with the system within one short session. All students got a simple manual. They learned more about additional features of the environments as they used them during their courses. <strong>VIII &amp; IX. Start the courses &amp; Educational support.</strong> The courses could start after the student session, and after the student had gotten access to the course-management environment. The use of the WWW made it possible to have interaction within the environment, and the possibility to let the environment 'grow' during the time the course was held. During the time that the courses were in operation, educational support was available to the instructors, as well as technical support (see Step IV). Most instructors however were capable of managing their own environments.</td>
</tr>
<tr>
<td>12. Structural support group</td>
<td>?</td>
<td>It is not clear yet how and who will be supporting the instructors in the future. This is of great importance for the successful institutionalization of the change.</td>
</tr>
</tbody>
</table>

Thus, as summarized in Table 1, the TeleTOP Implementation Model did seem to reasonably describe the experiences of the Telematics Faculty in initiating and implementing the use of a WWW-based course-management system.

**Differences in the use of a WWW-Based Course Management**

For almost two years, courses have been using the TeleTOP system at the faculty of Educational Science and Technology. The Faculty of Telematics has used the system for half a year. At both faculties an evaluation was carried out to look at the use of the systems. It is interesting to look at differences in use between the two faculties, of which one is more technical (Telematics) and one of which is a social science (Educational Science and Technology). Are there differences in the use of the TeleTOP system and what factors influence these differences? In particular, both groups of instructors have found a WWW-based matrix (which we call a roster) as an organizing structure for course content and activities to be particularly useful. Figure 3 shows the options that were chosen by the instructors of samples of 26 courses of Educational Science and Technology and 10 instructors of the Faculty of Telematics.
Central in the course environments is the roster of a course, integrating study materials, contact-session notes, assignments, communication, and feedback. Figure 4 shows the roster of Telelearning, a course of the faculty of Educational Science and Technology. The roster in the TeleLearning course gives an overview of the assignments and meetings of the course. The course was organised around contact sessions. Instead of lectures, the students present could interact with each other in a variety of ways, and students not present would join in, within the next 48 hours, via the course WWW site. For students not able to be involved for reasons of work or distance as part of the real-time group during any of the sessions, participation in the group session was also expected, but asynchronously and via the WWW. Figure 5 shows the roster of Switching and Control Systems, a course given at the Faculty of Telematics. In this course, students were reasonable for presenting more than half the lectures. Students formed groups and chose a topic, about which they presented material to their fellow students and to the instructors. All material was placed in the session row of the roster of that particular week. The first part of the lecture session was the actual lecture, the second part was intended for questions and discussions. Also after the sessions the discussion would go on in the discussion area of the site. The site was therefore intended as a real support site, to be used for information, materials and communication.

Figure 4: The roster of Telelearning.
Figure 5: The roster of Switching and Control Systems

Differences in use?

Looking at Figure 3 and taking into account the two examples of the use of the roster shown in Figures 4 and 5, it can be concluded that the differences in use of the system between the two faculties are not very large. It seems that the Faculty of Telematics focuses a little more on communication via the support environment, and Educational Science & Technology focuses more on collaborative work through the support environment. Both faculties are still in the implementation phase, and have a long way to go until full institutionalization. It is therefore interesting to follow the faculties and see where they will be at in one or two years. Maybe the differences will fade away or maybe they will increase?

gpaquette@teluq.uquebec.ca

Abstract: As the capabilities of information technologies increase, the success of developing learning environments adaptable to individual learner's needs and preferences depends more on design planning than on technical features. This paper focuses on a design method grounded in knowledge modelling, evincing its use in the design of a flexible learning environment for the Web, aimed at three different target audiences. It is proposed that modelling techniques can be used to represent the generic parts as well as the specific activities of each one of the target audiences from four different perspectives: contents, pedagogical strategy, learning materials and delivery platform.

Introduction

In the past decade, the potential of learning environments adapted to the learners has been put forward by studies interested in user centred design (Nikolova and Collis, circa 1997; Larin, 1997; Hannafin et al, 1992). Recent technological advances in the Web have increased that interest because it offers a promising option to deliver such environments, thanks to the capacity to combine the advantages of different media, to handle large amounts of interconnected information and to facilitate social interactions by linking people throughout the world (Knowles, 1996). Before making this potential concrete, however, there remains an array of challenges for instructional designers since design methods addressing environments adapted to learners are still sparse and/or haven't been empirically tested (Pulkkinen, 1997 and Larin 1997).

This paper reports an experience using MISA, a courseware engineering method, in the design of a Web course aiming to meet the needs and characteristics of three different target audiences. It first describes the issues addressed by MISA. In particular, it discusses how a modelling approach has been used in the representation of four different axes (content, pedagogical strategy, learning materials presentation and delivery infrastructure). Then, it explains how this method has been adapted to represent the generic parts (shared by the three target audiences) as well as their specific conditions.

1. The Method: MISA

For more than seven years, a multidisciplinary team at LICEF Research Centre has engaged in the development of tools to assist the designers of telelearning environments. The expertise from various fields has resulted in the development of a courseware engineering method named MISA (French acronym for Learning Systems Engineering Method). MISA proposes an approach to learning systems design based on 4 axes that are created individually but are closely related. The multidimensional structure of each axis is represented through a knowledge modelling technique (Paquette et al, 1998). A software called MOT is used to graphically describe different types of knowledge and their links (Léonard and Lalonde, 1997).
Empirical evidence of the effectiveness of MISA is elicited by the successful application of its principles in different courses designed to be delivered in telematic contexts. MISA doesn't presuppose a particular pedagogical orientation or a specific technology; it is learner centred and considers eventual differences between target audiences according to their profile. The attributes of the target audiences determine the basis upon which the modelling of axes is to be done. To identify these attributes, MISA offers a set of electronic forms including sections to describe each target audience. Currently, MISA considers different target audiences as belonging to one single organisation. This may be seen as a constraint in the design of learning systems involving several organisations in which each one of them brings their own set of target audiences. In order to analyse this limit, MISA has been used in the design of a Web course aimed at three different organisations, corresponding to three professional associations: accountants, managers and notaries. The next sections describe the process of examining this issue.

2. Target Audience Profile

The first phase of MISA's pedagogical engineering process addresses the learner's profile. Since MISA considers different target audiences as belonging to the same organisation, each professional association (PA) has been taken into account as an organisation on its own. In so doing, it was possible to get a general characterisation of each PA as well as to identify the profile of their own different target audiences. Among the distinguishing attributes were the number of participants, language, availability, learning preferences and attitudes.

The information gathered from the three PAs culminated in a generic profile of the target audiences. Generic attributes were the academic level (a university degree) and similar computer literacy. All of them were familiar with Web navigation. The characteristics of specific target audiences were drawn and compiled in families pertaining to a single generic trunk with branches both specific and generic. The target audience profile would define the orientation of the four models described below.

3. Subject Matter Model

The modelling of the subject matter has been done in the second phase of the engineering process. The challenge was to create a unique model that could be adapted to each of the professional associations. A procedural model was chosen in order to accommodate the general objective of the course: to use information technologies (IT) to improve the effectiveness of professionals in their tasks. Figure 1 shows the first level of the subject matter model.

In this model, the main knowledge, “Using IT in professional activities”, is a process (grey oval) having as input the knowledge unit “IT tools” which, in turn is determined by the type of task to be done. The general process starts by defining the task to be accomplished and is followed by the identification of the appropriate tool to be employed.

Since this generic model had to represent the specificity of each target audience, different means were used. First, a ruling principle was applied to the main knowledge unit. The hexagon “Professional Context” indicates that the
leading process varies according to the context in which ITs are to be used. In this case the context is given by the professional associations (A=Accountants; M=Managers; N=Notaries).

Secondly, a learning skill has been associated with each knowledge unit according to the requirements of different target audiences. For example, the learning skills "Memorise", "Analyse" and "Transfer" could be joined to the knowledge unit "IT tools" to respectively illustrate the needs of each professional association.

Finally, the creation of sub-models enabled us to represent a knowledge unit as seen from different perspectives. The knowledge "Type of tasks", in figure 1, has been further divided into five knowledge units corresponding to the five sorts of tasks identified as important in the subject matter model: self-management, information, production, collaboration and assistance. These tasks were created as a sub-model inside the hexagon "Type of tasks".

For each professional association, a series of tasks embodying their professional practice were selected. A comprehensive analysis of the specific tasks led to the classification of families of tasks named "common tasks" that were shared by at least two target audiences. The common tasks were integrated into the generic task branches of the model and were separated into new sub-models to represent the specific tasks.

4. Pedagogical Model

The third pedagogical engineering phase suggests the description of the activities available to the learners as well as to the instructors (if any) through a pedagogical model. This model indicates how the activities are organised and which learning materials and tools are necessary to accomplish them.

The pedagogical model is nurtured by the subject matter model and is oriented by the target audience profile depicted in the first phase of the engineering process. Since the specific aspects to be considered in a learning environment can be numerous, the diversity of pedagogical possibilities in a learning environment adapted to learners can be difficult to represent.

To facilitate this kind of modelling the activities were combined to form groups named "learning units". The purpose was to discern different alternatives according to the two main learning preferences of the target audiences: guided learning or autonomous learning. The model offers different possibilities to the learners through seven learning units (LU). All LUs are generic, excepted for LU5, which was conceived to answer some specific needs of one target audience: the manager's professional association (M).

The first learning unit (LU1) introduces the general concepts regarding IT and enables the learner to get a glimpse of the different decisions s/he can take, among others, to select the content to learn and the pedagogical path to follow. The pedagogical model is not linear and after completing LU1, the learner can choose any other LU. To assist the learner in her/his choice, LU2 offers activities to help her/him identify her/his profile whereas LU3 contains activities to help in the planning of her/his learning process.

If a learner's preference is for autonomous learning, s/he can accomplish the tasks in LU4, which are exploratory in nature. LU4 covers the same subject matter as LUs 5, 6 and 7, but the learner can decide on the content to be learned and can progress according to her/his own pace. Assistance of tutors, pairs and advisors is always available.

When a learner's preference is for guided learning s/he can choose the content to learn from LU6 or LU7. Whereas LU6 aims to improve the effectiveness of a professional when doing a research task on the Web, the LU5 intends to enhance effectiveness in communication and collaborative tasks.

As stated before, the pedagogical model is generic; its specificity is emphasised in the activities of each LU through 1) the principles applied to the learning materials and 2) the sub-models in pedagogical scenarios representing distinctive characteristics.

The pedagogical scenarios contain the activities of a LU describing the interventions of learners and the tutors (if any). Figure 2 shows the representation of the learners' activities of LU 6.
In this model, principles (hexagons) designating the target publics have been used to refer to the nature (generic or specific) of the inputs and products of the activities. The principle PA indicates that the material exists in three versions, (one per professional association). "N" implies that the element applies only to notaries. The absence of a hexagon indicates that the element is generic, i.e. is the same for the three target audiences.

5. Media modelling

The media model has been constructed during phase 4 of the MISA method and according to the orientation principles proposed in phase 2. These principles had stated the types of learning materials, the selected media support, their size or duration properties, and their actual status: existing, to be adapted or to be built from scratch.

For each learning material, its media model describes its main components. For example, Web pages, video sequences or book chapters are, each in turn, subdivided into smaller components, down to the media element which will correspond to a text, an image, an audio or a video file called “content objects”. These media components and elements are structured together by transition links and regulated by principles (norms to guide their presentation).

Each learning material is associated with one or more target populations. Some of the materials are generic, intended to be used by every target population even outside a specific course, for example, the "User Guide of the Virtual Learning Environment". Others are specific to a target population such as the case studies "Will in Trust" for the notaries, "Exporting marble products" for the managers or "The Verdi inc." for the accountants; while others are specific to the course but common to all target populations, such as “Tools for Efficient Communication”.

In the media model, learning materials and their components are organised around a metaphor, in this case an exposition hall on information and communication technology. Such a metaphor makes it easy to separate the generic, common and specific components, while keeping them related in a consistent way. The metaphor also gives a concrete meaning to the pedagogical scenarios through an analogy with a familiar situation.

In our case, the exhibition hall contains booths corresponding to the generic tasks in the pedagogical scenarios: Self management: the “Welcome Kiosk” (Learning Units 1, 2 and 3); Exploring tools: the “Smart Explorer” (LU 5); Information search: the “Successful Prospector” (LU 6); Production: the "Efficient Communicator" (LU 7); Collaboration and assistance: the “Bistro”, the “Auditorium” and the “Idearium” are all sections of the exhibition in which contacts, exchange of ideas and assistance can be requested or given (LU 5).

On that basis, a media model of the website could be built as a MOT graph representing media components and elements as concepts (rectangular boxes), transition links as procedures (oval boxes) and norms as principles (hexagonal boxes). Figure 3 presents the main model, together with the corresponding main Web page of the exposition hall. In the model, the transition links a, b, c, d, e and f, lead to pages where other components correspond to activities and resources that will be accessible in the future website.

Based on the orientation principles and each target population profile, we have first built a generic model (mainly independent from the subject matter but relevant to the metaphor). Then, in a second step, we have identified the
specific media components addressed to each target population, and also the common components and their media elements.

![Figure 3. Media model and corresponding Web page](image)

The main media model of figure 3 shows how we have grouped the generic aspect related to the metaphor, for example the booths. It shows the common components linked to the course content, for example "Principles of communication" in the Efficient Communicator’s booth. Each booth has transitions towards specific files, such as the assignments for learning activities using situational descriptions such as "Mediation familial" (for notaries) or "Planification stratégique" (for managers).

Important constraints have influenced this media model. We wanted to have a single interface for every target population in order to minimise the development costs, while still ensuring that each target population would have access to tools and learning materials appropriate to them. To achieve this, the generic and common components have been integrated in the main model, while the specific components have been represented in sub-models of the media model and their corresponding Web pages.

Finally, in a third step, to insure consistency between this media model and the knowledge model, each main component of the media model has been associated with a sub-model of the knowledge model that had been developed in phases 2 and 3. This is particularly important for some material components such as the self-diagnosis grid, which requires the learner to answer questions about his or her actual skills, followed by a piece of advice from the system on the next activities to tackle.

6. Delivery modelling

Also in phase 4, a delivery model has been developed in tandem with the media model, based on the orientation principles stated in phase 2 and revised in phase 3. The principles had identified the technological infrastructure (networks and tools) and the services (for example, of a training manager) required for the delivery of the course. The delivery model is another specialised MOT graph based on the relations between users requiring services to access the learning materials, tools and telecommunication services.

In our case, there were many challenges. We had to provide Web-based training including asynchronous as well as synchronous activities. We were to build a single website for three professional associations, each having their specific needs to reach learners distributed at home or at work within a large territory in Quebec, using various communication services that would require the participation of many service providers.

The Explora virtual learning centre model and system (Paquette, 1997; Girard et al, 1999) has been a good way to fulfil all these conditions. This system is now in full operation at Télé-université and in other organisations. The Explora system supports learners and the other actors in their interactions. Each actor has a specific environment enabling him/her to manage his/her activities, consult and produce information, engage in collaboration and receive assistance from different sources. Some of these resources are linked to the specific website, such as the one intended here for professional associations, to provide user tracking, reports on progress and counselling.

Using the Explora system, we were able to provide an efficient telelearning environment to each of the three target populations, using either broadband communication from Bell Canada for ADSL lines and from Vidéotron for cable-modem lines, as well as narrower ISDN lines more available to some of the participants.
7. Results and Discussion

The four models developed in this project have been useful to structure the main dimensions of a telelearning environment, producing a course design that proved to be an efficient way to communicate with the development team, and also to prepare the delivery of a Web-based course and its technological environment.

Graphical modelling, as proposed by the MISA method, has been a good way to represent the course content as related knowledge and skills, the learning scenarios with their activities and resources, the structure of the website based on a metaphor, as well as the delivery infrastructure and services. The graphical representation of these elements has helped the design team to produce a consistent blueprint of the system in all its dimensions, while considering the many alternatives possible to fulfill the learner’s training needs. It has been helpful in decision making on how to support different target populations, types of learning materials and delivery infrastructure components, within the same website.

Two limitations have been identified. First, the many models, generic and specific, each with their sub-models, even with a well developed and useful representation tool like MOT, have proved a bit cumbersome. Second, instructional engineering is a complex iterative process that requires constant updating of the models. Revising one model entails modification in the others, so the designer has to be helped in his or her tracking efforts for possible inconsistency between models.

To overcome these barriers, the LICEF Research Centre will deliver a more powerful knowledge editor, which is an extension of the actual MOT software, based on a effort started in spring 1997. This software has new capabilities to link different models together so that the designers more easily identify incompatibilities. Also, some help functions are integrated to support team collaboration, as well as variant scenarios or media models addressed to different target populations.

A further effort was started in the summer of 1999, to built ADISA, a Web based performance support system for designers that will cover all the 30 main tasks and processes of the MISA method. ADISA will integrate seamlessly the actual and the future MOT modelling tool, together with forms describing the main objects such as knowledge units, learning activities and resources, media components or delivery services. ADISA will enable designers, possibly working at distant locations, to work together on-line or off-line to design telelearning environments.

Acknowledgements

We wish to thank the three professional associations involved in this project: la Chambre de notaires du Québec, l’Ordre des administrateurs agréés, and l’Ordre des comptables agréés du Québec, and also the CEFERIO who has been a facilitator before and throughout this project. Thanks also go to Lise Damphousse, Hamadou Saliah, Juli Aubin, Louis Guerette, Guillaume Binette, Alexis Miara and Frédéric Bergeron of LICEF Research Centre for their participation in the development of the learning environment. Finally, we wish to thank TL-NCE and OLT, two Canadian organisations that have partly funded this project.
Abstract: The design of an online knowledge community is described. A online knowledge community serves as the socio-technical infrastructure for tele-learning. The E-Study Europe project is taken as an example of the design and development of an international online knowledge community in an university setting.

Introduction

Developments in technology, society and new pedagogies have changed the education last years (Tempelaars, Jager & de Vries, 1999). New technologies offer a wide variety of instructional, information and communication functionality. With the development of new technologies a whole new range of possibilities become available.

The educational concept we apply is the online knowledge community. In the E-Study Europe project a knowledge community is being developed to foster tele-learning activities in Eastern Europe. To enable tele-learning there is a need for a socio-technical infrastructure. A socio-technical infrastructure refers to a hardware and software infrastructure embedded into an organizational infrastructure. The main question of this paper is how a international online knowledge community can be designed.

Online knowledge communities

We see an online knowledge community as a group of like minded people who band together for frequent interaction by means of (an) online gathering place(s), where they share knowledge and
work together onto a specific knowledge domain through communication and knowledge services, because it is mutually beneficial. Online implies the (technical) infrastructure that is used to unite the group of people and to enable them to share their interests. The key elements of an online knowledge community are the members, the shared interests, and the instrumentality. The members can be described by role models. We distinct for instance: the organization, the expert, the master, the external and the apprentice role model. The shared interests can be described by the mission of a community. Knowledge sharing and knowledge creation activities in a community require thoughtful and careful design. Two educational views are used for the design of a socio-technical infrastructure for a knowledge community:

- **constructivist view of learning.** This view implies that knowledge is not seen as an accumulated body of empirically verified facts, but rather is derived directly from observation and experimentation. In this view, it is assumed that knowledge is something that is constructed by people. Learning concerns the individual construction of knowledge as schemata, concepts, attributes, links, forms, etc.

- **cognitive apprenticeship approach.** In this approach, a master and apprentice work together on tasks in order to enable the apprentice to become a master. The purpose of Cognitive Apprenticeship is to transfer conceptual and problem-solving knowledge in an integrated and connected way (Collins, Brown & Newman, 1986).

Based on these educational viewpoints a technological design encompassing the technical configuration as well as more social requirements like the functionalities, services and resources available is needed. From this point of view, four design requirements for the technical system can be formulated:

**Technical design requirements:**

- The system has to be functional. The technical system should include all the functionalities users want from the information system and it should support the user while working with it.
- The system structure should be efficient. The design of the system should provide appropriate information to the user and should support the navigation through the system.

**Social design requirements:**

- The system has to be usable. Usability means the extent in which an user can work with the system easily and the amount of system support the user gets.
- Users should acknowledge that the system is valuable to work with, because of effective and efficient system use.

The technical and social requirements are presented in Table 1.

Table 1: Technical and social design requirements for an online knowledge community.

The requirements in Table 1 provide a framework for the design of an online knowledge community in the E-Study Europe project.

The E-Study project

The main goal of the E-Study Europe project is the development of a tele-educational infrastructure for life long learning purposes concerning the design of ICT-applications for organizational communication purposes as a mean for setting up a knowledge community. The project aims at the implementation of an European socio-technical infrastructure for enabling tele-learning in CCE that makes it possible for students from the CCE to set up and follow personalized curricula based on available certificated online courses.

The project comprises seven partners from four different countries (The Netherlands, Bulgaria, Poland and Germany). Every partner has a specific role or responsibility in this two-year project, for example being the project coordinator, scientific coordinator, course developer or design expert. In the first year of the project the knowledge community was designed and preparations were made for the technical infrastructure (computer network). At this moment courses to be used in the knowledge community are developed.

In the E-Study Europe project, the concept e-study is used (Vries, 1998). The e-study concept refers to a socio-technical infrastructure for life long learning. To enable life long learning there is a need for a socio-technical infrastructure, that is, a hardware and software infrastructure embedded into
an institutional infrastructure. To describe such an infrastructure, the concepts Interactive Study Environments, Interactive Study Systems and online Study Services are used. These concepts are illustrated in Figure 1.

![Diagram of institutional infrastructure based on the E-study concept]

**Figure 1:** Example of a socio-technical infrastructure based on the E-study concept.

An Interactive Study System (ISS) can be seen as a software system consisting of study task views, study tools, information resources, and if needed additional materials. The main goal of an ISS is to enable an interactive study process between a user of the system and other users and/or between the user(s) and educational resources.

To give the needed support to teachers, there is a need for Interactive Study Environments (ISE's). An ISE is a software system for the preparation, application, and evaluation of ISS’s. Such an environment consists of the following basic components: preparation, application, and evaluation tools and Interactive Study System Components. The main goal of an ISE is to improve the effectiveness, efficiency and attractiveness of the (re-) design, use and evaluation of ISS’s.

In the E-Study concept teachers and learners will be supported by means of a wide range of communication and information services, summarised in the concept online Study Services. For instance, educational publishers as 'content owners' may act as a Study Service Provider. They provide teachers and learners, who apply study books of the involved Educational Publisher with services linked to the study books. In the e-study concept ISS’s, ISE’s and study services are interrelated.

In the E-study community the mission is 'the acquisition, creation, management, sharing, and incorporating of knowledge about the design of media applications for educational and communicational use'.

The infrastructure of a knowledge community refers to the ict-applications which form a meeting place for the members. This meeting place enables them to accomplish their mission. Application of modern ICT in education requires high performance backbones for data transmission. In Figure 2 the telecommunication model used in the E-Study Europe project is displayed.
The presented telecommunication model enables a broad international propagation of the project's results and make easier utilization and dissemination at European level. On the other hand, at local level the high-speed requiring technologies could be run on a local network.

Designing the E-study community

In the E-Study Project an Interactive Study System is seen as a study service platform for students and teachers. A study service or a closely related set of study services is made accessible by a workspace. A workspace is defined as a framework which consists of a set of views and interactions (with other users and/or the study environment) needed to make use of services. A view in this context is a set of knowledge objects dynamically created by a specific query on either the Knowledge Object database or the Person/Group database.

In E-Study we distinguish three basic types of workspaces: Personal Workspaces, Community Workspaces and Knowledge Workspaces. Personal Workspaces contain all views and interactions related to the personal housekeeping of the community member. Examples are the personal mail/agenda or portfolio. Communication Workspaces contain all views and interactions related to the co-operation and communication processes between the community member and the other members. Examples are group management, project management and/or communication tools. Knowledge Workspaces contain all views and interactions related to the creation and management of knowledge objects. We distinguish three types of knowledge objects: knowledge items, knowledge collections and knowledge sequences. Knowledge items are media products containing distinct messages. Examples are documents (like a MS Word file, a Quicktime movie or a Webpage) or links to external websites or ftp-sites (URLs). Knowledge collections are unstructured collections of knowledge items or other (sub) knowledge collections. An example is a collection of knowledge items about a certain topic.
Knowledge sequences are structured knowledge collections where a certain (non-)linear path exist between its components. An example is a course which is sequenced by a time schedule. By maintaining metadata, created knowledge objects can be reused and shared among members of the local knowledge community or members of other knowledge communities.

Based on these basic workspaces, customized workspaces can be constructed for certain types of interactions and views. In E-Study we distinguish a Guest Workspace (based on the Personal Workspace) and several workspaces based on the Knowledge Workspace: Tutorial, Support, Design, Archive and Explorative workspaces. In some cases, combinations of these workspaces are possible.

Workspaces contain a set of views and interactions. We distinguish the following views (and related interactions) in E-study: 'What's new?' View, Identity View, Agenda View, Portfolio / Showcase View, Records View, Personal Education Plan View, Notations View, Groups View, Knowledge Object View, Overview of relevant tools, Communication tools, Collaboration tools.

By using workspaces as a framework to organize views, interactions and tools, study environments gain a more dynamic and adaptive way to accommodate several types of learning in the knowledge community.

Further developments

The development of the knowledge community is still under way. The next step in the E-Study project will be the development of courses to be used within the developed knowledge community. The courses planned to be set up have to contribute to a trans-national on line curriculum on "Design and use of Interactive Media for Corporate Communication". Two trials are going to be carried out to identify the viability of the concept used in the E-Study project, the effectiveness/efficiency of applied tools, services and approaches.

Abstract: We describe a prototype environment for programming. The Specification Oriented Language in Visual Environment for Instruction Translation (SOLVEIT), is designed to address the novice programmer's problem solving and programming skills by providing a collection of tools that students can use in formulating the problem, planning, designing, testing, and delivering the solution.

The SOLVEIT Prototype

SOLVEIT is a prototype of an integrated environment to support students through all problem solving stages, including formulating the problem, planning and designing a solution, testing and delivering that solution. Students who use SOLVEIT not only learn programming but also gain experience in problem solving by using strategies and tools that help them understand the problem, develop a plan for solving the problem, and then produce the design needed to implement the solution. The SOLVEIT system is based on an underlying process for problem solving and program development (Deek 1997), together with the tools needed to support that process. This work is based on the premise that the programming language itself is only one of the necessary skills in writing programs and that there is a complementary relationship between efforts to develop environments and tools to support problem solving and programming, and research into understanding the fundamental cognitive skills and effects of learning programming (Weinberg 1971; Shneiderman 1980; Mayer 1988; Hoc, Green, Samurcay, & Gilmore 1990; Lemut, du Boulay, & Dettori 1993; Deek, Kimmel & McHugh 1998; Deek & McHugh 1998).

The Process

The conceptual framework underlying the SOLVEIT environment joins the problem solving method with the tasks of program development into a common model for problem solving and program development. Each stage of this model relies on specific activities to integrate and support the tasks of both problem solving and program development (Deek 1997). Specifically, the framework articulates the details of the activities required to support: formulating the problem, identifying a plan for solving the problem, specifying a solution design, translating the solution specification into programming language code, testing and delivering the results. Thus, the framework explicitly unifies problem solving/program development into one methodology.

The Tools
The SOLVEIT environment complements existing tools of traditional programming environments (syntax editors, compilers, linkers, loaders, code libraries, debugging utilities, tracers and code watchers), with additional tools to support the process of problem solving in problem formulation, planning, designing and delivering the solution; translating and testing are facilitated through existing programming environment tools.

Tools are available for specific stages of the process and are used to perform the various tasks of problem solving and program development. There are shared tools, such as project notebook, recorder, reference database, and algorithmic toolbox, that can be used in most of the stages. Compiling and debugging tools are pre-existing utilities that are already available in traditional programming environments. The SOLVEIT environment's architecture establishes relationships among the different tools and components that support the activities within the stages of the problem solving and program development process, that is, the architecture realizes or embodies the methodology. The tools for formulation and planning stages were fully developed, i.e. operational prototypes, but the tools for the remaining components of the system we only simulations. The students used these simulated components to mimic the activities of those stages. Figure 1 provides an overview of the functionality of this prototype system.

**Figure 1: An overview of the SOLVEIT prototype**

**Tools for Problem Formulation**

Three tools are used for problem formulation: (1) the problem description editor; (2) the verbalization tool; and (3) the information elicitation tool. The problem description editor is invoked from within the problem formulation stage to enter and save the problem statement into the system. If the problem is already in electronic form, the file can be opened and read into the editor. The problem description text is stored in the multiple-view reference database.

The verbalization tool is active in all stages of SOLVEIT, but is invoked automatically in problem formulation after the problem statement is saved. Questions are presented to the student while the problem statement is still visible in the editor. The student can answer the questions or can skip the entire verbalization session. These questions will provoke the student to re-examine the problem statement which remains displayed throughout the interaction session. The results of this verbalization session are saved, along with subsequent verbalization sessions, by the recorder and are available to the student during the entire problem solving process. A complete transcript is created as part of project deliverables. The verbalization questioning in SOLVEIT is general, but can be adapted to fit a specific class of problems. In addition to questioning, users have access to a project notebook/diagrams editor in order to draw and make notes as necessary. The interaction transcript is stored in the project notebook/diagrams editor.
The information elicitation tool is invoked from within the problem formulation stage. It is used to extract and organize relevant information, found within the problem description, in a structure suited to perform the transformations of subsequent stages and to carry out the tasks that will lead to the solution. This technique of information elicitation will transform the problem description from its text format into a database of problem facts. Using the information elicitation tool, the student returns to the typed problem and extracts the goal, givens, unknowns, conditions and constraints. All gathered information is stored in the multiple-view reference database and is accessible from within other stages of SOLVEIT.

Tools for Solution Planning

In conjunction with the tools used for problem formulation, there are three tools used for solution planning: (1) the plan definition editor, (2) the goal decomposition tool, and (3) the data description tool. The plan definition editor is invoked from within the planning stage. The student uses this simple text editor to describe various alternatives and the steps required for solving the problem, but it does not impose a specific solution or a rigid sequence on the student. This initial plan will help coordinate student’s thoughts and actions in solving the problem. The plan is written to the project notebook/graphics editor.

The goal decomposition tool is invoked from within the planning stage, allowing the student to begin transforming the goal identified in the information elicitation phase into subgoals that need to be completed to solve the problem. The student refines the goal into a collection of subgoals and associates two attributes with each subgoal: an identification name and a description. A goal can have multiple subgoals and subgoals themselves may be decomposed into smaller subgoals. A decomposition tree and information about all the subgoals are stored in the multiple-view reference database.

The data description tool is invoked from within the planning stage to transform the givens and unknowns identified in the information elicitation phase into data representation. Givens are the problem’s input-data or constants. Unknowns are output-data or intermediate data elements. Using the editor, the student associates a series of attributes with givens and unknowns: name, description, origin/source, type and structure. A data description table is stored in the multiple-view reference database.

Tools for Solution Design

Three tools are used for solution design: (1) the module organization tool, (2) the module communication tool, and (3) the module logic specification editor. The module organization tool is invoked from within the design stage. It is used to establish the hierarchy of the subgoals, using a structure chart approach, already refined in previous stages and now contained in the reference database. There is an implied left to right organization and top to bottom hierarchy of subgoals. To reorganize or change the hierarchy, subgoals can be repositioned vertically and horizontally. New subgoals can be added, and others can be removed or merged. Information about the organization/hierarchy of subgoals in the structure chart is also maintained in the reference database and can be viewed in a convenient manner.

The module communication tool is invoked from within the design stage. It is used to establish the data flow relationship between modules. Communication between modules is formed using information gathered during the planning and design stages, now stored in the reference database. Additional data may be defined and added to the database as needed. Data elements can be associated with specific modules as a sender or receiver of that element. The result is a data dictionary table, also stored in the reference database, that includes the data element names, type, description, the associated goal/subgoal and the direction of the data flow.

The module logic specification editor is invoked from within the design stage. It is used once the organization and refinement of the structure chart and data flow have been completed. This tool enables the student to develop module logic for each box of the structure chart. Module logic is constructed using an algorithmic constructs toolbox. A program shell, based on the structure chart, is displayed in a “table of contents” form to facilitate module logic development.

The “table of contents” gives the name of the main module and all other program modules along with the data flow and the direction of each. Each module and associated entry in the “table of contents” is hypertext sensitive and when selected it invokes the module logic development window.

A SOLVEIT algorithmic constructs toolbox, which is used to describe the logic for each module, contains templates for a SOLVEIT-specific algorithmic language consisting of basic data types, control
structures, a simple list structure and modular abstraction. Syntax templates are selected and copied into the student's workspace.

The module logic is saved in the reference database as a text file using the SOLVEIT algorithmic language. General-purpose routines that are developed in this stage may be stored into a library of functions for reuse in other problems. Similarly, any modules developed and saved in earlier problem solving sessions that are appropriate for other situations may be integrated and reused. The algorithmic logic created in the specification editor, stored in the reference database, cannot be compiled directly. It must be copied into the syntax editor of the target-programming environment (i.e. Pascal, C, and C++) and the student uses it as the basis for code translation from algorithmic logic into language syntax.

The next two stages of translation and testing are performed within the programming environment.

**Tools for Solution Delivery**

*The file management tool* is invoked from within the delivery stage. It is used to organize and produce the complete solution package consisting of the outcome of each stage and, if desired, the content of the reference database and project notebook/graphics editor. The result is a fully documented program maintained in an organized manner and can be printed or saved on a disk. In addition to the specialized tools in each stage of the process, SOLVEIT provides a host of environment-wide tools that may be invoked from within any stage of SOLVEIT.

*The Project notebook/graphics editor* is a text and graphics editor used as a scratch pad by the student. The student is prompted to invoke the editor during the problem formulation stage, but can also be invoked at any time during the problem solving process. Text and graphics capabilities are available for the student to make notes and to draw.

*The recorder* monitors the student’s activities within SOLVEIT and acts as an event-capture log. It allows the student and teacher to replay the activities of a problem solving session at a later time. Each time the student enters a stage within SOLVEIT, the event is recorded, and the task performed is also recorded. Upon exiting, a snapshot of the reference database is copied to the recorder. Activities logs are listed in the sequence they occurred. The recorder content cannot be edited. *The multiple-view reference database* contains the result of all data transformation within SOLVEIT, beginning with entering problem description through the development of the algorithmic solution. The database organizes this information and makes it available to the student at different stages of the problem solving process. *The algorithmic constructs toolbox* is a logic template database represented as icons and is accessible from within the design stage to specify modules' logic.

In summary, the process of the SOLVEIT environment, the tools supporting this process and the existing tools of a traditional programming environment are combined to form an integrated environment for problem solving and program development.

**Conclusions**

Students’ difficulties with learning basic programming go beyond the scope of language syntax because programming is an activity that demands the development of problem solving skills. Command of language syntax must be acquired, but in conjunction with problem solving skills and analysis and design methodologies. With the development of composite methodological/software environments like SOLVEIT that supports teaching students programming, the role of language syntax in the overall process of programming instruction will be redefined in a manner that gives appropriate weight to both language issues and problem solving.

**Acknowledgements**

The authors wish to thank Richard Ordowich, an NJIT Computer and Information Science student for his role in the implementation of the initial SOLVEIT prototype.

Authoring Educational Hypermedia Using a Semantic Network

D.J. Mullier, M.B. Dixon
Faculty of Information and Engineering Systems
Leeds Metropolitan University
England
[d.mullier][m.dixon]@lmu.ac.uk

Abstract: Authoring hypermedia is a difficult process and any deficiencies in the authoring process are likely to be reflected in the student’s educational experience. This paper is concerned with providing the author with a framework and process so as to reduce the possibility of producing a poorly structured domain. The discussion is centred on practical experiences with an educational hypermedia system produced at Leeds Metropolitan University that helps the author to structure the domain by the use of a semantic network that is used to represent the essential structure of the domain. Since it is an educational system tutorial nodes are used within the hypermedia to provide the student with tasks to reinforce their learning. The location and use of these tutorial nodes is discussed, in that they may be used as landmarks to help orientate a student.

Introduction

It has been argued by Pereira et al (1991) that all hypermedia systems should have a semantic network (or similar structure) defined within them to aid both the author and the end user. Jonassen and Wang (1993) have further suggested that structures such as semantic networks provide the student with structural information that aids them in the retention of hypermedia material. Further studies have shown that complex information and arguments can be represented in semantic network-like web like structures, termed mind-maps or concept maps and that the use of such structures can aid the author of the structure to remember the information stored within them (McAleese 1998, Holmes 1999). Given this, this paper discusses the implications and the process of defining a semantic network.

In order to explore the issue of authoring an educational hypermedia domain, and other issues described in Mullier et al (1998) and Mullier (1999), a prototype educational hypermedia system, called “Hypernet”, has been developed at Leeds Metropolitan University. The remainder of the discussion uses Hypernet as an example of an educational hypermedia system, but the discussion is not restricted to Hypernet itself.

Domain Types

The exemplar domain designed for the conception and implementation of Hypernet was an astronomy domain. This domain was chosen for the reason that it is highly structured and hierarchical, making it ideal for application to this system, since it allows the rapid design of a semantic network. However, the goal of the project as a whole is to devise a paradigm that is as generic in approach as possible, so that it can be applicable to a multitude of domains. In practice, however, it is likely to be the case that some domains are easier to describe as a semantic structure than others. This is because some domains do not exhibit an obvious and generally accepted structure. This could result in a new hypermedia problem similar to “Linkitis” (Conklin 1987), in that if an author is unsure how a domain may be structured then they may be tempted to force a structure on the domain that may not necessarily exist or be helpful. This may result in the student becoming confused and hence render the domain difficult to navigate, exacerbating the lost in hyperspace problem. It is not an ideal situation, however, to allow the students to identify the shortcomings of a domain’s design. It is suggested, therefore, that it is the author’s responsibility to ensure that the domain is designed correctly before it is exposed to students. It is accepted that this is not a trivial task however.

The authoring process is a complex one and has often been overlooked by hypermedia designers (Theng and Thimbleby 1998, Conklin 1987). It is, however, fundamental to the student’s learning needs that the domain is authored to a sufficient standard (Jonassen and Wang 1993). This is especially
true for “fixed-link” systems (systems that do not provide dynamic links). In fixed-link systems it is vital that the author provides the correct links for every possible user of that hypermedia system. Bell (1995) argues that people are not good at writing in a non-linear fashion, therefore hypertext (hypermedia) documents tend to become linear and do not model the true (semantic) structure of the domain itself. By producing hypermedia systems that require a semantic network forces the domain author to consider the structure of the domain and hence is far more likely to result in a domain that provides an adequate structure for the student to navigate. Further, if dynamic links are employed the student is provided with links that more closely meet their requirements and so reduces their cognitive loading.

Defining A Domain

Here Hypernet is used as an example hypermedia tutoring system. The process of defining a domain for use in Hypernet involves the following steps:

- Structuring the domain into a semantic network (defining its structure) by providing typed links between class nodes (class nodes may also be used as hypermedia nodes).
- Forming a semantic hypermedia domain by attaching instance nodes to the class nodes (instance nodes may be used as hypermedia nodes).
- Storing suitable exercises within tutorial nodes, which are connected to the semantic hypermedia.

For a standard hypermedia system it would usually be the case that none of the above stages would be employed, since the majority of hypermedia systems remain unstructured (Dillon and Gabbard 1998). Instead, the author determines for every node in the domain how it connects to all of the other nodes, typically an extremely complex task. However, the application of the semantic network encourages the domain author to organise the domain in a more logical fashion. The final stage is unique to a computer based learning system, as opposed to a general browsing hypermedia system. Since it is difficult for a student to learn in an undirected environment (Jonassen and Wang 1993) it is appropriate for the domain author to require the student to accomplish some task, at least until they have become proficient enough in the domain to be allowed to browse freely.

![Figure 1 An Example Domain](image)

The Semantic Network

A semantic network can be defined as a graphical representation relating concepts and information (Beynon-Davies 1994). A concept in a semantic network is defined as a node and labelled arcs (links) define the relationships between concepts. The example semantic network, shown in figure 1, describes part of a simple astronomical solar system domain. The oval nodes represent class nodes and form the
overall structure of the domain. The square nodes represent the instance nodes that are subsequently attached to the class nodes. Each class node is therefore used as an anchoring point for instance nodes. Therefore every instance node in the hypermedia is connected directly to the class structure of the semantic network. For example, the instance node “Earth” is attached to the class node “Planet”, thus all “Planets” are logically collected around the “Planet” class node. Each instance and class node is visible to the student as a hypermedia node. It is therefore of potential use to the student and author to utilise the class nodes for presenting higher-level information that relates to the nodes connected to it. For example, the instance nodes “Earth”, “Mars” and “Jupiter” are attached to the class node “Planet”. The instance nodes contain information that relates purely to the node itself (the “Earth” node contains information about the Earth). The class node “Planet” may therefore hold information, useful to the student, about the higher level “Planet” node (which may not have been present without the need for the semantic network) and may provide information as to why each node attached to it, should be attached to it. In many hypermedia systems the only way to discover this fact is to traverse a link that exists between the two and rely upon the domain author providing the information within both nodes that each is a volcano. If the student is forced to undergo this procedure in order to discover the relationship between two nodes then they are further exposed to the “risks” of navigation in a complex information structure. The semantic network however reduces the danger of the cognitive loading problem and navigation problem associated with the hypermedia paradigm, by providing a student with contextual information and by forcing the author to structure the domain more logically (Pereira et al 1991, Jonassen and Wang 1993).

Link Types
This standardised set of link types, described fully in (Beynon-Davies et al 1994) are defined below as:

ISA – relates an object to a class, i.e. it defines an instance of a class. For example “Mars” ISA “Planet”, “Mars” being the instance of the class “Planet”. This link is unidirectional in that properties are inherited in one direction only. For example the “Mars” node inherits all properties from the “Planet” node by virtue of this link (such properties or attributes may include the fact that a Planet orbits the Sun, thus Mars orbits the Sun). However “Planet” does not inherit properties from “Mars”. The IS-A relationship usually represents information towards the top of a hierarchy and therefore represents more general information (Tudhope and Taylor 1997).

AKO (a-kind-of) – relates a class to another class, or may define a subset. This link type demonstrates the relationship between classes. This type is fundamental in connecting a class nodes together to form one semantic network. For example “Planet” AKO “Solar System Body”, meaning that a “Planet” is a kind of “Solar System Body” and that a “Planet” inherits all properties of the class “Solar System Body”. Tudhope and Taylor (1997) have referred to the AKO link as ‘narrower-than’, since it represents information at the bottom of a hierarchy, which is usually more detailed or narrower in scope.

PARTOF (part-of) – represents how an object is composed of other objects, or inherits only part of the parent class. This link type demonstrates how a class may be associated with component parts. For example, “Geographical Feature” PARTOF “Planet”. The part-of link implies that there is a relationship between instances of classes connected via a part-of link.

HASA (has-a) – relates an object to a property or attribute. This is not used to represent structural information (it is not used as a link type). Instead it may be used to represent knowledge within a class. For example, a “Planet has-a Diameter”. This may be used to ensure that an object conforms to a class exactly (i.e. the author is aided in deciding if a node belongs to a particular class by virtue of it having the same attributes). As noted by Beynon-Davies et al (1994), this link type also aids queries in that a search may search for exact matches, such as “Planets with diameters greater than 100”.

The above link types allow the structure of a domain to be represented. However, further link types may be required to represent course material. For example, it may be necessary to represent dependencies, if one concept must be learned before another, or to represent counter arguments. Extra link types such as "dependent-on" could be used by hypermedia systems to determine whether a node is relevant to a particular student. If a student has not visited the node at one end of the link then the node at the other end is not relevant and may be hidden or greyed out in accordance with the hiding method discussed in Brusilovsky (1996). The "dependent-on" link can therefore be used to represent course information, where it is common to lead a student through topics that are dependent upon each other.
Further link types may include "example-of", "counter-example-of", "supported-by" and "disputed-by". Link types such as these provide a greater depth of information about a particular node. Therefore it may be necessary to separate a node into several nodes representing various levels of detail. It is arguable that some node types such as "counter-example-of" may not be beneficial to lower-level students, since they may contain contradictory or otherwise confusing information, therefore there may be a case to make such links available to only the higher level students. Further, in the area of concept mapping, which can be said to share some common attributes with hypermedia, there can be any number of author (of the concept map) definable link-types (McAleese 1998). In essence it does not matter whether the domain author uses a predefined set of link types or whether they use their own. Other researchers have attempted to produce automatic links differently, depending upon the link types that connect two remote nodes. Tudhope and Taylor (1997) calculate automatic links by giving a stronger relationship between nodes connected by AKO relationships than IS-A relationships. The reason for this is that relationships at the bottom of hierarchies, represented by AKO relationships, are thought to be more closely related than those at the top, represented by IS-A relationships (Tudhope and Taylor 1997). The use of different strengths of relationships has not been explored as part of this research project, although it may prove to be beneficial as part of further work. Further, it may be possible to combine the information potentially available from the student's browsing pattern to dynamically alter the strength of the link types, in that if a user is determined, by virtue of their browsing pattern, to be interested in general information then the strength of the IS-A link type could be increased and vice versa.

Adding Nodes to the Domain

Once a semantic network has been defined for the domain in terms of class nodes, then instance nodes may be added to it. The author must decide to which class a new node belongs, a class being represented by a class node (connected to other class nodes via ISA and/or AKO link types). If there is no such class node, then the semantic network has not been sufficiently defined for the domain or the new node does not belong to the domain. This is an important restriction, since there may be more than one author for the domain. It is possible that a domain may be initially defined by an author, but extra nodes are added to it subsequently, perhaps after students have begun using the hypermedia. The addition of the semantic network is an aid to all such authors, since it has the potential to help them to decide if a node should belong to the domain. An author who is unsure as to the legitimacy of a node's relationship with the domain, may succumb to the "Linkitis" problem, i.e. if unsure then link. The semantic structure aids such an author by providing them with a structure into which the node must fit. It is possible that the responsibility for deciding whether a node should be added to the domain lies with the original semantic network author, since it could be stated that if a node cannot be typed to an existing semantic network node, then it should not belong to the domain. This could be achieved by allowing only certain classes of author to modify or otherwise add to the semantic network. Thus, the integrity of the domain is protected to a far higher degree than would be the case with a hypermedia system without a semantic network.

Once a node has been correctly typed, it is connected to the semantic network. This immediately connects the new node to all the other nodes in the hypermedia system, via paths of varying lengths, thus the author need not specify any other direct links. It is likely however, that an author wishes to add a series of related nodes. For example, the author may wish to add the node "Pluto" to the domain. This could involve the addition of several new nodes, namely the node "Pluto" representing the planet itself and "Charon", representing Pluto's only satellite. The author therefore types "Pluto" is-a "Planet" and "Charon" is-a "Satellite". Once "Charon" has been correctly typed, the author is required to connect it to a host "Planet", since this is an explicit requirement of the "Satellite" type (a reasonable requirement since satellites do not exist in isolation). The original author of the semantic network encodes this requirement within the semantic node itself.

The semantic network is therefore a structure that connects the entire domain together. It is vital that the author connects the class nodes together in an accurate fashion. As discussed above, it may not be clear cut decision whether to connect a node to a particular class node or not. The author may have to make a decision about connecting two class nodes together when the relationship between them is not a definite one. The author should detail this relationship within the class node so that any future author is clear about the defined relationship. It may not always be the case that such a one to one relationship can be defined, i.e. an instance node may not fit exactly into the semantic structure of the domain, but may still be valuable to the student studying the domain. In this situation the author should provide a suitable "non specific" semantic node. For example, the domain author may wish to add information.
about probe missions to various planets. The author may decide that it is not appropriate to add the semantic node “Probe Missions” as a-kind-of “Planet”. However, it may be appropriate to have information about the Voyager missions to Jupiter, with the “Jupiter” instance node. The author could therefore define the semantic node “Related Material” as part-of “Planet”. It is important that this facility is used sparingly, otherwise the benefits of structuring the domain could be lost.

Defining Tutorial Nodes

Tutorial nodes are employed by Hypernet as a means to aid the student’s retention of the domain contents. Jonassen and Wang (1993) suggest that information is retained by providing a context into which the information fits, thus aiding the student in determining where the information fits within their own knowledge representation structures (schema). In Hypernet this is aided by providing the students with tasks to complete, via the tutorial nodes. Tutorial nodes may take the form of a simple question and answer session, or they may involve a more complex task that requires that the student to visit several nodes. Such tasks may require the student to traverse the hypermedia looking for various pieces of information. Requiring the student to find and examine the relationship between concepts may also aid their retention of structural knowledge of the domain (Jonassen and Wang 1993). It is therefore paramount that tutorial nodes are designed and placed within the hypermedia in order to render this transfer of knowledge as efficient as possible.

The tutorial nodes are designed to remove the danger of passivity from the system, i.e. the student is not always left to wander through a hypermedia system, without a task or guidance, especially if they are a novice of the domain. It could be argued that a human teacher could present the student with a learning task before they are exposed to the hypermedia system. However, this would require the human teacher to supply the student with a complete task that would detail requirements for the student, as they become more proficient with the domain. Alternatively, it would require that the human teacher is constantly present, in order to gauge when the student requires a new more advanced task. The latter situation is not always possible, since the human teacher is an expensive resource and the need for ITSs has been driven by this fact (Woods and Warren 1995). The former situation is also not desirable, since providing the novice student with expert level tasks (for their future use), may be providing the student with a level of complexity that is not beneficial to them (Ridgeway 1989, Kinshuk and Patel 1997).

Tutorial Nodes are embedded within the hypermedia, although they do not strictly form part of the semantic network, in that they do not represent the structure of the domain. A tutorial node may be triggered by a simple rule, defined by the domain author. For example: “Activate Tutorial Node 1 when the student enters the system”. The student is therefore given a task to complete as soon as they enter the system. It is advised that such a task should concentrate on providing the student with information about how to use the hypermedia tutoring system itself and not necessarily be related to the domain, since initially, a user who is new to a system expends most of their “cognitive power” learning how to use a new system.

Linear and Non-Linear Tutorial Nodes

Tutorial nodes may exist in “linear hyperspace” and “non-linear hyperspace”. They may be designed to be encountered one after the other, guiding the student through the hypermedia (linear hyperspace). Alternatively, they may be activated by a student following their own interests into a particular area of the hypermedia (non-linear hyperspace). Linear hyperspace is similar to Trigg’s (1988) idea of paths authored into a hypermedia system. Trigg’s system, “TexNet”, allows the author to specify default paths for the student to follow, in order to reduce the chances of them becoming lost. Such a method has been criticised by Jonassen and Wang (1993), for providing the student with a path that they may “blindly” follow, i.e. they are encouraged not to search the hyperspace. The same criticism cannot however be levelled at the linear hyperspace tutorial nodes (LTN) employed by Hypernet, since they are not providing a node to node path. Instead the LTNs are providing the student with useful landmarks with which to orientate themselves, in that the student can navigate from one LTN to the next. They may therefore travel through the hypermedia in freedom, between such tutorial nodes. These nodes are suitable for novice students, since they are guided (as opposed to forcefully directed) by the tutorial nodes.

The non-linear hyperspace tutorial nodes are intended for more advanced students, since they do not provide the guidance that the LTNs provide. This is because the NLTNs do not appear in a predefined
sequence. Instead, it is a matter of when the student uncovers them. They therefore do not offer the same landmark qualities as their linear counterparts. Such nodes are therefore more suited to students of higher levels, since the student may randomly encounter them and are not lead from one to the next.

The LTNs may be useful for lower level students and the NLTNs for higher level students. It may be desirable in some instances to use the two types of tutorial nodes interchangeably; for example, using LTNs for an expert level student who has entered an unvisited section of the domain. It may also be desirable for the author to target certain tutorial nodes at certain levels of students, or to have slightly different tutorials, for each student level, present within the same tutorial node. Figure 9.3.1.A (shown previously) shows two NLTNs, labelled "Planet Tutorial" and "Volcano Tutorial". These nodes are invoked when the node to which they are connected to via an "Invoked-by" link is selected. For example, the "Volcano Tutorial" is invoked when the "Volcano" class node is visited.

Conclusion

Experiences with Hypernet suggest that the use of a semantic network does indeed help the author to represent their knowledge in a formalised way, suitable for expression as a hypermedia domain. Whether this domain representation is more of less useful to the student is open to educational debate, however, the literature concerning the use of semantic networks would strongly indicate that it is (Tudhope and Taylor 1997, Pereira et al 1991, Jonassen and Wang (1993).

Abstract:
Many colleges, universities and businesses recognize the rewards of teaching on the Internet. As each organization rushes toward cyberspace, they bump into a variety of potholes that cause resistance and discouragement among the faculty. Sometimes poor administrative strategy leads faculty members to abandon a technology that may become the most effective tool in the history of education. This session emphasizes methods of successfully introducing faculty to teaching in virtual classrooms, and points out strategies to be avoided.

Interactive media and web-based instruction have repeatedly proven themselves to be effective and efficient tools for classroom support and distance learning. Compared to traditional modes of instruction, students learn the same amount of material in half the time or less with equal or better understanding and equal or better retention when using interactive learning materials. To use these new instructional tools, colleges and universities need the technological infrastructure and a profound cultural change within the institution. If funding is available, the technological infrastructure is relatively easily achieved.

The greater challenge is achieving the necessary cultural change. Simply putting traditional materials on the Internet doesn't work. Using this tool requires a new teaching/learning paradigm. Faculty must alter their teaching methods and styles to teach successfully in cyberspace. Student preconceptions of education will need to change to accommodate this non-traditional moderated mode of learning.

Effective change is not mandated, but adopted because of obvious benefits to the users. A top down approach is likely to meet resistance, but a bottom up approach can generate enthusiasm. In the early stages of the move to virtual classroom use, top down standardization and policy-making inhibit progress. If administrators support grassroots faculty and student use of the Internet the school will avoid stifling the initiative of individual faculty members.

The initiative is likely to go nowhere if the faculty senate, administration, union, and dozens of committees pool their ignorance and discuss ad nauseam issues they do not fully comprehend. During the early years administration should simply support voluntary initiatives of early adapters. Otherwise peer pressure among faculty members to maintain the status quo is likely to subvert use of technology in the classroom. If the administration does encourage specific software, it should be the simplest to learn and use available. Once the majority of the faculty has adopted Internet tools and understands how the virtual classroom works, the peer pressure supports adoption of this new technology rather than the status quo.

Once the majority of faculty is knowledgeable about use of the Internet to teach and learn, discussions are informed, and better decisions will be made. Standardization and policy-making will be easier and more appropriate, because most faculty members will be familiar with the technology and issues and will have learned what works and what doesn't. Since the WWW Consortium already promotes HTML communication standards, it is relatively easy to switch from one software package to another. Switching from one virtual classroom program to another is analogous to switching from driving a car with automatic transmission to a semi-truck.
Faculty training is the key to success. The technology should be as simple and transparent as possible. The important issues here are about learning, not about technology. Many faculty members are attracted to experiences that promote teaching and learning but tend to avoid experiences emphasizing technology.

Time commitment, compensation and recognition are key elements in the adoption.

Most Colleges and Universities recognize the rewards of teaching on the Internet if it is implemented properly. As each organization rushes toward cyberspace, they bump into a variety of potholes that cause resistance, discouragement, and sometimes abandonment of what may become the most effective technology in the history of education.

This workshop will examine the potholes (false assumptions) every institution should avoid, and examine strategies (fastlanes) that lead toward successful implementation of the virtual classroom and Internet supported and Internet based programs. Some of these will include:

| Pothole: | Implementation should be organized and standardized from the top down. |
| Fastlane: | In higher education, the top down approach frequently generates resistance - the bottom up approach generates enthusiasm. |

| Pothole: | The greatest obstacle is the technology. |
| Fastlane: | The greatest obstacle is social inertia of the institution. |

| Pothole: | Learning in cyberspace is just teaching repackaged. |
| Fastlane: | Learning in cyberspace requires a fundamental paradigm shift on the part of students and teachers. |

| Pothole: | e-Mail is a great way to manage distance learning. |
| Fastlane: | e-Mail has its place, but using e-mail as the primary technology to manage distance learning is nearly equivalent to tutoring each student individually. |

| Pothole: | Unions, Administration, and Faculty Senate should get involved early, because otherwise their interests may be hurt. |
| Fastlane: | Arguing about theories that no one has put into practice or really understands prevents progress. |

| Pothole: | This endeavor is about technology. |
| Fastlane: | This endeavor is about learning. |

| Pothole: | Faculty training is best done by techies, and implementation of the virtual campus can be done by staff. |
| Fastlane: | Faculty training should be done by faculty. Faculty must play the leadership role in decision making about the technology after experimenting with various systems. The role of the techie is to serve faculty needs and help faculty promote student learning. |

| Pothole: | Relationships with students will degrade when teaching in cyberspace. |
| Fastlane: | Relationships improve, as the lecturer becomes a coach, mentor and guide. |

| Pothole: | Relationships between students and with teachers are not as important in cyberteaching. |
| Fastlane: | Relationships in the virtual classroom are more important to learning than in the traditional classroom. Steps must be taken to build cooperative relationships. |

| Pothole: | Create a rich didactic site with lots of information no matter how much time it takes. |
| Fastlane: | Use a minimalist approach and the Socratic method. |

| Pothole: | Use all the information available on the Internet. |
| Fastlane: | Pace and organize material so students don't become overwhelmed with information. |

The potholes (false assumptions) and fastlanes (successful strategies) will be discussed in this presentation.
Appendix: Quotes and Notes

Analysis of Effectiveness and Costs of IVD Instruction in Defense Training and Education, summarized of over 600 research studies of interactive training programs. This metastudy, done by the Department of Defense Analysis (1801 Beauregard Street, Alexandria, VA 22311-1772), concluded: Compared to traditional modes of instruction, students learn the same amount of material in half the time or less with equal or better understanding and equal or better retention when using interactive learning materials. To see or contribute to a summary of research studies dealing with the effectiveness of interactive multimedia and the Internet follow the hyperlinks to the Interactive Virtual Classroom Discussion from http://www.alsi.net.

Some aspects of the new paradigm for online learning are discussed in Using the Internet and CD--ROM for Classroom Support at http://www.alsi.net/WEBLEARNING.htm

Distance learners found faculty to be more accessible than in the typical classes. All types of learning styles can be successfully taught using distance education technologies. Threlkeld, R., & Brzoska, K. (1994). Research in distance education. In B. Willis (Ed.), Distance education: Strategies and tools (pp. 41-66). Englewood Cliff, NJ: Educational Technology Publication.

To be effective distance educators, faculty should participate in a training program designed specifically to meet their needs (Threlkeld & Brzoska, 1994, p. 58).

Clark, R.E. (1991) maintains that instructional strategies, and not the medium, are the key to effective learning. Unfortunately, technology and production considerations rather than teaching-learning theory or the instructional development process are often the driving force behind distance education programs.

Jerald G. Schutte of California State University, Northridge did a comparative study of two statistic classes, and reported: "Quantitative results demonstrated the virtual class scored an average of 20% higher than the traditional class on both examinations. Further, post-test results indicate the virtual class had significantly higher perceived peer contact, and time spent on class work, but a perception of more flexibility, understanding of the material and greater affect toward math, at semester end, than did the traditional class." Virtual Teaching in Higher Education: The New Intellectual Superhighway or Just Another Traffic Jam? (http://www.csun.edu/sociology/virexp.htm)

In Dancing with The Devil, Duderstadt maintains that education used to be "just in case". It is now "just in time" in corporate America, and in the future it is likely to be "just for you".

Relationships between students and between students and faculty are important to the learning process. Does use of technology degrade the relationship? Does talking on the phone degrade the relationship? Prejudices fall away online, and relationships focus on ideas. Students become more intimate rather than more distant when they learn online. Professor Joe Schramer, Teacher of the Year at the University of St. Thomas said, "I had over 70 comments posted by students in my virtual class last night. In my traditional classroom, I'd be lucky to have 70 student comments in an entire semester."

Problem: Students can become overwhelmed with information. How do you pace an online class? How do you help the students choose among the activities and information?

Abstract: The ExploraGraph interface was designed to facilitate interaction in the context of distant learning. It was developed as an alternative to simple web interaction, in order to increase flexibility, visibility, and structure in the learning environment. It may be used as a front end to existing courses on the web. The ExploraGraph Navigator makes it possible to navigate through conceptual graphs with automatic arrangement of elements, zoom and "fish eye" effects. Each node of the graph may have a description attached to it and may give direct access to an application, a document or an Internet site. Graphic structures may thus be used to represent the organization of tools, activities, concepts or documents. The Navigator offers each user a tool to specify his goals and the system can support him, using multiple modalities: Hypertext, graphical cues (Lee & Lehman, 1993), Ms Agents avatars, voice, visual demonstrations and force feedback guiding.

Introduction

LICEF is developing, in the context of the Canadian TeleLearning Network of Centres of Excellence, a distance education environment on the web. The Center for Virtual Learning developed at LICEF offers not only hypermedia content on the web, but different tools for conferencing, planning meetings, videoconferencing, presenting scenarios and knowledge, etc. The modeling of users in activity has illustrated the difficulties they experience in learning the efficient use of such a complex environment, first as they learn it at the training session, and then on their own when they are at distance. To offer contextual help to learners, we have designed a supportive interface that will adapt to each user, unfolding gradually as s/he acquires expertise and offering adaptive support using different modalities.

The ExploraGraph interface was designed to facilitate interaction in the distance learning context. After studying learners in various distance learning situations, it became evident that existing interfaces could be improved to better support the interaction and the learning process. Learners have to navigate between pages of web documents, search engines and text instruction. They must use various communication tools and organize their activities with little support. As DiSessa (1986) explains, they encounter the "utility barrier", not knowing how the system should be used and how to modify their activities to better use it. They find it difficult to transpose their activities in multiple environments. The ExploraGraph interface was developed as an alternative to simple web interaction, in order to increase flexibility, visibility, and structure in the learning environment. Inspired by the Explora interface developed at LICEF (Paquette et al., 1996), we tried to develop a more dynamic and flexible interface for the learner to access the Center for Virtual Learning. The
learner navigates in graphic conceptual structures of tasks, knowledge elements and documents, that give him a schematic idea of what is to be learned and what s/he has to do. Automatic arrangement of elements, zoom and "fish eye" effects are used to increase visibility as each user manipulates the graphs. Each node of the graph may have a description attached to it and may give direct access to an application, a document or an Internet site.

The Importance of Adaptive Interfaces

The need to integrate adaptive interfaces in the domain of learning environments has become an important field of research (Dufresne, 1997; de La Passardiere et Dufresne, 1992; Brusilovsky, 1997), especially as it appears to play an important role in reducing navigation disorientation and encouraging exhaustive learning in hypertext systems, particularly in web learning applications. Adaptation may take many forms, modifying content and/link access and annotations.

One of the main limitations to adaptive interfaces is the amount of information obtained by the system on user activity and knowledge. In order for adaptive interfaces to increase the salience of some elements, the next best to be learned, it is necessary to define what is the proposed structure for learning, what has been seen, but also, what does the user want to learn next. If the structure of the content is encyclopedic and easy to chunk, then direct manipulation may be used, giving access to graph representing the structure of concepts to be learned. An overlay model of knowledge may then be extracted from the trace of the user's navigation: What information has he read? For how long? How long ago? In such a context, adaptive links annotation can suffice to support the user's navigation and encourage him to complete his navigation and understanding.

However, some pedagogy and learning theories insist that it is better that learning take place in a more active, situated and collaborative setting. In this context, content has to be organized in a more complex way and this complicates the possible support to navigation. According to the MISA model (Paquette, Aubin, & Crevier (1997), learning activities are organized around many structures, including : knowledge structure, scenarios of activities and documents structure. In this context, there may be many paths to access knowledge and the user needs some coaching and adaptation at a more general level to better assimilate content. For this meta-level of support to be implemented, the system must use strategic information on both content structure and the user's higher level of activity. The present project proposes a model and generic prototype to facilitate navigation and adaptive support, based on the intentions of the user and on the structure of his activities.

We were among the first to experiment with links annotation (Dufresne, Jolin, & Senteni, 1990), where visited links are hierarchically modified as the user finishes visiting the information within them. In the context of distance education, our interest was more proactive, in order to attract the user's attention to tasks or contents that were more pertinent at one point in time. We were interested in the pacing of the meta-level of information attached to a content to be learned, in order to follow the evolution of user expertise and to support learner.

System Structure

The architecture of the ExploraGraph (Dufresne, Cosmova., LeTran, & Ramstein, 1999) system is partly local and partly shared: it is an integration of commercial Office applications and applications we developed in Visual Basic using an Access database. Figure 1 show the architecture of the system and of the interaction, with the different input and output paths used in system adaptation.

The system main features are the dynamic arrangement of graphical structures, the Control Panel that allows each user to specify his/her intentions and to delegate actions, and the system's various modalities of support.
Navigation: A Metaphor that Helps You “Stretch Your Mind”

The ExploraGraph Navigator was designed to facilitate the visualization of graphical structures. A physical model of nodes (mass and repulsion), links (elasticity) and of the general organization (gravity and friction) is used to simulate the relations between sets of elements. As concepts are added (editor mode) or as they are
traversed (navigation mode), nodes rearrange themselves in order to maximize visibility and contextual relation to what is at the focus of interest. Zoom and "fisheye" effects make it possible for the user to pop out and concentrate on an area of the graph knowledge or task representation. Such relative accentuation may also be driven by the system adaptive functions, which may use it to highlight areas of the information to be explored; this corresponds to concept of map adaptation (Brusilovsky, 1997).

The ExploraGraph Navigator makes use of a generic representation of types of nodes and types of links that may be changed to represent structures of tasks, concepts, tools or documents.

Figure 2 ExploraGraph Navigator showing the graphical structure, the Control Panel and the avatars’ contextual help.

In figure 2 the User have chosen the goal “Communicate a technical question”. Depending on the task model, the Avatar may suggest a specific technical problem and propose help related to it. He may zoom on the right discussion Forum and eventually launch it with appropriate help depending on previous interaction with the user. Eventually, looking at others user’s model he will suggest someone to ask for help.
Activities: Let the User Choose What S/He Wants to Do.

In fact, the context of distance learning is one where the system is not at the center of the interaction: the teacher and the other learners are also there, so the system is seen more as a tool than as the only field of interaction. As such, the system cannot assume the full direction of the activity: it must be transparent to the user goals and activity and cannot be too unpredictable. In this context, what the user needs is not as much a feedback on his/her progression in the content but a guide as to how s/he may use them to achieve the proposed learning objectives. The adaptive interface should coach the learner, according to the schedule, and to learner progression and context. It must then cue the learner to links between tasks and documents, between tasks and the structure of concepts, between tasks and his/her utilization of tools, methods and external resources like discussion forums.

For the interface to adapt its support to the user’s higher level of activity, a Control Panel is incorporated in the Navigator, where he may choose a general intention: Explore, Plan, Revise his own progression, Adjust the system (each with various options). Choosing a goal may trigger a set of actions in the system, opening multiple applications, choosing a specific navigation environment. The Control Panel also enriches the user’s model, making it possible to adapt system support, which may propose different contextual explanations or guidance for each goal, depending on task schedule and on user profile.

Support with Multiple Modalities

The system may propose different types of adaptive support, taking into account the potential of each modality to guide the user. Support could take the form of:

- Graphical highlight and links annotation, which give a general idea of the structure and which are more passive and less intrusive than more formal guiding and demonstration.
- Avatars animations which are used for graphical demonstrations (attention seeking, pointing, etc.), but also for non-verbal communication and motivational purpose.
- Avatars audio voices, which serve to attract attention and are more easily combined with visual demonstrations than text.
- Visual guiding to present to the user procedures and actions which s/he may use to realize his/her chosen intentions
- Force feedback guiding, which, combined with visual demonstration, obtains more attention, takes less cognitive concentration, facilitates memorization (Arcand, 1995) and ensures that the user follows the demonstration to the end.

Avatars were introduced in the environment partly “to fulfill the need for social context” when no other learners are on-line (Kearley, 1993 in Pentti, 1998; Rickel & Johnson, 1999; Grégoire, Zettlemoyer & Lester, 1999) and to serve as the interface to the advisory system.

Some adaptation of the support will eventually be under user control. But for the user in the fire of action, adapting the interface might be a tedious and bothersome task, so we intend to integrate adaptive functions that will integrate both global and individual users’ feedback on the help system, in order to adjust future help both in general and individually. Such a mixed adaptive learning environment appears to be important in guaranteeing adaptation of systems to longer learning situations. A mixed adaptive environment appears to be the best way for the environments to be really adapted to the user’s longer learning situations and to his evolving wishes (Brusilovsky 1996).

Abstract: The technology-based Curriculum Integration project in the Plano Independent School District is presented as a model for successful implementation of large-scale technology integration projects. The project addressed relevant components: teachers, students, curriculum, learning theories and materials, technological infrastructure, and school architecture. It was found that systemic change in the learning culture among district teachers and students resulted from a convergence of forces. These forces included changes in teaching methods, the curriculum, and the physical learning environment, as well as the planning, development, and implementation of the project as a collaborative effort between Plano educators and various professionals within an educational software company.

Introduction

In the last decade, there has been an increasing number of publications reporting the minor impact that, despite substantial investments, the integration of technology in schools has on the teaching culture, the school environment, and the students' attitude to learning (e.g., Bryson & de Castell 1998). In addition, teachers report dissatisfaction with the applicability of off-the-shelf multimedia products to their curriculum. For example, in a survey conducted in United States in 1999, 59% of teachers who use software for instruction report that it is "somewhat" or "very" difficult to find software to meet their classroom needs (Resnick 1999). However, it is not only appropriate software that is the issue. Successful technology implementation into schools requires a holistic approach that addresses all relevant issues, including design of custom curricular materials, learning theory, pedagogy, staff development, technology infrastructure, management, finance, and school architecture.

The technology-based Plano Independent School District (PISD) Curriculum Integration Project is an excellent example of such holistic implementation. The large-scale systemic project was implemented in the PISD between 1993-1998, involving approximately 40 elementary schools and 60,000 K-5 students. Two of its unique features were that teachers played a leading role in collaboration with an education computer company to design an interdisciplinary curriculum with custom learning materials based on a constructivist approach to teaching and learning as well as recommended the classroom's architecture and technology infrastructure.

The paper reports the Plano Curriculum Integration Project to highlight necessary ingredients for a successful wide-scale integration of technology in a school system.

Launching the Plano Project

The decision to launch a systemic curricular change in 1993 was based on the recognition that the PISD school system "suffered" from problems such as those listed in Table 1 as well as an understanding that introducing technology, without addressing other educational and architectural issues, would not be enough. Therefore, the project was designed to address the factors in Table 1; these are subsequently discussed in the
paper. The PISD contracted Edunetics, a multimedia production company, to help it redesign its curriculum, inservice the teachers in the area of computer technology, and develop educational computer software that would serve as a crucial component of the new integrated curriculum. In addition, PISD established the Curriculum Development Center in which a team of 30 to 40 selected K-5 teachers, supervised by PISD curriculum coordinators, cooperatively developed the new thematic curriculum with the pedagogical, content, and instructional technology design experts in Edunetics (Otto 1997).

Table 1: Decision Factors Influencing Curriculum, Teacher Involvement, and Architectural Change

**Curriculum redesign**

Plano Independent School District’s pre-1993 segregated curriculum (Table 2) was designed to follow the curriculum standards in the various disciplines (cf. Bybee & McInerney 1995; Texley & Wild 1996). A major task of the project was to convert this curriculum into a thematic one (Table 3), without giving up the disciplinary depth of content. It was argued that thematic learning enables the student to perceive curricular topics in a broader and more interconnected way (Jacobs 1989, 1997; Kovalik & Olson 1994; Marzano 1992).

Table 2: A section of the pre-Plano Curriculum Project K-2 discipline-segregated curriculum

In a thematic curriculum, the learning objectives are organized in themes, or “big ideas,” and not necessarily in segregated disciplines, as in most traditional curricula. Thus the first stage in designing the new curriculum was to identify six major themes (Overarching Concepts) under which the entire new curriculum was organized: Communication, Continuity and Change, Interactions, Diversity, Systems, and Balance and Stability (Table 3). The thematic curriculum was designed as a matrix that matched a six-week thematic learning unit, called Organizing Idea (OI), for each of the K-5 grade levels. Each OI belonged to a specific.
theme. The OIs' design presented the disciplinary content (Table 2) in a thematic way, supplemented and reinforced with technology (Table 3). For example: Grade Two's science disciplinary curriculum (Table 2) included topics such as grouping of animals and ancient living things in Life Science, as well as fossils and dinosaurs in Earth Science. In the thematic curriculum, these topics were clustered into the OI, "What Evidence Tells Us About Our World?" under the Overarching Concept (theme) of "Communication" (Table 3). In this OI, the students use, among others, fossil evidence to communicate and draw conclusions about the world. This approach to curriculum design is a modification of the original curriculum integration model of Jacobs (1989) in the sense that it focuses on maintaining the disciplinary learning objectives, but presenting them in a thematic manner. In this way, the teachers, supported by PISD's curriculum coordinators, designed an array of 36 OIs (Table 3).

Map Room and Visual Planner (Tools) are used throughout the OIs from 1st through 5th grades. Interactive Computer Lessons are utilized through Grades 1 - 5. Names of OIs are in normal text; names of custom educational software programs are in italics.

Table 3: Plano ISD Integrated Thematic Curriculum: Organizing Ideas and Custom Edunetics Software

Almost all of the OIs included custom multimedia learning products that were used as a crucial component throughout the six-week learning period in the OI. The multimedia products were designed and produced by Edunetics' instructional design specialists, with the full involvement of, and guidance from, PISD
teachers. All OIs were designed to follow a general basic structure exemplified by the Grade Two OI, "What Does Evidence Tell Us about Our World?" (Figure 1) under the theme, "Communication": An introductory 1-week unit, followed by 3-5 interdisciplinary-based units, and a 1-week culmination unit. The culmination unit brought the thematic activities and understandings together through further synthesis, analysis, and application, providing a "big picture" thematic overview. Plano's curriculum design process was unique also in the sense that the teacher teams took the leading role in this design process thereby ensuring that both the overall curriculum structure and the computerized and off-line learning materials complied with the teachers' and students' curriculum needs.

**Organizing Idea:**
What Does Evidence Tell About Our World?

**Introductory unit:**
What is Evidence?

**Interdisciplinary unit:**
What Does Evidence Tell Us of the Past?

**Interdisciplinary unit:**
Steps in Solving Problems & Mysteries

**Interdisciplinary unit:**
Evidence Helps Us Solve Problems & Mysteries

**Culmination unit:**
Can Evidence Help Us Find Him?

**Figure 1:** Basic organization of a six-week thematic unit (OI), using a Grade Two OI as an exemplar.

**Developing the learning materials: A unique teacher-multimedia producer interaction**

The Plano Project included the production of mainly three types of learning materials:
1. Hundreds of offline written and hands-on-small-group activities developed by the teachers.
3. 26 multimedia interactive learning environments (Table 3), mainly microworld simulations, databases, and learning tools that served as crucial components of the OIs. In addition, PISD teachers incorporated some off-the-shelf computer products that were available on the market. However, according to the Science Coordinator in PISD (Mainwaring 1999, personal communication), teachers found their use somewhat limited because these products were not custom-designed for the project.

To ensure that the computerized learning materials dovetailed with the pedagogical concepts and the content requirements of the integrated curriculum, a special interactive production process was established. The process consisted of the following stages: preliminary ideas, product specification, prototype alpha and beta versions, implementation, and evaluation. Review of the processes occurred throughout production. Both the consumers (teachers) and the producers (Edunetics) were equally engaged in this process. According to Hord (1992), long-term changes occur if teachers take part in corporately contributing towards re-educating their own values and attitudes and changing the school's culture. This includes collaborative in-situ identification of issues by the change agents; in our case, these were the teachers, curriculum coordinators, and Edunetics pedagogical content and software producers. From the PISD experience, such a process requires long-range planning and can be challenging to execute due to a variety of difficulties. One of these is, not surprisingly, given their differing professional backgrounds, the different approach to planning and design brought by the teachers on the one hand, and the software instructional designers, on the other. The successful implementation of the computer products in PISD schools (Henderson, Klemes, & Eshet 2000) illustrates the value of producing custom-made products for such technology integration projects.

**Integrating the software into the curriculum**
A major impact of computers and instructional software on the learning process of children is achieved only when they are integrated into the curriculum as a vital element for instruction (Shade & Watson, 1990). In the Plano project, the custom-developed educational software played a significant role in the instruction within each OI (Table 3) in supplementing the disciplinary and interdisciplinary content, encouraging students to engage in higher order thinking about the concepts, and in creating thematic understanding. An example of this approach is seen with Message in a Fossil (MIF), one of the 26 multimedia products that were developed for the project (see Figure 1; Table 3). MIF is a microworld simulation in which the student plays the role of a paleontologist who excavates in virtual dig-sites, discovers plant and animal fossils, and reconstructs the prehistoric world by constructing a museum diorama. According to a second grade teacher, MIF was "the thematic and content backbone of the Organizing Idea, 'What Evidence Tells Us About Our World'" (Henderson, Klemes, & Eshet 2000). The major theme of the OI was gathering, interpreting, and communicating evidence to solve mysteries and problems, particularly those that inform our understanding of the past. For approximately 45 minutes each day, the class worked in stations where each small group activity integrated the OI and themes across curriculum areas. One of these daily rotating activities was learning with MIF, which was also included in the time allocated for reading. This meant that each student used the software each day for at least 20 minutes, for a period of 6 weeks. Henderson et al. (2000) concluded that the length of time students accessed software was a significant factor in student learning outcomes.

Each of the computer products was used in a similar way to MIF, although their role in the OI may have varied from one OI to another. In the course of developing the project's learning materials, it was found that while it was relatively easy to incorporate the science and social studies topics in the thematic curriculum, it was much harder to do so for topics in Arts and Language Arts. Therefore, these topics continue to be taught separately, in a disciplinary manner, during part of the day.

Technology and class redesign

Papert (1993) advocated the incorporation of computers inside classrooms rather than in computer labs in order to increase their impact on children's learning and a reconceptualization of classroom layout to enable thematic learning and group work (Jacobs 1989; Marzano 1992; Brooks & Brooks 1993). This influenced the PISD project as it included a complete redesign of the architecture of the classrooms and the each school's technological infrastructure. In order to enable an open and more flexible learning atmosphere, the "frontal chalk-and-talk classrooms" were redesigned as spaces that allowed an easy access to the class computers and promoted team work and group discussions. The large computer labs were dismantled and replaced by networked computers in each classroom, at a ratio of three students per computer, and in the library and administration areas. Accessory equipment such as a video player and a large TV monitor were included as classroom equipment along with a printer for each four classrooms. The networked computers enabled student access to the available on-line learning environments and utility programs. This combination, of new classroom architecture and new technology infrastructure design, have contributed to the establishment of a new teaching and learning culture in the PISD participating schools (Henderson, Eshet, & Klemes 1998; Kent & McNergney 1998; Provenzo, Brett, & McCloskey 1999).

Impact of the Plano Project

The Plano Curriculum Integration Project had a decided impact on the teaching, learning, and management culture of the entire district, affecting the teachers, students, and district administration. (Eshet, Klemes, & Henderson 1999). One such impact is provided in a study of second grade children who participated in the Plano Project (Henderson et al. 1998; Henderson et al 2000). The authors report several clear changes in the classroom culture. The new classroom architecture and the introduction of computers into the classroom promoted team and small group work. This also affected the teacher's teaching culture that became more student-oriented and problem-solving based. The research findings also indicate, in comparison with the way it was taught pre-MIF and the new thematic integrated curriculum, an increase in students' engagement in the learning processes and an improvement in transferring their learning into other domains (Henderson et al. 2000). A second, and probably the biggest impact of the project, is best portrayed by the fact that today, the 30 to 40 teachers who participated in designing the thematic curriculum, are engaged in training teachers nationwide in developing similar curriculum integration projects. A final impact, the decision of PISD to
extend the Curriculum Integration Project into their middle schools, illustrates successful implementation of systemic change in a school district.

Conclusions

The technology-based curriculum integration project in Plano provides a valuable opportunity to identify the ingredients of a successful technology integration project. The following are highlighted:

1. Introducing hardware and software is not enough; an educational technology-based project must involve appropriate curricular considerations that might require the design of an entire new curriculum.

2. Learning materials should be developed especially to complement and be integral to the curriculum. This applies particularly to computer-based learning materials.

3. Teachers should be involved in agenda-setting and decision-making, including those concerned with the curricular approach and production of learning materials, both on-line and off-line.

4. The introduction of technology into schools requires consideration of classroom architecture, placement of in-class computers, and technology infrastructure, and, not least, their effect on the teaching-learning culture in school and school-home interconnectivity.

Abstract: This paper is a report of the findings of a study that describes the development, evaluation, and revision process for an on-campus graduate level Statistics course website. Focus groups, interviews, and document analysis were examined to determine patterns and amount of student use during the website’s initial semester of use. Findings indicate a lack of integration into course activities contributed to minimal student use of the website throughout the semester. Student expectations about the currency of information on a course website suggest that regular review and updating of on-line materials should be planned for and accomplished. If on-line conferencing is to be part of a course website, it needs to be both required and structured by the instructor to be successful. Finally, a comprehensive review of printed course materials should be performed in order to ensure that website contents are not simply a redundant collection of course materials.

Introduction

Since 1994, when the worldwide web became available to most colleges and universities, the number of websites for on-campus courses has grown exponentially. The World Lecture Hall, a directory of these websites at the University of Texas-Austin, lists 129 websites in the field of Education alone, and this listing is far from comprehensive. But too many of these websites, we would argue, are thrown together quickly, almost immediately become outdated, and do not effectively serve the needs of the students taking the course, their primary audience. And once created, these websites often tend to be ignored by the instructor, becoming outdated and irrelevant, filled with useless information about past semesters and a graveyard of dead links.

This paper describes the systematic design and development process for a graduate-level statistics course website, with a special focus on the continuing development and revision process after the initial semester of use of the website is over. We wanted to discover how the website had actually been used during the course of the semester, and how it met, or failed to meet, the needs of the students and the course instructor. We also undertook a careful review of the website usage logs to determine patterns of use.

The design team consisted of three advanced doctoral students from the Instructional Systems Technology department at Indiana University. During the initial design process, the project team followed a common instructional design and development model. Major sections of the design effort included: analysis of the task and audience, prototype design and testing, design revision and full-scale development, final usability
testing and revision, implementation and summative evaluation. In this paper, however, we will focus our description and analysis on our post-instructional website development activities.

Methods

Our analysis in this study focused on two major questions. The first question was, “How (and when, and where, and why) did the students actually use the course website?” The second question was, “Based on the patterns of student usage found in the initial semester of use, what changes in the course website (in terms of content, structure, etc.) need to be made?” To answer these questions, we conducted focus groups of a random sampling of students who had just taken the course. This was followed up by a survey of the entire population of students who had taken the course. The instructor was interviewed about her use of the website and her perceptions of student use. Finally, the website usage logs were carefully analyzed.

Focus Groups

A random sampling of students enrolled in the Spring 1999 section of the course were invited to focus group sessions to discuss their use of the website during the semester. A sequence of questions was developed for these sessions by the design team, and additional questions were added during the sessions themselves. These questions were chosen to gain an understanding of several issues: which sections of the extensive website were most commonly used; the ease of use of the website; the times during the semester that the website was used, and the tasks associated with that use; and those aspects of the website that were incomplete or lacking.

Surveys

With that data in hand, we then sent, via email, a survey to all of the students who had taken the course in the past semester. The survey was designed to help us confirm the findings, and assure us of the accuracy, of our focus group data. The survey asked the students questions similar to those asked during the focus groups, simply revised and refined versions to fit the survey format.

Instructor Interviews

Throughout the semester previous to the first usage of the website, and during the website’s initial semester of use, we had met with the instructor of the course, a tenured professor in the Counseling and Educational Psychology department. We again met with her, just before our focus groups with the students, to gain an understanding of her use of the course website during the semester, how she had introduced the website to the students, and her perception of the amount and quality of student use of the website.

Document Analysis

We had access to the usage logs for the course website, which gave us information on how often each page (of the over 100 web pages of the site) was accessed and when it was accessed during the semester. We were able to determine the most popular pages on the website and the days during the semester that the website was most often used. This information was compared with the course schedule to help understand patterns of student use as they related to course assignments. We were also able to view aggregate information about website visitors. This information helped us determine whether the students were accessing the site from computer labs on campus, dormitories on campus, or through dial-up connections.

Findings
Student Use of Site

Unfortunately, we found that the course website was not used much during the initial semester, according to the students we talked to. Server logs back this up, though use did increase from 729 page requests in January to a high of 5162 requests during March, before falling back to 765 students again in May, as the course was ending. For comparison, another course offered by the same department had 10571 requests during March, almost twice as much activity (Bonk, 2000). As one student noted regarding the website, “Didn't use it much. Didn't have to.”

Students indicated that the professor’s reference to and use of the website in course meetings was minimal. Several mentioned that they might have used the website more if they had a better understanding of its contents. During one of the focus group sessions, one particular student discovered many useful and interesting resources when he was reviewing the site contents. He commented that, “I am currently working on a research design and I can really use these resources right now. The instructor should have emphasized this more during the class.”

Technology Details

The campus provides both Windows and Macintosh computers in student computer labs, and both platforms were used to access the site. The server logs confirmed student reports that they accessed the website from university labs, dorms and libraries and off-campus homes. Both high-speed networks and slower modems were used to access the site.

Both Internet Explorer and Netscape web browsers were used by students to access the site. Interestingly, many students reported using both web browsers depending upon the location from which they accessed the site. Perhaps surprisingly, students reported no technical problems accessing or using the site, even though it included advanced Javascript features on every page.

Site Content

Students primarily used the site for one purpose: viewing and printing examples of assignments and bibliographies (which were not in the course reader) as models for their own work. The article review samples and bibliographies were cited by many students as by far the most useful elements of the site. For example, in March and April, 1999, during the part of the semester that the students did the majority of their assignments for the course, the page that included links to these items was the second most popular page on the site, after the home page.

Other sections of the site that were favorably mentioned were: the links to information about the software that was to be used in the course, sample questions for the test, instructor contact information, and the links to professional journals. Students reported that they occasionally recommended the site to other students or referred peers to information they found on the site, especially information regarding assignment completion. One feature of the site, the bulletin board, a feature that can produce much site activity, was not used at all, and some students commented that they wished it had been used. One student said, “The discussion section would be helpful for after-hours help.” Normally when the students sought after-hour help, they sent email messages to the professor. The professor would send a reply directly to the student and forward a copy of the message to the whole group. Students commented that the communication between students and professor might have been more efficient if the bulletin board had been used.

Some students mentioned material that could have been included on the site but wasn’t, such as: links to the library’s online article search systems, answers to lab assignments, lab assignment handouts, case study examples, and sample problems to use with the statistical software. One student complained that while they read from several books, only the readings from one of the books were included on the schedule. Some of the content, specifically examples of studies cited in the bibliography, seemed out of date to the students as they were several years old. The list of scheduled readings was also out-of-date, referring to the schedule of a past semester.

We got the strong indication from students that because use of the site was not necessary to be successful in the course, they therefore had little motivation to visit it. Several commented that because much of
the site's contents were already in their printed course reader, it was not necessary to access them via the website.

Site Design

Overall, students reacted favorably to the look of the site and the utility of the navigation options. Several students commented that they appreciated the large image on the home page and the color scheme of the site (Fig. 1). One student said the site was "fun looking," though another complained that the light blue of the central image made the site look "faded." After extensive usability testing, detailed earlier in this paper, several methods of navigating the site (menu bar, sidebar, search, pulldown menu) had been provided for student use and each of these systems was in fact used by some students in our focus group interviews, though some showed strong preferences for one system over another. For example, one student said, "I never used the buttons at the top, I just used the links at the bottom." Students pointed out that some secondary pages lacked the navigation elements found on primary pages of the site.

![Figure 1: Website Main Page](http://www.indiana.edu/~japeng/Y603/index40.html)

The website did not influence student's feelings about the course in general; however, some students felt Dr. Peng was a strong advocate of instructional technology because she had her own website.
Recommendations

Based on our findings, we have made the following recommendations to the instructor of the course.

- A careful review of the contents of the printed materials given to the students needs to be made. Which of these materials would more appropriately be provided in print form, and which in online form? Are there materials that should be available in both formats?
- Students expect online resources to be regularly updated, providing them with the most current information available. Because of this student expectation, materials on the website should be periodically reviewed and updated to reflect changes in the course, related materials, and on-line resources.
- The instructor should consider methods by which the students can be made more aware of the resources contained on the website from the very beginning of the semester. Perhaps part of the initial class session should be used to introduce the website. Throughout the semester, the instructor could also point out occasions when the website could be profitably used.
- Course activities which require more use extensive use of the website resources should be integrated into the course.
- The instructor should take advantage of the interactive potential of the website by providing opportunities for students to discuss issues related to the course. Specifically, if the bulletin board conferencing tool is to be included as part of the website, students need to be made aware of its existence and encouraged to participate in the discussions. We suggest that use of the tool should be made a required part of class participation, since, in our experience with courses using such tools, unless use is mandatory, some students will only minimally use the tool and many will avoid it altogether. (ARTT: Practical Strategies for Using IT, 2000)

Limitations and Recommendations for Further Study

While we do not claim that our experiences are generalizable beyond this particular website design project, we do believe, based our experiences as instructional designers for other course websites, that our findings and recommendations will be useful to other instructional designers working on similar projects. Regarding the limitations of this study, obviously it is only one course of around 35 students, and the particular subject of the course, statistics, may have had some important implications regarding the students' use, or lack thereof, of the site. Also, the fact that the website design team also interviewed and surveyed the students may have had some influence on their responses, though we attempted to minimize this.

Conclusions

Course websites, even given their growing numbers, are still a new resource for instructors and students; they are exploring an unfamiliar realm when it comes to using this new technology in their teaching and learning. As instructional designers, we need to keep the academic needs of both students and instructors as our main focus throughout the design and revision process. Unless the course website serves their needs as efficiently and effectively as possible, it will not be utilized and our time and energy in developing it will be wasted. We hope that in this study we have added to the knowledge available about this design task, and hope that other instructional designers will find our experience useful.

Abstract: The capability of Hypermedia to exploit associative linking between contents and to provide multiple navigation paths through them makes this medium predestinated for mapping and representing knowledge spaces (Bush 48). Especially the possibility of mapping knowledge makes Hypermedia a very interesting medium for educational purposes. But access to information, as e. g. in the Internet, does not equal learning. In educational settings, we must adapt the mere access to information to educational needs. On the one hand we need to support the authors in the production and maintenance of these non-linear contents, on the other hand we must give the students tools to be able to work with these contents. In this article, we present the core functionality of an adaptable learning environment, ALIS. The ALIS project aims to support the production and use of interactive Web-based learning applications. We have developed an authoring System for organizing the contents of the learning system and an editing tool for the students, which allows them to adapt the learning material while working interactively with the learning materials.

Introduction

In the recent years the demand in computer-based learning systems has been growing continuously. This is due to the need of life-long learning and the fact that most of the students wish to be able to learn any time, any where. Using hypermedia systems for achieving these goals seems very reasonable because of the characteristics of this medium. A hypermedia system is a good platform for representing knowledge spaces and for interacting and navigating in them. The very strength of hypermedia as a medium to transfer knowledge is the mapping of nonlinear content.

Normally, when writing course material, the authors convert their nonlinear knowledge into a linear form to be able to transfer this knowledge on a linear medium such as written text. The learners on the other side must de-linearize the contents to be able to embed this knowledge in their own knowledge space (Lowe, Hall 99).

It is clear, that both, the authors and the students, would not need to go through this process, if they were able to work at the non-linear level. On the other hand the capabilities of hypermedia to exploit associative linking between the learning objects and to provide multiple navigation paths through them make the production and the maintenance of material very difficult. These difficulties are increased by the rapid technological progress and constant change in tools and standards. Especially the building of hypermedia learning systems is a cumbersome and expensive task because the authors need various skills to develop the solutions. They have to decide how to model and represent the knowledge to be transferred to the students, how to organize and administer this material, how to embed it in existing technology standards (browsers, operating systems, ...) and how to offer the students tools to work effectively with this learning material.

The Idea

The idea behind the ALIS System can be summarized by the following requirements for a learning environment:

1http://www.fernuni-hagen.de/ALIS/
Learning is the process of knowledge construction, not knowledge recording or absorption (Harel & Papert 91).

The learners need environments, in which they can be an active designer rather than a consumer (Fischer 98).

Consequently we need a learning tool which has the following characteristics:

- it is adaptable, and expandable
- it visualizes also the semantic interrelation of the contents and gives the learner the possibility to use this as an interface to adapt these structures to his own needs.
- it must be a generic tool, so it can be used for any kind of domain.

The interesting question at this point is, how is it possible to build a generic system, which can map a knowledge space independent of its contents. As a solution, we have chosen to give the learner always two visual perspectives of the knowledge space. On the one hand we have the presentation of the particular content (at the present time made of HTML pages) in which other media types (e.g. JPEG, GIF, MPEG, applet) are integrated. Thus one special aspect is covered and shown in a browser window.

On the other hand we have got an overview of all pieces of content and their relations within the whole context. For this purpose we use the mind map, which is a specialized form of a concept map.

A concept map is a well-known formalism for representing structural knowledge (Jonassen 93). Concept maps tend to be much easier for human users to understand than other knowledge representations such as pure text or predicate logic (Nosek & Roth 90). It is a directed acyclic n-dimensional graph consisting of a set of m concept labels \{C1...Cn\} and a non-empty set of r relationships between them. Different diagrammatic representations are used to visualize such graphs. One of the most popular study aids in educational settings are mind map (Buzan 93). Their advantages for the learner are described e.g. in (McAleese 98, Novak & Gowin 84). McAleese stresses the role of concept maps for the important self-regulatory study process, which he calls "reflection".

The Learning Tool

We have developed a Java and XML-based learning tool, which aims to provide more flexibility for students while working with courses and allow them to personalize them. It can be used online, off-line or in a mixed way.

Its user interface provides two separate windows: one of them is a normal browser window presenting the content, the other one is a structural navigation tool as shown in Fig. 1. The navigation window includes a concept map (right and lower left window pane), a navigation tree (upper left pane), and a pyramid shaped depth indicator (middle left pane).
With ALIS, the learners are able to access the content directly in the browser window and navigate from content page to content page. Alternatively, they can manipulate a visual concept map. The manipulations of ALIS' concept include: shifting the focus to the topic of interest, folding or unfolding concepts nodes, adding nodes or associative links among nodes that are not member of the same sub-hierarchy, or select presentation pages to be shown in the browser window in a point-and-click fashion. In addition the learners can easily insert their own notes and select bookmarks in the map and save same a personal bookmark register in the navigation tree. The navigation tree, which shows a folder hierarchy, allows the learner to access the content by clicking into a selected folder hierarchy and selecting a leaf item denoting a content page opened up in the browser. The nodes or folders in the tree are color coded. Red indicates an unread item, blue indicates items visited, and green refers to a page or collection of pages the user confirmed explicitly to have understood. There is also the possibility for the user to create context sensitive views on the content in different trees, which can be accessed by separate registers. For instance, a student's learning application might include a tree for examples, for related links, for exercises, and for definitions allowing him/ her, for example, to quickly refresh the content before entering an examination. Another pane of the navigation tool shows a 3D visualization of the focus depth hierarchy. The idea behind this view is to indicate the level of detail a knowledge piece as belonging to. The assumption here is that the deeper the content is placed in the hierarchy the more specific the selected information is. The pyramid window also includes a learning progress indicator (the bar on the right side of this pane), which shows the learning progress percentage-wise using the same color coding as in the tree representation.

The different views on the course material are always synchronized. This ensures that the structural navigation tool always refers to the page shown in the browser window and vice versa. The learning tool supports also a merge
functionality. This means that the students are able to synchronize their own extensions with other students or with the update information about the course on our servers. This functionality gives them the possibility of collaborating with other students.

Implementation

The first version of the navigation tool is operational and in use.

The Authoring System

According to Elliot and al. (Elliot et al. 95) "if an authoring environment were to allow developers to" draw "their subject domain on a screen as a semantic net and then add the hypermedia features it would considerably facilitate development". In the ALIS project, we are developing an authoring system, which allows authors to use this framework to gather pieces of information and weave them into a hypermedia system. For doing so, ALIS offers several views upon the content and its structure. Our main goal by developing the authoring system was to give the authors the possibility to concentrate on forming and designing the subject domain and to be able to store this knowledge into a database.

In the first pane the authors define the educational objectives to be able to control, whether all of the relevant themes are included. In a second pane, they use the concept map designer to structure and organize the information space. While working with the concept map, they are able to compare the consistency of the contents with the educational objectives and check the associations between contents. After putting up the main semantic structure of the contents, the authors can use this scaffold and fill it with contents and style information by clicking the nodes of the concept map and adding the descriptions to this particular topic. After collecting and structuring the information in this way, it is possible to automatically generate and build up the learning application out of the data base. The advantage of this approach is a high level of separation between knowledge, its presentation and its implementation in a hypermedia application. The authors don't need to take care about the presentation of the contents, the navigational support, and other facilities of an learning application.

Implementation

The first version of the authoring system is operational. It supports the building and organizing the of contents at the semantic level. The screen units can be edited with external HTML Editors. In the next level of development we will also separate the style and markup information from the contents to store them also in the data base. Doing so, the authors can assemble the course and the contents with their style and markup information, at the time of delivering.

Conclusion

In this article we have illustrated the learning environment ALIS with its generic functionality. ALIS lets the students adapt the learning material to their own needs by adding links to up-to-date information and integrating their own elaborations. Students collaborating in geographically dispersed teams can make their personal extensions accessible to their peers through a simple update function that just exchanges the differences in the individual link structures. Flexible navigation mechanisms support multiple perspectives on the course material and allow them to find their own tour through it. Personal notes and links to related material of their choice can be added by drag-and-drop functions.

We know that the author's task of developing such flexible applications is difficult and hardly supported by suitable tools reaching the comfort of traditional CASE tools. Commercial authoring tools such as Director, Toolbook, or Authorware can at best be considered low level design and programming tools.

Few tools and techniques are available at present that help authors to elicit the requirements for a new course (including learning objectives, subject topics to be taught, appropriate didactic approach, learning material and
presentation media suitable for the clients, navigation structure) and systematically evolve such requirements into a hypermedia application. The extensions we plan for ALIS aim to overcome some of these difficulties in the near future.

References

Abstract: This paper describes research being conducted at Rutgers University into the design of Distributed Learning Systems for asynchronous delivery of multimedia educational material to students via broadband networks. A pilot system called Aristotle comprising videotaped lectures, text transcripts and textbook figures all organized into short synchronized presentations has been successfully implemented and is described in detail. The experience gained during the project has fueled ongoing research in the areas of automated speech recognition, automated question-answering, and development of tools for generating and organizing media content, all briefly described herein.

1. Introduction

This paper describes the design and implementation of the Aristotle system, a web-based educational tool intended to supplement classroom instruction for an introductory course in General Biology. The Aristotle system is a Distributed Learning System that makes a multimedia database containing segmented lecture material augmented with text and graphics available to students via a broadband network. Section 2 of this paper presents the design approach. The implementation of the Aristotle system is described in sections 3 and 4, which contain an architectural overview followed by a more detailed discussion. Section 5 describes the deployment of the system and the design of an ongoing study to determine its effectiveness. The paper concludes in Section 6 with a summary of proposed enhancements, which are currently under development.

2. Approach

In the development of Aristotle as well as its ongoing work, the project team considered three main objectives:

1. to present information to the student in a highly-integrated manner
2. to organize information content in a way that facilitates learning
3. to develop tools and processes for efficient capture of data

These objectives form the basis of an approach to the design of Distributed Learning Systems which is discussed more fully in the following paragraphs.

Integrated Presentation of Information

We seek to provide students with a learning experience that is convenient, engaging and saves time. The presentation of information will be attractive, and facilitate the cognitive processes used in learning. To achieve these goals, the system will support user interaction via all the sensory modalities employed during traditional classroom-style instruction: visual/auditory (while listening to the lectures), visual/tactile (recording notes), verbal/auditory (asking questions), visual-only (reading textbook). Moreover, all interaction can occur at a single time and location, by contrast with conventional learning where information delivery is disjoint (lectures, reading, and visits to library and instructor must be done at different times and places) and the student must expend extra effort to integrate these experiences into a consistent framework.
Content Organization

We will introduce new logical structures for defining and linking objects within multimedia databases. The objects, which we call "knowledge containers", will present educational information pertaining to concepts or ideas. The links will describe relationships between the objects and will facilitate learning and rapid information retrieval. For example, a student learning for the first time about viruses may obtain a clearer understanding by referring to a description of a specific virus such as influenza or by contrasting it with a disease caused by infection, such as scarlet fever. However, the student may not initially know enough about a high-level concept to search for the correct terms or phrases. In this example, the "virus" container could be connected to the "influenza" container via a link of type "example", and to the "scarlet fever" container via a link of type "counter-example".

These new types of data structure will also facilitate so-called "meta-cognition" or "meta-learning" -- that is, a student's conscious awareness of the process by which he or she acquires knowledge. Through a visual representation of the knowledge containers and their relationships, a student can track his or her progress in learning a subject, and to make better decisions regarding which topics or ideas to consider next.

Content Generation

A key design goal will be to minimize the labor required for capture and organization of lecture material. We will seek methods for unobtrusively capturing lectures as they are delivered within the normal classroom setting. Automated tools and methodologies will be developed for video capture, speech transcription, and multimedia presentation authoring. These tools will be custom-built for the distributed learning application in order to ensure that they will be simple and efficient.

3. Project Overview

The Aristotle project is a pilot program whose purpose is to explore the technologies and concepts described in the introduction. For this project, a web site was created containing multimedia instructional material derived from an introductory Biology course (http://lilac.rutgers.edu/bio/aristotle.html).

Twenty-five lectures from the course were videotaped at an on-campus television studio. Using written outlines of the lectures, the project team prepared many brief multimedia presentations that could be indexed, and retrieved using a personal computer. Software utilities were written to generate the hundreds of files associated with the presentations automatically. The presentations include video and sound clips from the lecture, textbook figures that pop up to illustrate concepts referred to in the lectures, scrolling text transcripts of the lecture, and written definitions of biology terms. Students view the material using a standard web browser. Headsets were provided in order to permit students to listen to lecture audio.

The multimedia presentations were classified into two types: topics, and key words. Topic presentations contain all the material relevant to a concept covered in the lecture, while key word presentations are very short and concise, designed to give only the definition of the term in question. Students search for topics using an index based on the lecture outlines just as they would search the table of contents of an online book. Key word indices are also provided for each lecture, but are organized in alphabetical order instead of the order in which the material was covered by the instructor. Information can also be located using full text search.

4. Implementation Details

4.1 Major components

The course content resides on a computer located in the research center's computing facility (Fig. 1). Media files, such as JPEG and MPEG files, are managed by a streaming media server (the RealServer from Real Networks Corp.) while HTML files are handled by a standard web server (Apache). Students access the course content from a computer lab on campus. A 100 Mb/s Ethernet connection links the two facilities. In the future, access will be extended to include any facility served by the Rutgers University Network (RUNet 2000).

A web browser configured to handle streaming of compressed video, can be used to access the web site. Two plug-ins are required: the Real Networks RealPlayer G2 plug-in, and the "MPEG by Bitcasting"
plug-in - designed specifically for streaming MPEG-1 system files (files containing audio and video data interleaved) at high bit rates.

Management of the web server, and video server is accomplished using Apache Administrator and RealAdministrator, respectively. These are web-based interfaces that allow configuration and control of the respective servers from any browser capable of connecting to the server computer. Using these interfaces, system administrators can start and stop the servers, set bit rate limits, enable or disable access control, and collect site usage statistics.

![Diagram of major components of Aristotle](image)

**Figure 1: Major Components of Aristotle**

### 4.2 Web Site Design

When students access the web site, they begin with the Aristotle Welcome Page which contains a brief description of the project, as well as a link to the Virtual Classroom page which lists the biology lectures that are available for viewing. Links from the Virtual Classroom page lead to HTML pages containing topic and key word indices which, in turn, lead to the core of the web content – the multimedia presentations for each topic and key word (Fig. 2).

Topic pages contain both standard links and embedded objects. On the left side of the page are links which:

1. lead back to the lecture outline and key word index
2. connect to the web search feature
3. lead to the previous topic or subsequent topic.
4. generate a pop-up list of the figures associated with the topic, if any are available

Helpful prompts describe each link when the mouse arrow is placed over the link text. The remainder of the page contains the multimedia window, which is split into: video region (view of professor and blackboard), transcript region (contains scrolling text), and illustrations region (contains pop-up figures – also contains a link to an expanded view of the figure which opens in a separate window). Across the bottom of the multimedia window there are playback controls and a playback status display.

Key word pages are identical to topic pages, apart from the fact that the links region on the left hand side contains a link which, when selected, activates a pop-up window containing a text definition of the key word in question.

The key component of a multimedia presentation for a topic or key word is a file containing code written in the Synchronized Multimedia Integration Language (SMIL). SMIL (Hoschka, 1998) is a markup language for multimedia presentations that can be interpreted by compatible media players (such as RealPlayer, in this instance). Using SMIL, it is possible to define screen regions, associate media objects with the regions, and synchronize the appearance of media objects (for example, to define when figures appear and disappear).
4.3 Search Engine

Students can access a site-specific text search engine via links embedded within several of the Virtual Classroom pages. To search for a word or phrase, without using lecture outlines or key word indices, they can go to the search page, type in their query and obtain a list of links to relevant pages within the web site.

4.4 The Lecture Production Process

The Biology course comprises 25 lectures amounting to over 36 hours of video and audio, 250 figures, and approximately 150,000 words of transcripts and other data. The web site contains presentations on 400 topics, and 1800 key words. Clearly the process of generation of this material needed to be as streamlined as possible. Through trial and error, a reasonably efficient approach was adopted (Fig. 3):

1. video tape lectures in studio (Betacam format)
2. edit lectures using an AVID Express non-linear editor
3. encode video in MPEG-1 format using a hardware encoder board (Optibase MovieMaker)
4. review lecture video and identify time codes for figures, and topic/key word boundaries
5. scan (digitize and compress) textbook figures
6. generate topic/key word files (HTML, SMIL, RealText)
7. generate transcripts
8. transfer content to server
5. DEPLOYMENT AND EVALUATION

A study is now in progress to determine the effectiveness of the Aristotle system. In the fall of 1999, informal anecdotal feedback was obtained from a pilot group of one hundred students who were given access to the web site during its development. A more formal study involving a group of similar size is planned for the summer of 2000. Final grades, a user satisfaction survey, and web site usage statistics will be used to measure the quality of the learning experience. Final results will not be available until the end of the semester; however, initial feedback has been very encouraging. In the meantime, several important lessons have been learned simply through the process of developing the Aristotle system, which help to point the way for further research. These lessons and proposed enhancements for the Aristotle system are described in the following section.

6. ONGOING WORK

Lecture Transcription

Currently, the process of generating lecture transcripts is by far the most time-consuming and labor-intensive step in generation of course content. Transcripts, however, are necessary for incorporating full-text search as a means of locating specific information; therefore, future generations of the DLS must incorporate more efficient methods for their generation. Experiments with a commercial speech transcriber indicate that automatic speech recognition is not yet sufficiently accurate for the task. One reason for relatively low accuracy is that the standard language model is not well suited to the biology domain. Although a significant error reduction (40% relative) could be achieved by training a biology-specific language model (using a biology textbook containing approximately 600,000 words as training text), the amount of the training data was not sufficient to bring the recognition error rate to the desired level. Analysis of the transcription errors suggests that a significant benefit could be realized by employing long range language models that attempt to deduce the current context based on words recently spoken and using the results to condition the predictions of the short-range trigram models that are currently employed. At present, our research is focused on investigation of such techniques.
Multimedia Authoring

We will seek to develop tools and procedures to make content preparation as painless as possible. As a first step, we are developing multimedia authoring software specifically designed for systems like Aristotle. Where standard authoring or editing tools use time lines and frame-by-frame playback of video content for segmentation and synchronization of media content, our tool will be based on lecture transcripts. The author will be able to use text search to quickly locate relevant sections in a video clip, then will employ a “point-and-click” interface to select words from the transcript that bracket a topic segment or figure reference.

To further enhance the functionality of the tool, we are investigating ways to automatically determine the location of topic boundaries within the transcript text. The segmentation algorithm will use lecture outlines and passages from the course textbook that have been labeled with the name of the topic discussed therein. Using labeled passages as templates, Local Context Analysis (Xu & Croft, 1996) will be applied to a large corpus of unlabeled biology text in order to find words that are strongly indicative of a given topic. Short segments from within the lecture transcripts can then be categorized by topic, and systematically clustered into longer segments, based on the presence or absence of such characteristic words.

Question-Answer Capability

Future versions of the DLS will allow students to find information by asking questions, as they would of a professor. We envision a user interface in which the student interacts with an animated character that is capable of speaking and responding to voice input. Research into question-answering techniques is being conducted using data and guidelines developed for the question-answering track of the National Institute of Standards and Technology (NIST) Text Retrieval Conference (TREC). The initial research objective is to find optimal methods for:

1. Question analysis with a view to predicting the type of answer required.
2. Full-text passage retrieval (using the question as a query).
3. Analysis of the retrieved text passages to select the most relevant given the question and answer type prediction.

Organizing Content: the Knowledge Web

Our future Distributed Learning Systems will go beyond the use of topics and key words for segmenting and organizing information. A new data entity called a Knowledge Web will be developed based on the eXtensible Markup Language (Bray, et al, 1998). The Knowledge Web will define Knowledge Containers, and the relationships that link them. Currently, fundamental software components are being developed that will allow experimentation with various web structures. These components include a graphical editor for creating and modifying containers and links, and a hierarchical visualization tool called a Knowledge Map for viewing and traversal.

6. REFERENCES

Abstract: This paper is a report in progress on a longitudinal case study over six years at Apollo Parkways Primary School. Apollo Parkways is an elementary school in middle to lower-middle class socioeconomic suburb in Melbourne, Victoria Australia. The study examines the changes in formal and informal conversations as the school evolved from a 'community of learners' to a 'learning community' (Sergiovanni, 1994) when a technology rich environment was created. The nature of the conversations is providing evidence, which supports the concept that conversation can be an indicator and catalyst of change. More importantly this study is identifying elements in the school, which have supported sustainable change.

Introduction

In today's society greater demands are being placed on education systems at all levels to produce citizens who can use knowledge in new domains and different situations. Members of society at every level are being asked to demonstrate advanced levels of problem solving to retain their utility as employees. Learning to think critically, to analyse, to synthesise information, to solve problems in a variety of contexts and to work effectively in teams are crucial skills for modern employees, and yet there is little evidence that our education systems are developing these skills in our children (Bransford, Goldman & Vye, 1991). Some (Schank & Cleary, 1995) argue strongly that our educational systems are not developing these essential skills. The Cognition and Technology Group at Vanderbilt (CTGV, 1993) cite Whitehead's (1929) notion of "inert" as opposed to "active" knowledge as a consequence of conventional approaches to schooling and teaching. Berryman (1991) has delineated several erroneous assumptions on which much of the teaching and schooling process is based.

Schools now faced with mandates for the infusion of information and communication technology (ICT) throughout the curriculum may feel they are at a crossroad. Technology is not universally seen as a panacea for current educational woes. As long ago as 1984 Cuban warned "there should be a page in the Guinness Book of Records on failed classroom reforms, for few ever seem to have been incorporated into teachers' repertoires". Like past revolutions in education, it will go the way of previous technologies unless there are changes to the educative framework.

In Australia, similar concerns were raised in discussions with senior departmental officers. In March 1991 Dr Terry Burke, Deputy Director-General, NSW Department of Education and Training raised serious issues regarding the implementation and long term viability of the Technology High School program (18 months into the program). In November 1996, Mr Phillip Arthur, Manager, Schools of the Future, Victorian Department of Education emphasised the need to model the Navigator School program on key findings from recent studies into the use of technology in teaching and learning.

In many similar programs, managers and administrators have simply said, "Pretty simple, just train them (the teachers) to use the computers – as experts in curriculum and instruction, the teachers will do the rest". In his critical review of computers in schools and universities, Bork (1995) argued that the effective use of new instructional paradigms required: "a shift in teachers' pedagogical approaches and software that supports modes of instruction with alternative frameworks". The failure of many programs to bring about sustainable change in the classroom may have been linked to ignorance of the need to change pedagogical approaches, and with them, the nature of interactions and conversations among teachers.

This paper outlines a study in progress of what occurred within one school as it traversed the crossroad – it is a study of whole school change through the integration of technology, using a model based on a decade of ACOT (Apple Classrooms of Tomorrow) research. The implementation model began with the key findings of twenty-two published ACOT reports, and the venue was Apollo Parkways Primary School.
The Setting

Apollo Parkways Primary (Elementary) School is a government school located in the north east outer suburbs of Melbourne, Victoria Australia. Socioeconomic area -middle class Australia. Prior to 1995, technology in the school consisted of one or two computers in some classrooms. In 1995 the school, with support from the local community, installed a single computer laboratory, increasing the total number by 16 computers. In October 1995, the school was named 'Navigator School of the Future' by the Victorian Department of Education. In August 1996, it was also announced as the eighth ACOT site in the world. As part of the ACOT and Navigator school programs, in July 1996, the school received over 200 computers, file servers, network and Internet connections. The computer student ratio had decreased from 1:30 to 1:3. During this time, the school population continued to grow by 5-10% per annum. Currently, there are nearly 700 pupils, 34.2 teaching staff, 3 executive staff and 4.2 administrative and support staff.

The challenge seemed simple - share key ACOT research findings (Fisher, Dwyer, & Yocam, 1996; Baker, Gearhart & Herman, 1993; Ferguson-Smith, 1998) with staff, give students and teachers immediate access to computers, show them how to use the technology, and introduce them to open-ended software.

The Study

From a research perspective, the key question was how to capture the essence of what occurred in some meaningful way so others could benefit. The formal and informal conversations within a school were initially considered in their capacity as an indicator. Lambert's (1995) 'typology of conversation' (dialogic, inquiring, sustaining and partnering) in a constructivist leadership environment suggested a vital role for conversations in the change process, thus elevating the status of conversation from indicator to focus.

The purpose of the study is to examine the change in conversation at the school before, during and after the introduction of technology rich classroom learning environments. It addresses three main questions:

1) How has the conversation changed?
2) How has the classroom practice changed?
3) How have teachers' views of learning changed?

A qualitative approach to the research is followed in this ethnographic study – the researcher is a participant observer in a naturalistic paradigm (Lincoln and Cuga, 1985) with an interpretivist goal (Wills, Thompson & Sadera, 1999). A variety of techniques have been employed for data collection and analysis, informed by researchers such as Dwyer (1985) – understanding stories, and Beittel (1973) – using artefacts and observation. Data sources have included official documentation, observations, unstructured discussions, interviews, questionnaires and personal diaries.

The analysis of all the school official documents and publications including daily bulletins, newsletters, annual magazine, the web site, teacher journals, student portfolios, student observations and reports involved identification then tallying of themes evident in these formal conversations.

The identified themes have generated questions to be included in interviews, questionnaires and unstructured discussions with community members including the school executive, teaching staff, administrative and support staff, the students and parents, visiting educators and participants of the different professional development programs.

School Change

During the first visit to the school, at the after school staff meeting, the vision of ACOT and the key research finding were shared. An underlying assumption was that the findings would translate from the American experience to an Australian school. Over the next twelve months, each of the 35 staff members participated in 3000 hours of professional development. These activities covered a wide range of topics. The exercise provided clear support for many key research findings, such as stages of adoption (Hall, 1997), the nature of learning (Roblyer, Edwards & Havriluk, 1997), constructivism (Cobb, 1994; Fosnot, 1996) and reflective practice.

Working in collaboration with the school executive and project coordinator, key issues of professional development (Hargreaves & Fullan, 1992; McLaughlin & Marsh, 1983) were revisited. These discussions soon highlighted many of the issues and concerns associated with school change (Hargreaves, 1994; Fullan & Hargreaves, 1996; Schlechty, 1997, Stall & Fink, 1996; and Sandholz, Ringson, & Dwyer, 1996). Reorientation towards constructivist learning environments (Cobb, 1994; Fisher, Dwyer, & Yocam, 1996; Fosnot, 1996; and Lambert, 1995) coupled with adjustments to the physical, technical and social ramifications of increased technology created a complex pattern akin to Rogers' (1995) diffusion of innovation model.

With a developing awareness, understanding and appreciation of key research findings from several technology based programs around the world (ACOT in the USA and River Oaks School in Canada) Apollo Parkways implemented support structures to ensure a successful and sustainable experience which could improve student outcomes and learning.

The successes and challenges faced by the teachers in the altered instructional settings resulted in a mix of readiness by individuals to accept and implement technology. Their willingness to accept and adopt change is described by Rogers' (1995) adoption and diffusion of innovation, "from first knowledge of an innovation to forming an attitude toward the innovation, to a decision to adopt or reject, to implementation of the new idea, and to confirmation of this decision". Researchers studying teacher development have found that all teachers who are implementing educational innovations progress through a series of stages:
survival, mastery, and impact (Stoll & Dean, 1996; Hall & Loucks, 1979). According to Rényi (1996), teachers make or break a school:

"To improve schools we must focus on the teachers. Schools can only be as good as the teachers in them. This is something that all other so-called 'reform efforts' have missed. It's what teachers know and can do that will make the difference in improved student performance." (http://www.nfte.org/takechar.htm)

Preliminary Data Analysis

Intuitive analysis of the formal publications have so far identified some key sub-questions that will be used to build the interview and questionnaire protocols:

- How did you implement whole school change?
- What protocols (strategies or formal elements) have been employed?
- What were their frequencies?
- Were they subjective or objective? Why?
- Were there any hidden messages? If so, how did they involve forward planning and reflective practice?
- Who did it impact?

Intuitive analysis of the informal themes of conversation identified the following key concepts:

- Spontaneous
- Subjective
- Circumstantial
- Current or immediate future or past (here and now)
- Formative
- Focused on the individual perspective

The complete data set for the formal conversations is too voluminous to interpret in its entirety, so sampling methods have been applied to certain documents. Bulletins have been sampled from the months of Term 1 - January, February and March each year. Table 1, provides the analysis framework for each publication type. This involves a 3-D graph for each year (1994-2000), with the following axes:

- x axis = dimensions of the publications
- y axis = characteristics of the formal conversation
- z axis = qualitative assessment of how these have changed over time (judgement / depth) or rate of change of the changes (using a rating scale 1-5, where 1 is the lowest)

Table 1 : Depth of assessment of the characteristic and dimension of conversation

</table>
The links between the dimension, characteristics and depth, from Table 1, will help formulate the themes and provide the basis for some of the questions to be raised in the interviews and questionnaires. Teacher interviews will be conducted with 5 to 6 teachers who have been with the school throughout the study, and 3 to 4 teachers who were new to the environment in 1999 and 2000. Interviews with other key staff include members of the executive, parent and citizen association, school council and a small sample of visitors.

Interview questions will originate from four sources:

- **Analysis of data** (above) – to triangulate findings from analysis of written documents
- **Theory** – to test the teachers’ understanding of certain theory, and to validate patterns suggested by research literature
- **The structural framework** for data analysis – to identify key features of formal and informal conversations across several pre-specified themes (see below).
- **Intuitive ideas** of the researcher who participated in the design of professional development experiences for staff within the time frame of 1996 – 1999.

Table 2, outlines some pre-specified arbitrary categories that have been chosen as a starting point to identify patterns and trends in data. The preliminary results from the analysis of formal and informal conversation before and after the introduction of technology in the school is providing evidence that supports the conversation as an indicator and catalyst of change.

The underlying reality that is being sampled: What happened at Apollo Parkways Primary School between 1996 and 2000.

The school, during 1996/7 implemented several guiding principles, highlighted by recent research about learning and technology. These principles can be summaries by the following:

- Provide continued and extensive professional development that was situated in the contexts of practice.
- Adopt a constructivist learning approach in the classroom.
- Create learner centred and technology rich learning environments.
- Engage teachers from the school in an ongoing conversation and reflection about their practice, their students, theories of learning, how they learn, alternative forms of assessment, the appropriation and integration of technology and what they would change or not change in their classrooms.
- Teachers in teams, develop integrated units of work, lesson plans and other learning tasks that were cross curricula used technology.

Conclusion

There is evidence to suggest that a new way of thinking about change and technology is required, based on a thorough knowledge of the processes and the people, blending research and experiential knowledge, Fullan (1991). Effective change management is facilitated by supportive management structures. The constant communication of outcomes and results is essential in order to maintain support and it is advisable to keep personal political agendas transparent.

This study may provide some insight into the key elements contributing to effective change management. The question is, do successful agents of change have a characteristic stance, a capacity for creating personal vision, inquiry, technology mastery and collaboration in addition to a sizeable 'repertoire of procedural knowledge'?

The implications of this whole school study can provide important lessons and strategies for administrators, educators, schools, districts and education systems in an Australian setting. Those at the crossroads would do well to listen to the conversations of those who have successfully traversed the terrain.

Adapting an Internet Based Learning Environment to a Hybrid Approach

Katrin Franze, Hagen Wahrig, Olaf Neumann
Dresden University of Technology
01062 Dresden, Germany
{kfranzewahrigneumann}@rn.inftu-dresden.de

Abstract: In the past years there has been a tremendous movement in the area of teleteaching/telelearning. Many institutions try to find solutions for distance learning that could be used especially with the Internet. Today's solutions cover synchronous scenarios like teaching using videoconference systems and asynchronous scenarios like putting teaching material on the web. JaTeK (Java Based Teleteaching Kit) is a system for both telelearning and teleteaching. Teleteaching, for us, means composing teaching material and using tools for self learning, seminars as well as synchronous and asynchronous communication and cooperation. JaTeK is completely implemented in Java and consists of client components and the JaTeK servers managing material, users, groups, and permissions as well as communication and evaluation. First experiences with JaTeK have shown that there is strong demand for the system on offline media. This article describes the realized approach of a hybrid version of JaTeK that solves the problems related with its availability off-line.

Introduction to JaTeK

JaTeK (Java Based Teleteaching Kit) is a three-tier client/server system with an underlying object oriented database (see fig.1). As both JaTeK and the DBMS are completely implemented in Java, the system is applicable on all platforms with a Java virtual machine installed.

![JaTeK Architecture Diagram](image)

Application data are managed by ObjectStore PSE, an object oriented DBMS completely implemented in Java that makes its functionality available via the database API. The JaTeK server provides high level functions to create and login users as well as to create, write, read and delete objects implementing the server API. The JaTeK clients allow to display and administer the teaching content (e.g. documents, exercises, and experiments), and encapsulate the JaTeK server interface. They consist of the actual applications realizing the graphical user interface and the data objects representing the teaching contents that will be read from the server.

When a user logs into the server-based system, the client application gets a reference to a user-specific server object via RMI naming service. That manages all subsequent user requests to data objects on the server. The data objects are read from respectively written to the database by the JaTeK server. The teaching content is implemented in form of different material templates that use methods of the JaTeK API to communicate with the client application or with the server, respectively (e.g. for receiving or saving material data).

For the hybrid system to work, JaTeK's functionality had to be enhanced by a new component responsible for controlling the hybrid mechanism, storing of data in the local database, and data equalization (see fig 2). The hybrid
control supplies the application with data objects by loading them from either the local database or the remote server, depending on the current application mode. Communication services that are part of the JaTeK system do not access the local database. Only if the remote JaTeK server is reachable their data are handed over.

**Figure 2. Architecture of the hybrid system**

**Scenarios of the hybrid approach**

Originally, the JaTeK system was required to be available over the Internet. However, our experiences and the results of evaluation cycles have shown that more flexibility regarding Internet connectivity is needed. To meet the requirements of a wide ranged usage the hybrid system has to cover the following scenarios:

1. **Usage as non-hybrid system via HTTP/RMI-server without client-side storing**
   An educational institute offers teaching material on a server that students may access over the Internet. Mostly they use the JaTeK clients from within a university computer laboratory, so a fast network connection can be assumed. All data - that are kept in a database on the server - may be transferred via the network.

2. **Local usage without communication- and write-requests**
   A student without network access can use the standalone version of JaTeK. All data are stored locally and the system will be started from CD-ROM or local hard disc. Since CD-ROMs are read-only media, in this case just read operations can be executed. For write operations a medium that can be written to, e.g. a hard disk, is required.

3. **Hybrid usage**
   A user with but a slow network connection would still want to access the most recent data. Using the system in the hybrid modus, the user would transmit as few data as possible via the network - thus minimizing network traffic and delays.

   In this scenario, the system is installed locally on the hard disk. For regular work, only data locally stored are accessed. They will be updated only if the data on the server have been changed since the last equalization. Write requests are performed on the server and on local data.

4. **Data equalization**
   Normally, if a local database is used it is not necessary to hold a network connection alive all the time one works with JaTeK. For instance, course material could be created in the standalone modus. When the work is finished, the server database can be updated with that material.

   This scenario supplements that of local usage without communication and write requests.
The scenarios described above are summarized in table 1. The need of connecting the server in one of the scenarios implies to respect its user and permission management. The permissions have to be applied to the local database in order to avoid inconsistencies between the server and client databases.

</tbody>
</table>

Table 1. Summary of the scenarios covered by the hybrid mechanism

The form of database access inevitably derives from the scenario currently used. Exclusively in scenario 3 and 4, the databases are equalized with each other.

System requirements of the hybrid approach

A system that covers all of the scenarios described above has to meet the following requirements:

* Work as "pure" client server system
  The system should be able to deactivate the hybrid functionality and to switch to a mode not using this additional functionality. That means the system must be workable without a local database.

* Data equalization in both directions client server and server client
  Usually, only client data will be updated with newer server data. However, if local data are changed in the standalone mode, these changes will have to be processed in the server database, too.

* Functioning without a server
  To use the system without network access, it has to be able to work in standalone mode with just the client database. Therefore, all necessary components (i.e. database, class files, etc.) have to reside locally, without network based communication services being available.

* Keeping resource consumption low
  Since the client computers running the hybrid component usually have fewer resources than the server computer, the hybrid component must not consume resources excessively.

* Automatic/manual start of the full data equalization
  Full data equalization can be run automatically at the start and/or at the end of a session, or be started manually to keep the entire database up to date while working in standalone mode.

* Data equalization on demand
  If the client is working online, local data will not be equalized until they are accessed by the application. Thus several small data transfers are performed, consuming less time than one big transfer.

* Transparent data access
  Accesses to the local and the remote database have to be realized transparently to a large extent. For the user and the application, there should be no difference between a query to the local or the remote database. Only the hybrid component has to know where the needed data are located and use this information.

* No separate application for data equalization
  In order to keep the user interface simple the hybrid functionality is integrated into the existing client software. No external application is needed for data equalization.
Database access in the hybrid system

Different possibilities of access have to be considered to determine the form of database access:

* Database access:
  * direct via the database API
  * via a server process

* Database Access by
  * a Single user
  * multiple users concurrently

* Using a database
  * on the local computer
  * on a remote computer

Since the used DBMS does not support a remote use of the database API, it is impossible to directly access a remote database API (e.g. via RMI). Neither is accessing a local database via a server process effective as this approach consumes resources and brings no advantages in the context of the system. The scenarios best applicable in the hybrid system are, therefore, the use of a local database directly via its API for accessing cached data, and of a remote database via a server process for updating data.

<table>
<thead>
<tr>
<th>Access</th>
<th>Local</th>
<th>Remote</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Single user</td>
<td>Multi user</td>
</tr>
<tr>
<td>Direct via database API</td>
<td>Local solution</td>
<td>Concurrency problems</td>
</tr>
<tr>
<td>Via server process</td>
<td>Incommensurate</td>
<td>Server solution</td>
</tr>
</tbody>
</table>

Table 2. Scenarios of database access

As the server process is capable of handling multiple users, remote access by multiple users has not to be regarded separately. A direct access to the database API in multi user mode could result in the database being opened by multiple processes. That, in turn, could lead to undefined database behavior since JaTeK uses the DBMS ObjectStore PSE, which does not provide cross-process concurrency control mechanisms.

Therefore, the hybrid system uses the database API to access the local database directly. The multi user server process is used for accessing the remote server database which in this case is shared with other clients.

Assigning client objects to server objects

For equalizing the objects of the local client and the remote server database in the hybrid system, corresponding objects have to be assigned. To unambiguously assign an object of the server database to one of the client database a unique external link must exist. Equivalent objects reside at the same position in the object tree of their databases. Client and server objects are thus identifiable database-independently by the object path – indicated by the names of the nodes - from the root to that object. To find the corresponding object one has to navigate along the path from the root to the object.

Another approach would be to use unambiguous identifiers - “external references” - for persistent objects in the server database. They contain information about the database, the segment in which an object is stored, and the location of that object in a segment. The problem, here, is that segment and location information are not identical for objects of the client and the server databases. Storing the external reference of the server objects together with the object data of the client database could solve this.
The two possibilities to allocate objects in the client and server databases considered here are compared in table 3. If the server database will never be reorganized, both segment and location of objects of the server database remain the same during the entire lifetime of the persistent server object. Thus, corresponding objects can be easily allocated and identified by the external reference of persistent server objects. As this is faster and more reliable than identifying objects by path, this method is used in the hybrid system.

### Timestamps

Another important aspect of equalizing data is the method of determining their age. The local data will have to be updated if comparing the timestamps of local and remote data shows that the server data are newer.

For that reason every object (in the server and client databases) contains a timestamp representing the time of its last modification. If the application changes an attribute, the timestamp will be set to the current time. As the real time clocks of the clients are not synchronized, they may differ. Therefore, timestamps are not created by each client, individually, but by the server. This timestamp is sent to the client during data equalization and applied to the according object.

The consideration of using timestamps led to the discussion of three different approaches:

1. To have only one timestamp per object would lead to the whole object tree having to be searched by comparing the timestamps of every client object with that of the corresponding server object. Especially for full data equalization, that consumes too much time.

2. To reduce network traffic and dispensable operations, objects have collective timestamps (called tsChild) summarizing the timestamps of the child objects reachable by the current object. The collective timestamp shows, for server objects, the timestamp of the youngest and, for client objects, the timestamp of the oldest child object. If the collective timestamps of the server object is not younger than that of the corresponding client object, no data equalization of the child objects is necessary. If this is valid for the root object, the client database is up to date and no data equalization is needed.

   If one object in the tree was modified, the collective timestamp has to be changed up to the root. Although this approach offers a better basis for optimizing data equalization, it does not produce enough information to unambiguously recognize modifications. That led to the following approach:

3. To avoid having to compare all nodes of the path another timestamp (tsSelf) - representing the time of the last modification of the current object - is introduced. For instance, if a Material object has been changed or added, tsSelf of this object and tsChild of all parent objects on the server are set to the current time. If a Material object has been deleted, only tsChild of all former parent objects are set. For a better handling collective timestamps are divided into one for every type of an object's children.

Timestamps are not used for data equalization on the server. Only in hybrid mode, all local changes will be put directly to the server. Otherwise all local changes that cannot be performed immediately on the server (e.g. client is started in standalone mode) are recorded to be processed when the server equalization is started.
Figure 3. Excerpt of an object tree with the use of timestamps (tsSelf and tsChild)

Instead of timestamps for client equalization changes may be recorded by the server and sent to the clients. But there is an indefinite number of clients whose local databases could differ considerably, if they exist at all. Trying to keep track of changes by recording them would therefor mean to store records of all changes since the creation of the database for an unlimited period. As this is inexpedient, the method of timestamps is used for updating the clients so they can create (if no local database exists yet) and update their local database by requesting just the needed server objects and comparing timestamps.

Outlook

The hybrid JaTeK system has been integrated in the real learning environments. It now has to prove its stability and usability. Until now the hybrid system can only be administered by editing a property file (e.g. naming the local database and determining the mode, i.e. local, hybrid, or server only). However, a more convenient graphical user interface will be implemented and embedded suitably into the user interface of the clients.

While work at the project is going on not only course data but also Java classes are subject to modification. A mechanism for updating Java class files would ensure that all client components are up to date.

Some data used by teaching content has to be accessed via the network - even if the client database is up to date. In a future version, these data must be stored in the local database to be available in the standalone mode, too.

Abstract: Development and implementation of systems for online learning is a major task for institutions. Policy must be based on a sound pedagogical knowledge and supported by strategic decisions at different levels. This paper examines two studies considering organizational strategies for IT policy. These views are related to the experiences of the individuals in a collaborative development of online learning materials. This development has simultaneously informed the design of a generic architecture for customizable online learning. Projects such as this are the direct outcome of University funding policy. This is high cost/high risk approach not suited to every institution and it is therefore essential to develop understanding of the relationship between policy, project and participants in order to maximize benefits to the institution. It is proposed that grounded analysis of representative projects can be used to more fully inform strategic thinking by management, academics and developers.

Background

Transformation of curricula into more flexible forms is a critical process for institutions in an increasingly competitive education market. Strategies adopted must balance pedagogical needs with rapidly changing technologies and should reflect the culture of the institution. The Multimedia Education Unit (MEU) works in conjunction with faculty units in providing educational design, evaluation, media production, programming and staff development services to faculties. From this position, MEU is well placed to identify and promote strategic approaches to educational technology in the institution. The operational strategies to bring about centralized teaching and learning systems will impact at different levels in the university. For the purposes of this paper, these levels involve the organizational ‘climate’ created by strategic management counterpoised against the working experience of teachers at the educational coal face, and somewhere between, a supporting technical infrastructure that ties together both sets of requirements. This paper contends that the complexity of decision making associated with institutional approaches to online learning environments requires active consideration and reflection on the interaction between top down and bottom up processes. In attempting to do this, the paper examines a model for strategic management of change in IT (Yetton 1997), its extension to a more functional level guide for online systems (Reid 1999) and relates these views to the actual experience of ‘producers’ engaged in development and teaching. The case examines one project, the direct outcome of central funding strategies, from the perspectives of the developer of scalable online learning systems and teacher creating innovative learning environments.

Models for Managing IT-based Strategic Change

1. The EIP Study
A study of the strategic approaches to IT in twenty Australian universities has been undertaken for the Department of Employment, Education, Training and Youth Affairs (Yetton 1997). In this, the institutions’ performance is analyzed against five key factors: strategy, structure, management process, roles and skills, and technology. The study uses a qualitative methodology, using in-depth, semi-structured interviewing and document analysis to investigate management issues. The strength of the approach is to ground the analysis in the trends and patterns observed in field research, rather than testing only against pre-determined theoretical frameworks.

Strategic choices made by institutions were found to depend on the historical context and capabilities of that institution, recognizing factors such as age, size, resources, location and reputation. To individually prioritize and manage the five key factors would be a complex task. What emerges from the study however are certain organizational forms, or patterns of factors, that serve to reduce the overall complexity of decision making. Three distinct approaches were identified, each related to the different contexts of the institutions (Tab. 1). Although more than one approach might co-exist within an institution, it would appear that pressure to reduce differentiation would be experienced. Yetton also anticipates that new models are likely to emerge with changing economic and technical environments. In looking at the organizational configuration as a whole, IT plays a central role in each model as an enabler, not driver.

<table>

</table>

Table 1: Yetton’s emerging organizational forms in universities managing the introduction of IT into educational programs and administration. Additional interpretations by Reid are in italics.

The University of Melbourne, to this point at least, has fitted the old university, or cottage industry, model with its strong research culture and tradition of intellectual independence of faculty. A Multimedia Development Fund has seen the distribution of large amounts of money into ‘innovative’ curriculum projects over a number of years. These have been primarily driven by individuals or small groups and are diverse in their technical and pedagogical approaches. Individual involvement is also encouraged by policies that recognize creative input in any commercialization of intellectual property and the contribution of good teaching practice to staff appraisals. Such a climate has encouraged innovative, and perhaps higher risk, application of new teaching technologies by faculty staff (Taylor 1998). Yetton's model illustrates broad institutional policies to create an organizational climate in which innovation is fostered, although offers little in the way of a decision-making framework for the new online learning infrastructures.

2. Reid’s University Strategy for Online Instruction

Reinterpretations and extensions to Yetton’s model reflect the emergence of highly scalable and interoperable online learning technologies (Reid 1999 p24). Reid identifies difficulties for each of Yetton’s models (Tab. 1) and proposes a fourth model, ‘Mass Customization’, to address problems of scalability and cost.
In this model, corporate IT systems support extensible frameworks to facilitate innovation and flexibility in the development by the user. For example, templates, simple authoring tools or communication components might be developed to meet particular local learning needs. These facilitate efficient development of learning materials and add value to the provider IP by leveraging off the functionality of corporate delivery and administrative systems. Reid defines criteria for system, producer and user issues for online instruction (Tab. 2). With these guidelines Universities can respond rapidly over time, according to the economic, social and technical environment. These criteria provide another perspective from which to generate policy for the development of online resources, extending Yetton’s broader organizational models to address system issues in greater detail.

Table 2: Reid’s criteria for judging policy for development of online resources.

**The Online Courseware Component Architecture (OCCA)**

OCCA is an online component framework under development at the MEU that displays many of the elements identified by Reid in his Mass Customisation model. It’s aim is to support creation of rich interactive learning customized to local requirements, while ensuring that both software and pedagogical techniques are scalable and transferable (Fritze & Welch in press). The component architecture is viewed here from Reid’s perspectives of functionality, extensibility and scalability.

**Functionality**

From a teaching perspective, OCCA provides a mechanism for academic staff to create various forms of online learning activity to solve their local teaching problems and create novel and flexible forms of learning activity. These could involve, for example, customized interactive interfaces, techniques for reflective & open-ended questioning or group interaction environments. Educational requirements targeted include:

1. customized interactive user interfaces to discipline knowledge;
2. provision of customized feedback in response to a student’s actions;
3. support for learning activities involving subjective knowledge;
4. capacity to design learning sequences that can incorporate elements of face to face interaction; and
5. provision of reflective summaries and overviews of the learning experience for both student and teacher.

Such requirements have been derived directly from the experiences gained working with faculty teaching staff on many real course projects over a number of years.
**Extensibility and Interoperability**

As a technology for online component scalability and inter-operation, the OCCA specification regularizes communication between conforming Web components devised in Shockwave, Java, JavaScript or HTML. It uses open protocols for information transfer including XML and a 'State Description Protocol' (SDP), with which 'snapshots' of arbitrary interactive Web pages can be saved, recalled or analyzed.

The online OCCA browser activity may involve user interface components such as forms elements and/or interactive Java or Shockwave interface objects, supported by generic OCCA 'glue' components (Fig. 1). The key to the inter-operation of these components is the SDP description of the page. As well as providing the means to save and restore the state of customized pages to a database, additional functions can be independently developed to provide specialized feedback, navigational management or access to SDP database records. For example, SDP records can be recalled from the database and embedded dynamically into other OCCA pages.

---

**Figure 1: OCCA component and protocol framework. Visible browser page objects are in bold text.**

---

**Perspectives on the development and implementation experience of OCCA**

In order to better understand the full range of processes by which a frameworks such as OCCA occurred, a reflective history of the development of OCCA and the earlier Learning Engines project is currently being undertaken. This is intended to make visible the coal face complexity of a real project development and to reveal models by which this complexity can be managed. This research is intended to complement that of Yetton and Reid by relating the bottom up experience, discovered through a grounded theory methodology, with top down strategic models (Glaser & Strauss 1967). Preliminary findings are given from the perspectives of the MEU developer focussing on scalable online solutions and teaching staff engaged in creating innovative learning environments. While the experience of this involvement is unique and does not by itself define any model to be adopted, the intention of this research is to better inform management decisions for IT at an institutional level.

**Framework Developer Perspective**

The current implementation has evolved out of prior work in the Learning Engines project (Fritze & Ip 1998), the Virtual Apparatus framework (Ip et al 1997) and Component-based Object Library (Ji 1998). Development has also depended on collaborations with numbers of independent faculty projects, but involved only a small number of MEU staff until the later stages of the project. Some characteristics that emerged:

1. The basic aim of the project, to provide a component based online component-based framework for rich learning activities, on the surface remained constant, but understanding of the pedagogical structures and specific technical implementations evolved significantly.
2. The framework progressed through a number of distinct phases, identified by different collaborative involvements, technical and pedagogical approaches, descriptive vocabularies and personal experiences.
3. The researcher/developer maintained substantial control of the framework technical and functional design until the transition and production phases of the project, when substantial shifts in roles occurred.
4. The continuous pedagogical input from involvement with a number of independent curriculum projects played a large part in the shaping of the functional operation of the framework (Fritze et al 1998b).
5. Although the project is now being integrated into general University IT strategy, the development process progressed along a number of 'dead end' directions, at times causing stress as different approaches were explored and rejected.
6. The online environment necessarily involves a number of parallel technologies and is fraught with technical challenges not present in equivalent stand alone developments. These are particularly prominent at the interfaces between technologies, for example between Shockwave, Java and Javascript.

Teacher Perspective

One of the main faculty projects associated with Learning Engines and later, OCCA, involved the development of tutorial systems for the department of Physiology. The project involved the writing of online materials extending across 24 weeks of campus-based tutorial workshops to make up time otherwise spent in lectures. The online techniques complemented the use of commercial applications and locally developed, highly interactive, single use CAL programs. The purpose of the customized online materials was to create an environment for timetabled workshops that would stimulate student thinking in a manner that had proved difficult with other approaches, such as using the TopClass learning framework. The aim was to develop the techniques that could be implemented as an ongoing process by local teaching staff. The experience of collaborating in the development of these online techniques was characterized by:

1. The need to work pragmatically with different versions of the software, adapting to the incomplete functionality where necessary, while still addressing the desired pedagogical approach
2. The online component technique made possible forms of interactions not possible with alternative approaches, e.g. particular question activities that involved sorting complex processes or use of a free form graphing object
3. Unexpected benefits could arise from situations where limits were reached with software implementations, leading for example, to improved understanding of computer supported collaborative classroom environments.
4. Teaching ideas developed as a result of 'negotiation' with developer over desired vs. possible functionality.
5. On campus collaborative learning within supported timetabled workshops has great potential. A close hands on involvement with classes needs to be maintained, for example to appreciate the cultural variation across student groups.
6. The availability of funding was a prime enabler for the exploration and development of new ideas for teaching.
7. Participation in conferences, seminars and academic papers provided valuable opportunities for reflection, development of ideas and documentation.

Discussion

For the University, OCCA fits the many of the criteria proposed by Reid for functionality, extensibility and scalability in an online learning environment. This is the 'mass-customization' model in which a centralized framework supports continuing innovation and customization of materials at various levels of involvement. Systems-focussed criteria however, while interesting to apply retrospectively, or in selecting between existing products, are fairly blunt instruments with which to guide the development of generic and innovative strategic frameworks. Reid's suggestion that functionality follows interoperability and scalability as 'the major determinant for product selection' is against our experience. We have found that the rapid evolution, problematic nature and complexity of online technologies demand a close connection between developer and academic teacher. The complexity of this connection was illustrated in the development history of OCCA and further grounded studies of this type should be used to inform strategic decisions coming from above. The balance between individual, faculty and institutional control will continue to fluctuate in response to changes in technology and environmental pressures.
The ‘Old’ University approach can foster an environment in which ideas and innovations can be successfully incubated. It is important however, that successes from this environment are effectively transferred into broader use within the institution or beyond. The development of OCCA was enhanced by ability to link developers and faculty teaching staff in real projects across a cross-section of discipline environments. The developing model could be subjected to a wide variety of probing from discipline, pedagogical and technical requirements. This approach however was characterized by directional changes and frustrations. In adopting such approaches, it is important for the both institution and participants to acknowledge the nature of these processes and the inherent risks involved.

The EIP study is an interesting snapshot of strategic IT practices of a cross-section of Australian universities and further broad studies like it are required to maintain pace with technological and social change. Deeper understanding of institutional development cultures and activities is also required to optimize strategies for transformation of teaching and learning with IT most appropriate for each institution. Grounded theory analysis of representative projects is one way in which strategic thinking by management, academics and developers can be informed.

The Reflection Assistant:
Investigating the Effects of Reflective Activities in Problem Solving Environments

Claudia Gama
School of Cognitive and Computing Science
University of Sussex

claudiag@cogs.susx.ac.uk

Abstract: This paper presents theoretical issues about the role of metacognition in learning, as well as the architecture and design of a learning system dedicated to monitoring and helping students to use their metacognitive skills. This system is called the Reflection Assistant and is supposed to be used together with problem solving or case-based learning systems. Thus, through interactions with the Reflection Assistant during problem solving activities, students can also improve their metacognitive skills (such as planning, self-monitoring and assessing), as well as their knowledge in the specific domain. The purpose of this research is to investigate better means to increase metacognitive knowledge, including awareness on the learning process and capacity of transferring skills to new learning situations. The motivation for this research is that it is necessary to focus as much on the metacognitive processes of problem solving as on the cognitive ones to develop good problem solvers.

1. Introduction: Theoretical Issues

1.1 Metacognition and Learning

The argument that drives this research is that metacognition plays a major role in cognitive development. Thus, enabling students to develop a conscious, explicit model of their metacognitive skills by means of reflective activities facilitates the improvement of both cognitive and metacognitive expertise.

Research in the area of cognitive psychology (Flavell, 1976, 1979, Schoenfeld, 1987, Derry, 1992, amongst others) shows that an important type of knowledge underlying the construction of complex representations and solutions strategies is metacognitive knowledge. Metacognition refers to a cognitive system's intelligence about itself and its ability to regulate and control its own operation. So, knowing about one's own cognition forms the basis for most metacognitive abilities. These abilities include knowledge about one's perceptions, memories, decisions, and actions (Shimamura, 1994, p. 253).

Metacognitive knowledge can be divided into three related but distinct categories of intellectual behavior (Schoenfeld, 1987):

Knowledge about thought process
This is related to people's ability to accurately assess their knowledge and knowledge acquisition process. In a learning situation one of the final goals is to help students develop good study skills. Those skills depend, in part, on students' ability to make realistic assessments of what they can learn. Hence, it is important to know how likely it is that students will reflect on their thinking and how accurate those reflections will be.

Control and Self-regulation
This aspect of metacognition is related to the monitoring of cognitive activities. One way to look at this aspect of metacognition is to think of it as a management issue, i.e., how well one manages her time and effort, as she is involved in cognitive tasks. In the context of learning self-monitoring or self-regulation refers to an individual's ability to conduct on-line self-checks of the problem solving process, for example; a skill that is particularly important when the student deals with an ambiguous
or confusing problem. Thus, this self-regulation could provide the student with information to guide her problem solving actions.

Beliefs and Intuitions

These are related to the ideas about a learning topic that the student brings to her work, and how it shapes the way the student faces the topic.

Another important aspect of learning is transfer. Educators hope that students will transfer learning from one problem to another within a course, from one year in school to another, between school and home, and from school to workplace. Transfer can be improved by helping students become more aware of themselves as learners who actively monitor their learning strategies and resources and assess their readiness for particular tests and performance. Metacognitive approaches to instruction have been shown to increase the degree to which students transfer to new situations without the need of explicit prompting (Bransford et al., 1999).

1.2 Problem Solving, Metacognition and Reflection

According to Schoenfeld (1987), problem solving activities can be divided into three conceptual stages, named: Preactive (activities performed before starting to solve the problem), Interactive (activities performed as the student works on the problem) and Postactive (all those activities performed after finding a possible solution to the problem). Considering these conceptual stages, three important metacognitive processes can play a major role: planning (mainly in the preactive and also in the interactive stage), self-monitoring (in the interactive stage) and assessing the problem solving efforts (in the postactive stage).

Metacognitive processes are important contributors to problem solving performance across a wide range of domains (Davidson et al., 1994). In problem solving situations there are always metacognitive processes involved, such as (1) identifying and defining the problem, (2) mentally representing the problem, (3) planning how to proceed, and (4) evaluating what you know about your performance.

The successful application of these metacognitive processes depends on characteristics of the problem (if it is a well-structured or an ill-structured problem), the problem solver, and the context in which the problem is presented. To the extent that what is desired is to identify and develop good problem solvers, what is needed is to focus as much on the metacognitive processes of problem solving as on the cognitive ones (Davidson et al., 1994).

Hence, it is important that students can recognize and explore their own metacognitive processes. Reflective activities encourage students to analyse their performance, contrast their actions to those of others, abstract the actions they used in similar situations, and compare their actions to those of novices and experts. The reflection on the metacognitive skills can bring awareness of their thought process and increase their capacity of transferring these skills to new learning situations. Fig. 1 summarizes the interrelationship between the problem solving conceptual stages, the metacognitive processes, and the role of reflection in this context.

![Figure 1- Metacognition, Reflection and Problem Solving](image_url)

2. The Design of the Reflection Assistant
The Reflection Assistant is a specialized system that monitors, analyses and improves student's metacognitive skills in problem solving situations. It is still in the design phase (it has not been implemented yet). It is designed to be used in combination with different problem solving systems (e.g.: mathematics problem solving systems, case-based medical system, geometry system, etc.). Indeed, the Reflection Assistant is disjoint of the specific domain learning system, and it has to be configured accordingly to the specific domain that it will be applied.

The two major goals of the Reflection Assistant are:
(1) Create learning environments that afford and encourage metacognitive processes.
(2) Improve metacognitive skills development in general and thereby enable the transference of these skills to future learning situations.

Through graphical tools and specific activities the Reflection Assistant makes perceptible to the student certain metacognitive skills used in distinct moments of instructional activities. Thus, initially students can use these mechanisms to monitor their learning process and become aware of the metacognitive strategies they are using when engaged in problem solving activities. After that, in a subsequent phase they can use appropriate mechanisms to help them to improve these metacognitive strategies.

The important points this research aims to investigate are:
(a) The appropriate timing for providing metacognitive scaffolding and reflection on the problem solving process.
(b) The effective balance between reflection focused on the learning task (domain specific) and reflection on general metacognitive skills (domain independent) for a particular problem solving situation.

2.2 Description of the Reflection Assistant

The Reflection Assistant contains four main components. The general architecture is shown in Fig. 2 and the function and characteristics of each component are explained.

![Figure 2 - Architecture of the Reflection Assistant](image)

**Metacognitive Knowledge Base**
This component has detailed information about metacognitive skills used in problem solving situations. Each metacognitive skill is described in the Reflection Assistant in terms of variables, which may have their values modified according to the importance that the specific skill plays in the specific domain.

**Student Metacognitive Model**
This is responsible for recording the student's responses and keeping track of the student's performance. The Student Metacognitive Model uses information from the Student Log and from the Metacognitive Knowledge Base to generate a structured model of the student's metacognitive capabilities and progress.

This model informs the kind of assistance that should be provided to a particular student and also serves as an inspectable model for the student (in other words, the student can also view her use of strategies).
**Interaction Generator**

This component combines information provided by the Student Metacognitive Model and Metacognitive Knowledge Base to elaborate the content and format of the metacognitive activity proposed.

**Translator**

This is the communication mechanism (or protocol) that will make possible the integration of the Reflection Assistant with the learning system. There is a two-way communication between the two systems: (1) the learning system provides information about the actions of the student during her interaction (in the format of a log file); then, the Translator interprets this information and a metacognitive log is created in the Reflection Assistant. (2) The reflection assistant sends suggestions of possible new actions to the learning system, so adapting the teaching strategy according to the student metacognitive model.

Despite being decoupled from the learning system, the Reflection Assistant is not completely independent of it. It keeps an intermediate level of interaction with the system through a communication channel. This interaction is reflected in the architecture of the system, where its main components need to contain several parameters that are modified depending on the circumstances under which the assistant is used (i.e., the specific learning system to which the Reflection Assistant will be associated with or the kind of reflective activities relevant to a specific domain or for certain problems).

### 2.3 The Different Types of Reflective Assistance

Following the idea of dividing the problem solving activities into three conceptual stages (as explained in section 1.2) the Reflection Assistant can be used in different configurations. The reflection activities can happen either before starting a new problem/case; or during the interaction with the problem/case; or even after finishing the problem/case. A specific visualization method will be selected depending on both the timing of the reflection and the particular metacognitive skill emphasized (e.g.: planning, monitoring, etc.). Indeed, the combination Metacognitive skills - Timing - Visualization method (or approach) is determined by the characteristics of the domain and task and, also the student's preferences. Besides that, the degree of specificity of the behavior of the assistant depends on the level of integration between the Reflection Assistant and the Learning Environment.

This integration is generated by the amount of information provided by the problem solving system to the Reflection Assistant's Translator.

To organize these different arrangements the system provides three basic types of assistance, corresponding to a particular moment of the interaction. Before solving a new problem (or case) the Preparation to Reasoning Assistant helps the student to recall previous knowledge or studied cases. While the student is trying to solve the problem he can interact with the Support to problem solving Assistant. And, finally, after finding a solution, the student could use the Reflective Follow-up Assistant that provides means to reflect on the performance in the task and the general progress. These assistants aim at providing structured support to the student, establishing "check-points" to reflect over the learning process. The kinds of assistants that comprise the Reflection Assistant and which metacognitive skills (or processes) they are mainly related to are detailed below.

**Preparation to Reasoning Assistant**

Questions like *What prior knowledge can help me with this particular task? What do I need to know before I can successfully deal with this task? What should I do and in which order? How much time do I have to complete the task?* drive the activities proposed by this assistant. The idea is to anchor new concepts into the learner's existing cognitive knowledge to make them retrievable. The aim of this assistant is to prepare the student for the problem solving activity, promoting reflection upon the necessary skills to solve the problem, more specifically, the capacity to recall previous knowledge and make generalizations.

Sometimes the reflection process does not occur, in part because students are not really motivated to perform reflection after solving the problem and in part because the current problem solving medium (paper and pencil) does not really lend itself to this activity (Collins, A. & Brown, J. S., 1988). Because the Reasoning Assistant is going to be used before the learning activity takes place, it may contribute to bypass problems of low motivation.

**Support to Problem Solving Assistant**

This assistant offers a means for monitoring the student's plan of action. It helps the student during the cognitive activity with mechanisms to reflect on the necessary skills to solve a problem, making
them think about, among other things: How am I doing? Am I on the right track? How should I proceed? Should I move in another direction? What do I need to do if I don't understand?

Also an important point is to use the Reflection Assistant as a means to aid the student when she feels stuck. Thus, the Support to problem solving Assistant should provide support for students to seek for clarification and to reexamine their problem solving strategy.

**Reflective Follow-Up Assistant**

After concluding the cognitive task the student can use this assistant to verify her performance and compare it with previous interactions. Here, generalizations are again used to help the student to organize the case or problem studied into a general knowledge framework. Examples of common points to reflect on in this moment can be:

*Did my particular course of thinking produce more or less than I had expected? What could I have done differently? How might I apply this line of thinking to other problems?*

### 2.4 The Design of the Reflective Follow-up Assistant: First Prototype

There are several points to take into account in the development of such a learning system. The abstract nature of the metacognitive processes is indeed a major concern. Also, the graphical tools used to represent these processes have to be adequately developed. Moreover, these tools and metacognitive processes probably vary from one student to the other, depending of their own characteristics.

So, in order to collect information about all these factors that influence the whole system, some initial studies are being performed. As part of this initial phase a first version of the Reflective Follow-up Assistant is being designed and will be used with the PATSy system. PATSy (Patient Assessment Training SYstem) is a case-based interactive learning environment that keeps a database of medical cases in the domain of aphasiology (Lum & Cox, 1998, Cox, 1999). PATSy provides a context in which students may practice diagnosis via deductive reasoning. Thus, the Reflection Assistant will help students to monitor their reasoning process. PATSy keeps an electronic log of all actions performed by the student (sequence of clinical tests chosen, cases studied, etc.).

The first version of the Reflective Follow-Up Assistant will provide two types of information: quantitative assessment and qualitative assessment of the metacognitive skills used during interaction with the PATSy system. Fig. 3 (a, b and c) show mock-ups of this prototype.

**Quantitative Assessment**

After each session with the PATSy system students will see a graph showing the time spent in cognitive and metacognitive activities. For example, Fig. 3a shows a sample graph of a student. Using that, the student can see graphically the amount of time spent analysing the problem, planning, exploring previous solutions or trying to solve the problem. Other information provided are the moments where the student reflected on her studying process. PATSy already provides some questions that should help students to step back and ask what they want to do next. Further information generated is the summary of the total amount of time spent in the task.

**Figure 3a - Quantitative Assessment (sample 1)**

**Figure 3b - Quantitative Assessment (sample 2)**
Another graph from the quantitative assessment is shown in Fig. 3b. It is a graphical comparison between the performance in the present case and in previous cases. Another possible comparison could be between the performance of one student with those of other students.

**Qualitative Assessment**

This kind of assessment aims at providing more detailed explanations to the student about how to improve her metacognitive skills. It is achieved by asking questions about the student's performance. For example, Fig. 3c shows a qualitative assessment of the planning skills of one student. The student is invited to explain why she failed in using the planning strategies she proposed to use at the beginning of the task. The idea is to make the student to reflect on the importance of a good plan of action that has to be followed during the problem solving. In addition, the system will provide scaffolding to increase the planning abilities of that student.

3. Conclusions

This research investigates better means to make students learn important self-monitoring and other metacognitive skills in computer-based problem solving environments. The final goal is the design of a new learning environment that extend the possibilities of interactive learning systems, giving students opportunities for reflection, revision and feedback over their problem solving efforts.

This paper has presented the design of the Reflective Follow-up Assistant Module to be used in the postactive stage of problem solving. It focuses on both quantitative and qualitative assessments of students' performance. More work has to be done in the design of the other modules of the Reflection Assistant: the Preparation to Reasoning Assistant and the Support to Problem Solving Assistant.

A distinguished characteristic of the Reflection Assistant is that it is both a domain independent system and also maintains an intermediate level of interaction with the learning system that uses it. The granularity of interaction is an interesting point of investigation. This relates to the tension between teaching metacognitive skills within a particular context and ensuring their transferability to other contexts. Some initial studies have been done and the first prototype is under development.

E-mail: garcia@uwosh.edu

Abstract: Classroom teachers' comfort and familiarity with computers and software influences student-computer use in the schools. Too often teachers and students remain mired in repetitive preoccupation with basic software mechanics to the neglect of interaction with the content at hand. To offload these tasks onto the software, an On-Line Assistant (OLA) was developed to accompany the commercial hypermedia software, HyperStudio. This OLA introduced the software, provided a framework for students to storyboard projects, sequentially introduced software mechanics, and suggested basic principles of good design. The impact of this OLA on the nature of classroom interactions and on the quality of projects produced was investigated. Control group students used the hypermedia software alone and the experimental group used the software with the OLA. Projects employing the OLA were consistently rated higher than those using software alone. Student usage of the OLA significantly reduced interactions dealing with basic software mechanics while significantly increasing interactions concerning design, stack issues, and content. Interactions significantly increased for the experimental group in the areas of advanced software issues, design, stack issues, and content. The OLA did not diminish the teacher's role but perceptibly shifted the nature of interactions to those areas requiring higher order cognition.

Introduction

The use of computer technology in today's schools is often limited by educators who feel overwhelmed by the demands placed upon them to become proficient at the hardware, the software, and curriculum development simultaneously (Howe & O'Shea 1980). The majority of educators are familiar with computer usage at a second state level of technological innovation (Maes 1994). At this level the computer is used in conjunction with existing technologies to do what can already be done albeit more efficiently. The majority of software developed over the past thirty years has reflected this second level of innovation. Computer assisted instruction has long focused on replicating the traditional classroom model of top-down teaching, drill and practice, and teacher directed learning (Naisbitt 1982; Glasser et al. 1988). However, later research began to acknowledge learning as a constructive process (O'Shea 1979; Druin 1998; Ennals 1983). Recent innovations in intelligent agents have pointed towards a collaborative partnership between computer and student (Lockard et al. 1997).

New epistemologies of learning are emerging that indicate a dichotomy between theorists' accounts of cognition and the actual practices of people in learning activities (Perkins 1993). It is increasingly evident that cognition does not reside entirely in the individual mind but may have portions of it distributed among other people and simple or complex tools (Papert 1980). One subset of the current work on distributed cognition is off-loading which occurs when a person places some of the cognitive burden for performing a task onto another person or tool (Salomon 1993). This can be a positive condition such as when one creates a list of items rather than trying to carry those items in memory. However, it can be a negative experience in the classroom. Educators have long assumed portions of students' cognitive burden when they make all the choices about what to study, how to study it and what resources to use. In computer usage, this off-loading is part of what makes meaningful integrated computer usage so overwhelming to teachers. It is simply too much to be the expert on the hardware, the software, and the curriculum while simultaneously planning the implementation of the project with integrated computer support.

The use of an on-line assistant, or OLA, can facilitate off-loading some of the teacher's responsibilities onto the OLA smoothing the way for better computer integration into the learning experiences of students. With this support, students are able to assume responsibility for learning the mechanics of the software and for planning projects. This study focused on the addition of an on-line assistant to commercial hypermedia software (HyperStudio) and the subsequent impact on the quality of the completed project, the nature of teacher/student interactions, and the nature of student/student interactions.
Study Design

A quasi-experimental design was used in this study. Two existing, intact 4th grade classrooms of nine year olds from an urban school were used as the experimental and control groups. Random assignment of subjects to groups was precluded. A nonequivalent posttest-only control group design was employed. Both classrooms and their teachers were pretested to determine familiarity with the basics of the commercial software program to be used in the study. In addition, NCE scores on the Iowa Test of Basic Skills were compared between the two groups. These comparisons determined initial equivalence of the experimental and control groups.

Both groups used HyperStudio to develop a project consisting of a stack with a minimum of five cards. Both groups had access to HyperStudio software as well as their classroom teacher. The control group of 22 students used the software in its unedited form while the experimental group of 23 students had access to an on-line assistant (OLA) developed by the researcher to assist students in planning their project, in learning the HyperStudio software, and in developing awareness of rudimentary design elements. Quality of the finished HyperStudio projects was assessed for both groups to determine effectiveness of the treatment.

Teacher/Student and Student/Student interactions were evaluated in both groups. Interactions in the following seven areas were tallied daily: Software issues - basic (new cards, buttons, text boxes); Software issues - advanced (graphics, transitions, new button actions); Design issues (color, font, layout); Stack issues (linking and layout); Spelling and Grammar; Content material (appropriate content); and, Content composition (appropriate discourse form).

Hypermedia projects completed during the research period were collected, copied, and distributed to raters. The MEDIA HCI Design Evaluation (Druin 1998) was used to assess four areas: Reaction to Visual Design (card layout and design, organization of information, and sequence of cards); Reaction to Stack Construction (user interface with the stack); Reaction to Content (content and presentation of information); and the Overall Reaction to Stack.

The teacher of the classroom using the software with OLA was interviewed to discuss her reactions to the presence of the on-line assistant, how effective she felt it was with her students, and her general reactions to helping students develop a project using HyperStudio. Her students were surveyed to assess their acceptance of the OLA. Additionally, an exit interview was held with the teacher of the classroom that used the software alone to discuss her reactions to helping students develop a project using HyperStudio.

The On Line Assistant

The researcher developed an OLA whose persona was based on Addy, a dog that already periodically appears in existing dialogue boxes in HyperStudio. It was felt that the appearance of Addy both in dialogue boxes and as the OLA would maintain consistency within the software. The name of the OLA service was Ask Addy and it first assisted the students in designing a HyperStudio stack by introducing a storyboard approach to design. This component of the OLA sent the students off-line to develop a storyboard. Students consulted with their teacher on the storyboard's links and content. The completed storyboard served as the working plan to be followed when students returned to the software to begin stack construction.

Upon returning to the software to begin stack development, the OLA sequentially guided the student through a series of steps. First, students created each card with only text boxes and content inserted in those boxes. Next, the portion of the OLA was brought on-line to assist students in adding buttons. After students had demonstrated their stack to their teacher the next portion of the OLA was added which assisted students in adding graphics to their existing cards. Finally, the OLA offered advice on modifying existing text and button objects. Concurrent with the on-line components that addressed adding and modifying buttons and graphics, the availability of design hints were added. These design hints covered such items as choice and variety of fonts, color selection, and button transitions.

The researcher developed the OLA using HyperStudio software. The OLA was implemented as a series of independent stacks, each linked to a menu card that was in turn linked to the cards in the students’ stack. This enabled the researcher to bring various components of the OLA on-line sequentially throughout the experimental period. To manage memory size, the OLA contained only text and graphics. No voice or animation features were included. This sequential introduction of the OLA enabled a certain amount of control over the students’ process.
Research Results

Results of the study suggest that the presence of an OLA significantly impacts the quality of students' completed hypermedia projects. There was a significant difference between the holistic quality scores of the completed projects of the group using software with the OLA and the quality scores of the group using software alone. The results of the MEDIA HCI Design Evaluation forms showed that the mean holistic score of the stacks completed by students in the group using the OLA was 38.9 points higher than the mean of those students using the software alone. See Table 1 at the following URL: http://www.coehs.uwosh.edu/faculty/garcia/addyres.htm.

To measure the nature of teacher/student and student/student interactions, seven areas were chosen for consideration. These seven areas formed a hierarchy of possible interactions. At a rudimentary level, the frequency of interactions concerning basic software issues about mechanics of the HyperStudio software and spelling and grammar was measured. Then interactions about advanced software skills such as importing graphics and specialized button actions were measured. Next, interactions were measured that required the application of more complex thinking skills such as design issues, stack issues, content material and content composition. Finally, the sum of the total number of interactions in all seven areas was computed and analyzed.

Results of the study suggest that the presence of an OLA positively impacts teacher/student interactions by increasing the number of interactions concerning areas that require higher-order thinking skills while reducing the number of interactions concerning basic software issues. There was no significant difference in the total number of interactions between teacher/students in the group using software with the OLA and the group using the software alone. However, a shift in the nature of teacher/student interactions could be seen as indicated by the frequencies of interactions occurring at the differing levels of complexity. The observed pairs in the group using software with the OLA had significantly fewer interactions with their teacher about basic software issues while there were significantly more interactions in the complex areas of design issues, stack issues, content material, and content composition. See Table 2 at the following URL: http://www.coehs.uwosh.edu/faculty/garcia/addyres.htm.

Further results of the study suggest that the presence of an OLA positively impacts student/student interactions by increasing the number of interactions concerning areas that require higher-order thinking skills. There was no significant difference in the total number of interactions between student/student in the group using software with the OLA and the group using the software alone. However, a shift in the nature of student/student interactions could be seen as indicated by the frequencies of interactions occurring at the differing levels of complexity. There were significantly more interactions between students in the observed pairs in the group using software with the OLA in the areas of advanced software issues, design issues, stack issues and content issues which require the application of complex thinking skills. See Table 3 at the following URL: http://www.coehs.uwosh.edu/faculty/garcia/addyres.htm.

The study results suggest that the presence of an OLA is accepted by students as most useful in helping design a hypermedia project and is an acceptable source for information. All students in the group using software with the OLA completed a Post Treatment Survey. From the responses on this survey it may be concluded that a majority of students found Ask Addy to be helpful, easy to understand, and quick to get help. A majority of students would like Ask Addy to be able to offer more help than was available in the prototype. However, the majority of students reported that they still had to ask their teacher for help even after using Ask Addy and the majority of students felt that they turned to Ask Addy less often than they did their teacher. Over fifty percent of the students indicated that Ask Addy was most helpful in helping them learn how to design a HyperStudio stack. Secondarily, Ask Addy was most helpful in assisting students in learning how to make text boxes. See Table 4 at the following URL: http://www.coehs.uwosh.edu/faculty/garcia/addyres.htm.

Finally, results of the study suggest that there is a positive relationship between student acceptance of an OLA and the quality of their completed hypermedia project. Data analysis confirmed that there is a moderate correlation between student acceptance of the OLA and the quality of their completed hypermedia stack. This acceptance of the OLA was indicated by ninety percent of the students indicating that they found Ask Addy helpful. Over fifty percent of the students also indicated that they would like to be able to use Ask Addy for getting more help. Students indicated that they found Ask Addy to be most helpful in the design process and in adding text boxes. This overwhelming student acceptance of Addy's assistance positively correlated with raters' assessment of the quality of students' stacks. See Table 5 at the following URL: http://www.coehs.uwosh.edu/faculty/garcia/addyres.htm.

Discussion of Results
The completed projects of the students in the group using software with the OLA were consistently rated higher than those completed by students in the group using software alone. Although both groups of students had been instructed by their teacher to create a minimum five-card stack, those students in the group using software with the OLA went well beyond that five-card minimum. The greater number of cards in these stacks and the more web-like construction may be attributed to the storyboarding process. The researcher observed that the use of storyboarding did not occur naturally to either teachers or students.

The teacher of the group using the OLA said, "I was pleasantly surprised by the fact that the five-card minimum was never a discussion point with these kids. They got all carried away with their storyboards and connections and put down so many more cards. I thought they'd never complete it but since they had this plan (storyboard) that they had committed to, they did it!" It is important to note the italics in the prior quote. The students had committed to the plan because they created it. The teacher did not impose the plan; the product was not the emphasis. The storyboard places the emphasis on the process instead. The creation of a storyboard allowed the students to assume responsibilities or executive functions (Perkins 1993)–deciding on content, locating resources, arranging those resources–that would have traditionally been off-loaded to the teacher. The storyboarding period provided a rich environment for teacher/student and student/student interactions on the content of the material to be presented in the stack. The group using the OLA showed a significantly higher number of teacher/student and student/student interactions about content material. The bulk of these interactions occurred during the storyboarding period.

The storyboarding process also provided opportunities for the teacher and students to talk about how their stack was constructed. The teacher of the group using the OLA averaged thirty-seven interactions with groups on the stack construction and layout while the teacher of the group using the software alone averaged only five interactions. This lack of interaction was reflected in the smaller stack size and linear design of the students using the software alone. Ask Addy was able to significantly reduce the number of teacher/student interactions that dealt with basic software issues. These mechanics form the foundation for all work in HyperStudio and are relatively easy to learn but require much repetition from the classroom teacher in a lab setting.

Total facility with any software is a matter of practice and experience. Educators usually lack the time to develop that facility and are therefore hesitant to move students ahead in a project using unfamiliar software. Ask Addy was brought on line sequentially in a manner that facilitated students' completion of their storyboard plan. Initially, Ask Addy only provided help in creating new cards and adding text boxes in which to enter text. Ask Addy asked that students make all the cards in the stack first before adding buttons and graphics. Because this involved the bulk of the on-line work (word processing) the teacher of this group became concerned. "Will they actually finish this project?" she asked, eight days into the data collection period. Having spent three to four days storyboarding and then another four to five days creating the rudiments of the cards for the stack, it did indeed seem that they were lagging behind. However, the finished products demonstrated that the sequential introduction of skills facilitated that completion of the stacks as originally envisioned by the student.

It is important to note from the data analysis of teacher/student interactions that the addition of an OLA did not significantly affect the total number of teacher/student interactions. However, it did impact the nature of the teacher/student interactions. As previously discussed, the storyboarding period required by Ask Addy did significantly increase the number of teacher/student interactions related to stack issues, and content material. In addition, there were significantly more teacher/student interactions concerning content composition and design issues during the time spent on-line with HyperStudio stack development. Students' self-assessments of the presence of the OLA also supported the conclusion that the need for a teacher is not diminished by the on-line assistance. Fifty-seven percent of the students indicated that they did not Ask Addy for help more than they asked it of their teacher. The same percent of students also reported having to ask their teacher for help even after asking Addy for assistance.

The total number of student/student interactions was also not significantly different in observed pairs in both groups. Again, however, the nature of that interaction was different as observed in the frequency of interactions in the areas of advanced software issues, design issues, stack issues, and content material. As previously discussed, the storyboarding period provided an environment in which students could have intense discussions on stack design and content material. During the actual stack production period on the computer, student/student interactions in the group using the OLA gradually shifted to design issues, advanced software issues, and appropriate discourse form for this media. These students actively debated over the quantity of print versus the ability of pictures to tell a story. They discussed what Ask Addy listed as good principles of basic design, deciding whether to listen to her advice or discard it in the interest of curiosity and personal taste.

An another interesting phenomena occurred as individual groups were freed by the OLA to move ahead with more advanced techniques. Groups or individuals began to emerge as resident-experts on specific techniques which resulted in an impromptu Jigsaw II (Slavin 1990) method emerging. Again, this emerged from the student process.
It did not require that the teacher assume the responsibility for building in the peer tutoring as part of the process.

Student responses on the Post Treatment Survey when correlated with the MEDIA HCI Design Evaluation form holistic scores indicated a moderate correlation between student acceptance of the OLA and the quality of the finished project. Students demonstrated a purposeful acceptance of Ask Addy. The majority of students indicated that they did find Ask Addy helpful particularly in the areas of design and adding textboxes. These two areas are indicative of student concern with the complex issues of content and process. The Ask Addy prototype was devoid of anthropomorphic qualities; Addy's assistance was straightforward and presented in a formal manner. Therefore, students acceptance of Ask Addy was based on the quality of help offered rather than an attraction to the character, Addy.

Students did indicate a fascination with the possibilities of an OLA. In discussions throughout the production period, they discussed their visions of what Ask Addy could be. Students wanted much more than what the prototype could offer. They wanted Ask Addy's bank of assistance to be much broader. Some students, familiar with Microsoft's Office 97, wanted more personas available as well.

Conclusion

An OLA can help students and teachers facilitate a process and produce better quality work. It can also suggest a learning environment that is conducive to a different, more complex nature of teacher/student interactions. While the act of directing students to make a storyboard prior to the production process did not require an OLA, it demonstrates that an OLA can provide valuable guidance in a suggested process for using that software. This would help a teacher who is unfamiliar with the basic hypermedia software in the implementation of a project.

The role of a teacher is not diminished by the presence of an OLA but that role is perceptibly altered in the interactions between teacher and student. The on-line assistant is able to assist the students in learning the rudimentary mechanics of a hypermedia software program while making them sensitive to the discourse form of hypermedia. The OLA may stimulate children to take more responsibility for higher level activities such as planning strategies, locating resources, and organizing information that have typically been off-loaded onto the teacher. This in turn can free teachers to interact with students concerning more complex content and process issues while guiding their discovery.

Abstract: Computer Algebra Systems (CAS) are complex computer systems that have not been designed for learning situations. In order to enhance their didactic capabilities, we study the possibility to graft mathematics interactive learning environments onto them. We present in this paper our approach that is centered on student interaction and we illustrate it with LIMITS a learning environment that helps students to study, work out and justify limits of rational functions. We describe three activities involved in limits study: entering and selecting sub-expressions, transforming expressions, and calculating the limit by applying theorems. We show how teaching goals have determined the characteristics of these activities.

Introduction

Computer Algebra systems (CAS) such as MAPLE, DERIVE or MATHEMATICA are powerful software tools able to perform a large range of calculus. At the same time, more and more computers are now available in secondary schools. Consequently, the question of how mathematics teaching can integrate this kind of tools is set.

Some research works pointed out specific phenomena which occur when students are working with a CAS (Artigue 1997). Others focused on a long time utilization of a CAS with students (Lagrange 1996). These works emphasized that the utilization of CAS in mathematics learning is not so obvious. The powerful calculus capabilities of CAS help students in the technical part of their work, but do not automatically lead them to master concepts they work on (Tall 1996).

We explore a new way of using CAS with students. CAS were not designed with a pedagogical purpose and we intend to include them in learning environments. These learning environments try to fit the calculus capabilities of CAS to the students levels and to provide them with relevant presentations and manipulations.

In this paper, we present the learning environment LIMITS which is based on MAPLE and allows the students to work on the limit concept. We describe this environment and discuss about some issues this work deals with. The first version of our environment allows students to work on limits of rational functions.

Learning Limit Concept

In the paper-and-pencil context, working on limits implies to carry out two different tasks. The first one consists in applying some transformations when the limit evaluation leads to an indeterminate form (such as 0 x infinity or +infinity-infinity). The second one consists in applying theorems and properties in order to calculate the limit. Teachers note numerous difficulties when students carry out these two tasks, such as calculus errors in the transformations on expressions or misapplication of theorems.

Using CAS to perform limit calculus is likely to help the students to verify their results and to focus on the strategic part of their work. Unfortunately, CAS utilization is not so obvious. Available functions are sometimes too powerful and students may have some difficulties in applying a precise transformation in a given sub-
expression. Other transformations are merely impossible to perform with a CAS because too simple functions (from a technical viewpoint) do not exist in a powerful software. Furthermore, CAS results can sometimes be quite useless for students. For example, CAS can display any limit values but this indication does not suggest any transformation to apply in order to eliminate an indetermination.

We think that the design of a learning environment based on a CAS is likely to solve difficulties that students encounter both in paper-and-pencil and CAS context. Our approach consists in specifying clear pedagogical goals and in designing an interaction that reaches these goals. Students will work with an environment that reifies identified properties and provides well suited functions and convenient calculus facilities.

From now on, we describe the LIMITS environment and explicit the teaching goals we try to meet.

**Architecture**

The Learning Environment LIMITS is composed of two units. The first one, called the Interaction Unit, interacts with the student in order to specify his/her request. The student can enter an expression, request a transformation upon an expression or a sub-expression or carry out a limit calculus.

On the basis of the student's demand, the Interaction Unit sends a request to the Adaptation Unit. The part of this second unit is to adapt the student's demand to the CAS and to collect the result from the CAS before sending it back to the first unit (see Fig. 1). These units have been developed in DELPHI and the CAS we used is MAPLE.

**Figure 1:** Architecture of the LIMITS environment.

We describe below three activities required to study limits: entering and selecting sub-expressions, transforming expressions, and calculating the limit by applying theorems. We show how didactic goals have determined the characteristics of these activities.

**Entering and Selecting Expressions**

When a student enters an expression using its linear form, the Interaction Unit parses this expression and displays it in its usual bidimensional form (Fig. 2).

**Figure 2:** Entering an expression in LIMITS.
The bidimensional display is achieved by using nested boxes which include operators (such as +), variables, numbers or sub-expressions. In order to calculate a limit or perform a transformation the student has to select expressions or sub-expressions. The LIMITS environment allows to select expressions or sub-expressions with the mouse directly on the bidimensional representations of expressions. Our assumption is that such a capability will lead him/her to a better understanding of expressions structures.

Some Difficulties

Different ways of selecting sub-expressions were possible. We chose to give a particular importance to root symbols because their identifications are necessary to deeply understand expressions structures. For example, we chose to select the whole expression \(x^2+x+1\) by clicking on the first or on the second + symbols.

Some situations were however more difficult to solve than others. For example, some operating symbol are not displayed in the usual bidimensional representation. That is the case with the multiply operator in \(3x\) for example. We planned to insert some space between the 3 and \(x\) boxes, so that students can select the whole expression \(3x\) by clicking in this space. Another difficulty we had to deal with came from the particular conventions concerning the minus symbol. For example, the real syntactic structure of the \(x^2-3x+2\) expression is \(x^2+(\text{-}3x)+2\). We had to decide what sub-expressions will be selected when clicking on the minus symbol of the previous expression. We have in this case two possible results, either the \(-3x\) sub-expression (if we consider that the + symbol of the whole expression is omitted), or the \(x^2-3x+2\) expression (if we consider that this minus symbol is at the same level in the expression that the plus symbol). We chose the second possibility in order to have a mean to select the whole term in expressions such as \(x^2-3x\). A space between the minus and 3 symbol allows the user to select the sub-expression.

Another difficulty was to explain to the user how to select sub-expressions with respect of our particular conventions. We designed a little tool that allows the student to see what expression or sub-expression he/she points out with the mouse.

When passing the mouse all over the expression without clicking, different moving frames are drawn, indicating the different sub-expressions that would be selected by clicking (see Fig. 3).

![Figure 3: Visualization of different sub-expressions (using the mouse).](image)

Adaptations Needed in the CAS

Expressions and sub-expressions are sent by the Adaptation Unit to MAPLE in order to calculate transformed expressions or their limits. But, working with MAPLE led us to take some precautions.

For example, some operators do not exist within the MAPLE representation. That is the case with the expression \(2/x\) which is parsed by MAPLE as \(2*x^{-1}\), because quotient does not belong to the MAPLE operators set.

Another difficulty comes from the simplification algorithm that MAPLE applies as soon as it receives any expression. This algorithm is tedious because it may eliminate some important characteristics of the expression structure. For example, the sub-expression \(3x+5x\) is immediately simplified by MAPLE in \(8x\), whatever the place in an expression it takes.

It was not possible to return to the student expressions or sub-expressions so deeply changed by MAPLE that the student may not recognize the original object he/she works on. Consequently, we designed a tool within MAPLE which aims at protecting expressions from the powerful algorithms of this CAS. This tool encodes expressions as soon as they are received from the Adaptation Unit. After working on these expressions, it decodes the resulting expressions and sends them back to the Adaptation Unit.
Transforming Expressions

In order to calculate limits, students have sometimes to perform transformations, specially when the calculus of the current expression leads to an indeterminate limit (such as 0 x infinity or 0 divided by 0). In LIMITS, to transform an expression, a student has to select a sub-expression and the transformation he/she wants to apply. The figure 4 shows the different transformations a beginner can do in order to calculate the limit of a rational function. He/she first factors out x^2 in the denominator, then x^2 in the numerator, before simplifying the whole expression by x^2. The limit of the whole expression can then be calculated.

Another Way of Transforming Expression

We aim at providing students with convenient capabilities for transforming expressions quickly and precisely. Consequently, we designed another way of transforming expressions by direct manipulation, particularly well suited for elementary syntactical transformation, such as inverting two terms of a sum (Avitzur 1998). This way of performing transformations requires that the student selects a sub-expression with the mouse and drags it then over the expression. The environment shows to the student what possible transformation he/she would perform if he/she relaxes the mouse button. To do that, the environment displays (when possible) a label pointing out the transformation corresponding to the place the mouse indicates (Fig. 5).

Figure 4: A sequence of transformations.

Figure 5: By dragging x^2 after x, the two terms commute.
Adaptations Needed in the CAS

MAPLE functions are generally not well suited for students work. For example, some functions are too powerful. The function expand works not only on polynomial expressions (as expected) but also on trigonometric, logarithmic or exponential expressions. It will be better from a pedagogical viewpoint to break this powerful function into several more precise ones working on specific expression forms.
We also noticed that some useful functions do not exist within MAPLE, which (as any other CAS) does not require too simple functions because its efficient algorithms don't use them. For example, no direct transformation in MAPLE rewrites \( x^2 - 3x + 2 \) into \( x^2(1 - \frac{3}{x} + \frac{2}{x^2}) \).
Consequently, we had to design a library of specific functions, closely corresponding to the student actions and respecting the types of expressions the student is working with.

Calculating a Limit

Several ways were possible to allow the student to calculate limits of expressions in the LIMITS environment. We noticed that when calculating limits students have often difficulties in applying theorems and properties. Consequently, we make students indicate the theorem they want to apply before proposing any result in LIMITS. In the example of figure 6, the student has first selected the expression 1 and determined its limit by choosing "reference limit". Then he/she has made the same actions with the expressions \( \frac{1}{x} \) and \( \frac{1}{x^2} \). Finally, he/she has selected the whole numerator and chosen a sum theorem.

![Figure 6: A limit calculus.](image)

Distinguishing different teaching levels

Different levels of justifications corresponding to different teaching levels are available in LIMITS (Fig. 7). At the first level, exhaustive justifications are required, but at higher levels some justifications can remain implicit. At level 2, making explicit the limits of \( x^2 \), \( x \), and of the constant terms is not required. Furthermore, unlike at the first level, the sum justification is not divided into several sub-cases. The only case is "sum without indetermination". The third level includes a supplementary choice allowing the student to apply a new property concerning the limit of a polynomial function when the variable approaches infinity. Thanks to this property, the calculus can be performed in only one step.
### Conclusion and future work

In this paper, we presented a Learning Environment based on a CAS. We specified clear pedagogical goals and designed a software providing the student with well suited calculus facilities. We hope consequently that our Learning Environment LIMITS will prevent the student from usual paper-and-pencil errors and will provide him relevant calculus tools.

We intend now to realize some experiments in observing and analyzing some students sessions and the errors they will make. We aim so at knowing how to improve our interaction with the student, for example by asking him/her some numerical results. A second direction of work is to extend the mathematical domain we deal with. Our intention is firstly to design another interaction allowing the student to calculate limits with the help of relevant inequalities. This domain is a more difficult one, because some useful inequalities cannot be found automatically and requires to specify what kind of help to provide to the students.

This reported work has been carried out with the helpful contribution of Hervé Hamon and Michel Enjalbert, mathematics teachers, who are members of our research group.
Abstract: Hypertext clearly has the potential to change the way students learn. However, the World-Wide Web lacks many of the features necessary for truly interactive hypertext; while hypertext pundits speak of students annotating existing pages, building new pages, and linking them into existing hypertexts, the World-Wide Web typically limits interaction to simple point-and-click browsing. At the same time, students encounter a quite different problem when they venture beyond course webs: they get "lost in hyperspace". That is, students have trouble determining where they are and where to go next.

In this paper, we suggest one solution to these two problems: Blazer, a system for extending the Web with trails, named sequences of annotated pages. When a student loads a page on a trail, she sees not just the page, but also information about the trail. Trails can give students increased interactivity while grounding navigation.

1. Introduction: Why the Web Needs Trails

The term "hypertext" suggests a rich environment in which readers could not only navigate between pages, but also extend and modify their own reading spaces. Hypertext visionaries suggested systems in which readers could add their own pages, make links between pages, and create trails between pages (Bush 1945) (Nelson 1974) (Landow 1997). Consider Nelson's first description of hypertext, in which he writes "links may be artfully arranged according to meaning or relations in the subject, and possible tangents in the reader's mind" (Nelson 1974, p. DM19, emphasis ours). Similarly, Bush envisioned a convenient mechanisms for constructing "useful trails through the enormous mass of the common record" (Bush 1945, Section 8). Clearly, linking and trailblazing are essential to interactive hypertext.

Compare this rich model to the typical Web site. Readers can click on links to select the next page they view, but that is the limit of the opportunity they have to interact with the hypertext. While some sites provide more interactivity, few provide the rich environment the hypertext pioneers envisioned. In particular, while it is certainly possible to link to a site, few sites let you link from them. But without such links, how can readers arrange links according to their "meaning [,] relations [...] and possible tangents"?

Are there ways to permit Web readers to make and share their own links? Are there ways for teachers to give their students appropriate guidance for traversing the morass of information on the Web? To help students, teachers often want to write:

To learn more about this subject, read the following Web pages in this specified order. I've included notes on each page to help you understand what is on the page. I've also suggested a few alternate sequences for those of you with different backgrounds.

Similarly, a teacher might wish to provide a sequence of readings and questions, with each element building on the previous ones. A teacher or student might also trace the evolution of an idea or design principle through a sequence of pages. These trails may also include a number of subtrails (which Bush calls "side trails").

How can a teacher implement such sequences? It is certainly possible to write a separate Web page that lists the elements in the sequence and links to each element. However, such an implementation is difficult for students to navigate, as they must go back and forth between the sequence and linked pages, often forgetting where they are. There are also a number of ad-hoc solutions. For example, a teacher might build a sequence of framed pages, each
Experienced computer users preferred the “table of contents at the left” or the “separate contents window” interfaces. Less-experienced users preferred the simpler interfaces. However, less-experienced users also noted that they wanted some way to “jump around” the trail. Almost all users noted that the “table of contents” interfaces used a lot of screen space. Because we were testing on large monitors, they did not find this a problem. However, many worried what would happen when used smaller monitors.

![Figure 1: Three trail mockups (Numbered “Blue Dot”, Just arrows, and Framed).](image)

Many comments also served to validate our initial design goals. For example, when an interface seemed to provide less context, readers asked for “more context, as in the other interfaces”. Readers also wanted clearer next/back arrows in all but the simplest interface.

Because different readers find different interfaces more intuitive, we decided to include configuration mechanisms in the program. That is, each reader can select which way trails are presented for her.

This decision also gives us the opportunity to do somewhat less direct and more realistic user testing. In particular, we can see how (and whether) readers switch trail interfaces as they become accustomed to using trails. Such testing is planned for spring 2000.

### 3. Architecture

The architecture of our system is fairly simple and takes advantage of the Web Raveler page-transformation infrastructure (Kensler and Rebelsky 2000). WebRaveler is an account-based system that mediates communication between Web browsers and Web servers. Each time a reader requests a page, Web Raveler intercepts the page before it is returned, looks up information on the reader, and transforms the page according to the needs of the reader. Because Web Raveler supports a plug-in architecture, we were able to develop trails as a plug-in for Web Raveler. (Fig. 2) illustrates the interaction between Web Raveler and Blazers.
of which includes the remote page, notes, and a link. Unfortunately, the construction of such solutions is often time-consuming and difficult.

We have developed a suite of tools to make it easier for faculty and students to build and use trails of pages, both local and remote. The suite includes a variety of trail-authoring tools intended for both novices and expert users. Similarly, there are a number of ways that students can view trails, so that each student can choose the way that best suits her. Trails have an added benefit: they ground students in their reading of the Web. Students on a trail know that there's always one good place to go next: the next page on the trail. The trail name also gives students some information as to why they're reading the page. Finally, because our trails can include notes from the trail author, the instructor can give additional context within the notes.

In this paper, we discuss selected issues in the design and implementation of our system, particularly our observations during close user testing.

2. Using Trails

While it is necessary to blaze trails before you can use trails, the technique for blazing trails is somewhat secondary to the interface for using trails, since trails will be more frequently used than blazed. Hence, our work began with the consideration of possible user interfaces for presenting trails to students.

Our work began with an analysis of the necessary components of any interface. We decided that,

- students must always know their current position: what trail they're on, where they can go next, where they can go back to;
- students must be able to reach an overview of each trail;
- a displayed page must include not only the page content, but also the trail context and, possibly, notes from the trail creator;
- pages on a trail must use standard URLs; and
- each page may, but need not, include links to all of the pages in the trail.

These design guidelines gave us a great deal of freedom in the ways to present these different attributes. There are clearly a number of design choices relating to

- positioning of the trail information, which might appear above the page material, to the side of the page material, or even in a separate window;
- the number of links to other pages in the trail, from just two links (next and previous) to a complete list of links, or even a small window on the trail;
- the level of detail in the links to the other pages, which might give the full name of the other page, or simply a position number; and
- the presentation of links to other pages, which might appear as a menu or series of textual links.

At this stage of the work, our goal was to evaluate how students might react to different presentations of the trail. We began with four mockup interfaces that explored different combinations of these choices. While it might have been more appropriate to test each design choice independently, it was also clear that some combinations were more natural. For example, if the trail is presented in a second window, it makes sense for that window to include many or all of the nodes in the trail with their name, and not just the next and previous nodes or numbers for each node. The four mockups were

- A simple interface which included the full list of pages in the trail at the top and bottom of each page. The links were numbers, giving the position of the page within the trail. To give the reader some context, we included a blue dot at the current position within the trail. The first picture in (Fig. 1) shows this interface with a course page.
- A simpler interface which included only trail name and next and previous links as arrows. The second picture in (Fig. 1) shows this interface with an institutional home page.
- A framed interface which presented a textual "trail table of contents" to the left of the page. The third picture in (Fig. 1) shows this interface with a set of major guidelines.
- A separate window listing the textual table of contents.

In almost every case, the design strategy for the mockup bore some resemblance to typical site interfaces on the Web. The two simpler interfaces resemble the lists of pages of search results typically given by search engines like Altavista. Similarly, the table of contents at the left format is a typical navigation tool for sites, one that is sometimes implemented with HTML tables and sometimes with frames.
Figure 2: The Relationship between Blazer and Web Raveler.

A student using Web Raveler with trails first logs in to Web Raveler. She then surfs the Web as normal. After intercepting the page from the server, Web Raveler sends information to the Blazer plug-in (6a) about the student, the URL of the page, and the content of the page to Blazer. The Blazer plug-in then sends the URL to the Blazer server (6b) to determine if the page is part of a trail. The server returns (6c) either a list of trails and associated trail information, or a note that the page is not on a trail. If the page is not on a trail, the plug-in returns it (6d) unchanged. However, when the server indicates that a trail is available for the page, the plug-in modifies the page to add information about the trail and then sends the page back to Web Raveler (6d). Web Raveler may then pass the page through other plug-ins (7) and then returns the “trailed” page to the Web browser (8). The Blazer server uses a simple database to associate trails with each URL.

One unresolved issue in this architecture is how to resolve situations in which multiple URLs are associated with the same page. Many Web servers return a default page when the URL requested is a directory. For example, http://www.math.grinnell.edu/ and http://www.math.grinnell.edu/index.html are the same page. Ideally, Blazer would add the same trail for each URL. Unfortunately, the overhead incurred in checking equivalence of URLs is currently quite great, so Blazer and Web Raveler treat them as separate pages.

4. Blazing Trails

While there are some clear guidelines for how interfaces should present a trail (or at least what interfaces should present), the design of trail blazing tools is somewhat less specified. Just as different Web authors have radically different techniques for building pages, from “raw HTML” to graphical editors like PageMill, from custom applications to “save Word as HTML”, so will different trail authors have different preferences for the ways in which they build trails.

To support different trailblazing techniques, we use a standard file format. Just as some authors write raw HTML, so too can some authors write “raw trails”. Authors can include comments by beginning a line with a pound character (#). An entry in the file begins with the URL, followed by a vertical bar (|), followed by the Web page title as it should appear to a person browsing the trail, followed by another bar (|) followed by any comments that the author wants to share about that particular Web page.

But few authors will want to create trails in this way. Hence, we chose to include two other mechanisms for building trails. Trailmaker, the authoring tool, for novices, runs in any Web browser. The tool presents two frames, one on top of each other. The bottom frame is used for a preview of the page to be included in the trail, and the top frame shows the additional information that will be recorded in the trail. The top frame, used for authoring, includes sections for the URL (which may be dragged and dropped from the top of the browser window), the author’s name, page title, and comments. In addition, a preview of the complete trail is shown in a separate Web browser window. Trails can be built from scratch or modified from existing trails.

While this interface is particularly appropriate for those whose primary Web experience is browsing, another interface might be more appropriate for those used to authoring Web pages. Hence, we built a second tool that reads the links in a file and turns those links into a trail. Since every page in a trail includes both title and comments, the link text is used as the comment and the title of the destination document is used as the title in the trail. Authors accustomed to building pages with links can use whatever system they prefer to build a “list of links” page and then run this tool to build their trails. This tool has been successfully used to build some very large trails, including one with over three hundred pages.

We tested the two interfaces on a variety of potential trailblazers, including some whose main use of computers is browsing and some experienced programmers. Surprisingly, users found little to recommend one over the other. Most found it comfortable to create trails in either way.

5. An Application: Student Trailblazing

Why build trails? In the introduction, we suggested two important reasons: trailblazing empowers students and trails ground students, thereby reducing the chance of getting lost in hyperspace. Yet trail-blazing has other educational uses. In particular, a teacher might ask students to create trails based on a particular subject. This activity differs in many ways from the related “build a Web on this subject”.

377
First, students must do more than collect resources; they must also order those resources. While hypertext encourages multidimensional structures, students must also learn the ordering and relating that is necessary for coherent arguments and narratives. Second, students must annotate these resources. Again, this requires students to do more than just decide “this page is interesting and about my topic”. They must explicitly indicate how the page fits into their “narrative trail”.

Our initial experiments with asking students to build trails have suggested that students find the task quite challenging. Since their primary experience on the Web is gathering, and not sequencing, they find it difficult to think about how one might sequence these pages that are related by topic but not by order.

6. A Risk: Page Modifiers from the Author’s Perspective

While there are many benefits to trail-blazing tools, there are also some significant concerns raised by the use of tools that modify pages on both local and remote sites. Consider the case of ThirdVoice (ThirdVoice 1999) (Warner 1999), a browser plug-in that allows readers to add and share annotations. Although there are many appropriate uses for this tool, such as instructors posting notes on remote pages for students to read, many made inappropriate use of the tool, such as posting links to pornography sites on common locations like whitehouse.gov and disney.com. Even without these abuses, many page authors were concerned that ThirdVoice usurped their literal authority, permitting others to “modify” their pages (Oakes 1999). Any page modification tool must consider such issues.

Because we rely on Web Raveler (Kensler and Rebelsky 2000) for our infrastructure, we are able to provide some support for page authors. In particular, Web Raveler includes a language that permits page authors to limit the modifications done to pages. Hence, authors can indicate that they do not want trails added to their pages, or limit trail use to certain domains. If authors permit trails for a page, they cannot specify that certain pages (or types of pages) should not be included in trails.

During early user testing, we built some prototype sites using local copies of remote pages, to support faster access to the locations in the trail. However, we did not always copy images. In one case, a subject-generated trail created some controversy, since the pages in that trail included images from another site. The owners of that site claimed that we were attempting to “steal” both their pages and their bandwidth. Fortunately, we were able to convince those authors that we were working on a useful research project and not attempting to create a mirror of their site. In subsequent work, we turned off remote access for any locally generated trails. However, such issues remain a concern.

7. Related Work

In spite of the importance of trails to the World Wide Web, there seem to be surprisingly few systems that permit readers to add links and trails to pages. The most notable trail-blazing system is Walden's Paths (Shipman et al. 1998) (Shipman et al. 1999). At times, trailblazing is subsumed under a notion of annotation, as in (Roscheisen et al. 1995).

Our Blazer system differs from Walden's Paths in a number of ways. First, Blazer provides more mechanisms for authoring trails. Walden's Paths provides one tool, which has some similarities to our novice interface. Because we use a simple, open, textual, trail format, it is possible to design new interfaces. Second, Blazer gives readers many more opportunities to customize their display of trails and have employed user testing to develop this interface. Walden's Paths uses one fixed display that consumes a significant amount of screen space. Third, Blazer users standard URLs and informs students about the availability of paths when they view pages that happen to be on paths. Walden's Paths assumes that students intentionally start on a path, and also uses special URLs for the pages on the path. Finally, because we rely on Web Raveler (Kensler and Rebelsky 2000), we have the opportunity to use information about the student in presenting path information and to interact with other Web Raveler plug-ins. For example we might automatically present a different path based on information about the student’s skills or browsing history.

Admittedly, Walden's Paths has some advantages over our system. It has been used much more widely and has been used successfully for a number of different applications at different levels. We hope to compare the applicability of the two trail-blazing systems for similar activities.
Both Walden’s Paths and the Blazer system have many advantages when compared to annotation-based trails. In annotation-based trails, page annotations can include links to the next and previous pages on a trail. However, such trails are clearly difficult to build and maintain. For example, inserting a page into an annotation trail requires that you modify the annotations in three different pages. While trails provide an interesting application of annotations, a separate annotation system is clearly preferable.

8. Conclusions and Future Directions

For the Web to empower readers, it must permit readers to do more than follow links and build pages that link to and never from other pages. The Blazer system empowers readers by letting them build trails through the Web, using both local and remote pages. It therefore provides an important resource for teachers, not only letting them build trails to help guide their students through the Web, but also providing context to browsing and empowering students to create their own trails.

Yet our work is not done. While we have done some user testing for various parts of the interface, we need a comprehensive study of how readers prefer to see trails (and forthcoming). We also need to study more closely how students and faculty will use trail-blazing tools and whether the assignment to “build a trail” can really make students think about linear structure.

Abstract: Recent technological innovations have substantially altered the ways in which colleges and universities deliver essential services. Among the academic units most notably affected by technological change has been the academic library. This paper will consider the impact of recent and emerging technologies on the services provided by academic libraries and on the evolving needs of library patrons in the new digital environment. I will argue that making digital libraries usable for patrons requires the development of effective and innovative forms of online reference.

INTRODUCTION

Recent technological innovations have substantially altered the ways in which colleges and universities deliver essential services. Among the academic units most notably affected by technological change has been the academic library. This paper will consider the impact of recent and emerging technologies on the services provided by academic libraries and on the evolving reference and instructional needs of library patrons in the new digital environment.

Since the development of the World Wide Web in the mid-1990s, colleges and universities have been undergoing a major shift in the nature of their communication with their various audiences. Now college web sites often serve as gateways for information to students, faculty and staff, prospective students, alumni, parents, and the general public. In addition to providing a platform for administrative functions, the web is effecting substantial changes in the way educational services are being offered. It has become the major vehicle for delivering distance education courses. Even locally within a campus, more and more courses are offered either partially or exclusively over the web, and many other more traditional on campus courses integrate the web as an integral part of the course (see, for example, Schulman & Sims 1999).

At the heart of the educational and research functions of the university is the academic library, and there is no part of the university whose services have been impacted by technological change more than the library. Technological innovations have been radically altering the kinds of service academic libraries offer and the way they do business since perhaps the mid-1970s. In order to properly consider the impact of the digital environment on the kinds of services academic libraries provide and the way they deliver these services, it will be useful to clarify the mandate of the academic library. While the digital environment indeed poses new challenges that must be met and possibilities to strive for, the basic mission that guides and informs our work remains unchanged: “to support teaching and research by acquiring and preserving materials in all formats, and by providing access to these materials through systematic organization” (Jayne & Vander Meer 1997:123). However we redesign our services in order to deploy the capabilities of the digital library to maximal effectiveness, we must do so in a way that is consistent with the library’s overriding mandate.

The potential of the technological revolution (often referred to as the information superhighway) has been touted for quite some time. It is often claimed that libraries in North America are experiencing a major shift in their mandate, which traditionally has been to collect, maintain, store, conserve, and preserve the printed artifacts that represent the recorded knowledge of our culture and society. Although libraries have always responded to the development of other media (LPs, CDs, videocassettes, etc.), talk of a substantial—even a paradigmatic—transformation of the very concept of a library began with the rapid development of computer and communications technology.

380
DIGITAL LIBRARIES

The concept of a seamless, electronic web of information, universally available on a twenty-four-hour-a-day, seven-day-a-week (24/7) basis, is regularly put forward as the natural next step on the evolutionary ladder, inevitably and inexorably replacing the traditional physical library in which things are stored that have concrete properties which are described in a cataloguing record. This argument is made from several quarters, spanning all types of libraries, although academic libraries are the most common focus. To take just a few examples from the library literature, Herron (1986) was among the early predictors of a virtual library, making no distinction as to type of library. Day (1998) makes the argument with respect to school (K-12) libraries, and Seiler & Surprenant (1993) make it with respect to academic libraries. Denton & Redmond (1994) predict that the days are numbered in which librarians will be needed as search intermediaries, since library “customers” get needed information by posting a query to a discussion list or by running a search on an Internet search engine.

This sort of futuristic or utopian--according to how one chooses to view it--forecasting may seem increasingly feasible because of the wealth of material--information, disinformation and everything in between--that is available over the Internet to anyone with a PC. Library catalogues from all over the world can be searched via the World Wide Web or a telnet connection from home. Even proprietary textual and bibliographic databases, which have customarily been available only from an IP address of a library that subscribes to them (or perhaps from other PCs within a university campus), are now increasingly becoming available remotely by means of some form of password verification or proxy server.

REMOTE ACCESS AND INFORMATION LITERACY

We in the library community can take genuine pride and satisfaction at the expanding level of service we can provide our patrons, service that extends well beyond the walls of the library into homes, offices, community centers, etc., and beyond the traditional hours of library service, toward a 24/7 model. We can not only make our catalogues and the databases we subscribe to available from outside the walls of the library, but our patrons can in many cases ask asynchronous reference questions via e-mail Ask-A-Librarian services, and some libraries have been experimenting with providing synchronous reference service via a MOO (Multi User Object Oriented) environment. For other examples of remote reference services, see Sloan (1998). See also the University of Leicester’s Electronic Library at http://www.le.ac.uk/li/distance/eliteproject/elib/, which provides links to numerous sites offering various types of remote reference, including the Remote Referencing Help-Desk Project at the library of the University of Edinburgh.[i]

On the other hand, as a counterpoint to this optimistic vision and to forecasts that libraries as we know them are destined to wither away and die, academic librarians confront daily the reality of students who do not know how to define the topic they are researching (beyond, say, educational psychology or history), much less how to break it down into key words using Boolean logic, or how to use the controlled vocabulary of a database. Sloan (1998) notes that discussions of digital libraries tend to focus on technology and information sources, rather than on service. However, Sloan points out, “[t]echnology and information resources on their own cannot make up an effective digital library” (Sloan 1998). Constant access to data does not by itself make that data accessible and it certainly does not transform it into information or knowledge. Information is accessible to patrons only if they know at a minimum 1) how to define their information needs, 2) how to translate those needs into effective search strategies, and 3) how to evaluate the information they locate.

CHALLENGES AND OBSTACLES

Let us consider some of the issues that might affect a patron’s ability to define an information need, to develop search strategies and to evaluate information. For the moment, let us assume as an abstraction a fairly level technological playing field, in which we take as a given that most library patrons have easily accessible Internet connections, can negotiate remote access to proprietary databases, have up-to-date hardware, sufficiently speedy levels of connectivity, and browsers that are capable of handling (and handling within a patron’s natural life expectancy) Java, multimedia, graphics, and whatever other features are used in the databases they need. Of course,

[i] Many thanks to Ilene Frank, Danielle Hinton, Laura Kortz, Patricia Memmott, and Diann Smothers, who shared much information on remote reference, in response to a query I posted to the DIG_REF Listserv (see http://www.vrd.org/Dig_Ref/dig_ref.html).
this is a major abstraction, and one, which is not likely to become a reality anytime soon. Nevertheless, even given all this, let us imagine the confusion of the novice patron when faced with our impressive selection of bibliographic and textual databases, not to mention the, to all intents and purposes, infinite possibilities of the Internet.

**QUERY FORMATION**

This patron may well not realize that in order to address the specific topic in question, he or she should be looking for articles on feminist interpretations of the works of Thomas Hardy, rather than Victorian literature, or for information on eating disorders in adolescent girls, rather than psychology. Despite the naïve, rather fantastical assurance of many people that the answer to the unformed question is “in the computer,” just waiting to extract itself, the fact remains that defining the query is the essential kernel of the research process. Stern (1999) notes that regardless of how powerful and sophisticated a search engine is, and no matter how much it can do for the researcher, the most difficult part of information retrieval is forming the appropriate question. He observes further that as yet “[t]here is no algorithmic substitute for good critical thinking” (Stern 1999:79-80).

**CHOOSING DATABASES**

Once the issue of query formation has been resolved, the patron is faced with the problem of how to choose the most appropriate resource from those that are available. That the differences between resources are not apparent to inexperienced people is clear to any academic librarian who has been told by a student, in response to a suggestion to search a particular database, that he or she has already “looked on the computer” and hasn’t found anything relevant. When the librarian asks the student whether he or she searched on the Internet or on one of the library’s databases, often the student does not know. Alternatively, if the student says that he or she found the information by following a link from the library’s list of electronic resources, the student often does not know which database he or she searched. Inexperienced users (as well as more experienced ones with complex questions) need guidance in selecting databases that are appropriate to their needs.

Often, in the ideal case, the patron would have the assistance of a trained information specialist. Certainly, as will be discussed below, libraries’ web pages can and should walk patrons through the steps of the research process and provide assistance in database selection. Stern (1999) provides examples of navigational tools that will point to metasearch indexes, subject specific indexes, web sites, etc. Still, as Buttenfield (1999) points out, what connects remote users with available resources is a software interface, an interface that cannot, at this point, guide users to the sources that are most relevant to their topic and most suitable to their level. Nor can an interface make eye contact with patrons, and respond appropriately to looks of confusion, disappointment or frustration. Moreover, as Shaw (1996) notes in her evaluation of the Internet Public Library’s pilot project providing synchronous reference in a MOO environment, the librarians involved in providing the service reported difficulties that resulted from the lack of the feedback present in face-to-face, or even telephone, communication. Librarians observed that information was lost as a result of the absence of feedback from voice inflection or body language.

**CONSISTENCY OF INTERFACES**

The third issue we will consider in relation to a patron’s ability to effectively exploit the digital library is the consistency of the interface itself. It is the interface, after all, that enables users to extract (or not, as the case may be) the information they need, and, as Buttenfield notes, for many users “the interface IS the system” (Buttenfield 1999:42). Since the rise in public use of personal computing applications, software has undergone substantial progression toward greater user-friendliness and standardization, evolving from often arcane command-driven interfaces to point-and-click G(raphical) U(ser) I(nterfaces). Since the advent of CD-ROM databases first made enduser searching feasible, the interfaces for electronic databases have undergone similar progressions. The early DOS-based CD-ROM products relied on a set of often idiosyncratic and counter-intuitive menus and commands that were challenging even for professionals to use. With the development of the Windows operating system and GUIs came the possibility of greater user-friendliness and consistency. During the last few years, we have witnessed the mass migration of electronic databases to the World Wide Web, with the possibility of even greater consistency, given the properties of HTML, the easy identification of hyperlinks, and people’s growing familiarity with the protocol of the web. However, the potential of consistency remains, to a large extent, elusive,
since there are still substantial and often confusing dissimilarities and inconsistencies among the products of different vendors. Among the searching capabilities users have to learn for each product are what fields are searchable, how Boolean operators are applied, what the wildcard and truncation symbols are, whether or not the user has access to the thesaurus, and whether or not nesting is possible. All of these can vary considerably from product to product.

If we take just a brief look at the interfaces of popular products from three well-known vendors (InfoTrac, produced by Gale, WilsonWeb, by the H.W. Wilson Company, and WebSpirs by SilverPlatter), we can see that in each case the search screens are quite different. The terms that are used to identify the different types of searching available are different for each case, and they are not prominently defined. The user has to do some digging through the online help in order to get information.

Fig. 1 shows the opening search screen for the InfoTrac product, Expanded Academic ASAP. The default screen is a subject guide. However, since the user has no access to a thesaurus, he or she must simply guess what terms are descriptors.

Figure 1: The default search screen for the InfoTrac databases. The arrow indicates the option available from this screen to limit the search to articles with full text and/or refereed publications
Now in the Wilson databases, the basic search screen does not give the user the option to limit the search, as we can see in Fig. 2.

![Figure 2: WilsonWeb Basic Search Screen](image)

Finally, Fig. 3 shows the opening screen for SilverPlatter’s WebSpirs databases, which has a completely different look and different options from either InfoTrac or Wilson Web. The user is presented with a Search Builder, and the option to “Set Other Limits,” neither of which is defined anywhere.

![Figure 3: The opening screen for SilverPlatter’s WebSpirs databases.](image)

CONCLUSION

When sitting in front of a computer at home or in a dormitory room and visiting an academic library’s web site, our user encounters an impressive array of resources that extend the walls of the library well beyond its
physical limits. Nevertheless, as we have seen, there are significant obstacles that confront our user, obstacles that are all the more significant for someone who is under the impression (or who's professor is) that the challenges of the research process melt away in a brave new cyberworld. As noted above, the academic library has at the heart of its mandate the responsibility “to support teaching and research by acquiring and preserving materials in all formats, and by providing access to these materials through systematic organization.” To this, it is appropriate to add a teaching responsibility: the responsibility to teach students how to locate, use and evaluate information in all formats for learning and research.

If we truly want to extend the walls of our libraries out to cyberspace, and to accommodate the researcher who is doing a literature search at 2 AM, it is essential that we design library web sites so that this researcher has a place to go for answers when he or she runs into obstacles. A library’s homepage should be designed as a self-paced tutorial. It should provide convenient and easy ways to locate links to all of its services as well as to tutorials on how to use them. We should make it easy to locate information on the research process, from the formulation of a topic, to tips on how to develop search strategies, to principles and procedures for documentation. The library’s web site should guide users on how to search electronic databases in general, as well as information on the unique characteristics of each one. We need to build on the efforts of some academic libraries to offer user-friendly, synchronous real-time reference that can guide users on database usage and selection. The library of the University of Edinborough, for example, lists on its web page the scheduled times that librarians who are experts on specific databases are available for interactive reference (see http://www.remote.lib.ed.ac.uk/). Building a digital library that is faithful to the finer traditions of librarianship requires not just that we develop technology, but that we deploy that technology in order to achieve excellence in connecting people with information.

Virtual Study Groups (VSG), an approach to networked collaborative learning

1. Introduction

The Open University of Catalonia (UOC) is a new university model that provides distance learning through a Virtual Campus. With the application of new information and communications technologies, the "virtual campus" becomes an alternative to traditional correspondence education. Students are in permanent contact with University services, professors and other students from their own home, via a Virtual Campus and a personal computer. In the distance learning system that UOC offers, students have a wide range of institutional elements to stimulate, guide and help them during their process of learning: counsellors, tutors, and support centres. They also have other common virtual spaces where to pose and solve doubts: the community forum, a space for debates and a classroom forum.

In this context, one of the student’s critical problems is the feeling of isolation. Lacking every day’s feedback, contact with other students and teaching staff, student’s motivation level can decrease substantially. Moreover, not having someone with whom to share impressions, difficulties, and projects around the studies, can diminish the desire for learning. During their studies, students need a considerable amount of support. They need aid with the understanding of study goals, clarification of doubts, problem resolution, evaluation activities, and keeping up the level of motivation.

From this point of view, collaborative work could be considered as a strategic tool to improve the study conditions and the quality of the learning context. In addition, collaborative work can be an important element of support and motivation front of the challenges students face at the beginning of theirs university life. In a broad sense, through a process of collaboration, students could share the discovery of a new virtual environment and build together a new reality that will surround them along their studies. This support between equals will allow the construction of social interactions and co-operative networks that will be basic to break the isolation that often implies distance learning systems.

In this particular scenario, our research focuses on co-operative learning in virtual environments. Our experience about VSG seeks to improve the formalisation of models of collaboration in virtual spaces of communication. The main goal of this paper is to describe the concept of virtual study groups (VSG) as the key element of our virtual learning system, as well as a central piece of the backup system for keeping student’s motivation high. A Virtual Study Group is created because students with similar types of needs form groups with the overall purpose of supporting each other educational needs, and, jointly, collaborate in solving learning problems.

2. Virtual Study Group

Collaborative learning methods were developed within the social-psychological tradition based on the idea that students working together are responsible not only for their own learning but for the learning of others students as well. From this perspective, we seek a methodological approach that will allow students give support and advice to each other as well as increase the degree of involvement in sharing knowledge and expertise. Different models and strategies have been proven in the past in pursuing the same goals. The aims and work distribution of the Virtual Study Group are in part similar to the ones described by Slavin for the group-investigation (Slavin et alt., 1985).
The main goal of a VSG is to create a learning structure in which students can study the contents of a subject matter in a better and richer manner that they would do otherwise. We expect students working collaboratively improve their achievement outcomes. The virtual study team is created by the students that gather together with the shared objective of helping each other to find the resolution of a problem generated around a specific learning problem. The concept of VSG claims for concretions related to the number of students per team, group creation, working and dissolution rules, and procedures and collaboration strategies.

For practical purposes, within the learning environment of our Virtual Campus, we define a Virtual Study Group as a group between 2 and 5 students, who have a reserved space in the Campus where they can communicate between themselves and swap doubts, solutions, advises, recommendations, suggestions, notes, etc. In this learning environment, students have the possibility to work together even if they don't meet at the same space or time.

In that regard, our previous experience shows us that during the training time and previously to the definitive constitution of the team, it is essential to clarify the goals and the level of commitment in order to establish good collaboration practices. There is need for putting in place the correct strategies from the very beginning. This allows students to realise their strong or weak points, and build a positive attitude towards their role in the new virtual study group. In this work we describe the useful strategies we have put into practice so far.

Our research aims to design instructional and learning systems that could allow students creating groups been fully aware of the advantages and disadvantages of it, and of the whole meaning of that way of learning. Student centred models of learning vary in their degree tutoring is centred on student, that is on the amount of intervention and guidance provided by the tutor.

The VSG could be situated in a continuum that ranges from high self-management by the students to high group control by the tutor. The table below illustrates the different models that could be employed in order to facilitate students' collaborative learning in the virtual environment:

<table>
<thead>
<tr>
<th>Type</th>
<th>Level of Tutor’s Involvement</th>
<th>Details of process</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>High</td>
<td>Tutors present a structure for the teaching/learning process. This includes detailed identification of the purpose of each section, the duration of each session, detailed readings that the students are required to have read prior to each session, definition of the extension activities from each session that students will be involved in and a clear description of the outcomes that are expected from each session.</td>
</tr>
<tr>
<td>2</td>
<td>Medium</td>
<td>Tutors identify the broad structure of the content of study. They provide an initial set of readings and other sources of information. Students become aware of their role in the learning process and the tutors’ expectations of them. Throughout the teaching/learning process, tutor is not in charge but takes notice of the thinking of the students and seeks, where possible, to incorporate their contributions into her or his teaching.</td>
</tr>
<tr>
<td>3</td>
<td>Low</td>
<td>Tutors identify the broad focus of the content of study. Students with the support and guidance (where appropriate) of the tutors define the initial structures that they will use in order to approach the subject. Tutors act as sources of expertise and mentors or facilitators. Tutors only intervene where there is a crisis in the process, this crisis may, for example, be where students step outside the natural boundaries defined by the subject or where there is tension in the collaborative process.</td>

involvement of the tutor's intervention. That is, students choose whatever learning activities suit better to their learning needs and objectives.

The main benefits for the students working co-operatively in a virtual environment can be twofold. First of all, co-operative learning creates the potential for cognitive and metacognitive benefits. On the one hand, it reinforces and improves the study and learning of the subject-matter contents. On the other hand, it engages students in a situation that requires them to make explicit both the process followed to carry out a learning activity and the strategies applied to resolve a problem. Making these facts available to everybody in the group can give rise to further discussion and reflection about issues of the learning process itself.

Second, co-operative learning promotes affective and social benefits. In particular, it increases the student interest and value that gives to the subject matter. It also increases positive attitude and social interactions among students, which results very positive and enriching for students with different knowledge levels and others characteristics.

Next section describes the two experiences we carry out in the subjects of Multimedia and Communication (MiC) and Information Structure (IS) in the OUC. The first of them involves high self-management by the students whether the seconded one is highly conducted by the tutor.

3. Initiating Virtual Study Groups within the subjects of MiC and IS

Multimedia and Communication at the UOC

Multimedia and Communication at the UOC is a specific, transversal and compulsory subject to any student that joins the university. This subject has a double value for the students: it reflects on Information and Communication technologies and promotes the strategies and tools students need in order to study in the virtual campus. This is fundamental for searching, organising, sharing and communicating information.

The main objective is that the students improve the conditions of study by collaborating in the process of learning in order to obtain the objectives of the subject. The creation of study groups is suggested to help themselves in the resolution of the inherent difficulties to the practical work of the subject.

The characteristics of the subject are:

- The students have just entered the university and the Virtual Campus is new for them.
- They do not know the implications of studying in a virtual environment, and they do not know how to use its resources.
- They have probably never met before. Consequently, interaction and collaboration level is really low.
- Students lack strategies for virtual work. In addition, they show a reserve attitude towards helping others with the resolution of problems.

In MiC students use the Campus v3 group tools. For information exchange purposes, students access two spaces called Forum and Debate. They also have access to a workspace where to send and download files and a link to a web page that can be modified as they work progresses. This web page can also be used as a tool to link the workspace files and organise information.
The VSG main objective is to support the achievement of the subject goals. The group self-manages and creates its own dynamics. The group is only an instrument for giving to each other support for solving individual activities. The work produced by and within the group is not evaluated. The tutor doesn’t propose concrete activities to develop in-group. Depending of students’ level of autonomy, tutor plays an important role in helping the group with study questions and guiding its dynamics. The procedure to start a VSG is the following:

- **Creation of groups:**
  The tutor makes a proposal in a face to face meeting, and also in the teacher virtual board. For creating groups students just introduce themselves using the virtual forum and not a concrete study activity is suggested. Students exchange information and explain proposals in the Forum. Once a group is created, one of its members informs the tutor.

- **Cohesion and development of the group:**
  The tutor informs about strategies, clarifies the conditions and promotes feedback. During that phase, students should:
  
  - Share experiences, create a common culture, develop common rules and construct frameworks in which create a new reality. Moreover, the group should develop activities specifically directed to reinforce the interaction among members.
  - Reinforce group cohesion as a factor to increase internal solidarity and decrease tensions and problems between group members.

While they consolidate themselves as a virtual study group, they reach the objective of helping each other studying the subject. In order to “pass” the subject of MiC, students have to complete five long evaluation activities. Although these activities are to be done and presented individually, VSG should be a tool for helping students with the difficulties that may arise during the resolution of these educational practices. In other words, students do not have a functional group goal, but to help each other to reach their personal goals within the subject.

**Information Structure**

In this section, we describe the methodology followed to implement the pilot experience of VSG in the course of Information Structure. First, we describe the tool used for its implementation.

Based on our previous experience with cooperative learning and problem-solving in virtual environments (Guitert, M. et alt., 1999), we chose the BSCW tool (http://www.gmd.gd/bscw). BSCW is a tool for cooperative work that offers a range of possibilities such as: group management, asynchronous discussions, document management and an automated daily workspace activity report. It also provides a help which explains how to use the tool (Bentley R. et alt., 1997; Horstmann T. and Bentley R., 1997). In addition, we also provided the students a brief help document with the most important functionalities of BSCW so that to facilitate a faster and easier interaction and involvement with the tool.

Given the above conditions, we propose a methodology which consists of a sequence of actions that we believe necessary to realise the experience. The type, goals and the way these actions are performed specify the organisation, content and structure of the interactions that take place in the shared workspace. The planning of the actions is explicitly presented to the whole class by means of a work
schedule which describes the type, goal and the timing of each action planned. Next, we describe the three main phases of the approach followed to carry out the experience: initiating, forming and performing.

- **Initiating: set up a debate of a case about virtual study group**
  The realisation of a case study constitutes the first action of our approach and its main goal is to initiate the students into the new experience. To that end, a specific case is presented to the students for asynchronous discussion. In fact, this discussion constitutes an initial, practical step towards the realisation of a group activity through an exchange of opinions and ideas, which can further motivate and push the students to be engaged in the real group study afterwards.

- **Forming: arrange group formation**
  This phase involves three main actions: introducing, negotiating and norming. In particular, students first introduce themselves by presenting information that their classmates could use to reach a decision about making a contact to possible candidate group members. Then, an interaction between possible candidates begins in order to form a group. The purpose of this discussion is to reach an agreement of the definite group normative (rules about group functioning, organization and planning of the work). If the negotiation phase has been sincere and effective, establishment of an accepted normative can be an easy and fast process.

- **Performing: virtual study group realisation**
  After a group is formed and its normative is clearly specified, it is the right time for performing: group members should be engaged in a collaborative study and learning of the subject matter. The first goal is to make students carry out learning activities that include the elaboration and resolution of assignments related to the concepts and notions of the theory to be studied. The second goal is to realise a learning task (a small project); this is the case of a practical problem-solving whose purpose is to demonstrate that the students have assimilated the conceptual contents of the subject matter and are able to apply them in a real problem.

Moreover, the timing and the order of carrying out these learning objectives is a very important factor for the success of the group study and for obtaining the benefits drawn from it.

Finally, cooperative learning methods are most likely to enhance learning outcomes if they combine group goals with individual accountability. That is, each group member will be held accountable for accomplishing the learning goals of an activity or task. For example, students should know that any member of the group may be called on to answer anyone of the group's questions. For this reason, to increase and make explicit students responsibility in group study, a particular workspace, called Reflection/revision of group work, has been designed and put at the disposal of all groups. This utility gives students the chance to be involved in follow-up reflection activities, which manifest and clarify the way students study in group, contribute to the group and learn. Making this explicit, it helps students critique and revise the process followed and thus it proves valuable as a way of engaging students in meaningful learning.

4. **Reflections from the experience**

We are at the initial phase of experiencing with VSG. The research we are doing is based on a methodological procedure of Research - Action and, consequently, we are taking decisions while the experience is going through, paying a special attention and reflecting on the following elements:
- **Group Objectives**: What is the objective of the group. It has to be concrete and precise and should imply a concrete formalisation level shared by all members of the group.

- **Level of tutors and students involvement**: Depending on the group objective, tutor's role may change: managing, democratic, making easy, etc., which at the same time will imply a student's role, more or less self-managing.

- **Cohesion level of the group**: The commitment level, the intensity of the interaction and the type of communication can influence or determine the achievement of the group goals.

- **Work methodology**: In a virtual work context, the notions of planning, task distribution, the tool used and the way it is used are the key elements for efficient group working.

- **Effects on the learning process**: Since improvement of learning and achievement of better outcomes are key elements for every student, it is necessary to investigate how virtual study groups affect and promote effective learning. For this reason, it is important to keep in mind the following influencing factors: motivation, satisfaction, support, accomplishment of learning objectives.

Email: rubyg@nortelnetworks.com, {frasson, kaltenba, gecsei}@iro.umontreal.ca

Abstract: This paper proposes a comprehensive model for editing and exploiting curriculum based ITS, relying strongly on visual information properties. In this system, a curriculum is a capability transition network that consists of two kinds of nodes: capability nodes representing teaching outputs and transition nodes organizing tutoring activities. The bridge between capability nodes and transition nodes is the prerequisite links from capability nodes to transition nodes and the output links from transition nodes to capability nodes.

Based on the domain capability transition network built by a curriculum author, a learner can visually view the domain knowledge structure and establish learning goals. The system then creates multiple alternative paths, each permitting the achievement of the learner’s learning goals. After the learner chooses his/her preferred course to learn, the system dynamically identifies necessary tutoring activities and orders these activities according to the current context.

1. Introduction

A curriculum is an essential component of recently proposed ITS (Intelligent Tutoring Systems) architectures (Gauthier 89, Frasson et al. 92, Gecsei & Frasson 94, Nkambou, 96, Guo et al. 98a, Zhou et al. 96). In essence, it is a structured representation of all kind of knowledge needed in the course of a tutoring session (Gagne 92, Merrill 87, 91, 93, Finch 86). In their work, the curriculum becomes the prominent part of the ITS.

The traditional GUIs (Graphic User Interfaces) are not well adapted to the exploitation of complex information structures such as a curriculum. Visualization technology (Gershon & Eick 95) (Gershon & Brown 96) points to interesting alternatives. Curriculum authors and students alike now require much more understanding of the information structures they are manipulating.

This paper describes interactive visual ways of guiding learning process including establishing learning goals, creating alternative courses for the learning goals, and dynamically guiding the learning process. In the first part we briefly describe the actual structure of a proposed curriculum model. In the second part we address specifically the visual properties for guiding learning process.

2. Representation and Organization of the Curriculum

This section briefly introduces a model for organizing various types of knowledge in a curriculum. In this model, we combine Gagné’s capability and instructional event theory with Bloom’s objective theory to define a kind of transition nodes that organize tutoring activities to achieve domain capabilities (Guo 98).

2.1. Tutoring Outputs: Capabilities and Capability Levels

Based on the analysis of human learning processes, Gagné classified human knowledge into following five kinds of capabilities: Intelligent Skills, Verbal Information, Cognitive Strategies, Attitudes, and Motor Skills (Gagné et al. 85, 92, & 93). The usability of such classification lies in that different teaching strategies can be used to teach them respectively. This theory is the foundation of our further discussion.
• **Capability Levels**

The capabilities defined by Gagné point to the general goals of topic teaching. In fact, teaching and acquisition of any capability contain some gradual sub-processes. For example, in the context of a course on Web page design, “Recognizing a Web page” is a capability. Some gradual sub-processes to teach the capability may be (1) teaching the Web definition, (2) teaching basic Web features, and (3) teaching advanced Web features. Corresponding to these sub-processes, the mastered degree to the capability may be divided into three incremental levels including (1) stating Web definition, (2) stating basic Web features, and (3) stating advanced Web features.

Our model associates tutoring activities with mastering levels of capabilities and students can choose any specified capability level as their desired learning goal.

2.2. Tutoring Activities: Transition Nodes

A major task in curriculum modeling is to organize tutoring activities effectively to support the achievement of teaching outputs. We define a kind of transition node for this purpose, which combines well-known instructional theories from Gagné and Bloom. Bloom (Bloom 69,78) proposed six levels of teaching objectives, including acquisition, comprehension, application, analysis, synthesis, and evaluation. These objective levels can be used to define various educational levels and position sub-processes of capability acquisition at a certain educational level.

Gagné (Gagné et al. 85,92) defined nine instructional events for capability transition. They are (1) gaining attention, (2) informing the learner of the objective, (3) stimulating recall of prerequisite learned capabilities, (4) presenting the stimulus material, (5) providing learning guidance, (6) eliciting the performance, (7) providing feedback about performance correctness, (8) assessing performance, and (9) enhancing retention and transfer. This theory outlines detailed sub-processes of human teaching. Gagné uses these events for individual capabilities.

In order to support the acquisition of multiple level and aggregated capabilities, we use Bloom’s objective level theory to organize tutoring units. For each objective level, Gagné’s instructional event theory is a good way to organize sub-units. Our transition nodes are defined based on both theories.

• **Transition nodes**

A transition node is a sequence of tutoring units (Fig. 1). Each tutoring unit consists of a sequence of sub-units and relates to certain output capability levels. These units correspond to and are not limited to Bloom’s objective levels. Each sub-unit contains one or more groups of resources and is where the actual teaching is taking place.
One activated condition of a transition node is that all its prerequisite capabilities be mastered at the required levels. When a tutoring unit is activated, a series of interactive activities takes place. The output of these activities is the acquisition of some output capability levels.

The Fig. 2 is an example of transition node for teaching “Stating what is a Web browser”. This transition node consists of three tutoring units that are “Teach browsers’ description”, “Teach browsers’ job” and “Teach popular browsers”. Each unit contains a sequence of sub-units. The prerequisite capability of the transition node is “stating Web” with 3 mastered levels: “stating Web description”, “stating basic Web features”, and “stating advanced Web features”. The output capability of the transition node is “stating Web browsers” up to 3 levels: “stating description of browsers”, stating job of browsers” and “stating popular browsers”.

In a transition node, each tutoring sub-unit contains one or more groups of didactic resources that consist of various organized media, simulation programs and guidance programs.

Figure 2 Example of transition node

Figure 3 Capability transition network for teaching a part of UML

2.3 Capability Transition Networks

A curriculum author can use prerequisite links to establish the relationships from capability nodes to transition nodes and use output links to associate transition nodes with output capabilities. Such constructed network is known as a domain capability transition network, simply called Tnet:

The Fig. 3 is an example of capability transition network for teaching a part of UML. In the example, there are four transition nodes (big nodes in Fig. 3): “analyze Scenarios”, “analyze Use Cases”, “analyze Objects (temporal) and “analyze Objects (spatial). The four transition nodes support the achievement of four capability nodes (small nodes in the Fig. 3) respectively: “define Scenarios”, “Identify Use Cases”, “create Sequence Diagrams” and “create Collaboration Diagrams”.

3. Visual Guidance in Learning Process

The originality of the visual representation in our curriculum model lies in the visual properties associated with the various graph components. These properties are highly dynamic, changing for instance with a student’s learning progress and with alternative information requests.

3.1. Visually Declaring Known Capabilities and Establishing Learning Goals

In our curriculum model, a learning goal is a specific level of a capability. For example the capability (shown in the Fig. 4) “Applying Links in HTML” contains four incremental levels: “creating links”,

394 BEST COPY AVAILABLE
"linking local documents", "linking other Web documents" and "linking specific place within a document". A learner can choose any one of the levels as one of his/her learning goals.

<table>
<thead>
<tr>
<th>Applying Links in HTML</th>
</tr>

</tr>
<tr>
<td>Linking Local Documents</td>
</tr>
<tr>
<td>Linking Other Web Documents</td>
</tr>
<tr>
<td>Linking Specific Place Within A Document</td>
</tr>
</tbody>
</table>

**Figure 4** A capability in HTML curriculum

In order to help students declare their known capability levels and establish their learning goals, the system defines a group of rules for dynamically infer students' current knowledge states.

Another group of rules is defined for setting learning goals. An example for setting a goal capability and its levels is as follows. Let $C$ be the overall cell of a capability icon, $L$ be the ordered set of all level cells in the capability, $L_i$ ($i = 1, ..., n$) be a level cell, and $L_g$ be the index of the goal level in the capability icon, one of the rules for the state transformation of goal capabilities is defined as:

$$R_{g5}: \text{if } C \text{ is not a goal } \& \ L_i (i < n) \text{ is clicked } \& \ C.\text{state} \equiv \text{CAP UNCONCERNED} \text{ then } C.\text{state} \leftarrow \text{CAP NOTHING MASTERED} \& \ L_i.\text{state} \leftarrow \text{LEVEL GOAL} \& \ \text{for all } j \neq i, j \leq n, L_j.\text{state} \leftarrow \text{LEVEL NOT MASTERED.}$$

3.2 Visualizing Alternative Courses

In order to individualize domain capability transitions, we define a course as a sub-network of the domain capability transition network, in which only the selected learning goals (i.e. some capabilities and levels) and some necessary prerequisite capabilities are included. Our curriculum model provides an approach to create alternative courses for the same group of learning goals (the details of course generation will be discussed in a separated paper.).

As soon as the learner selects a course, the system assigns the selected course as the learner’s current course. With the help of tutoring delivery module in ITS, the learner, then, can leaner the course.

The following Fig. 5 presents an example of creating multiple alternative courses based on the previous Tnet in the Fig. 3. A learner sets the first level of the output capability "create Sequence Diagrams" as his learning goal. The learner can choose one of the four alternative courses as his/her current course to learn, according to the information about effort, resource types and involved sub-goals provided by the system.

3.3 Sequencing Tutoring Activities by State-Driven Reasoning

In order to identify the availability of a tutoring unit in a learning process, we define five kinds of states for transition nodes, tutoring units and sub-units, which are **recommended**, **enabled**, **partlyEnabled**, **disabled** and **passed**. If a unit or sub-unit’s state is **recommended**, it is the best tutoring unit or sub-unit for the learner to learn immediately. If its state is **enabled**, it is not the best tutoring unit or sub-unit though it can be learned currently. If its state is **partlyEnabled**, only parts of the unit or sub-unit may be learned. If its state is **disabled**, the learner cannot learn the unit or sub-unit immediately. If its state is **passed**, the unit or sub-unit has been passed successfully by the learner.

- **States of Transition Nodes**
We define 19 rules to identify the states of tutoring units and sub-units, in which, for example, let $U$ be a tutoring unit, the rule No. 5 is

**Ra5**: if $U$ is enabled & $U$ and the last executed unit have the same parent goal, then $U$ is recommended.

Based on these rules, the system dynamically refers the current state of teaching activities and guides the learner with rich visual properties.

![Figure 5 Four alternative UML courses](image)

**State of Capability Nodes**

The states of capability nodes reflect the mastering degree of domain knowledge of a learner. We define two groups of states for capability nodes and their levels respectively, in which each group consists of five states: UNCONCERED, NOTHING_MASTERED, PARTLY_MASTERED, GOAL_MASTERED, and FULL_MASTERED. Based on the evaluation to the results of teaching activities, the system uses a group of rules to dynamically change the states of capabilities and their levels. Meanwhile, a group of visual properties related to capabilities and their levels are used to guide the learners.

**Conclusion**

The paper focuses on the visual navigation for learning processes based on a curriculum model proposed. The model supports aggregated domain capabilities so that it simplifies the overall system structure. Its visualization properties and the integration of well-known instructional theories achieve a practical and useful application of these theories.

A student can use various visual properties to establish his/her learning goals. The system, then, creates and displays multiple alternative paths to achieve these learning goals. In the learning process, the system
dynamically catches and displays the learner's current states and displays the next recommended step. The proposed approach is implemented as a Java application called VITCAM (Guo et al. 98b).

Abstract: This paper describes a distance-based collaborative process undertaken to evaluate an asynchronous web-based course designed to teach web design skills to students enrolled in a distance-based Master’s program. Several forms of collaboration were used to allow two expert reviewers to share their opinions on the course without actually meeting face to face. Comments and suggestions were passed between the reviewers and the course designer, culminating in a comprehensive review document containing aggregated suggestions for revision of the course. Although the process proved successful, care should be taken when undertaking such a process to avoid stumbling blocks brought about by the psychological distance involved.

Introduction

The purpose of this paper is to describe a distance collaborative evaluation method employed to analyze an asynchronous web-based course. This course is offered through the Instructional Technology department at Virginia Tech as part of a distance education Master’s program. An initial Expert Review of the course was commissioned by the Virginia Tech Instructional Technology department as part of an assignment for a graduate course in product evaluation. A first year doctoral student from Virginia Tech followed specific guidelines provided by the department to complete the review process. Several leading instructional design models were utilized to conduct this initial review and will be described below. After completion of this initial review, a second doctoral student, this one from the University of Georgia, reviewed both the web-based course and the first reviewer’s comments. The cumulative review of the first two students was then passed on to the course developer. The course developer added his own comments and incorporated student feedback into this collaborative review. All of the information was then re-circulated and a consensus reached that incorporated all the information into a collective list of evaluative recommendations. All correspondence between the three reviewers was accomplished using a variety of distance-based collaborative processes, including phone, email and videoconferencing. The background behind the initial online course offering will now be discussed.

Background

With the recent adoption and mandate of the Virginia Standards of Learning (SOLs), k-12 instructors throughout the state are now required to take coursework for re-certification that demonstrates a set of core technology competencies. In efforts to support this statewide endeavor, Virginia Tech developed and implemented an Instructional Technology Distance Education Masters Program (ITMA). This online program consists of 13 unique ITMA modules that can be taken independently of each other as needed to satisfy Virginia SOL re-certification requirements, or in total toward the Virginia Tech Master’s degree program. The instructional delivery methods Virginia Tech utilizes employ an assortment of strategies such as intensive workshop-style courses offered within individual school districts (on-site); interactive television courses offered...
through a number of state-wide facilities; web-based courses; week-long, on-campus summer courses; open-
studio development; and individual computer-based programs.

Our evaluation concerned itself specifically with "Module 4: Web Site Development" (available at
http://psyche.ed.vt.edu/module04/). The intent of this module is to provide learners with basic HTML design
skills using Netscape Composer, such that they develop a 7-8 page standalone web site. Should the learners not
be taking this module independently, but as part of the overall Virginia Tech ITMA program, their product will
be integrated into a larger electronic portfolio. There were 51 students who participated in the first iteration of
the module. These students were divided into three cohort groups based on their geographic location within the
state of Virginia. They constituted a diverse mixture of elementary and middle school teachers, librarians, and
instructional technologists in the public school system. The initial Expert Review evaluation process will be
discussed next.

The Initial Review Process

The overall model of the Expert Review was patterned after the procedure outlined in the book Planning and
Conducting Formative Evaluations (Tessmer, 1998). Tessmer delineates the steps and values behind
conducting the following types of reviews: One-to-One, Expert Review, Small Group Evaluation, and Field-
testing. The Expert Review conducted on Module 4 focused specifically on the following areas: General
product description, instructional components, instructional contexts and functions, and overall instructional
message display. A brief description of these areas will now follow.

The general product description delineated the developers, clients, module objectives, learning environment and
media characteristics incorporated in Module 4. The "instructional components" section evaluated the overall
structure of the module from a Walt Dick and Lou Carey instructional design perspective (1996). In addition,
several other ID research theories were employed which will be discussed later. The instructional context of the
module was examined to evaluate the synergism between all the factors influencing the appropriateness of
context chosen and under what functions it was intended to facilitate instruction. The overall message display
was additionally evaluated with respect to the following: layout, color, density of information, perceived units
of information, rate of information presentation, and appropriateness of images and/or audio used. Now that an
understanding of evaluation components has been described, an elaboration of the ID research models
employed will be discussed.

To evaluate the overall module from a "Big Picture" perspective the Walt Dick and Lou Carey model was used
(Dick & Carey, 1996). The following components were examined in the module for their inclusion of
appropriate sub-component characteristics: Introduction, activity, practice & feedback, review, assessment and
transfer. Within this overall structure, the individual instructional objectives were examined using the
were examined with respect to observable and measured behaviors, with proper attention to conditional givens
and standards.

The work of Tessmer & Richey (1997) was used to classify and evaluate the module with respect to the
appropriateness of context and its function within the overall design stages of orienting, instructional, and
transfer (Tessmer & Richey, 1997). Module 4 employed the contexts of "Real" and "Tutorial" appropriately.
J.M. Keller's ARCS model of instructional design was utilized to evaluate the module from a motivational
perspective, attempting to identify if the following strategies were implored: Attention, Relevance, Confidence,
and Satisfaction (Keller, 1987). Finally, the work of Gagne and Driscoll was utilized to measure the
appropriateness of instructional objectives to specific tasks or lessons at hand (Gagne & Driscoll, 1998). Now
that the research behind the initial Expert Review has been presented, the process of the distance collaborative
Expert Review model will be discussed.

The Collaboration Process
The original Expert Review (ER) paper was circulated to the second distant expert reviewer. The second reviewer then visited the Module 04 web site, reviewed the ER paper, and evaluated the initial reviewer's criteria against the originally commissioned guidelines and the actual module, inserting comments into the original ER paper using a different colored font. The updated ER paper with comments was then circulated to the module developer and the initial reviewer.

Next the developer's implementation perspectives were incorporated as a separate section at the bottom of this evaluation paper, describing the technical difficulties encountered during the module's first field test, including student impressions of Module 4's effectiveness. This updated document was then sent to both reviewers who additionally commented on the developer's implementation analysis. Finally, having now seen both sets of Expert Review comments in a single document, the developer offered his impression of the expert reviews. Needless to say, this asynchronous distance evaluation approach involved several iterations of circular review, providing a thorough analysis of the module from an ID Expert Review perspective.

The techniques employed in the collaboration process utilized several forms of distance communication. The review document was created in Microsoft Word and passed between reviewers via email attachment. Discussion and debate between the reviewers took place using email, teleconferencing, and videoconferencing. The important realization to come out of this process is that without in-person, face-to-face contact there is a higher probability for miscommunication to occur between participants, especially when those participants have never met face-to-face. At several points during this collaborative project there was confusion due to misunderstandings created by the psychological distance between the three reviewers. Next discussed will be a synopsis of the aggregated conclusions found between the three independent reviews.

### Aggregated Conclusions

Both expert reviewers agreed that overall the site was exemplary. The module was well designed, easy to understand, implement and execute. The site was additionally aesthetically pleasing from a graphical design standpoint. Most importantly the asynchronous module was successful in its instructional goal of facilitating the learner with the creation of standalone web sites. Both the director of the ITMA module, Dr. Greg Sherman, and the participants commented favorably in survey reviews at the completion of the module.

From an instructional design standpoint, only a few suggestions were put forth, which may improve the effectiveness and efficiency of the module. The comments that follow were the collective agreement from all three parties. First, there may be a benefit to incorporating an official assessment for each sub lesson within the overall unit by way of a rubric. This rubric would specify evaluation criteria, thus providing a way for the learner to check their work prior to submission. In addition, the Composer tutorial should include instruction specific to the Macintosh platform. This could be done by incorporating Macintosh examples in the existing tutorial, or by creating a new tutorial specific to the platform.

Also, a separate lesson dealing specifically with tables may be warranted, incorporating additional instruction and a student-2-student collaborative constructivist model. Finally, the overall module may be made more effective should all lessons utilize more examples of student work tied to reflective collaboration. It should be made clear though that these suggestions are unproven at this juncture, and their success must still be borne out in future revisions through evaluative field-testing.

Prototypical Development of Multimedia Explorations with Preventative Medicine as an Example

Thorsten Hampel, Thomas von der Borch

Germany
hampel@uni-paderborn.de

Abstract: Explorations evolve from the concept of developing modular designed learning software. As the prototype modules are for a specific subject field, they represent an interactive environment, which— independent of a didactical global concept— can be flexibly embedded in currently available web-based learning environments. Unlike a classical simulation, one has the possibility whilst carrying out given experiments, medical processes or technical construction problems to individually customise the structure or even produce one's own constructions or parameters—not only to adjust parameters. With it, an instructor is able to set constraints in order to achieve a specific learning goal, and in turn their adherence can be proven. The immediate response allows the learner to gather experience in an easy and playful way, and it guarantees direct and clear access to a region of imparted knowledge.

Introduction
A very important problem, for which a need of information exists that should not be underestimated, is the hardening of arteries. According to a number of statistical surveys growing prosperity in the industrial nations gives rise to heart and circulation diseases, which represent the most common cause of disease and death in such countries. Damage to the artery system is usually the culprit, where in such cases cholesterol (see Roche, 1998) has been the major cause of the contraction of the artery.
An excessive intake of the "nasty" cholesterol "LDL" (Low Density Lipoprotein) cannot be counteracted fast enough with the good cholesterol "HDL" (High Density Lipoprotein), and thus it lingers in the internal layer of the artery (Initima), and, after a short period of time, it is modified by a chemical oxidation. HDL is no longer able to transport modified LDL away, and so the so-called "eat-cells" (macrophages) must absorb the modified LDL through a process called phagocytosis. If the macrophages absorb too much of the modified LDL, they die and mutate into Xanthom-cells and deposit plaque on the walls of the arteries. The balance between LDL and HDL is crucial, which should not rise the limit of 3.5. Malnutrition, smoking, lack of physical exercise and an excessive consumption of alcohol give rise, among other things, to a dangerous surplus of LDL.

Figure 1: Cholesterol, C_{27}H_{46}O (left) from (Emsley 1996), right picture (CPRRC 1999): "Cross section (right) is that of an artery wall showing atherosclerosis plaque (middle layer) with cholesterol 'clefts'. The cholesterol 'clefts' are shown as the white streaks throughout the plaque layer."
A second fundamental cause of the hardening of the arteries is the natural deposition of calcium in the arterial system. It is possible to dissolve the calcium attached to the artery wall with particular injections. The calcium is then broken down in the kidneys and later excreted. A risky surgical operation, involving the pumping up of the artery with the use of, for example, a balloon, is thus unnecessary.

With high blood pressure over 150 mmHG the danger exists that apertures form in the artery walls. A large amount of blood platelets (thrombocytes), which are responsible for the blood clotting, travel to the apertures and attempt to close them up. The accumulation of the thrombocytes leads to a so-called thrombus, where a blood clot forms within a blood vessel and remains attached to its place of origin, hindering the blood flow.

Over time these causes lead to an artery blockage, which can then lead to an insufficient supply of oxygen to the organs. If arteries attached to the heart or near to the brain are affected, in the worst case it can lead to an acute myocardial infarction or stroke.

Information for people affected and for those interested in effective preventative measures is ample. Due to its degree of complexity and current relevance this medical application is ideal to use for the development of a three-dimensional exploration (for the concept of explorations see (Hampel & Nowaczyk 1999) and (Hampel 1999)).

Developing a three dimensional exploration

The exploration environment "Athero" developed from this specification can provide information about a person at any time. Thus exploring with the system is made possible, in which the user is able to input the initial situation and continuously adapt it to his/her way of life during the simulation at their will. Finally, the user is able to observe which processes within the arteries are provoked, depending on the input parameters. Through interactive intervention in the scene, the user is able to gather information about single blood components in the form of HTML texts and images as well as in the form of audible documents. These forms of media are opened in an additional browser window. It is expected that the provision of a greater number of interactive possibilities will provide the user with a better understanding of the problematic nature.

To ensure that the public at large have unrestricted access to "Athero", it should be made available via the internet. In order to do so it was necessary to develop "Athero" in such a way that it could be loaded into a Web-Browser such as "Netscape" or "Internet Explorer" (At the moment with a Java plugin as current browser do not support the newest Java-version (see Java Plugin)).

In order to provide a clearer understanding of the 3D-System, and to reach a suitable speed, at which the complex 3D-scenes will be displayed, the visualisation is limited to the effects of the LDL, such as the natural hardening of the arteries at age of 40 and the creation of thrombocytes in the case of endothelium related injuries. The information system can, however, be extended at any time. For example, additional objects could be inserted into the scene, which could also lead to arteriosclerosis, without sacrificing its clarity. The rules used to calculate the HDL and LDL concentrations, with relation to the other adjustable parameters, are easily interchangeable.

Figure 2: The Athero main window
The model and the scene

One section of a pulsating artery is displayed in a graphic formation, in which different components of the blood flow; such as thrombocytes (responsible for clotting), erythrocytes (red blood cells, responsible for the transportation of oxygen), leucocytes (white blood cells, responsible for the repulsion to penetrate cells during an infection), macrophages (so called eat-cells) and LDL. The user can see that under normal external conditions, the erythrocytes, on which it mainly depends, as they supply the organs with essential oxygen, still flow unobstructed through the arteries. If there is an increase of artery blockage through the formation of calcium, plaque or thrombocytes, the flow of blood cells is restricted, and the cells are left to revolve on the spot for a while to allow a smaller number of erythrocytes to flow out the other end of the artery. This leaves the organs with a lack of oxygen. It is possible to influence the external factors such as appearance of age, height, weight, exercise, consumption of alcohol and cigarettes, and blood pressure. The individual parameters are analysed by the program and displayed accordingly in the 3D-scene with the increases and decreases of LDL and HDL. On the other hand this has an effect on the other components of the blood as well as on the artery walls.

With the use of the mouse the user is able to interact with the 3D-scene from, for example, expanding the artery to giving a virtual injection. With a single mouse click accurate information regarding individual objects can be obtained. In order to describe the physiological construction, the task and possibly the current condition of the selected object more closely, a text, graphic, video-sequence, or an internet link to a web-site will be displayed in the browser. In another control window the user has the possibility to select a number of different viewing positions for the artery. And finally, a "camera tour" can be initialised, in order to view some objects more closely.

As mentioned earlier, the LDL and HDL concentration is a very important factor for the development of arteriosclerosis. Unfortunately, it is not possible to draw up "ten golden rules" for the calculation of LDL or HDL concentrations, rather the values rise and fall, depending on the probabilities to be calculated. To determine the concentration of cholesterol details such as age, height, weight, physical behaviour, cigarette and alcohol consumption, blood-pressure, and a person's vitamin E content need to be given.

Depending on these parameters updates and "calculations" are carried out at regular intervals in an update method, which, in accordance, controls the processes in the artery.

![Figure 3: Erythrocytes (red blood cells, responsible for the transportation of oxygen), leucocytes (white blood cells, responsible for the repulsion to penetrate cells during an infection) and thrombocytes; from (DRK Lichtenstein 1999)](image)

Establishing the factors that influence the rise in LDL by calculating the BMI value (Body Mass Index: determined from the age, height and weight and used to determine whether a person is overweight) is among the steps belonging to the updating process. Another is the evaluation of cigarette and alcohol consumption and adjusting the LDL values accordingly. Reducing the LDL values and increasing the HDL values through exercise as well as a low alcohol consumption leads to an LDL reduction which, in turn, leads to increased HDL values.

After adjusting the LDL and HDL values, the LDL-HDL relationship is calculated, and depending on the result a modification probability of the LDL particles that are momentarily present in the internal artery layer is calculated. The LDLs are then possibly modified, absorbed by the tissue or are taken away with the HDL. In the latter case the cholesterol concentration must be reduced in the tissue.

In addition to the LDL-HDL relationship, the probability for an endothelium-related injury caused by high blood pressure is calculated and an instruction to close the endothelium-related injury up is passed on to the thrombocytes. From an age of 40 years the probability for calcium deposits that occasionally need to be produced increases. A serum can be administrated with a virtual injection, which prevents the development and the growing of calcium deposits. If this serum is available in the blood it will be reduced over time.

Leucocytes, which are responsible for the transportation of bacteria, are produced when an infection exists in the body that gives a higher reading than 37.5 °C on the thermometer. On transportation the body temperature is reduced.
slightly, showing the fight that the leucocytes put up against the infection. If modified LDL is found in the blood, macrophages are produced, which eliminate them.

The demand for three-dimensional representations of objects, increased interaction, exploring with the system, publication in the internet and last but not least the possibility to develop the software in an object-orientated way has led us to the use of Java3D.

Figure 4: The Athero main and navigation window

**Developing Athero in Java 3D**

Ever faster processors and graphic cards offering ever more memory enable complex and detailed real-time three-dimensional universes to be displayed. Going under the idea of "Learning with multimedia" one can build virtual models, which provide the building blocks for three-dimensional exploration systems. Both Java3D (see (Java 3D API), (Brown & Petersen 1999) and (Sowinzal et al 1997)) and VRML (see Web3D Consortium) are suitable for the representation of these animations.

Java3D is a class library for Java. It makes an extensive range of commands and 3D-features available to the developer, as well as high- and low-level graphic programming to create interesting three-dimensional models. It should not be forgotten that VRML is a description language that is totally independent of a programming language. It is a file-format for 3D-data in WWW that allows complex fixed 3D-universes to be presented. The more animations, interactions and calculations are integrated into the 3D-models, the more suitable Java3D is.

The Java3D API (Application Programming Interface) is a library of Java classes for the presentation of 3D-universes. It contains a graphical run-time system that offers an object-orientated, high-level programming model to the developer, with which they can develop sophisticated, interactive 3D Java applications and web-based applets.

As Java3D is a class library of Java it offers the developer all graphical support within the three-dimensional area, with which they are able to construct 3D-objects as well as different structures, with which the objects are rendered ready.

On the one hand it is a matter of suitable data structures, while on the other hand it is matter of methods used to display data. The fundamental concept of this implementation is to cover the hardware specific details with a general interface. Java 3D relies on low-level technologies such as OpenGL (see SGI OpenGL), Direct3D (see Microsoft DirectX) and inherits ideas from QuickDraw3D (Apple's implementation of a 3D graphics library, see (Apple Quicktime)).

Java3D fits seamlessly into the whole concept of Java. A great advantage of this programming-language is the flexibility offered by such platform independence. Implementation is currently provided for Windows, Solaris and Linux. During the development a lot of weight was placed upon the performance, which was achieved with parallel rendering. In addition, Java3D was optimally designed for the future development of hardware such as cluster and multiprocessor systems, as one stays on a comparatively abstract level whilst programming and allows Java3D to do the optimising.

Another advantage is the support of different file formats. For this purpose, among others, the portfolio-package by NCSA (see NCSA Portfolio) offers loader-classes of all current 3D-graphic formats, such as 3D-Studio, True-Space,
Digital Elevation Map, Lightwave 3D and many more. During run-time in the 3D-scene additional complex VRML-universes can be loaded with a so called VRML-loader (see VRML loader) available from Sun Microsystems. Java3D is not exclusively for laying out static 3D-universes, it also explicitly supports the drafting of dynamical 3D-scenes. Applications are able to react to user inputs, perform calculations, construct 3D-objects, manipulate them in any way, and add or delete them, all during run-time. These objects (3D-models and sounds) are placed in an virtual universe, which is then rendered functional. To increase the multimedia quality of the applications they can be fitted, without great effort, with extra characteristics such as video sequences and pictures.

Apart from its "Write once, run anywhere" philosophy 3D API has other advantages. Because it is a member of the Java family it is entirely designed in an object-orientated way. Although the object-orientated design usually offers itself to the programming of graphics, in previous packages such as Open GL this aspect was generally dealt with in a secondary fashion. Thus the job of development, servicing and the extension of existing software has been enormously relieved.

The scene graph based 3D-modell, which is based on Java3D, helps even the inexperienced developer with the integration of multimedia and graphic programming and 3D-effects into its applications. Despite the wide scope of functions offered by Java3D an experienced Java programmer will find it easy to learn—in contrast to low-level, procedural APIs such as Open GL. The rendering of objects is handled in an automatic way and with the insertion of threads it is possible to work on different functions in parallel. They can also be carried out with the use of different computers. Apart from simplifying the development of software with Java3D, the package also offers sufficient performance for computers currently available. This is quite remarkable if you stop to think, that Java belongs to the interpreted languages.

A Java3D program creates Java3D objects and places them in a scene-graph. The scene-graph resembles a tree data structure constructed by different objects; it describes both the content of the virtual universe as well as the rendering of it. In order to optimise the scene-graph it is possible to compile it after its creation. In order to manipulate the scene-graph during run-time, so called capability bits are used, which define the manipulations that are allowed to be made.

As a result Java3D is ideal to be used in interactive 3D-environments such as games, simulations and explorations. Effective animations can be produced with the Java3D class within a short time. While experimenting with Java3D a simple driving program was programmed within a few hours. The Java3D program creates a street with an asphalt texture and with median strip that moves to the direction of the viewer. Street poles pass rapidly on both sides of the street to give the impression that the user is really driving. To give the appearance of driving around curves the horizon moves from side to side of the street; just like the horizon created by a cylinder is produced with a scenery texture. The whole scene can be rotated, zoomed in or out and moved by the mouse on its axis. On a Pentium PC the animation runs astonishing fast. (A Java 3D program runs on Microsoft DirectX (see Microsoft DirectX) or OpenGL graphics devices and libraries installed).

To represent the street a simple rectangular plain was created with a 3D-geometry modelling program and converted according to VRML97. In order to reproduce the streets as true to life as possible, the street is given an asphalt texture, also showing the markings on the streets. Every single straight element on the street is given a "position behaviour", which moves the element on a straight route in the direction of the viewer. A number of elements lined up create an effect of driving.

The curves are also created with these street elements, but instead of being manipulated with a position behaviour, they are manipulated by a "rotation behaviour", which rotates them slowly from left to right. Because the elements of the curves are very close to the horizon, making them barely recognisable to the spectator, a shift in direction is avoided. The background is created with the help of a cylinder at the zero point. As a large enough radius and landscape texture are provided, the spectator receives the perfect illusion.

The architecture of Athero—overview
In Athero the 3D-capabilities of Java3D API were used extensively in order to develop an attractive exploration. The ever present object-orientated programming makes maintaining and extending the application considerably easier and simplifies the transferring of real objects with their tasks and characteristics to the computer model. Extending is particularly important, as—out of time and technical reasonsthe simulation is not limited to itself, rather continual development in the knowledge of hardening of the arteries is necessary. The possibility should exist to integrate, for example, new blood-particles that participate in the hardening of arteries in the simulation. Moreover, it is possible to change the method, with which the LDL/HDL-concentrations are analysed, by current calculation possibilities. The behaviour of the single objects always tends to direct to this method.
The application has two frames. The main frame includes a panel with the 3D-canvas, on which the 3D-simulation is displayed, and beside it is a panel with sliders and buttons to adjust the parameters. The second frame is equipped with a 3D-canvas, on which VRML-models of video-cameras are placed around a cylinder representing an artery. The cameras are situated at four different positions in the virtual room, from which the viewer can follow the scene at the main window. The use of a menu was avoided, as the influence of the simulation is limited to changing the parameters of different objects with the help sliders and buttons and also from mouse clicks.

All 3D-models used such as the artery, the erythrocytes, the leucocytes etc. are loaded as VRML-models and can therefore be replaced by the user. On slow computers for example 3D-objects can be exchanged with models with a low level of detail. Athero runs equally well as an applet in a web browser and as a stand-alone application in a DOS-Box.

Outlook

In the future smaller exploration systems, in which constructive theories are transferred, can be used for teaching in schools or in universities. Due to the ease and quickness of production, not everything depends on developing lifelong simulations. If an application proves to be useless, it can be simply done away with.

It is realistic to imagine that pupils and students will develop applications on their own with the help of Java3D explorations or work with them to gain a better understanding of complicated issues. The availability over the net also offers an advantage. People wanting to learn have the possibility to do it simultaneously without being restricted to a specific place and through it gain experience with mutual interaction and a better learning affect. These kinds of exploration environments could find an application in the school classroom or in local or even intercontinental seminars.

The use of such systems, such as the simulation of the hardening of the arteries, is conceivable in hospitals or therapy centres. They could contribute to a better understanding of diseases and thus help a doctor or therapist to explain a diagnosis or its effects.

Scenarios of a New Dimension of Learning by the Co-operative Structuring of Knowledge

Thorsten Hampel
University of Paderborn
Heinz Nixdorf Institute
Computers and Society
hampel@uni-paderborn.de

Abstract: The initiative sTeam—structuring of information within a team—in Paderborn is developing an open and co-operative platform in order to equally enable learners as well as lecturers and scientists to organise and structure knowledge in a co-operative way. The following article presents the possible use of such an environment in form of application scenarios. In this context special emphasis is placed on integrating the developed tools and methods into a way of co-operative teaching that will also work in everyday life, i.e. the development of the so-called learning supportive infrastructures will be accelerated.

Introduction
Since the emergence of the Internet the application scenarios of this new, exciting and constantly expanding medium have continuously increased. Apart from the most well-known application, the WWW, different technologies have been developed such as chats, video-conferencing or network-supported multimedia databases which have gained broad acceptance by users. Current developments such as the expansion of e-commerce solutions or extensive network-supported libraries are unfortunately characterised by a limited commitment of users to contribute individual abilities or actively participate in organising the presentation of information.

The WWW has emerged as mere medium of information providers for the consumer. What is less important for online shops and web performances of companies turns out to be the decisive criterion for the use of the WWW as teaching and learning environment. Today’s WWW offers only marginal opportunities for the consumer to structure the presented information, to work on own documents or contribute them. Already at an early stage it had been realised from different angles that the possibility to contribute annotations and individual comments on the pages and texts is an important prerequisite for the successful application of such a medium in teachings (see Engelbart 1984). If the network is to be used as co-operation-supporting tool it will be essential for students and lecturers as well as for all users to have personal structures in the jungle of the WWW. Bookmarks as browser-dependent rudimentary structures are rather unsuitable procedures since it is neither easy nor unproblematic to provide them with annotations, pass them on (i.e. supporting co-operation) or structure them sufficiently. For this reason the so-called “lost in hyperspace” syndrome—a synonym for an inherent navigation problem in the network—is still omnipresent. It is true that the ever increasing number of Internet users has led to a shooting up of information, but the way of cooperation among users, i.e. the exchange of documents and information is furthermore limited to the sending of documents and web addresses (URLs) per e-mail.

sTeam—create an open and flexible platform for knowledge management
The following article aims at outlining new ways of using the Internet and its services (mail, news, ftp, WWW) to support teaching and is based on experiences of many years by the group “computers and society”. This working group has dealt with questions concerning the organisation of infrastructures for an active support of human learning. Basing on a number of existing technologies the sTeam approach contains the claim that existing services and systems can be integrated—by justifiable efforts—into an open user-centered platform.
During the last two years essential efforts have been made to approach our target regarding an open and individu- 
ally-made platform of existing and future technologies. The last paragraph of this article outlines the technological 
requirements to such an environment and makes clear that the only practicable way will be the implementation on an 
on-open-source basis.

In order to obtain an exact idea regarding the functionality of a platform that is supporting teaching at the university 
as well as scientific work, the focus of interest—as already mentioned in (Hampel 1999)—will not be the architec-
ture of such a system, but rather a possible scenario of the application in everyday teachings whereas this scenario 
will function as guiding criterion for creating the conception of a core architecture of the sTeam approach—"struc-
turing information within the team". Already existing prototypes of the sTeam system exactly aim at the fulfillment 
of the above-mentioned scenarios and will continuously be extended for realisation.

The lectures offered by the "computers and society" group such as "software ergonomics" aim at the active collabora-
tion of students. Apart from lectures, students will—in interactive exercises—be encouraged to develop own soft-
ware-ergonomic organisation processes and to evaluate existing systems. In the course of the work with a broad va-
riety of sources of knowledge such as laws, standards, style-guides or scientific essays, a number of systems have to 
be evaluated according to a number of software-ergonomic criteria. Experiences that have been gained in events 
during the last years show that students are only able to actively understand and internalise the handling of a multi-
tude of knowledge when they co-operatively use different media. In addition to this materials should be available at 
any learning places (see Keil-Slawik & Selke 1998). Already for some years sTeam has been working at the re-
search of concepts and tools to ensure the availability of documents at each learning place for the support of the stu-
dents.

Scenario of the application during lectures
In the scenario of the "software ergonomics" lecture the students are in the foreground. The lecture takes place as 
reference event in one of the interactive lecture halls (digital infrastructure for computer-supported co-operative 
learning) at the University of Paderborn1. sTeam as infrastructure and a number of co-operation-supporting tools 
provides so-called semantic spaces for the topic "software ergonomics lecture" (see Henderson & Card 1985). Se-
monic spaces contain all sTeam objects such as links, documents, texts, graphs, tools, annotations and any applica-
tion objects (presentations, spread-sheet calculation etc.). In relation to the example of the software ergonomics lec-
ture, current slide presentations as well as background information of the lecture can be presented, i.e. all docu-
ments, graphics and external resources the lecturer is referring to.

This inherently accessible stock of documents enables e.g. the lecturer to have direct access to a number of sources 
of knowledge during the lecture, to illustrate them actively or to react to checkboxes and suggestions of the students 
by additional illustrations or modifications of the material. Participating students are able to make annotations, i.e. 
adding personal notes to slides and documents or write down own texts or simultaneously link documents by hyper-
links.

The process of developing own mental structures during lectures has to be actively supported by sTeam and can—in 
contrast to most other available systems—also take place co-operatively. The hierarchy of groups and rights that 
refers to all objects within the sTeam system allows a complex specification of the access to annotations, links and 
documents. Such a concept allows students to meet in smaller groups and to more easily obtain specific information 
or to write down notes co-operatively as learning group. Apart from being a presenting event, the lecture also ac-
tively integrates spatially absent participants by means of communication mechanisms such as audio-, video chats, 
that have to be integrated into sTeam in advance. Thus students or lecturers are able to ask questions, make com-
ments or contribute documents to the lecture within the sTeam room via Internet. However, the sTeam approach will 
be most efficient if synchronous procedures change to asynchronous procedures, e.g. on supporting scenarios of 
practising individuals or groups, whereas the system—with all the documents and structures stored serves as basis 
for individual and group work. The students have access to learning material and their personally written down texts 
from different places (practising room, library, personal working place).

Application scenarios during practising include a fluent change of teamwork and individual work phases. The pro-
cedure of practising software ergonomics today, includes the active commitment of students to organisational mat-

---

1 DISCO (digital infrastructure for computer-supported co-operative learning), an advanced infrastructure in Paderborn, sup-
ports teaching and learning by means of multimedia. It comprises interactive lecture and seminar room, places of production 
for multimedia documents as well as working places that are connected with each other via networks, servers and services 
(more details in Keil-Slawik 1999).
ters. Solution proposals concerning exercises such as the software ergonomical evaluation of user interfaces can smoothly be performed by the sTeam concept. 

Students insert their solution proposals into the system in advance or find solutions by linking existing documents, e.g. screenshots of user interfaces or criteria catalogues with personal solution proposals within the learning and document environment. This process can be realised individually or even better in a co-operative way by combining different solution alternatives. The actual practising can be described as interrelation of presenting and discussing solution alternatives. After a short presentation of different alternatives and mutual constructive criticism and evaluations the found solution proposals will be linked as well as stored permanently and archived within the sTeam system.

In order to facilitate preparations for the exam later on, it will be very important to permanently store the found structure. Thus the students are e.g. able to evaluate co-operatively different e-commerce solutions of the WWW (e.g. by a shared browser) during practising “software ergonomics” whereas comments will only be visible for the participants. In a parallel working step links are installed to software ergonomical criteria or available laws and standards of the learning environment (e.g. European Union ergonomic guidelines). Important passages out of textual chats can be used, i.e. translated as annotations or new documents by means of drag&drop mechanisms. Organisation proposals done by the students can be filed in the same way and without difficulties in personal and mutual working fields (semantic spaces). Thus the students are able to develop drafts and prototypes of user interfaces in Java by using tools for organising the surface (interface builder, e.g. by visual programming) and file them in context to corresponding lecture documents.

The concept of the so-called semantic maps (see Klemme et al. 1998) which was developed by the group “computers and society” has proven to be one further indispensable instrument to media-supported learning and has also been integrated into scenarios of the sTeam concept.

Students use semantic structures—provided by the lecturer—to navigate or make cooperatively semantic survey maps of the software ergonomics as part of an instructed exercise or for their own orientation. These maps may e.g. serve as criteria catalogues for the design of interactive systems or to point out the integration of this special field into other disciplines of the “Human computer interaction HCI” while the procedure itself demonstrates essential cohercences. Further application scenarios are the realisation of virtual office hours as periods of presence of responsible persons within documents and communication environments. The virtual office hours will as a consequence be able to contribute to an unproblematic clarification of content and organisation matters.

A close linkage of the synchronous communication mechanisms to an awareness information and the world of documents creates a new quality concerning computer-supported communication. Thus co-operative partners can be ascertained at any time while taking essential personal rights into consideration (all mechanisms are available on a voluntary basis), as well as documents and sources of knowledge they are currently working on or (by consulting the temporal history) who has performed which action (see Nomura et al. 1998). [Parallel to this it is possible to directly address individuals—by presenting the so-called Avatars—or a group of participants, thus encouraging discussions.] (The term “Avatars” is not necessarily connected with the concept of “spatial navigation”, which is a spatial real-world navigation). A shared-whiteboard supplies documents, tools or graphical elements to participating students. The students are able to transfer elements of their desktop, graphs, links and documents by drag&drop to a synchronous desktop without any difficulties, i.e. this desktop will—in virtual space—be visible for all participants at the same time. Designed to be an object-oriented whiteboard, i.e. some kind of desktop that acts with plain objects, such an approach allows to work with any digital media and resources within the team. Thus the dragging of a link from a browser leads directly to installing a link object within a sTeam space that has been assigned to the whiteboard or documents will directly be transferred to the database and are available to other users—in dependence of their documents—for co-operative processing and editing.

2 The term “Avatars”, i.e. the image of a user in a virtual world is—by sTeam—not understood as three-dimensional representation of users as it is in so-called Avatar-worlds (see Damer 1998).

3 The concept of “spatial navigation” has experienced formative influence by Greenhalgh and Bendford and their treatises concerning the MASSIVE system. It is about a three-dimensional world where Avatars move in “natural”, real-world forms and communicate by textual- and audio chat. This communication is controlled by the “spatial model of interaction”, i.e. communication will be conducted by the so-called “focus”, “nimbus” and “aura” of objects, i.e. their relative position and direction to one and another. The so-defined directions and spheres of activity of user awareness establish concrete fields of interest as well as differentiate between communicating groups and interactive persons (see Greenhalgh & Benford 1995).
Scenario B: sTeam as working place for scientists

The sTeam approach also offers new qualities regarding the use of the system as prospective working place for scientists. Analogous to the support of learning processes, certain functionalities concerning the filing, semantic structuring and linking of articles, publications, essays and documents are useful for the daily work of scientists. The discussion of different positions (articles and treatises) and its linkage beyond the limits of one server as well as the inclusion of any other sources of knowledge of the scientific network like other national and international research institutes permit a new form of high-quality co-operation in research and science.

In support of such co-operations it will be essential to have the opportunity to annotate different sources of knowledge in close connection to network-supported synchronous and asynchronous communication forms. Besides the co-operative processing of documents, the essential criteria for the acceptance of the tool strived for are conceptions of the development of different views within the sources of knowledge, i.e. the possibility of dividing a text into different paragraphs in order to sort them and make individual sections available for colleagues and co-operation partners. The individual marking of texts ("textmarks") is also an essential criterion to guarantee the acceptance of the tool. Facilities exist to work with texts and graphics actively and connect forum discussions and textual online communication forms to the capabilities of document management.

Approaches have been made in the field of graphical navigation and orientation maps (see supportive learning scenarios). These maps represent the semantic structure of learning materials and help to give learners and teachers orientation in various sources of knowledge. Therefore they also compensate the inherent problem of losing orientation in large hypertext structures such as the WWW.

Our approach—sTeam—as open-source initiative

The spectrum of concepts and approaches that have to be considered is very large when taking into account an open platform with a multitude of services, tools and architectures. Due to this, the following representation of current technological aspects only provides a brief and incomplete outline. The architecture of sTeam is based on a CVE—Collaborative Virtual Environment—and can neither be characterised as a mere synchronous CSCW (Computer Supported Cooperative Work) tool (see (Roseman & Greenberg 1996), (Patterson et al. 1990) or (Chabert et al. 1998)), nor as mere management of documents or workflow-oriented tool.

At the same time sTeam combines important concepts concerning the structure of paths through existing contents of networks—that aims at the navigation support of the user (concerning other similar approaches compare (Wexelblat 1999) or (Furuta et al. 1999)). By coupling one or several databases, managing abilities of users and objects will be supplied. In this sense sTeam impresses less as closed application but rather by its open and expandable framework architecture.

In this connection programming interfaces to individual tools and objects as well as a broad adaptability will be supplied to the users. Objects will—in sTeam—be provided with access rights and filed in this database while being able to access them by the network. sTeam offers the possibility by different access tools (frontends, clients) to file—in a structured way—objects such as documents, graphics, annotations or tools like shared whiteboards or message boards in semantic spaces. Within semantic spaces users are able to create their own links, modify any object and insert it again in dependence of their access rights. It is important that all abilities concerning the annotation of documents and inserting of links do not refer to locally filed documents within the sTeam databases. For this purpose solutions are searched that allow to include most technologies of the Internet. Thus it will be very important to intensify the integration of existing Internet formats and services. Within the application spectrum of the supplied communication mechanism, the conception of sTeam will on the one hand be designed for a mere asynchronous use (working with documents, supplying information by annotations) and on the other hand also for an intensive synchronous use (online co-ordination and online discussion, chat). In order to meet this requirement the supplied awareness information also has to be adjusted to this situation. The information degree that users reveal and receive

4 This process e.g. intends to integrate different functionalities out of the field of office systems such as data processing, picture processing or spread-sheet calculation by providing Java-based, i.e. browser-oriented services (e.g. the StarPortal approach of the SUN company: http://www.sun.com/products/staroffice/starportal/)

5 Compare the "lost in hyperspace syndrome", e.g. (Theng et al. 1996) "In general, the lost in hyperspace phenomenon refers to any of the following conditions: users cannot identify where they are; users cannot return to previously visited information; users cannot go to information believed to exist; users cannot remember what they have covered; and users cannot remember the key points covered."
of other users (where they are, what they perform at present) has to be designed for flexible use and adjusted to the
application context of the corresponding client.

An open platform requires the realisation of different clients and the use of specific tools within semantic spaces,
both in dependence of the users' needs. Thus tools for accessing materials have to be designed with different ap-
pearances and functionalities with regard to the number of users co-operating at the same time. The appearance of
the client concerning the integration into a conventional Internet browser as well as the adjustment of a working
environment and its fusion with the client (drag&drop of application objects into the sTeam environment) also have
to fulfil the above-mentioned prerequisites. The procedure of realising the idea of sTeam can briefly be outlined as
follows:

In the last two years the first step was taken by developing prototypes for the scrutiny of the conception. On the one
hand these prototypes try to realise the idea of semantic spaces in practice or to discuss details of the performed
coupling of a CVE with a database and its network-supported access. On the other hand these prototypes are to
guarantee the suitability of such an architecture for everyday use in teaching and research. Parallel to first pilot ap-
lications the creation of an open-source initiative (community)—concerning sTeam—is planned in expectation of
a broad integration of existing standards and tools. Moreover an open-source community concerning sTeam seems
to be a permanent alternative to commercial solutions and to guarantee constantly the topicality of the developed
platform. Under the aspect of topicality, expectations exist to place sTeam on a broad basis with co-operating and
discussing project partners as well as collaborating developers and thus being able to come up to the rapid develop-
ment of current Internet standards. Corresponding examples are the document format XML6 or the ISO-standard
“Topic Maps”7 which provides a standardised notation for interchangeably representing information about the
structure of information resources used to define topics, and the relationships between topics.—These new tech-
nologies have to be considered within the conception.

In order to realise an open-source initiative it will be essential to define interfaces carefully and to write sufficient
documentations to be able to co-ordinate a high number of developing initiatives. This can be pointed out as primary
tasks for the next months. In this sense the expectations are to break with usual practices of clarifying research
questions by prototypes and the consequences of not being available for a wide range of users. The bundling of ideas
and efforts within the community of developers of computer-supported co-operative work tools and Internet tech-
nology can only be realised by synergies of an open-source community. From this point of view sTeam represents a
consistently open platform for bundling the released energy.

Abstract: If a "picture is worth a thousand words," then why have attempts over the past decade to use pictures and animations to replace or supplement traditional instructional methods for teaching algorithms produced such disappointing results? In an earlier paper (Hansen et al. 1998) we described a research project based on the premise that a rethinking of algorithm animation design is required in order to harness its power to enhance learning. The key insight was that for algorithm animations to be effective, they had to be "chunked" and embedded within a context and knowledge providing hypermedia information environment. In this paper, we report on studies designed to discover which aspects of the prototype hypermedia visualization system that was developed (called HalVis) contributed to student learning. These preliminary studies led to a surprising discovery that interactive and animated analogies appear to significantly prime learning about abstract and dynamic algorithm behaviors from subsequent visualizations. This paper briefly describes the interactive features and learning modules of HalVis, then presents the results of two series of experiments conducted using HalVis that give insight to the use of animated analogies to enhance learning.

Introduction

Over the past decade, numerous studies and experiments have been conducted to evaluate whether graphically animating algorithm behavior improved student learning of this dynamic, abstract, and difficult subject (e.g. Byrne et al. 1996; Stasko et al. 1993). While the addition of pictures and animations are enthusiastically received by students, these studies have not proven conclusively that algorithm animations actually improve learning (see Hundhausen 1996 for an excellent survey).

We believe that previous attempts at using algorithm animations as learning tools were unsatisfactory not due to any flaw with animation as a technique, but because of the approach used to convey information using the animations. Animations by themselves, even when accompanied by some textual feedback and interactive control, may not be enough. In earlier papers (Hansen et al. 1998, Hansen et al. 1999), we presented research projects aimed at rethinking algorithm animation design. The prototype visualization system we designed is called HalVis (for Hypermedia Algorithm Visualization System). It is not a mere animation presenter in the mold of prior algorithm animation research prototypes. In some ways, its architecture resembles that of the algorithm animation system described in (Recker et al. 1995) containing multiple representations in addition to the animation itself. Following the design principles outlined in (Narayanan & Hegarty 1998), HalVis incorporates four unique features: (1) Providing three kinds of animations to illustrate different views of algorithm behavior - an animated analogy that illustrates the operational characteristics of an algorithm, a micro-level animation that focuses on details of the algorithm's behavior on small data sets, and a macro-level animation that shows the algorithm's aggregate behavior on large data sets; (2) Embedding animations within a hypermedia visualization that also employs textual descriptions, audio narratives and static diagrams to provide contextual information; (3) Presenting animations in discrete chunks accompanied by explanations of the specific actions being accomplished; and (4) Encouraging student participation by allowing rich interactions with the animations and using probes or questions to stimulate critical thinking.
Two empirical studies demonstrated that students using HalVis significantly outperformed those learning from a traditional textbook. Later, a third experiment compared learning about an algorithm from HalVis to learning from a compilation of the best algorithm descriptions and illustrations (generated by examining 19 textbooks published between 1974 and 1997) and subsequently solving a set of typical problems on the algorithm. In this case no significant differences were found between the group of students who learned by interacting with HalVis and the group which perused the printed materials and then solved several exercise problems, though the HalVis group had a higher post-test mean score. Two subsequent experiments compared learning by interacting with HalVis against learning from a typical classroom lecture and learning from an algorithm animation typical of prior research on this topic (Stasko 1997). In both cases statistically significant performance improvement was found for the groups of students working with HalVis. Thus, five empirical studies (summarized in Hansen et al. 1999) involving 133 undergraduates have thus far demonstrated that the HalVis system significantly improves student learning.

These results led us to ask the question: Which individual or combinations of features are producing the observed learning benefits? This paper describes the results from two experiments we carried out to help answer this question. These studies led to a surprising discovery that interactive and animated analogies appear to significantly prime learning about abstract and dynamic algorithm behaviors from subsequent visualizations. First, we present the interactive features and learning modules of HalVis. Then we describe the experiments conducted on HalVis. Finally, we conclude with a discussion of the implications of the results of these experiments.

Architecture of HalVis

HalVis is structured as three primary modules and two secondary modules. The primary modules are called the Conceptual View, Detailed View and Populated View. The secondary modules are called Fundamentals and Questions. The Fundamentals module provides basic knowledge and a context for understanding the algorithm being presented by the primary modules using illustrated and (in some cases) animated explanations of basic algorithmic concepts such as complexity, recursion and iteration. This module is accessible from all of the primary modules via hyperlinks. For example, if the primary modules are presenting a recursive algorithm, all appearances of the word "recursion" in these modules will appear as underlined hyperlinks to the corresponding descriptions and depictions in the Fundamentals module. The Questions module provides the learner with an opportunity to assess understanding of the algorithm by posing a series of questions and providing immediate feedback. These two modules were not the focus of the studies described in this paper.

The Conceptual View (CV) introduces a specific algorithm in very general terms using a real world analogy. The analogy is interactive (students can manipulate it), animated, and accompanied by text and audio explanations. Each analogy highlights the central conceptual elements of the corresponding algorithm. For instance, the analogy for the Merge algorithm (Figure 1) is animated playing cards which are divided into stacks and merged to create a sorted sequence of cards. A gaming mode is provided for the student to try to 'merge' the cards with fewest errors and minimal time. The animated analogy for the QuickSort algorithm is that of a coach ordering a set of players by height, using a series of moves illustrated through smooth animation that capture the essence of the QuickSort algorithm in terms of its fundamental operations. The Shortest Path algorithm used an analogy involving airfares between various cities, a typical problem facing travelers.

The analogies in HalVis can be described in several dimensions: (1) dynamics, referring to the sophistication of the animation; (2) fidelity, referring to how closely the features of the analogy maps to the central characteristics of the algorithm; (3) interactivity, referring to the level of immersion allowed to the user, ranging from simple pacing to competitive simulation; and (4) familiarity, referring to how common the objects of the analogy tend to be. The notion is that more is better for each of these dimensions to reduce the cognitive load imposed by the analogy. The more dynamic, the better the fidelity, the more interactive, the more familiar, the better.
The Detailed View (DV) is a module that takes the multiple representation approach to presenting detailed information about how the individual steps of an algorithm, when executed in sequence, manipulate data and accomplish a specific task (e.g., sorting a set of numbers). It presents four windows containing information that are synchronously updated as the algorithm processes user-selected input data sets: (1) the Execution Animation window shows how steps of the algorithm modify data structures using smooth animation of micro-level operations; (2) the Execution Status Message window provides comments and textual feedback to the student about key events and actions occurring in the animation, also available as an audio commentary; (3) the Pseudocode window shows statement-level algorithm operations by highlighting the statement being executed; and (4) the Execution Variables window contains a scoreboard-like panorama of the variables involved in the algorithm and their changing values. These four windows are shown in Figure 2a, which is a screen capture of one frame of the DV micro-level animation for the Shortest Path algorithm. The Execution Animation Window appears on the upper left (below the control buttons) of this figure, the Pseudocode window appears on the upper right, the Execution Variables window appears on the lower left, and the Execution Status Message window appears on the lower right.

The Populated View (PV) module presents a macro-level animated view of the algorithm's behavior on large data sets. A novel feature of this module is a facility for the student to make predictions about different parameters of algorithm performance, and then compare those against the actual performance when the animation is running. A sample screen of this module appears in Figure 2b.
Experiments

The number of novel features and modules that distinguish HalVis from prior algorithm animation approaches led to encouraging results but begged the question: Which individual or combinations of features produced the observed learning benefits? Our approach to answering this was to build different versions of HalVis by selectively disabling individual or groups of related features, and experimentally evaluate student performance using these versions against the original. We designed and carried out two such studies. The first experiment disabled one of the three views, giving the student two views with which to learn the algorithm. The second experiment disabled two of the three views, providing the student with only one view, as shown in Table 1. Each experiment is described below.

Table 1. Views Available to Groups for Experiments I and II

Experiment I Procedure: The first experiment involved 32 undergraduate computer science students enrolled in a third year algorithm analysis course at Auburn University. Four matched groups of students interacted with one of four versions of HalVis illustrating the QuickSort algorithm: (1) a complete version with all three primary modules/views enabled (referred to as the CV-DV-PV group or CDP for short); (2) a version with the CV disabled (referred to as the DP group); (3) a version with the DV disabled (the CP group); and (4) a version with the PV disabled (the CD group). A pre-test/post-test combination measured individual learning and improvement with questions that probed conceptual and procedural knowledge about the algorithm. Students were tested on their ability to recognize and reorder pseudocode descriptions of algorithms, mentally simulate algorithmic operations, and predict resulting data structure changes. Each group received a brief, navigation-only orientation to the version of HalVis they were to use, then were assigned to a computer and instructed to interact with the visualization until they felt they understood the algorithm. No time limits were imposed for the tests or the visualization.

Experiment I Results: Our hypothesis was that the most important view was the most information rich view—the Detailed View—and the groups that interacted with this view would outperform any group that was denied this view. Furthermore, we expected the Populated View would follow in significance and that the contribution of the Conceptual View would be the least. Figure 3 (left side) shows the average group improvement. As expected, the group that received all three HalVis views performed the best. However, these results also reveal a surprising impact of the Conceptual View. Contrary to our expectations, the groups that performed best were not the ones exposed to the Detailed View but rather the groups that interacted with the Conceptual View. The improvements of the groups that received the Conceptual View with another view were more than twice the improvement of the DP group. Table 2 shows a statistical summary of this experiment, presenting data for pairwise comparisons between each of the groups with access to the Conceptual View and the one group—DP—that did not have this access. Note that all comparisons yielded statistically significant results. Perhaps the most noteworthy observation from the results of this experiment was the effect of the Conceptual View in priming the learning of information presented in subsequent views. The groups that interacted with the Conceptual View in any combination with other views performed better than the group that lacked the Conceptual View. The impact of the Conceptual View was examined further in the next study that elided two views at a time.

Table 2. Statistical Summary for Experiment I
Experiment II Procedure: This experiment was designed to isolate each of the three views of our algorithm visualization framework to measure their respective impact and effectiveness. Procedurally identical to experiment I, twenty-seven undergraduate students enrolled in a third year algorithm analysis course at Auburn University participated in four matched groups: (1) the CDP group worked with a full version of HalVis illustrating a graph algorithm to find shortest paths between nodes; (2) the C group worked only with the Conceptual View of this algorithm; (3) the D group worked only with the Detailed View of this algorithm; and (4) the P group worked only with the Populated View of this algorithm. Our hypothesis was that the Detailed View would prove to be the most valuable because of the amount of information it provided. We were uncertain how the performances of the other views would get ranked, since neither the Populated View nor the Conceptual View contained the volume or depth of information available in the Detailed View.

Experiment II Results: Figure 3 (right side) shows average improvements observed in each of the groups. As expected, the CDP group outperformed the others, followed closely by the D group. Interestingly, the C group outperformed the P group by 21%. It is illuminating to note how well the C group did with the limited amount of information that they received. Table 3 summarizes the various statistical comparisons between the full-version group and groups with individual views, and between groups with individual views. Except for the CDP/D comparison, the results are all statistically significant.

Table 3. Statistical Summary for Experiment II

The importance of the Detailed View was confirmed, as was the value of the Conceptual View. We were surprised at the level of improvement observed in the group that only interacted with the Conceptual View, and this suggests that having a good analogy can produce surprisingly positive results. The performance of the Populated View group lagged behind the others. Yet the interaction logs we collected revealed that in each of the experiments, the animation in this view was executed about the same number of times as the animations in the other two views. Perhaps this serves as confirmation that some animations are merely 'candy for the eyes' in that they are entertaining to observe but not particularly informative. It should also be noted that the animation in the Populated View closely resembles algorithm animations developed in prior research. Interestingly, students generally commented most favorably about the animation in the Populated View. It appears that they thought they were learning more from the Populated View than was actually the case.
Conclusion

While we initially believed that the analogy/real-world example was a minor educational addition and feature of our framework, it appears to have a pronounced effect in peaking student interest and priming them for learning from subsequent views of greater detail. There exists a significant body of psychological literature on the role of analogies in communicating a target concept (e.g. Gentner 1989). Researchers have also investigated the educational value of paired interactive simulations as analogies which complement each other (Brophy & Schwartz 1998). However, we believe this is the first time that the role of animated analogies in understanding computer algorithms from visualizations has been empirically studied. The power of animated analogies in this domain arises from the fact that these provide conceptual bridges between familiar scenarios and abstract components of algorithms. It has been noticed that students tend to employ analogies in describing how algorithms operate (Douglas et al. 1995; Stasko 1997) and analogies can serve to provide a form of scaffolding (Hmelo & Guzdial 1996) for subsequent learning. Results reported here lead us to speculate that concrete dynamic analogies can prime students to learn better from visualizations of abstract dynamic phenomena. If confirmed by additional experiments, this has important implications for learning technology. Therefore, our future research is aimed at seeking additional empirical evidence regarding this conclusion. Finer grained ablation studies are being planned to examine the differential effects these features have on the ability of analogies to prime subsequent learning. Additional studies looking at the other features—animation chunking, animation embedding and rich interactivity—are also on the drawing board.

Designing Interactive Learning Environments to include construction tools for personally meaningful artefacts

Barry Harper, University of Wollongong, Australia
John Hedberg, University of Wollongong, Australia
Rob Wright, University of Wollongong, Australia

Designers of interactive learning environments, applying contemporary views of learning, are now employing design models that incorporate the variety of ideas that are based on constructivist frameworks. Designers are attempting to give learners control over their actions and place them into worlds that can be manipulated and interrogated. These environments, if well designed, can support learner construction of knowledge through structured or ill-structured problem solving experiences. Such frameworks are based upon arguments that learners should be placed in authentic environments that incorporate sophisticated representations of context through such constructs as "virtual worlds". Within these modern constructions, learners are often given a rich set of resources to construct artefacts which reflect their problems solutions.

However, researchers such as Seymour Papert have long called for more open environments drawn from a theoretical view of learning termed constructionism which is based on two different senses of 'construction'. It is grounded in the idea that people learn by actively constructing new knowledge as well as asserting that learners are particularly likely to create new ideas when they are engaged in 'constructing' personally meaningful artefacts. Multimedia authoring tools have long been used to address the latter component of constructionism. The challenge for researchers and developers is to find the balance between resource rich 'virtual worlds' with embedded tasks and open ended construction that may not be goal driven, both resulting in personally meaningful artefacts, i.e. are we designing for learning, or are we learning by designing? This paper examines three projects that demonstrate these issues.
Abstract: In recent years, virtual reality (VR) has become an increasingly powerful and inexpensive tool for developing interfaces for a variety of applications. Even though there has been an increase in the use of virtual reality (VR), there is a lack of software that bridges the gap between existing application programs and VR. This type of middleware is needed to manage the navigational interaction between existing application programs and VR. This paper describes a language for describing navigation behaviors in 3-dimensional worlds that could potentially serve as middleware. The formal language described in this paper permits precise navigation path specification and can be used as the means of mediation with application programs. The language can be used in achieving tasks such as exploring virtual worlds, programming the navigation and routing strategies for avatars, simulating the trajectories of virtual objects, and providing a formal description language for documenting user navigation in VR environments.

Introduction

In recent years, virtual reality (VR) has become an increasingly powerful and inexpensive tool for developing interfaces to applications such as architectural modeling, computer-aided design, data visualization, telecommuting, and environments for simulation and entertainment. Interaction in applications that incorporate VR as an interface is dynamic by nature. Users immerse themselves in 3-dimensional (3D) environments using specialized peripheral devices including head-mounted displays, data gloves, 3D-trackers and body suits. These devices enable users to experience rich stimuli and give them control over where they go and what they do within the confines of an application. This freedom is enabled by the ability to navigate in the world.

Navigation is an aspect of behavior that causes an object to change its location, orientation, and/or relationship to other objects in its environment (Matsuba, 1996). User interface designers have previously investigated navigation in 2-dimensional (2D) spaces and developed design principles that guide them in the development of effective and efficient interfaces (Beasley, 1992; Beccue, 1994). As designers work with 3D worlds, it will be useful to know whether the principles and findings of research related to two-dimensional navigation can be applied and extended. Since virtual worlds represent real worlds, the impact of real world navigational behaviors on interface design must also be studied.

A review of the literature related to navigation patterns in human computer interfaces indicates that research on navigation in 3D environments focuses on three areas: navigational awareness, spatial ability, and wayfinding (purposeful, oriented movement during navigation) (Satalich, 1995). Darken and Sibert found that the organization of elements in a virtual world and the provision of an absolute frame of reference improved navigation performance (Darken, 1995). In a subsequent study, Darken and Sibert also reported an
improvement in the performance of navigation tasks in virtual worlds that had been created using environmental design principles (Darken, 1996). Among their observations were that (1) path following (a form of wayfinding) is a natural spatial behavior, (2) the lack of adequate directional cues inhibited wayfinding performance, (3) a structure must be imposed on large complex worlds in order to navigate in them, and (4) a conceptual coordinate system is often imposed on the world in an attempt to structure it. Each of these studies required that the researcher track the users' navigational patterns in a virtual world. Vila, et al. (Vila, 1997) reported on a tool that provides a template and efficient data collection capabilities for studying the navigational behaviors of users. Additional efforts to improve navigation performance by addressing issues such as the psychology of navigation, the use of navigational aids (e.g., maps), the effects of different types of worlds on navigation, and the design of an environment for navigability were the subject of discussions at the 1997 ACM Computer Human Interaction Conference (Furnas, 1997). In reviewing the literature, the authors found virtually no reports on tools for connecting an existing application program to a virtual world. This could be resolved with the development of middleware to manage the navigational interaction between an application program and a virtual world.

The purpose of this paper is to describe the prototype for a language for navigating in 3D worlds that has the potential to serve as a mediator between an application and a virtual world. Mariner, the language discussed in this paper, was designed using formal language specification techniques and implemented in a Web environment using Javascript and Virtual Reality Modeling Language (VRML).

Virtual worlds provide a forum for developing simulations of real world situations for education and training that are less costly than real experiences. Applications like these need to be able to interact with a virtual world. Mariner provides an initial step in connecting existing applications and VR worlds. Because Mariner provides a formal method for specifying navigation, it may also prove useful to researchers in the field of human computer interaction who are interested in describing and studying navigation behaviors in 3D worlds by documenting how users navigate in VR environments.

Development of the Mariner Language

The authors' objectives in the design and implementation of Mariner were to:

1. define the specific navigation behaviors in a 3D virtual world that need to be modeled,
2. use formal language specification techniques to define the syntactic and semantic structure of Mariner,
3. implement a prototype for an interpreter using standard compiler design techniques that would translate Mariner language statements into VRML statements allowing the visualization of an object as it navigates in a 3D world,
4. determine the effectiveness of Mariner by evaluating the accuracy of programs in Mariner that generate navigation actions for an object defined in a VRML world.

Defining Behaviors

The first step in developing Mariner was to determine what type of navigation behaviors occur in 3D worlds. The authors identified movement, rotation, collision detection, conditional behavior and repetitious behavior as the behaviors to model in the language.

Movements in a 2D world are usually expressed using a grid coordinate system. Movements can either be direct (e.g., moveto 138,34) or relative (e.g., move forward 10). Some parameters to commands may be implied; “move forward 10” implies that the object is facing in a specified direction and will continue to move in that direction when it moves. In a 3D world, some 2D concepts have the same meaning. For example, movements may also be expressed using a grid (now a 3D grid) and the concept of moving forward a specified number of units remains the same. However, the movement of objects is no longer defined in a plane; objects have the freedom to move (and rotate) in all of the directions that can be defined by a 3D space.

Whether in a 2D or 3D world, objects have relationships to other objects in the world. An object may be to the right of another object or in front of another object. As an object navigates, its relationship to other objects changes. Correct and incorrect behaviors must be defined. In navigating within a world with multiple
objects, for example, it would not be correct for an object to move forward "through" another object as if it did not exist. An object should be able to detect and avoid an impending collision with another object.

Objects in virtual worlds often exhibit repetitive behavior or behavior that is based on conditions that must be evaluated before performing the behavior. For example, not to move if there is an object directly in front of the object to be moved. Hence, control structures that allow for conditional or repetitious behavior are also needed.

Syntax and Semantics

After defining the behaviors to model, the syntax and semantics of the Mariner were specified. Because languages that have been unambiguously defined using Backus Naur Form (BNF) can often be easily implemented using recursive, top down analysis techniques and automatic compiler development tools, the syntax for Mariner was specified using BNF (Alblas, 1996). The BNF for Mariner appears on page 5.

The semantics were implemented as paragraphs of text describing the behavior of each statement. For the most part the meaning of program statements can be inferred from their syntax. While developing the semantics, it proved useful to identify potential errors in syntax and behavior so that error handling routines could be later developed.

Currently, the syntax represents a language in which small programs can be written to manipulate a limited number of objects in a 3D world. The objects that can be manipulated include a sphere, cone, cylinder and cube. The current syntax and semantics will form the base for implementing the language as a form of middleware to interact with other applications. An example of a small Mariner program is shown in Figure 1. Note that the object that has been defined is a cone and all subsequent movements apply to that object. In its current form, there are no variables in Mariner, so there is no way to reference the cone in later segments of code that are separated from its initial definition.

```
Cone:
    Size = 2
    Height = 4
    Color =120 0 0

Movement 1
    Move 5 Units Along X Axis
    Move 0.0 Units Along Y Axis
    Move 0.0 Units Along Z Axis
    Rotate Counter ClockWise Along Z Axis by 90 Degrees

Movement 2
    Move 0 Units Along X Axis
    Move 5 Units Along Y Axis
    Move 0.0 Units Along Z Axis
    Rotate ClockWise Along Z Axis by 90 Degrees
```

Figure 1: Program Example

The Mariner Language Development Environment

The Mariner language development environment, shown in Figure 2 below, has two components, the Mariner code generator and the Mariner interpreter. The Mariner code generator allows the user to define objects and their navigation paths within a virtual world through a user-friendly interface. The user can select pre-defined options for each object for which Mariner statements will be generated and displayed in the text area, or he/she can type Mariner language statements directly in the text area. The language development environment was constructed as a Web page using Javascript and VRML 2.0.
The code generator permits the user to define an object geometry that includes traditional VRML nodes such as cones and cubes. In addition, the user can define navigational movements for each defined object using translation and rotation transformations. All object dimensions and movement distances are specified in pixel units. After completing a Mariner program, the user can choose to have it interpreted into VRML statements which can be executed in a Web browser.

Summary

A prototype for a 3D navigational language, Mariner, was described in this paper which has the potential to serve as a link between 3D worlds and software applications. The language, written in Javascript and VRML, currently generates VRML code which can be viewed within a Web browser. Future development includes the transformation of the language into code segments that can be embedded within an existing 3D world and act upon existing or newly created objects within the world.

Abstract: This study investigated how differences in task affected learner navigation choices, transfer of knowledge, and attitude toward the topic when using hypertext materials about sexual harassment that were designed using cognitive flexibility theory as a theoretical basis. Based upon the findings of the study, it appears that the two tasks (juror verdict and policy creation) did not have significant impact upon learner criss crossing or transfer. Therefore, it was also apparent that task had no relationship to transfer. Post hoc analyses on other variables, including learner beliefs about knowledge, were also not significantly related to the outcomes regarding navigation and transfer. However, there did appear to be a relationship between task type and learner attitude changes from the beginning to the end of the study, suggesting a possible affective dimension to the use of cognitive flexibility hypertexts that has not been previously reported or considered in the research literature.

Introduction

This study investigated the practical application of cognitive flexibility theory (Spiro, Vispoel, Schmitz, Samarapungavan, & Boerger, 1987) as the basis for designing case-based hypertext learning materials. Results of this research could aid in furthering the utilization of this approach for facilitating learning within instructional settings.

Cognitive flexibility theory posits that effective learning of complex knowledge in ill-structured domains cannot be supported by those cognitive theoretical frameworks that support learning in well-structured domains (Spiro et. al., 1987). This is due to the fact that those frameworks focus more on the retrieval of information and necessitate fairly rigid structuring of the domain knowledge, compartmentalization of concepts vs. interconnecting concepts, simplification of complex concepts for instruction, and assume knowledge will be applied consistently within the domain. These approaches inhibit the new transfer of learning within ill-structured domains where flexible knowledge assembly is required based upon the context of the situation in which the knowledge is applied (Spiro et. al., 1987).

Cognitive flexibility theory assumes that in order to affect the optimal cognitive processes for near transfer within the learner, instruction must stress “flexible reassembly of pre-existing knowledge to adaptively fit the needs of the new situation” (Spiro et. al., 1987) by mirroring that flexibility within the instructional materials. This is done using a case-based approach in which learners are shown multiple representations and perspectives on each domain-specific case, with cases interconnected across themes and perspectives. The theory contends that this prepares the learner for transfer through a complex understanding of the complexity of the domain and the interconnectedness of the domain knowledge (Spiro et. al., 1987). This more complex understanding comes from learners reconciling the
perspectives and contexts of the cases, and theoretically should support the construction of individual knowledge representations that are flexible and adaptable to new situations (Jonassen, Dyer, Peters, Robinson, Harvey, King, & Loughner, 1997).

Transfer in cognitive flexibility literature is considered the application of new knowledge in new situations (Spiro et al., 1987). Spiro et al. (1987) argue that the problem with applying new knowledge in ill-structured domains is that the original presentation of that knowledge is usually simplified, thus resulting in simple understandings of the domain by the learner. The problem is that such simple understandings do not readily allow for application when the domain is inherently complex. Therefore, it is necessary to present the domain knowledge in a form that retains the complexity of the domain. Complex understandings, the theory holds, should then be more flexibly reassembled, or reinterpreted, in order to address a wide range of new situations based upon the context of each situation. Transfer in ill-structured domains, according to cognitive flexibility theory, is then considered to be a product of the learner being able to think about and structure domain knowledge in accordance with the new situation.

To date the research has supported the transfer claims of cognitive flexibility theory by showing an improved transfer of knowledge application, as measured by essay answers given by learners, when approaches based on cognitive flexibility theory which emphasize complexity and the goal of flexible assembly of knowledge are compared to other instructional techniques which promote simpler understandings and outcomes such as retrieval of knowledge (Spiro et al., 1987; Jacobson & Spiro, 1995; Jacobson, Maouri, Mishra, & Kolar, 1996). However, the learners had to be managed through the instruction by providing a list of only those thematic links that were considered by the designers to be relevant to the particular case being viewed. From a design and implementation viewpoint, it would seem that managing the learner would be unnecessary if the learning task could promote criss crossing by the learner as effectively.

While research has provided some additional theoretical justification for the potential benefits of cognitive flexibility hypertexts, it is necessary to extend understanding of the application of the theory through research into the methods through which cognitive flexibility is applied to the design and implementation of hypertext/hypermedia learning materials. The research study conducted sought to accomplish this goal by examining the combination of cognitive flexibility hypertexts with two general types of learning tasks, one which promoted looking at cases individually and another which was believed to promote cross-navigation of cases.

Task and Learning Outcomes

The relationship between the nature of the learning task and learning outcomes has been shown to be significant in several studies of text processing. Pichert and Anderson (1977) found that asking learners to take a certain perspective when reading a story improved the memorization and retrieval of information. Pichert and Anderson concluded that the improvements were the result of the learner placing an emphasis on certain ideas presented in the text based upon the perspective they were taking. Wittrock and Alesandri (1990) studied the impact of generating summaries and analogies and found that learners were more analytic in their understanding of text passages than if they only read the passages with no specific task. The body of research on text processing suggests task plays a primary role in how people learn when reading.

However, the analysis of some of the findings regarding task are flawed in the view of cognitive flexibility theory. While text processing researchers have looked at the task as impacting information processing and/or schemata, Spiro et al. (1987) posit that in ill-structured domains there is a need for flexible schema organization. Rather than merely “matching the information in the message to the slots in the schema” (Pichert & Anderson, 1977), the learner needs to gain an understanding of the situational nature of the information in order to reassemble their knowledge to fit a given instance within the domain. Therefore, task is important not because it cues relevant schemata, but facilitates construction of relationships between domain knowledge and situations.

Description of the Study

Specifically, the present study sought to identify the effects of two different types of task on the navigational paths of learners using a cognitive flexibility hypertext concerning issues of sexual harassment. In addition, the effects of the navigation path on transfer of learning were also examined. Finally, the type of task, navigation path, and transfer test scores were studied for significant interactions. In this manner some of the primary assumptions of cognitive flexibility theory were be tested, including the role of criss crossing navigation as
a primary component for improving transfer, and the constructivist nature of the theory in terms of using a meaningful task to promote active learning.

The hypotheses of the study were that:

1. The two tasks would facilitate two different types of navigational paths, either a non-criss crossing path the juror task, or a criss crossing path for the policy task.
2. Learners taking a criss crossing navigation path through the hypertext would significantly enhance their transfer of learning as compared to learners who take a non-criss crossing path.
3. Difference in transfer would be the result of the policy task engendering a more criss-crossed navigation path through the hypertext than the juror task.

In order to test the hypotheses, the study was designed as an experimental study with subjects grouped by task. The participants were adult graduate management students enrolled in a course on business. Learners were randomly assigned to one of two task types. One task involved the learner in the role of juror, in which they were instructed to look at each individual case and render a decision as to whether it involved sexual harassment. The jury verdict task was expected to facilitate a linear, case-by-case path since it directed the learner to examine each case in its own context. The second task asked the learner to devise a policy for dealing with sexual harassment within a fictitious company, and directed the student to develop a complete picture of the issue as it relates to the workplace. This was expected to facilitate a less linear, and broader investigation of the case information by the learner due to the comprehensive nature of the task.

Attitude Factor

Attitude regarding sexual harassment was measured both just prior to the treatments and again prior to the transfer test. Beauvis (1986) considered attitude to be a combination of knowledge, sensitivity, and awareness of the issue of sexual harassment. In her study attitude changes were scored by comparing participants answers to how they matched the answers that would be expected based upon the desired goals and outcomes of the training program. In the present study, a similar method was used for scoring attitudinal differences between pre and post treatment answers on an attitude survey, comparing participant answers with those of an expert from the Affirmative Action Office of a university who was highly knowledgeable, sensitized and aware regarding the issue of sexual harassment. The resulting difference was used for statistical analysis of the impact of treatment variables on attitudes towards sexual harassment.

Measuring Criss Crossing

Using the description of “criss crossing” as entailing “revisiting the same material, at different times, in rearranged contexts, for different purposes, and from different conceptual perspectives” (Spiro et. al., 1992), it was decided that criss crossing would be evident from any navigational choice which resulted in one of three types of criss crossing:

- **Within case criss crossing** – revisiting the same information on a case previously viewed immediately after viewing other information about the same case.
- **Internal criss crossing** – revisiting any part of the case information immediately after reading case specific theme, perspective, or legal commentary related to the same case.
- **External criss crossing** – revisiting case information or case specific commentaries immediately after viewing overall theme commentaries or information in other cases.

Using the three types of criss crossing to determine how many of the participants' navigational choices were characteristic of criss crossing, the next step was to determine what methodology to use in order to measure navigation style for further statistical analysis. The most direct and appropriate measure was considered to be the total number of criss crossing choices made by the participant. This represented the simplest and most direct measure of the basic premise of cognitive flexibility theory that criss crossing impacts transfer. Statistically, it allowed the entire sample to be maintained as a single group for the purposes of measuring transfer. Using the raw number of criss crossing, analysis of the data was conducted regarding each of the hypotheses of the study, beginning with the effect of task on criss crossing.
Measuring Transfer

Transfer was measured using essay questions that presented new cases and asked the learner to apply what they had learned to make a determination regarding the case. Three independent raters, including the primary researcher, rated the transfer question essays according to a five point rubric. The final transfer score for each learner was the combined total points for each question, with a maximum possible score of 10 points. Interrater reliability for the transfer scoring was 91.8 percent between raters 2 and 3, 91 percent between raters 1 and 3, and 93 percent between raters 1 and 2.

Summary of Results

The results regarding the primary hypothesis revealed no significant impact for task type. Specifically, the results for each hypothesis were:

- An ANOVA revealed no significant relationship between task and criss crossing (F=1.61, P>.05, N=34), which means the hypothesis that the type of task would affect navigational style in this study was not proven.
- Analysis showed no significant effect between criss crossing and transfer (F=0.083, P>.05, N=34). Therefore, the total number of times that a student criss crossed the hypertext had no statistically significant impact on the transfer of knowledge.
- An ANOVA was run which showed task had no significant relationship to transfer (F=.324, P>.05, N=34).

However, the findings regarding attitude did show a significant effect for task type. A repeated measure statistical analysis revealed that there was a significant interaction between pre-treatment to post-treatment attitude survey scores and the type of task (F=4.86, DF=1,33, MS=2.431, P<.05). Inspection of the data revealed that the policy task group (N=16) showed a mean positive change of 1.25 points on the attitude survey from pre-treatment to post-treatment, while the juror task group (N=17) had a mean negative change of -0.41.

Discussion of Results

Task and Criss Crossing

It is possible that the lack of differences can be attributed to the policy and juror tasks being equal in how they were perceived by the learner. It seems clear from the navigation data that a learner was just as likely to criss cross if they were engaged in the juror task as they were in the policy task. In fact most of the learners in the study chose a relatively low amount of criss crossing (average of only ten criss crosses out of fifty total navigational choices) regardless of task type.

A more theoretical explanation of the results is that learners have a predilection towards certain kinds of navigation patterns. The findings of Lawless and Kulikowich (1996) support this interpretation. In their study, hypertext learners appeared to fall into three types; those who explored the navigational options of the hypertext, those who were concerned primarily with seeking out particular information, and apathetic users who simply did not spend time in the hypertext. Beasley and Waugh (1996) also reported that learners seemed to approach hypertext systems with a general navigation pattern in mind, one that emphasized coverage of material rather than underlying structures or important information. In the present study, it is possible that, regardless of the nature of the task and the navigation options of the hypertext, learners used their preferred style of navigation to study the hypertext information and complete the task instead of adapting their navigation to the task and/or the prevalent hypertext structures.

Task and Transfer

As was the case for task and criss crossing navigation, it is likely that the tasks were not different enough in nature or importance to engender strong changes in learner reactions or understandings. This explanation is in
keeping with previous research regarding task and perspective. Pichert and Anderson (1977) used two very different perspectives (home owner vs. burglar) and found that learners attended to different information when reading. In the present study, it may be that learners simply took a very similar perspective, perhaps viewing the cases from a legal viewpoint, in both tasks.

Other hypertext studies involving task differences have also had difficulty showing a significant link between task impacts on transfer via navigation variables. Beasley and Waugh (1996) found no differences in learner scores based upon the number of times they revisited information when given the goal of reviewing material. Given equal goals, but different amounts of return visits in a hypertext, it appears that learners scored relatively equally regardless of navigation. Jonassen and Wang (1993) found that without tasks that focused learners on different aspects related to the structure of the knowledge being studied, no significant differences could be found.

Task and Attitude

An apparently strong relationship existed between the pre-treatment and post-treatment scores on the survey of attitudes towards sexual harassment. Students who engaged in the jury task actually appeared to become somewhat less sensitive to the issue, while policy makers gained a greater understanding of sexual harassment. One possible rationale for this difference is that the natures of the tasks, while not different in terms of learning transfer, were different in terms of affective outcomes.

Beauvis (1986) notes that sexual harassment training is designed to change attitudes by challenging trainees' opinions on the issue. The goal is to make participants more aware and more sensitive, which means they may need to be exposed to information contradictory to their beliefs. Some research regarding the exposure of learners to information inconsistent with their prior knowledge suggests that the accommodating of the contradictory information is a necessary step in learning through attitude change.

Chinn and Brewer (1993), based upon a study of adults presented with contradictory information regarding physics concepts, theorized that learners take four different approaches to dealing with contradictory information. One was to simply reject the new information, while another was to reinterpret it to make it fit with their present beliefs. Both of these meant that the person was unwilling to move from their beliefs as a result of the exposure to the new knowledge. The final two methods were partially changing their beliefs so as to allow for the new information without totally giving up old beliefs, and finally to restructure their beliefs around the new information.

In explaining the results of the present study, it seems reasonable that perhaps the two tasks were different in how participants encountered contradictory viewpoints on sexual harassment. Learners asked to provide a verdict in each case were perhaps more likely to hold on to their beliefs in the face of new information, since they were stating and defending their personal opinions in light of legal standards. This could be construed as meaning they were forced to either accept or reject new information on the basis of their personal understandings regarding sexual harassment law.

On the other hand, the learners developing policy may have been taking a more open perspective on the information they encountered, since developing a comprehensive policy meant taking into account as many different possibilities and perspectives as possible. In order to do this, these learners may have been acting less on personal belief than those in the juror group, and therefore they were more willing to accommodate information that contradicted their beliefs.

Considering that ill-structured domains tend to involve a great degree of variability, with no true "right" or "wrong" answers, then the findings suggest a possible new direction for studying cognitive flexibility theory. Findings of previous CFH research examined beliefs regarding the nature of knowledge (Jacobson & Spiro, 1995; Jacobson et. al., 1996), but not specifically the nature of the domain being studied. For ill-structured domains in which the learning outcomes may be affective, it may be that the nature of the task could play a significant role in learning by virtue of how the learner approaches information contradictory to their beliefs.

Conclusion

Cognitive flexibility theory has been widely touted as a strong basis for the design of hypertext learning environments. However, to date little research has been conducted on this claim. One contribution of the study is to begin to examine the importance of the type and nature of the learning tasks associated with CFH implementation. It appears that the amount of criss crossing that occurs is not by itself an important variable in achieving the learning
outcome of transfer that the theory supports. In this study it has been suggested that perhaps the task must be meaningful to the learner, such that they are intentional in their navigational choices. This implication may extend to other theory-based hypertext designs, in that if learning is intentional then the task must fit the goals and contexts of the learner as well as the theoretical basis for the hypertext structure.

Perhaps the most significant finding of the study was that task might be very important when considering the types of ill-structured domains for which a CFH is developed. When dealing with domains which involve strong emotional opinions, and are perhaps controversial for learners, then the task may need to be devised such that learners remain open to the complexity and ill-structured nature of the knowledge being represented.

Abstract
This paper reports on a course-support system for English learners of Greek which is built around an Intelligent Language Tutoring System (ILTS). Meaningful interaction between the learner and the system is achieved by a number of means: First, students provide natural language input rather than selecting exclusively from among pre-defined answers. Second, the ILTS uses Natural Language Processing to analyze the learner’s input and to provide error-specific feedback. Third, the system contains a Student Model which keeps a record of students’ performance histories. The information about each learner in the Student Model determines the level of specificity of feedback messages, clues, and exercise difficulty. In addition to vocabulary and grammar exercises, the system also contains oral dialogues with translations, a glossary, and cultural information. The system is designed for introductory learners of Greek and is implemented on the World Wide Web.

1. Introduction
As the Web begins to mature and technologies for adapting existing content in language learning converge with increased bandwidth, the desire grows to develop uniquely Web-based applications. Convenient access, currency and variety of material, and integrated multi-media can extend traditional language instruction, but truly new forms require a more profound degree of interactivity than provided by conventional forms.

Interactivity has become a key term in Hyper/Multimedia and although it is used extensively, its definition and scope is still not precisely determined. However, Laurel [1991] provides a useful definition by making a distinction between frequency, range, significance, and participatoriness. With respect to frequency and range, we may count the number of times a user can interact with a system and how many choices are available, respectively. Significance and participatoriness both require a qualitative analysis to determine how the user’s choices affected matters and to which degree the user is participating in ongoing system decisions [Ashworth 1996]. But to achieve a high degree of interactivity with respect to significance and participatoriness, the software requires intelligence to consider user’s individual differences. For example, students learn at a different pace and have different sets of skills. These student variables need to be considered for a system to be highly interactive.

The course-support material described in this paper differs from others in that it is built around an interactive Intelligent Language Tutoring System (ILTS). Interactivity is achieved in a number of ways. The system provides a wide range of exercises covering vocabulary and grammar practice. For some tasks, students provide natural language input rather than selecting exclusively from among pre-defined answers. The tasks are independent of each other and the exercise types range from drill-and-practice to more game-like tasks. In addition, the system contains oral dialogues, a glossary, and cultural information. Significance and participatoriness is achieved through Natural Language Processing (NLP) and Student Modeling. The system consists of a grammar and a parser which analyzes student input and provides error-specific feedback. The system also maintains a Student Model which keeps a record of students’ ongoing performance, alters system decisions accordingly, and provides learner model updates.

In the following, we will first discuss the goals of the system and address the grammar, parser, and Student Model components. We will then describe the modules involved in analyzing student input. Further we will
illustrate the exercise types of the system and provide examples of learner modeling for each of them. Finally, we will conclude with suggestions for further implementations.

2. Goals and System Requirements

The goal of the ILTS for Greek is to provide meaningful and interactive vocabulary/grammar practice for English learners of Greek. Meaningful tasks and interactivity require intelligence on the part of the computer program. Unlike existing course-support systems which use simpler grammar practice and feedback mechanisms, the ILTS for Greek emulates two significant aspects of a student teacher interaction: it provides error-specific feedback and allows for individualization of the learning process [see also Heift, 1998]. In example [1] the student provided an incorrect Greek sentence:

(1) Ο ο κοσμος μαθαινει Ελληνικα.
Ο o κοσμος μαθαινει Ελληνικα.
The whole world is learning Greek.

In such an instance, the system will detect an error in subject-verb agreement and, in addition, will tailor its feedback to suit the learner’s expertise. Tailoring feedback messages according to student level follows the pedagogical principle of guided discovery learning. According to Elsom-Cook [1988], guided discovery takes the student along a continuum from heavily structured, tutor-directed learning to a point where the tutor plays less of a role. Applied to feedback, the pedagogy scales messages on a continuum from least-to-most specific guiding the student towards the correct answer.

There are three learner levels considered in the system: novice, intermediate, and advanced. For example (1), the novice will receive the most detailed feedback: “You have made a subject-verb agreement error.”, while the intermediate learner will be informed that an error in agreement occurred. In contrast, the advanced learner will merely be told of an error in the sentence. The central idea is that the better the language skills of the learner, the less feedback is needed to guide the student towards the correct answer. This analysis, however, requires:

a) an NLP component which can analyze ill-formed sentences, and
b) a Student Model which keeps a record of the learner.

The NLP component consists of a grammar and a parser. The system is written in LOPE, an ALE style extension of Prolog [see Carpenter and Penn, 1994]. LOPE is a phrase structure parsing and definite clause programming system in which the terms are typed feature structures. Definite Clause Grammars (DCGs), like other unification-based grammars, place an important restriction on parsing, that is, if two or more features do not agree in their values, a parse will fail. However, in a language learning system, these are the kinds of mistakes made by learners. To parse ungrammatical sentences, the Greek grammar contains rules which are capable of parsing ill-formed input (buggy rules) and which apply if the grammatical rules fail (see also [Schneider & McCoy, 1998], [Liou, 1991], [Weischedel, 1983], [Carbonell & Hayes, 1981]). The system keeps a record of which grammatical violations have occurred and which rules have been used but not violated. This information is fed to the Student Model.

The Student Model is a representation of the current skill level of the student. For each student the Student Model keeps score across a number of error types, or nodes, for example, grammar or vocabulary. For instance, the grammar nodes contain detailed information on the student’s performance on subject-verb agreement, case assignment, clitic pronouns, etc. The score for each node increases and decreases depending on the grammar’s analysis of the student’s performance. The amount by which the score of each node is adjusted is specified in a master file and may be weighted to reflect different pedagogical purposes.

The Student Model has two main functions:

First, the current state of the Student Model determines the specificity of the feedback message displayed to the student. A feedback message is selected according to the current score at a particular node. A student might be advanced with regard to vocabulary but a beginner with passive voice constructions. Hence, a feedback message about vocabulary would be less detailed than a feedback message about passive-voice constructions.

Second, the difficulty of the exercises presented to the student is modulated depending on the current state of the Student Model. For example, if a student is rated as advanced with respect to vocabulary, then some of the
vocabulary exercises are made more challenging. The same thing can be found with some of the grammar exercises.

In the following, we will discuss the error-checking mechanism performed by the system in analyzing student input.

3. Error-Checking Mechanism

In addition to the grammar and the parser, the system contains additional error-checking modules which get evoked when processing a student answer. For example, consider the task in (2a) where the student was asked to make a sentence with the words provided.

(2a) ισπανικά μιλάω Νίκη
(2b) Νίκη μιλάει ισπανικά
niki – speak – Spanish

The student answer given in (2b) contains a number of mistakes: an error in subject-verb agreement, a spelling mistake, and a missing article. While the grammar will detect the agreement error, the remaining mistakes will be discovered by additional modules of the system. Figure [1] illustrates the modules of the Natural Language Processing system.

```

   |
   Grammar Check
   |
   Match Check
   |
Feedback Message to the Learner
```

Figure 1: Error-checking Modules

The first module in analyzing student input is a spell check. During the spell check, the system also extracts the base forms of each word from the grammar. The uninflected words are needed to determine whether the learner followed the task, that is, whether the student answer contained the words which were provided. Such errors cannot be determined by the grammar and the parser because the parser can only judge whether a sentence is correct or not.

In defining an exercise, we store possible answers of a given task and the Answer Check module determines the most likely answer (MLA) the student intended. The Answer Check module further matches the extracted base forms with the MLA. If any of the words in the task are not contained in the student answer, the system will report an error.
The following two checks, Extra Word Check and Word Order Check, refer to additional words in the student answer and errors in word order, respectively. While these two checks are commonly handled by the grammar [Schwind, 1995], preliminary testing of our system showed that the system performs faster if these two error types are treated outside the grammar. Naturally, the speed is also influenced by the grammar formalism used.

The Grammar Check is the most elaborate of the modules. Here the sentence is analyzed by the parser according to the rules and lexical entries provided in the Greek grammar. Currently, the grammar covers a wide range of grammatical concepts, from early beginner constructions (verb 'to be' and the concept of null subjects) to fairly advanced structures (passive voice). Development is still ongoing to achieve a complete coverage of Greek grammar.

The Match Check looks for correct punctuation and capitalization by string-matching the student answer with the MLA. By this time in the evaluation process, it is very unlikely that the sentence still contains any errors other than punctuation or capitalization. If the sentence passes the Match Check successfully, the sentence is correct. If not, an error is reported to the student.

The system is organized in a way that if a module detects an error, further processing is blocked. As a result, only one error at a time will be displayed to the learner. This was implemented mainly to avoid overloading the student with extensive error reports in the case of multiple errors. According to van der Linden [1993], displaying more than one feedback message at a time makes the correction process too complex for the student. After correcting the error, the student restarts the checking mechanism by clicking the CHECK button.

In the last section, we will briefly describe the six exercise types implemented in the system and discuss the role of the Student Model for each.

### 4. Exercise Types

The system consists of three vocabulary and three grammar exercise types: Guess the Word, Find the Word, Which Word is Different, Word Order Practice, Fill-in-the-Blank, and Build a Sentence, respectively. Student performance in each exercise contributes to the Student Model. However, the nodes that get updated for each exercise differ. In addition, there are two ways in which this information is used by the system:

1) feedback messages tailored to student expertise
2) difficulty of exercise presented to student

In the following, we will discuss the nodes which get updated and illustrate the feedback message and exercise difficulty modulation for each exercise type.

#### Vocabulary

**Guess the Word**

This is a slight variation of the vocabulary game ‘Hangman’ where students guess a word by entering one letter at a time. To avoid making this a purely guessing game, a clue is provided for each word. This clue may be the English equivalent of the answer, or a picture or sound representing the answer. For each correct word, there is an increment for the vocabulary node, for each word missed, the system registers a decrement. In this exercise type, the feedback messages are the same for all users. However, advanced students, that is, students with a high vocabulary score get fewer tries to complete the task.

**Find the Word**

In this exercise type, students need to find several words in a grid. The system increments the vocabulary node for each word found and decrements for each incorrect guess. The maximum increments and decrements per game are equal to the number of words in the table. The feedback messages are the same for all students. The exercise difficulty is modulated: advanced students receive clues in English, while other students receive clues in Greek.
Which Word is Different

This exercise displays a number of words all except one of which belong to the same category. The student task is to identify the one which differs from the others. The divergent word may differ syntactically, semantically or pragmatically from the remaining words. There is an increment for each correct word selected, for each incorrect selection a decrement is recorded. The feedback messages are the same for all students and there is no difficulty modulation.

Grammar

Word Order Practice

In this exercise, students practice Greek word order with a 'drag and drop' task: words have to be arranged in an appropriate order to form a grammatical Greek sentence. For this exercise type, the word order node in the Student Model is updated. For a sentence with incorrect word order, the system records a decrement, else an increment. There is no feedback or difficulty modulation for this exercise.

Fill-in-the-Blank

The student’s task here is to complete sentences by filling in any blanks that appear in the example. The Student Model records each grammar node that is detected in the student input. For example, if students are asked to supply the correct conjugation of the verb, then the system records an increment/decrement for subject-verb agreement. The feedback messages are modulated according to the level of the learner. Also, advanced learners obtain more difficult tasks. For instance, novice and intermediate students will find only one blank per example. Advanced students may be presented with examples that contain more than one blank.

Build a Sentence

In this exercise type, students are provided with a set of words. Their task is create a grammatical Greek sentence using all the provided words. This was illustrated earlier in example (2). All grammar nodes activated during the processing of the student’s input are updated in the Student Model. An increment is recorded if this aspect of the student’s answer was correct. A decrement is recorded for any grammatical errors made by the student. Feedback messages reflect the current state of the learner’s expertise, as represented by the Student Model. There is no difficulty modulation.

It becomes apparent that the modeling process has to be decided for each exercise type independently. Not only does it depend on the task but also the possibilities the exercise offers in adjusting the level of difficulty.

5. Future Work

We plan to extend the range of exercises available to students. Since students are particularly appreciative of the opportunity to practice grammar in such a constructive environment, we will focus on developing further exercises that exploit the Natural Language Processing and Student Model functionality that we have developed. Two exercises under construction are Dictation and Translation.

In the Dictation exercise, students listen to an audio file and then type the text they have heard. The student’s input is analyzed by the grammar and feedback is provided for any grammatical errors. Feedback is modulated according to the current state of the Student Model. In the translation exercise, students are provided with an English phrase or sentence and are required to translate this into grammatical Greek. Again, feedback is modulated according to the current state of the Student Model.

6. Conclusions

In this paper, we discussed an interactive course-support system on the WWW. Interactivity is achieved by a wide range of exercise types which are arranged in an independent order. NLP and Student Modeling also contribute to the interactivity of the whole system by providing error-specific feedback and adjusting to different learners. The Student Model is based on the performance history of the student. The information about each learner is recorded in the Student Model and determines the level of specificity of feedback messages and exercise difficulty.
Preliminary testing of the content of two modules and the overall functionality of the system has taken place. While the performance of the system is accurate with respect to feedback and student modeling, student responses are currently being analyzed and results will be reported during the presentation. In the meantime, the system is being further developed by adding more content and implementing further grammatical constructions.

Abstract: The current trend to use the World Wide Web as a vehicle for the delivery of distance education units has required educators to adopt innovative approaches to the design of learning materials for this medium. However, the temptation to place large tracts of text online is deeply entrenched. This paper describes a project where guidelines for the design of authentic activities have been derived from a broad literature base. The guidelines have been used in the development of Masters subjects, where authors are encouraged to use learning activities as the central focus of study—the activity does not supplement the unit, it is the unit. The emphasis is placed on the design of activities, integrated assessment of the activities, identification of resources and establishment of collaborative tools. Examples of activities, together with the instructional design guidelines, are provided, and the use of theory and research to inform the instructional design process is discussed.

Authentic activities

Activities, investigations and problems are at the heart of student involvement in meaningful learning contexts. Teachers provide such activities to enable students to interact with the learning environment, and to learn, apply and practice newly acquired skills. Activities are defined by Brophy and Alleman (1991) as: ‘Anything students are expected to do, beyond getting input through reading or listening, in order to learn, practice, apply, evaluate, or in any other way respond to curricular content’ (p. 9).

This paper describes the development of a university-based online project where activities are used, not only as opportunities for students to learn, practice, apply and evaluate, but also as central organising devices for the design of entire online units of study. Clayden, Desforges, Mills and Rawson (1994) point out that the kind of activities frequently used in education simply lead to an enculturation into the practices of classrooms rather than the real-world transfer teachers expect. They note that students’ efforts to make sense of classroom experiences generally lead them to focus on working practices rather than abstract ideas. ‘What they learn ... is how to do work, how to be neat, how to finish on time ... and how to tidy away’ (p. 164). While these comments are most appropriate for school (and to some extent university) classrooms, the same conclusions may be drawn for the design of online learning environments. Students frequently learn to invoke ‘sub-optimal’ schemes to enable them to proceed, rather than deal with the content in a way that promotes true understanding. Many of these online programs are so ‘well designed’, they fail to account for the nature of real-world problem solving, where the solution is rarely neat and the salient facts are rarely the only ones at students’ disposal. In contrast, a number of authors suggest that authentic activities should be ill-defined—students find as well as solve the problems. Learners need to have the opportunity to: explore a situation with
all the complexity and uncertainty of the real world, have a role in determining the task and how it might be broken up into smaller tasks, select relevant information, and find solutions that suit their needs.

The Cognition and Technology Group at Vanderbilt (1990b) stress the importance of complexity and the necessity to provide an environment capable of sustained examination. They describe authentic tasks as ‘generative’ because the completion of the task requires the students to generate other problems to be solved. They draw a distinction between these authentic tasks and simple word problems that already define the problem, such as: ‘If you travel 150 kilometres at 90 kph, how long will the journey take?’ By comparison, Reeves and Laffey (1999) describe a complex learning environment where, for an entire semester unit, the students’ task is to establish a research station on Mars, including designing an energy plant to sustain life once a station is established. Similarly, Pennell, Durham, Orzog and Spark (1997) describe a web-based environment where students learn business communication skills by accepting temporary employment in a virtual recording company. They are given a complex task to complete, and in order to do it, they make appointments and keep a diary, ‘interview’ the director and other employees, and write letters, memos and reports.

Several authors have attempted to delineate characteristics of authentic activities. For example, Jonassen (1991) defines authentic activities as tasks: that have real-world relevance and utility, that integrate those tasks across the curriculum, that provide appropriate levels of complexity and that allow students to select appropriate levels of difficulty or involvement (p. 29). Similarly, Bransford, Vye, Kinzer and Risko (1990) Young (1993) Lebow and Wager (1994) and Savery and Duffy (1996) among others have nominated criteria of authentic activities.

Recommended design features of authentic activities

It is possible to use these findings of the research and writing on authentic activities to produce guidelines for the design of learning environments. Accordingly, authentic activities:

- have real-world relevance (e.g., Brown, Collins, & Duguid, 1989a; Cognition and Technology Group at Vanderbilt [CTGV], 1990a; Jonassen, 1991; Resnick, 1987; Oliver & Omari, 1999)
- are ill-defined (e.g., Brown et al., 1989a; CTGV, 1990a; Young, 1993)
- comprise a single complex task to be investigated by students over a sustained period of time (e.g., Bransford, Vye et al., 1990; CTGV, 1990b; Jonassen, 1991; Savery & Duffy, 1996)
- require students to define the tasks and sub-tasks required to complete the activity (e.g., Bransford, Vye et al., 1990; CTGV, 1990b; Collins, Brown, & Newman, 1989; Young, 1993)
- provide the opportunity to examine the task from different perspectives, (e.g., CTGV, 1990a; Young, 1993; Spiro, Feltovich, Jacobson, & Coulson, 1991; Lebow & Wager, 1994; Savery & Duffy, 1996)
- enable students to detect relevant from irrelevant information, (e.g., CTGV, 1990; Savery & Duffy, 1996)
- provide the opportunity to collaborate (e.g., Young, 1993; Lebow & Wager, 1994)
- can be integrated across subject areas (e.g., Bransford, Sherwood, Hasselbring, Kinzer, & Williams, 1990; Bransford, Vye et al., 1990; Jonassen, 1991).
- are seamlessly integrated with the assessment (e.g., Reeves & Okey, 1996; Herrington & Herrington, 1998).

These principals have been incorporated into the design of activities within online units currently being designed for a suite of Masters level courses.

The Masters Online project

Fifteen professionally oriented Masters courses are presently being developed, in areas such as health, teaching, business, finance, computing and information science. Students in these courses are mostly experienced in the workplace and authentic learning activities are likely to be highly valued by these students. Many of the students live geographically distant from the university, whilst others have such busy lifestyles that on-campus study is impractical. The university has an established tradition of providing external courses for these students. The use of computer technologies to offer enhanced learning environments to external students is a natural next
step. However, it is a significant challenge to provide the required staff development to support such effective change.

In total, the 15 Masters courses offer over 250 subjects or units and involve over 150 academic staff, some of whom have limited experience of working in the online environment. The project has an initial development phase of three years. During the first three years, all units will be adapted for use online, but at differential levels:

1. New units receive the highest level of attention. Lecturers are funded through time release or additional payments to design the new unit. They are supported by an instructional designer and a multimedia development team. These units are designed to use authentic activities as a central focus of the unit. Authors are supported through: information workshops; demonstration, development, discussion and evaluation workshops; group and one-to-one consultations; and an information and example(s) web site.

2. Major revision units (existing distance units in print mode) where the focus is on developing sections of the unit to include authentic activities, and also encouraging students (and staff) to use the research and communication capabilities of the Internet.

3. Minor revisions (existing distance units in print mode) receive minimal content change but provide the staff and students with enhanced communications facilities (bulletin boards, chat rooms, Email, etc.).

**Designing authentic online activities**

As Salomon, Perkins and Globerson (1991) have pointed out: ‘No important impact can be expected when the same old activity is carried out with a technology that makes it a bit faster or easier; the activity itself has to change, and such a change cannot take place in a cultural vacuum’ (p. 8). The Masters Online project has a cultural history in the domain of the traditional printed distance education unit. The temptation for many of these authors is to produce blocks of text, similar to chapters of an external unit, and to design a variety of activities to accompany the text, with separate assignments. Encouraging the writers of new units not to put copious ‘content’ on the web generally requires a huge cultural shift, and a substantial rethinking of what they want students to achieve and how they could enable that learning to occur.

In designing the new units, a complex and sustained activity (with strong teacher support and peer collaboration) is the focus of the entire unit. Students use a purposeful activity to organise their study, to give meaning to their acquisition of information and to provide a framework for the creation of a realistic product. There is no attempt to divide the course into discrete fragments of easily digested information. In this sense, the activity does not supplement the unit—it is the unit.

The notion of the activities effectively being the unit is one that is quite foreign, and one that requires a major change in direction for these teachers. The first suggestion from an instructional design point of view has been to encourage the writers not to begin with the traditional scope and sequence, followed by the division of the content into chapters or modules. In the first instance, we ask the writers to plan the activities and to consider that their units might comprise one or two of these sustained and lengthy activities. In order to assist the design process, and to enhance the likelihood that the importance of the activity as a central organising device in the unit is prominent, the following design matrix (Table 1) is given to each writer, with its four main planning areas, together with space for them to jot down their initial ideas. These are then ‘brainstormed’ and refined in consultation with the instructional designer and the project team.

The design of the activities, and supporting resources and collaborative tools, in many cases require the authors to create scenarios which call for the students to adopt a role or persona. While the option of creating real problems, as recommended by Savery and Duffy (1996) is always preferable, simulated situations are also prepared and are considered an acceptable vehicle for authentic student learning (McLeBall, 1994). Table 2 provides an example of a plan for a simulated activity together with its assessment, resources and communication strategies. The activities being designed for the units vary enormously (across 15 courses). Further examples of the kinds of activities being produced include:
In a computer graphics unit, students produce a piece of software for a particular target group, together with documentation and users' manual. Each assignment represents a stage in the completion of the final product.

In an environmental management unit, students evaluate and prepare a report on whether a proposed housing estate development will pose a risk to nearby ecosystems.

In an educational theory unit, students write journal articles in groups and submit their articles to the editorial board of a journal (effectively the other student groups for peer review).

Lebow and Wager (1994) contend that 'Human learning is essentially a matter of self-regulation' (p. 239). However, this does not mean that students can be given complex and authentic tasks with no support or coaching to guide their learning. Wade (1994) points out that the promotion of learner autonomy means increased responsibility for the student which, if it is to succeed, requires 'a strong framework of support and guidance for the student from the outset' (p. 13). The support to be provided by the tutor of the online unit is
also planned concurrently with the design of the learning activities, together with opportunities for students to collaborate with each other in their learning. It is hoped that development through group activity and dialogue will be more enjoyable, more meaningful and more effective.

Table 2: Example of plan for authentic online activity

<table>
<thead>
<tr>
<th>Stage of development</th>
<th>Example activity: The ethics of research</th>
</tr>
</thead>
</table>
| 1. Designing the activities | "For this activity, you are required to assess the ethical conduct of a proposed piece of research. You are to imagine that you are on the Committee for Ethical Conduct of Research with Human Subjects in your University. Members decide on whether research meets ethical standards, but the whole group never meet in person. You decide each case after an email discussion. (You will be on this committee and the other members are students from your group also studying this unit.)

The committee receives an outline of a research proposal from a mature student, who is also a teacher in a primary or elementary school. The student will use her Year 6 class as subjects for the proposed research. The students' research proposal is given below:

**Title of research:** The influence of stated teacher belief on student assignment writing

**Subjects:** Entire group of Year 6 students in Social Science class

**Research overview:** The researcher will adopt the position of participant-as-observer in order to conduct the research. In order to test the effect of stated teacher belief (as opposed to a genuinely-felt belief) on the students' assignments, the researcher will conduct a short survey of students beliefs on the environment at the beginning of the school year. In the second term or semester, the teacher will state a strongly pro-logging position with regard to the logging of forests, prior to the commencement of a new topic area in social science class. The topic will include discussion of environmental issues relating to deforestation and its impact on ecosystems. The assignment given to the class will require an evaluation of the pros and cons of logging, together with an overall assessment of whether or not logging of old growth forests should be permitted. The influence of the teacher's stated belief will be tested against the survey results obtained earlier in the year.

After reading the brief research proposal, you need to respond to the members of the group with a summary of the ethical issues involved and the conditions under which the research could be supported. Your task is to frame a considered response to the student."

2. Designing the assessment | "Because the Ethics Committee would otherwise be snowed under with responses, a word limit of 1000 words has been placed on all committee members for each response.

"Send your evaluation to the Unit Online Discussion and participate in the discussion to decide as a group how the Ethics Committee should respond to the student. You will be assessed on your initial response and your final group response to the student."

3. Identifying, locating and/or producing resources | **Resources created, e.g.**

- Create email message for members of the committee, and student's research proposal

**Links to outside sources, e.g.**

- The Ethics Resource Center: http://www.ethics.org/

**Books and journals: e.g.**

4. Selecting collaboration coaching and communication tools | **Communication tools: e.g.**

- Online threaded discussions board
- Email

**Established listserves: e.g.**

- Ethics Update Discussion Forum: http://ethics.acusd.edu/kant.html

By the end of the initial three year phase, all units in the Masters courses will be available in an online mode and a significant number will use authentic activities: they will act as models for the future. Teachers will have developed the technical skills necessary for online teaching in a real but supported context, and engaged in a range of problem-based, reflective activities which seriously probe the nature of teaching and learning.

**Conclusion**
The adoption of online learning environments has frequently been an ad hoc affair in universities, often led by one or two computer enthusiasts or early adopters (Bates, 1999). While the individual approach has the advantage of commitment and speed towards implementation, there can be a tendency for early users to simply replicate existing teaching and learning practices in the online environment. Many staff development programs provide technical assistance to academic staff wishing to apply new communication and learning technologies to their teaching. Technical advice alone, however, seldom challenges teaching staff to reflect deeply on the nature of learning and to reconsider the learning goals and values which underpin their choice of teaching methods. The project described here was developed specifically to encourage academic staff to move beyond replication of existing ideas and to restructure their units according to the recent theory and principles of authentic learning.

Abstract: A novel system for teaching computer science online is presented. The ProgrammingLand MOO is a multiple user environment where students may learn content, exercise skills, collaborate with other students and demonstrate competencies. It is intended to deliver content in a learner centered fashion that is both engaging and attractive to students. The system is designed for distance education but has also been used with traditional classroom instruction. It has been used for introductory programming classes as well as for certain junior level classes.

Introduction

The ProgrammingLand MOO (Hill & Slator 1998; Slator & Hill 1999), is a computer aided instructional system to teach students the introductory ideas of Computer Science. It has been developed and used in conjunction with traditional classroom instruction. However, its goal is for distance learning and non-traditional classes. It is intended to deliver the content that would normally be obtained from a lecture or textbook, yet have many of the attractive qualities of games and other learner centered activities.

Content in ProgrammingLand

A typical session for a student starts with the execution of a client program. There are several applets that allow the student to use their web browser for this, as well as many good standalone clients. The student connects to the MOO and is registered for tracking purposes. The MOO itself is structured into rooms, with exits being the path from one room to another. Each student has a home that is usually the main entry way of the MOO, but the student may change their home if they desire. The MOO is built on Version 2.0.1 of the enCore database (Holmevik & Haynes 1997). The motif of ProgrammingLand is that of an Exploratorium style museum. Therefore the term exhibit is usually used instead of room. Whenever an exhibit or room is entered, the MOO displays a description. Typically this is a paragraph or two of instruction on some topic. The MOO will also indicate what exits exist and where they lead. The student is always free to choose which path to take and what to look at next. Although an exit is a one way path from one room to another, they often come in pairs so that a student may return to an exhibit conveniently. The student entering the Compound Statement Room would see the following display.

|The Compound Statement|
The compound statement is not a flow of control statement, however it is used in most flow of control statements and is essential to the Structured Programming model.
In the Structured Programming model there is the notion of a block. The block in C++ is the compound statement. It is a wrapper that binds several statements into one. It is also the block that greatly affects the scope of variables.

You may choose any of the following exhibits to consider next.

a) The syntax of the compound statement
b) Scope of variables in the compound statement

Figure 1: The Compound Statement Room

In summary the student meanders through the museum, picking and choosing what they want to read and also choosing the order to consider topics. If this were the extent of the techniques used in the MOO it might be useful, but would not be superior to a series of web pages. What must be considered next are the objects that work together to make this experience more educationally beneficial.

Fundamental Objects

In a MOO every thing is an object. Rooms are objects, exits are objects, players are objects and everything else that we will later consider are objects. These objects have properties that may carry information and methods that may perform useful functions. The student is oblivious to most of this, they walk through the museum without much thought to the processing the server is doing. The first objects that need to be considered are the student’s character and the rooms.

When a student logs into the MOO, the student’s character is activated. This character is the object that the server uses to manage everything that is known about the player. There are several important properties that are attached to the student object that have an impact on the educational use of the MOO. The first is list of every room that the player has visited. There are certain objects that mark events and make awards. The student scores points in this way, either by visiting an exhibit, taking a quiz, or achieving some other accomplishment. Finally, a student has a goal, which is what they should be working on currently.

There are two types of room in the MOO. The first type is called the lecture room, since it delivers a paragraph or so of the virtual lecture. This is the object that tags the student character with the fact that it had been visited. Its description property contains the text displayed when entered. It also contains a property that holds quiz questions, discussed below. The second type is called a workroom. The lecture room is the only type of room that records a visit on the student character and is the most common type of room. A workroom is only used to house some other types of interactive object.

Currently there are two such objects that are frequently used in workrooms: the code machine and the workbench. At any one time any number of students may be present in the MOO. They may interact with each other, since every room of the MOO is a chat room. However, when two or more students try to use either of these types of machines at the same time there will be confusing results. Neither student will be able to see what the other has done. Therefore, a workroom only allows one student into itself at a time. Furthermore, when the student leaves the workroom, the workroom will reset the contained machine to its starting state. Most objects other than rooms, exits and players can be picked up and moved. Few students realize this, but those that do can move a machine far from its intended location. Therefore, if a student does pick up the code machine or workbench, the workroom will remove it, when they leave.

Interactive Objects

Some of the objects discussed in this paper could be generally used in many disciplines but the code machine and workbench are specific to the programming discipline. The code machine contains a piece of programming code, which it will display, explain or trace. The code machine may display the code with or without line numbers. The line numbers are important for the explanation and trace. The code without the line numbers allows the student to copy the code from the MOO client and then paste it into an edit
window and actually compile the code. The explanation of the code works on a line by line basis. The
text is displayed with an explanation. The student then requests the next line. The trace of the
code is a simulated execution. The code machine displays the lines that are executed along with a
description of what is happening at run time, including the new contents of any variables that are
changed. When a student completes either the explanation or trace of a code machine, an event is posted
to their event property. The event captures the particular code machine in question and whether this was
an explanation or trace.
The MOO is not used to compile student programs. The compiler resides on the student’s own computer
or perhaps in a publicly available machine. Hence, some of the practice that would be desirable for a
programming class must be done out of the MOO. However, the workbench represents an attempt to place
part of this practice into the MOO. A workbench is a table driven parser, with enough of the tokens of a
program fragment to allow the student to test whether they have the syntax of a construct correct. The
student builds a statement or program fragment from the pieces that are inserted into the workbench.
When complete the student can ask the workbench to determine if the fragment is correct or not. In very
simple instances the workbench may also interpret the code and run the program fragment. Like the code
machine a successful parse of the code produces a point-scoring event on the student character.

Lesson Structure

ProgrammingLand is not a random collection of rooms containing instructional material any more than a
textbook is a random collection of pages. There is an order imposed that organizes rooms into related
clusters of rooms called sub-lessons. Sub-lessons have no required shape or size but often have some
common characteristics. They are always a group of rooms on a single topic. There is often only one
entrance in to the group and usually just one or two exits out. The first exhibit in the group is usually an
entryway room with a short introductory paragraph and then a menu of available rooms. Often one of the
rooms has only text that attempts to motivate the student or explain how the topic fits in the overall
scheme of things. There is often a workroom in a sub-lesson as the final example. A sub-lesson may be
nested within a larger sub-lesson.
The following objects were created to support the lesson: a sub-lesson, a sub-lesson-exit, a quiz room, a
dispatcher and the roving goalie. These work together to post events on the student object and test the
events. When students have enough point-scoring events, they can be given an “out of MOO”
programming assignment to finalize their learning.

Sub-lessons

The head of the structure is the sub-lesson exhibit. It is a descendent of the lecture room so contains all the
properties and methods of that object. It contains two additional properties as well, the all_rooms property
and the requirements property. The all_rooms property is a list of all the exhibits in the sub-lesson. If a
student is given credit for the lesson then the rooms on this list are removed from the student’s history of
rooms visited. This is done to shorten what can be a long list of rooms, under the assumption that mastery
of the sub-lesson is more important than any subset of rooms visited. The requirements property states
what is expected for a student to gain credit for the sub-lesson. It is a list of lists. If they satisfy any of the
sublists they are given credit for the sub-lesson. However, to satisfy a list they must satisfy every
requirement of the list. Each of the sublists may require any combination of simple room visits or specific
events recorded. The order that these requirements are satisfied is irrelevant, only that the students did
each of the items on one of the sublists. A requirements property does not have to contain multiple
sublists, but that is often the case.
The sub_lesson_exit is a descendent of the normal exit object but behaves in a rather different way. When
a student chooses an exit that will leave the sub_lesson, their progress towards satisfaction of the
requirements is checked. If the student has previously met the requirements, the exit moves the student to
their intended destination with no action out of the ordinary. If any of the sublists of the requirements of
the sub-lesson have been fully met, then the exit tells the student that they have completed the sub_lesson.
It also posts a completion of sub_lesson event to their event list. If they have not completed the sub_lesson
they get a different set of messages. The first sublist of the requirements is checked and one or two unmet
requirements are displayed. They are then asked if they want to continue to their destination and finish the
sub_lesson later or if they want to prove their mastery with a quiz. If they opt for a quiz they are
transported to a quiz room.

Quiz Rooms

The quiz room is a special room that is a descendent of the regular MOO room and not any of the
aforementioned rooms. It always has a single exit, which is the destination that a student usually arrives at
when leaving the sub_lesson. It has no entrances; the only way in is to take the quiz option when using a
sub_lesson_exit. It has a single new method, which administers the quiz to the student. The quiz is
randomly generated based on the requirements of the sub_lesson and the state of the students progress
toward the satisfaction of the requirements. The quiz generator determines the rooms that the student has
not visited by looking at the requirements of the sub_lesson and the history of the rooms from the student.
Each lecture room has a property that contains quiz questions. These questions should be about the
content of that room only. It then gathers the available quiz questions from the unvisited rooms and makes
up a quiz of no more than five questions. If there are not enough questions in those rooms it will look at
the sub_lesson for a store of more general quiz questions to get the total up to five.
A quiz consists of up to five questions. Each question is a four or five answer multiple choice question.
The questions stored in the lecture rooms are coded with three distinct pieces: the problem statement,
possible right answers and possible wrong answers. The quiz generator will randomly select one of the
right answers and four of the wrong answers. Therefore it is desirable to form questions that have several
right answers and many wrong answers to prevent students from communicating these questions to their
peers. The randomization of the answers disallows certain types of multiple choice answers like both b)
and c) and discourages answers like all of these and none of these. When the student answers, they are
given immediate feedback, either that the answer was correct or the letter of the correct answer. If the
student answers correctly a sufficient number of questions then the quiz posts the sub_lesson completion
event on the student character.

Lesson Dispatcher

The sub_lesson_exit or the quiz room may give the student the event for completing the sub_lesson. This
notice is put in the student’s events property. It also notifies the dispatcher object of the student and the
event. Certain sub_lessons are allowed to change the goal of a student. These sub_lessons are noted in the
dispatcher. When the dispatcher receives the sub_lesson notification, it compares the sub_lesson with a
list of sub_lessons and roving goalie objects. If this sub_lesson is on the list, then the matching roving
goalie is activated. It will wait for three seconds and then move to the location of the student. It will assign
them a goal and tell them some messages pertaining to that goal.

Goalies

A roving goalie is an object with several important properties for the interaction with the student.
Generally, it is intended to give each student a separate, personalized assignment, usually a programming
assignment. This is accomplished by three message properties. The first is the prefix message. This
congratulates the student for completing the sub_lesson and usually starts to introduce the assignment.
The second message is selected from a list of equivalent assignments. The roving goalie maintains an
index which records the next assignment to be given. When an assignment is given, this index is
circularly incremented. If there are more assignments than students each student will get a different
assignment. If there are more students then several may receive the same assignment. The third message
adds whatever concluding information may be appropriate. Every student receives the same first and third
message, but the second message will vary between students. This message may be quite lengthy, not just
a single sentence. If the student ever wants to reread the assignment, the goal and roving goalie are noted
on their character. They have the showgoal command which shows them the three messages again. Moreover, the roving goalie records the student which received each assignment index. A student may only receive one such goal from a particular sublesson, since the sub_lesson_exit first checks that they do not have the sub_lesson completion event.

Toys in the Attic

In the spirit of the Exploratorium, the ProgrammingLand MOO is populated with a range of demonstrations, toys, robots, and interactive exhibits. These artifacts are intended to engage a visitor in the exploration of the content stored in the museum. It is hoped that these playful, interactive objects will serve to both engage and teach.

Demonstration Machines and Checker Machines

Demonstration machines were built for Lisp functions as an in-class project in the summer of 1998. A class of 50+ students were each assigned a unique Lisp function, and instructed to create a machine with a 'demo' function that would illustrate the operation of the function. For example, the Lisp 'cons function' room contains a description of the 'cons' function, written on the wall, a 'cons' machine that will give a demonstration of how the 'cons' function works, and a 'cons checker' machine where players can plug expressions in to see if they're well formed. When the student plugs a correct value into the machine a congratulation message is returned and an 'award' is added to the player's history. When the player makes a mistake, the feedback includes the correct answer.

The Recursive Leprechaun

Since recursion is one of the most difficult concepts for students to master, it is important to expose the students to recursion as often as possible. One approach is to implement a recursive leprechaun, which resides in the Realm of Recursion. The recursive leprechaun demonstrates a recursive counting function in a visually descriptive manner. For example, the Leprechaun gives demonstrations of recursive counting by producing new leprechauns from a sack, and handing them an N-1 value to count; when N reaches zero, the leprechauns shout their value, pass it to the next, and jump back in their neighbor's sack.

The Ring Toss Game

The Ring Toss game is intended to provide an amusing challenge in the area of associating programming languages with their historical antecedents. The goal of the ring toss game is to associate languages with people and other concepts. More than one ring can be tossed on a single peg.

The History Jukebox

The History Jukebox is a device for summarizing programming language history in an entertaining and on-demand fashion. If a player were to 'press 1959 on History Jukebox' they would be told about John McCarthy at MIT and the origins of Lisp.

Tutor Robots
Tutor Robots were implemented to make the function rooms in the LambdaMOO wing more active and engaging. They are created from a prototype Turing Robot developed by Ken Schweller, based on the Eliza model (Weizenbaum 1966) which was inspired by Turing (1950). The Robots are user programmable and capable of matching key words and sentence patterns, and can be implemented with random responses and question responses. However, Tutor Robots can display both remarkable responses, and remarkably obtuse responses.

Conclusion

ProgrammingLand was never designed to be completely self-contained. The student will always need access to a language system. Thus the goals assigned by the roving goalie are externally satisfied. Related MOOs such as the Geology Explorer (Slator et al. 1999) have a goal system that is completely internal. When a student is interacting with the Geology Explorer, they always have a goal, usually the identification of some mineral on the virtual planet. When they find that goal they are congratulated and given a new goal. The system itself may monitor the progress toward the goal. If they need a particular instrument to properly distinguish a mineral from others that may appear to be similar and they leave the starting point without it, a tutor may appear and give them some instruction. Similarly, if the goal mineral is in a room and they leave without identifying it, then a tutor may appear and give them some instruction about that as well. These advantages stem from the fact that the goal is issued by the MOO and progress towards the goal may be monitored by the MOO. Though there are many parallels between Geology Explorer and ProgrammingLand, there are some differences as well. Specifically Geology Explorer is a virtual laboratory, the student should gain experience and hone skills. ProgrammingLand is designed to replace either the textbook or the lecture or both. However, its laboratory features are substantially weaker, due to the topic. ProgrammingLand provides some facilities such as code machines and workbenches but the bulk of the experimentation must be outside of the MOO.

Student evaluations of a course using ProgrammingLand were generally quite high; in one survey, 92% of the students responding rated the quality of the course as either above or much above average. Similarly, 88% of the students believed their understanding of the course content was either good or very good.

The ProgrammingLand MOO is an interactive learning environment. It attempts to balance content material and immersive exploration. It is more interactive than a textbook or a lecture, it keeps better records than web instructional pages, it also productively uses the information that it records.

Abstract: Increasingly Educational Hypermedia Systems (EHSs) are using the World Wide Web (WWW) as the medium of delivery. Many of these systems use methods and techniques from Adaptive Hypermedia Systems. This paper focuses on the interchange of information about the student's knowledge between EHSs over the WWW. A conceptual framework based on a 4-dimensional representation is introduced. A proposed implementation of this conceptual framework within the eXtensible Markup Language (XML) is described. The paper concludes with a brief summary of future work.

Introduction

The field of education has always been a research area of Adaptive Hypermedia Systems (AHS) [Brusilovsky, 1996]. Every Educational Hypermedia System (EHS) that not only displays prepared content to a student but also changes certain styles of display or paths through the system is an AHS. Increasingly hypermedia projects use the WWW as their delivery medium [Brusilovsky et al., 1998; De Bra & Calvi, 1998; Specht & Oppermann, 1998; Nkambout & Gauthier, 1996]. Most of them lack the capability to share information about the users or students with other EHSs and are therefore isolated or closed. The result of this isolation is that every EHS has to organise information about the users by itself. To overcome this isolation we introduce an approach to "open" the EHSs. The approach will concentrate on information about the student but will also identify different areas where openness of the EHSs would be possible. A conceptual framework for an n-dimensional User Profile Interchange (UPI) is shown and future work in this area is outlined.
How could Educational Hypermedia Systems be open?

EHSs that use adaptive techniques are AHSs [Brusilovsky, 1996]. So, it can be assumed that EHSs implement the basic processes of an AHS, which are:

- Gather information about a student. This can be done fully automatically or collaboratively with the student. It is also possible in an educational context that the teacher provides the system with information about the student.
- Create a user profile of the student based on the information.
- Adapt the content, the content presentation, the teaching strategy or the navigational support to the students profile.

It would be beneficial if an EHS could be open in each of the aspects named above. This means that the information about the student as well as the teaching and learning strategies and the adaptation processes might be exchanged between the different systems. However, in this paper we will concentrate on the interchange of the information about the student's knowledge.

User Models in Educational Hypermedia Systems

Data about the student is important for an EHS because the adaptation process depends on this information. Most EHSs are require information such as:

- Learning preferences: What kind of teaching or learning strategies does the student prefer, e.g. case studies, problem solving, and so on?
- Presentation preferences: Has the student any preferences for specific presentation styles or particular media-types?
- Background and experience: What background and experience does the student have?
- Goals: Which goals or learning goals does the student have? What goals does the teacher have for the student?
- Knowledge: What knowledge does the student have?

Additional information about the student can be gathered during the usage of the system. The system could, for example, analyse the path taken by the student through the document or content space. It could analyse answers to tests or interaction during a problem-solving module. The system is then able to update the user profile during the presentation and adapt the presentation on the fly.

The information about a student is processed by an EHS to build a user profile for the student. If the same student were also working in another hypermedia system, then this system would also have to build a new user profile for the student. A very challenging part of the user profile is the representation of the knowledge of a student. Therefore we concentrate on this part of the user profile. Different approaches have been tried in the past by different systems:

- Stereotype [Boyle & Encarnacioni, 1994], e.g. students are classified into groups rather then being classified as individuals.
- Boolean [De Bra & Calvi, 1998], e.g. several variables are used to classify a student. Each variable represents a specific knowledge the user has or has not.
- Percentage values [da Silva et al., 1998], e.g. variables represent the users knowledge about a certain domain. The variable has furthermore a graded value that holds the graded knowledge of the student about that domain.

The information about the user could also be represented within an n-dimensional framework that will be now introduced.

N-Dimensional knowledge representation

A feature of the above user modeling techniques is that they differ in the level of detail used to describe a student. The more accurately the individual student and his knowledge is to be modeled the more variables are needed. It is rather difficult to convert one of the user models into another whilst they are in their native state. For a working UPI model we have to build a framework that allows us to describe all user model structures, such as stereotype,
Boolean, and so on. For this task we introduce an n-dimensional user knowledge representation scheme. Each
dimension represents the extension of a user model with the capability for a more fine-grained representation of the
students' knowledge.
The following table explains the different dimensions:

<table>
<thead>
<tr>
<th>Dimensions</th>
<th>Description</th>
<th>Corresponding user model concepts in AHS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-adaptive Model</td>
<td>No explicit user modeling technique is used. The systems user model is static and implicit. The user model can not be changed and the presentation is not adapted.</td>
<td>Every non-adaptive EHS</td>
</tr>
<tr>
<td>(0-dimensional)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single Variable</td>
<td>The student's knowledge is modeled only with one variable. The users are classified into groups rather then being classified individually.</td>
<td>Stereotype user model</td>
</tr>
<tr>
<td>(1-dimensional)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Multiply Variable</td>
<td>The model of the knowledge is extended by one dimension. There are now multiple variables available to model the student’s knowledge. The additional dimension indicates whether the knowledge modeled by one variable is present or not.</td>
<td>Boolean approach</td>
</tr>
<tr>
<td>(2-dimensional)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Value dimension</td>
<td>Each of the variables used by the 2 dimensional approach can be extended with an individual or range of different values. These additional values allow an even more detailed description of the users knowledge.</td>
<td>Scalar or Percentage approach</td>
</tr>
<tr>
<td>(3-dimensional)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Time dimension</td>
<td>There is not much research work available about 4-dimensional approaches. A promising idea is to introduce time as a fourth dimension [De Bra, 1999]. Every value of the variable could be marked with a time-stamp, after some time the knowledge of the student begins to degrade.</td>
<td>Knowledge degrades over time.</td>
</tr>
<tr>
<td>(4-dimensional)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Possible future dimensions</td>
<td>Each additional dimension offers the system an even more detailed view of the student’s knowledge. Future research in the area may discover more dimensions that need to be considered. The problem with too many dimensions is that the implementation overhead grows enormous with every new dimension.</td>
<td>Theoretical</td>
</tr>
<tr>
<td>(n-dimensional)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Mapping approaches**

The UPI between n-dimensional Open Educational Hypermedia Systems (OEHS) is difficult. After analysing the
different dimensions it is important to realise that there are just 3 different approaches to map the information about
the user from one OEHS to another. Depending on the dimension of user knowledge representation of the OEHS is
it necessary to perform a simple mapping, downsize or expand on the information about the user. The different
approaches will be now introduced in more detail.

**Simple Mapping**

The approach of simple mapping covers all the cases of UPI of OEHSs that have the same dimensional structure of
their user model. No dimensional conversion has to be done. The information about the user can just be copied from
one OEHS to the other. The problem of what to do if the different user systems do not have the same knowledge
domain structure remains.
Downsizing

Downsizing the user information from one OEHS into another is necessary whenever the source OEHS has a higher dimensional user-model than the destination OEHS. During the transfer of the user profile information from the source OEHS with a higher user profile dimension to a destination OEHS with a lower user profile dimension it is quite obvious that there will be a loss of information about the user. The loss of information is larger the larger the dimensional gap between the two OEHSs is. A user profile that is transferred from a 4-dimensional OEHS into a 1-dimensional OEHS loses all the information of dimensions 2-4. The downsizing process itself has either to be done manually or with a sophisticated automated process. This will not be easy and requires further development of the technologies and the framework.

Expansion

The user-model of the source OEHS has to be expanded if the user-model has a lower dimension than the destination OEHS. The expanding process is therefore the opposite approach to the downsizing approach. The difficulties within this approach lie in the need for creating additional information about a user. This is the biggest problem found in any of the three named approaches.

The following chart visualises our n-dimensional mapping approach of UPI in OHES:

![Diagram]

The problem of different knowledge domains

We have to differentiate between two cases of user profile interchange. In the first case the two AHS have the same structure for representing the knowledge domain. Furthermore, not only the representation structure is the same, but also the perspective of the domains is the same. For example, the source and destination AHSs have the domain "multimedia" and the domains have the same meaning and scope in both AHSs.

In the second case the structure of the knowledge domains of the two AHSs are different. Either the different domains are named differently or the have the same names but not the same meaning for the two AHSs. For example, the domain knowledge concept multimedia symbolises a complete knowledge about multimedia in the one AHS but only coverage of video, audio and text elements in the other AHS. The mapping between non-identical knowledge domains in this second case is very difficult to implement and is left at the moment for further research.
The technique of the user profile interchange and the implementation will however stay the same in both cases. The only area where the two approaches differ is the grade of sophistication in the mapping of the user knowledge from one OEHS to the other.

**Implementation**

To describe the different dimensions of the students knowledge we use the eXtensible Markup Language (XML) [XML, 1998]. XML is a markup language that allows the creation of customised markup Languages and is used in several projects for describing educational metadata [ARIADNE, 1999; Ram et al., 1999]. We propose the creation of a new XML Document Type Definition (DTD) specially designed for User Profile Interchange over the WWW. This DTD would offer the possibility of describing every category of the user model of an EHS. It would be designed so that it can be extended dynamically to describe new dimensions of the user model.

If two OEHSs want to exchange information about a specific student they would create XML files based on the UPI-DTD and exchange these XML files over the WWW.

As soon as the destination OEHS receives the UPI-DTD tagged information about the student it can start to import the user profile. The technical realisation of this import process could be done with any program language capable of reading XML files. The implementation has to provide the different mapping approaches to the OEHS introduced above. The authors are planing to use JAVA for this task, because it is particularly suited to working with the WWW and secondly, there are tools and classes being developed to provide XML capability.

**Advantages**

The biggest benefit of this approach is that the n-dimensional UPI builds a meta-framework for student knowledge representation. The XML implementation will permit an interface for every EHS that wants to exchange user specific information over the WWW. Other advantages are:

- Information about a student and his knowledge will no longer be isolated into separate systems but can be exchanged between them.
- It provides an easy and dynamic extendable framework that is able to describe the entire present user modeling techniques in AHSs and EHSs.
- XML allows the easy and standardised implementation of the n-dimensional UPI model for the WWW.

**Problems**

Despite the advantages of this new framework covers there are still some problems which have to be solved. The biggest one is probably the one about the different knowledge domains of the OEHSs. This situation is difficult to solve without additional information about the different systems. The problem is not so big if one of the two systems, either the sending or the receiving one knows the user model structure of the other EHS. In this case the system that knows the others user model structure can export or import the user information in the proper way. Some other problems that need more research are:

- At the moment there is a lack of a common terminology for describing student knowledge variables.
- How can variables of certain dimensions be converted to variables of other dimensions?
- How are individual-based user modeling techniques transferred into group-based modeling techniques and vice versa?

**Conclusion and Future Work**

In this paper we have introduced a new conceptual framework for User Profile Interchange in Open Educational Hypermedia systems. This new framework is based on an n-dimensional projection of user models. The framework will be implemented in XML and evaluated in our future work. Subsequent work will concentrate on the interchange of teaching and learning strategies, content organisation and adaptation processes in Open Educational Hypermedia Systems.

Abstract: This paper explores the consequences for the design, development and evaluation of educational software of a model of understanding information technology based upon teachers' concepts and beliefs about this technology. The model was the result of a case study and considers two dimensions. The first dimension is the role of the computer, conceptualizing it as a teaching resource that helps teachers to develop their teaching strategy, replacing them in the role of managing students' rehearsal of materials and serving as a classroom management tool. The second dimension is the pedagogy that teachers embedded into the characteristics of the software, such as classroom atmosphere in the human-computer interface scenarios and elements, the teaching routines in the design of the navigation structure of the software, and the learning strategy in the human-computer interaction. The main consequence of this model is in illustrating a specific integration of pedagogy-related concepts to the design, development and evaluation of educational software, thereby demonstrating the need and usefulness of such integration.

Introduction

This paper explores the consequences of a model of understanding information technology in the processes of designing, developing and evaluating educational software. The model is the result of a research study aimed at understanding teachers' concepts and beliefs about educational software (Hinostroza, 1999). The research was designed as an instrumental case study (Stake, 1994) to provide insight into teachers' concepts and beliefs about computers. The process of definition of the study followed (Yin, 1994)'s recommendations. The 'case' was a process of educational software development, in which two primary teachers, a software engineer, a psychologist and a graphic designer were committed to the development of a piece of educational software over a period of seven months. Each session of the development process was observed and video recorded. The data was analyzed from both, qualitative and quantitative stand points, using systemic networks (Bliss & Ogborn, 1979) to organize and give a structure to the categories of analysis and the software QSR NUD*IST to support the coding process.

The unit of analysis was defined as a sequence of utterances made by members of the team in which they refer to one particular aspect of the software. Where they referred to two (or more) aspects simultaneously (in parallel), these have been considered as two (or more) separate units. This unit was named 'Discussion about Software Design' and was described through the systemic network.

The two main attributes that characterized the unit of analysis are: the 'Topic' discussed and the 'Participants' in the discussion. The 'Topic' of discussion was divided into three main subjects related to the software design. The first one was related to the dimensions of software engineering ('Subject Areas', 'Content Organization', 'Navigation', 'Interaction' or 'Interface Element'); the second one was about the characteristics of the user ('Teacher', 'Pupil' or 'Group'); and the third one dealt with 'Pedagogic Issues' that were related to software and/or computers ('Aim', 'Teaching Strategy' or 'Actions').

The data classified was analyzed using three methods: (i) participation analysis, aimed at establishing individual participation profiles during the development process; (ii) sequence analysis, aimed at establishing the inter-relations among the different components of the software based on the analysis of the patterns of sequences of
units in the data for the group and for each team member, and (iii) contents analysis, aimed at looking for the meanings expressed by the teachers about the different dimensions of the piece of educational software. These analyses were used in a complementary way, enabling the researcher to focus on relevant issues and to enable some triangulation of the implications drawn.

The main implications of this study were represented through a model of understanding information technology that is presented in the next section.

The Model of Educational Software

This model, firstly, shows, what the participating teachers conceived of as the role of the computer, and, secondly, presents the characteristics of the educational software that these teachers designed and shows the dimensions of their teaching strategies that were embedded in these characteristics.

In discussing the role of the computer in the classroom, the teachers indicated how important for them the role of the computer as rehearsal tool, this was the role that they naturally picked up and expanded on. They designed this role by integrating it into a larger teaching strategy that separated teaching into two stages: learning new concepts and rehearsing these concepts. This model of use of the computer is represented in Fig 1.

![Figure 1. Model of the role of the computer](image)

In this model the computer is acting as a resource for the teacher that helps him/her carry out some of their current tasks more effectively. Some ground rules in this model are that (Hinostroza & Mellar, 2000):

- the teacher teaches new concepts in the classroom and not in the computer room;
- the teacher does not interact with the computers;
- the teacher when working in the computer room guides the pupil’s construction of knowledge through managing the classroom and solving computer problems, but (s)he does not engage with the contents to be learned;
- the teacher manages the pupil's access to the computers, and by incorporating them within the punishment-reward system of the classroom (s)he is able to use them to manage the class.

Regarding the design of the piece of software, it was found that they transferred several teaching principles, or classroom routines, to characteristics of the educational software. These principles can be classified as the three different types of classroom routines described by (Leinhardt, Weidman, & Hammond, 1986):

- **Management**, this includes housekeeping, discipline maintenance and people moving tasks.
- **Support**, that is, specific behaviors and actions necessary for a learning-teaching exchange to take place, for example ‘how to pass in papers’.
- **Exchange**, that is, the interactive behaviors that permit the teaching-learning exchanges to occur. They govern the language contacts between teachers and students - for example, routines for choral responses.

The correspondence of these routines and the software characteristics is presented in Tab. 1 (Hinostroza & Mellar, 1999).
### Table 1. Correspondence between teaching routines and software design domains.

<table>
<thead>
<tr>
<th>Teaching Routines Domain</th>
<th>Software Design Domain</th>
</tr>
</thead>
<tbody>
<tr>
<td>Management: In this case classroom atmosphere and tone.</td>
<td>The human-computer interface elements (scenarios, backgrounds, characters and particular functionality of these elements) and the overall organization of the subjects.</td>
</tr>
<tr>
<td>Support: In this case, lesson flow, contents provision, and control of the user’s progress.</td>
<td>The navigation structure of the software and the response to certain situations (for example, feedback on errors).</td>
</tr>
<tr>
<td>Exchange: In this case, learning strategies or theories.</td>
<td>Particular human-computer interaction and user’s actions.</td>
</tr>
</tbody>
</table>

The model was grounded in two sources of evidence, first, the data collected in the research and second the evidence reported in research studies about teachers' everyday practices in the classroom, (i.e. their strategies, routines, roles and beliefs). This latter source of evidence expands the theoretical framework of the study, covering not only the area of information technology in education, but also the area of pedagogy. In this sense, this model of educational software constitutes an interesting starting point for further research in this area. We now turn to the discussion of the consequences of this model for the design, development and evaluation of educational software.

### Implications for Educational Software Design

Educational software is still an arena for debate and controversy, and as yet there are no clear design prescriptions that could ensure its actual use nor its effectiveness (see for example discussions in: Cuban, 1997; Johnson, Cox, & Watson, 1994; Lowther & Sullivan, 1994). We (also) suggest that much of the reason for this continuing controversy is that little attention has so far been paid to a consideration of teachers' actual classroom practices.

Based on the model presented in the previous section it is possible to argue that in order to design software one important issue to address is the role of the software in the teaching strategy that the teacher will implement. In this case the software was defined in such a way as to have a role in the rehearsal stage of the teaching strategy, but it is also possible to imagine that it could have a role in the stage where the teacher explains new concepts (for example a piece of simulation software would probably fit into this stage).

The implication of this definition is that the software is designed to play this and no other, role while teaching. This helps to focus the design of the software to meet a particular set of learning requirements only, without pretending to support the complete teaching and learning process.

Given the role of the computer in a given teaching strategy, the other consequences are related to the design of the characteristics of the software (Human-Computer Interface, Navigation Structure and Human-Computer Interaction) and will be presented in the following sections.

### Human-Computer Interface Elements

It was argued that this characteristic of the software was related to the design of management routines, particularly to the creation of a 'classroom atmosphere and tone'. Regarding the latter, (Woods & Jeffrey, 1996) describe how primary teachers create 'atmosphere' and use different 'tones' in interaction with the children to achieve different effects, they describe it as having the following characteristics:

- **Anticipation and expectation**: teachers are skilled in the construction of situations and in their sense of timing.
- **Relevance**: teachers are able to ensure that pupils feel a strong sense of involvement by making the pupils identify and get involved in the atmosphere.
- **Achievement and success**: there is a sense of high teacher expectations and confidence in children’s abilities to meet them.
- **Satisfaction**: Pupils feel satisfaction and the sense of ‘a job well done’ because of the achievement.

These characteristics are part of the techniques that teachers use during their lessons. (Woods & Jeffrey, 1996) also describe the different tones that teachers use during the lesson as “Andante (to be performed in moderately slow time)”, “Legato (smoothly and connectedly, no gaps or breaks)” and “Spiritoso (with spirit)".
These techniques can be considered in the design of the human computer interface (HCI) elements of the software, for example:

- Creating the background of the HCI as a story, so that students can get involved in it and believe it.
- Designing the storyboard so that it can be reviewed in one lesson and that, independently of the particular path followed by the users, they find a coherent end to the story.
- Designing the graphic representation of the characters and scenarios of the HCI so that they are known to the users.
- The organization of the 'contents' of the software should take care that users can review the complete story in one lesson.

The Navigation Structure

It was argued that the design of the navigation structure was related to the support routines, in this case this implies that the software should implement the 'flow' of the lesson. With respect to this, (Hammersley, 1990) says that teachers present the lesson "pitched at a certain level of 'difficulty' according to the co-ordinate position of the class in relation to age and ability" (p. 47). He argues that teachers gradually provide more and more clues to 'what the answer is' in order to pace the lesson in such a way as to get the answer to emerge towards the end of the lesson. Further on, he gives some reasons why they do this: "this pre-setting is designed not only to ensure that pupils are taught something 'new', that they 'keep moving', but also that they have the resources to understand what the teacher is to teach" (p. 47).

This strategy can be transferred to the design of the navigation structure of the software using a schemata such as the one presented in Fig. 2.

In such a structure users can navigate through different sequences of 'contents' accordingly to their 'level' of achievement and will have the opportunity to learn something new and to keep moving as Hammersley describes students as doing in a teacher taught lesson.

Human-Computer Interaction

It was argued that the design of the human-computer interaction was related to the exchange routines, in this case that is to the teachers' learning theories (conceptions) that govern the teacher-student dialogue. The literature describes the teacher-student interaction as based mostly on dialogues that have the structure of question, answer, and feedback. About the former, (Gall & Artero-Boname, 1995) classifies teachers' questions during a lesson as: lower or higher cognitive questions; recitation and discussion questions; or as test-relevant questions.

The feedback provided to students has also been studied. (Mayer, 1995) describes the educational uses of feedback as corresponding to academic learning tasks, behavior management tasks and skill learning tasks. In the first, feedback provides information concerning the correctness of students' performance; in the second, it provides information concerning the appropriateness of students' behavior; and in the third it provides information concerning the accuracy of students' behavior.

Figure 2. Navigation structure of the software.
These two areas provide a rich framework for designing the human-computer 'dialogues' that take into consideration the type of questions that the software should consider and the different types of feedback that need to be considered.

**Implications for Educational Software Development**

Looking at the literature that describes educational software development (for example: Eraut, 1996; Galvis, 1994; Squires, 1996), there are few references to issues such as 'Classroom Atmosphere', 'Lesson Flow', or 'Classroom Management'. Although some of these reviews mention 'pedagogy' as a dimension that needs to be considered (for example: Squires, 1996), they do not expand on these issues. Whilst it is true that teachers have sometimes been incorporated into the software development process, they have generally been asked to contribute to the learning and curriculum design issues, and the issues of actual classroom practice have been neglected.

This lack of material discussing these issues indicates the low importance that seems to have been given to knowing and considering the actual use of the software in order to design it. Through a study of the literature relating to pedagogy it was possible to identify at least three theoretical areas that could influence the development process of educational software (i.e reported techniques for classroom atmosphere, lesson flow and learning).

These findings have clear implications for the software development process, in so far as they show the need to incorporate these dimensions during the development of a piece of educational software. Some concrete consequences are for example:

- The need to define a teaching strategy first and then analyze in which stage the software should play a role.
- The need to define what teaching-learning problem(s) will be addressed through the software. For example, improvement of the efficiency and/or effectiveness of the teaching-learning process.
- It places the teacher as a relevant user of a piece of educational software and therefore the software engineer needs to take into consideration a new area of expertise (i.e. pedagogy) to inform the decisions during the development process.
- The test procedures during the development process should contemplate observations of teachers using the software in a normal lesson.

**Implications for Educational Software Evaluation**

As mentioned previously, the design of educational software to date has been primarily focused on learning and has paid little attention the teaching dimension, and as a result, teachers have difficulty incorporating it into their practice. Software evaluation has paid little attention to this area, and has only recently begun to give serious consideration to the teaching dimension (for example see: Wishart & Blease, 1999).

So, it could be argued that the evaluation and selection of a piece of educational software could be improved if these issues were considered and 'evaluated', defining additional standards to judge and characterize a piece of software. For example, to evaluate the interface elements of a piece of software by considering the design of a 'Classroom Atmosphere', the navigation structure should be evaluated taking into consideration Hammersley (1990)'s descriptions of the strategies that teachers use in the classroom and the human-computer interaction should be evaluated considering the principles of what the literature defines as good practice in questioning and providing feedback. Some specific implications for this area are, for example:

- Prior to the evaluation of a piece of software, the teaching strategy should be defined, this in order to specify the context (teaching aims, environment and techniques) in which it would be used.
- The evaluation criteria should consider the teaching routines used by teachers of the subject area and school level in which the software is to be used.
- The evaluation should know and consider the users' previous knowledge (abilities, skills), given the stage of the teaching-learning process in which it will be used.
- The evaluation should consider measurements to qualify and/or quantify the improvements in the teaching-learning process. For example in terms of the efficiency of the process, this is, instead of investing five lessons to teach something, with the software it can be done in three lessons with the same (or better) results.
Conclusions

These implications for educational software design, development and evaluation indicate new issues that should be considered. They show that there is a need for further research that could help to define the specific teaching-learning strategies, principles and routines that should be known and used to define and evaluate the particular characteristics of a piece of educational software. If considered, they can change the very conceptualization of such products and eventually transform them into teaching aids or ‘professional tools’ for the teachers.

Finally, it must be considered that whilst our intention here was to present one model of educational software and thereby to illustrate how the prescriptions of this model could be use to improve the processes of designing, developing and evaluating educational software, it must be kept in mind that this model is the result of a small case study and all that it enables us to do is to propose this model and its consequences tentatively, recognizing that it requires much wider verification.

Abstract: This paper explains how a WWW site was designed to assist preservice teacher education students in using a reflective framework to study how they learned in university classes. There were three phases in the reflective framework: (i) analysis; (ii) synthesis; and (iii) theorizing. In this last phase the students developed a metaphor to represent an optimum classroom learning environment. The web site was designed using a FileMaker Pro database with a template for each category of learning—personal, teaching, peer and situational—to assist students in managing, sharing and theorizing about their reflections. Students claimed that the web site supported their reflections and the metaphor helped them to conceptualize the dynamics of classroom relationships.

Introduction

The notion of being reflective means rethinking experiences, particularly ones which are problematic, to make clearer sense of them and to gain insights for subsequent experiences (Dewey, 1933; Schön, 1983; 1987). It is now common practice in preservice teachers education programs to encourage students to use reflective journals to rethink and analyze their experiences in university subjects (Loughran, 1995; McRobbie, 1994; Wilson, Hine, Dobbins, Bransgrove, & Elterman, 1995). This includes reflecting upon education readings, class discussions, personal thoughts or school experiences. However, the focus of the reflection is often about what students understand, what they don't understand and to specify areas which require further readings or explanations. Rarely are preservice teachers asked to reflect upon how they learn, how they are being taught, or how they interact with other students.

During their training, preservice teachers are exposed to a wide range of teaching strategies and content as well as interacting with a variety of students. This exposure to a variety of learning situations provides a wonderful opportunity for preservice students to study how they learn. When trainee teachers gain these insights, they can deduce implications for their own pedagogy based on personal experiences. Although this idea was raised over 30 years ago, it is a rare practice in teacher education programs:

The student in the process of becoming a teacher is not made acutely aware of how he is learning, that is, to utilize himself as a source of understanding of the nature of the learning process. . . . one of the major reasons so many teachers are dissatisfied with themselves in their work is that their training did not illuminate the nature of their learning process and how this relates to and affects the learning process of their pupils. (Sarason, Davidson, & Burton, 1962, p. 118)

When preservice students are asked to reflect upon complex interactions such as how they are learning, technologies such as the World Wide Web can be a useful tool to support students in documenting, analysing and sharing insights (Bennett, 1998). The purpose of this paper is to explain a reflective framework which encourages preservice teachers to study how they learn in university classes and how a World Wide Web site was designed with templates to help students manage and theorize about their reflections.

Using WWW Templates to Support a Reflective Framework for Studying Learning in University Classes

Over the last four years, a reflective framework has been developed to guide preservice teachers in studying how they learn in university classes (Hoban, 1995, 1997, 1998). This framework encourages each preservice teacher to be “a researcher in the practice context” (Schön, 1983, p. 68) with the context being their experiences as learners in their university classes. There are three phases in the framework which encourage students to analyze their experiences, synthesize key factors which influence learning and to develop a metaphor.
to represent an optimal learning environment. The first phase occurs for the duration of the subject and the second and third phases are completed by students towards the end of the subject, although they can be completed concurrently by students.

In 1999, a WWW site was designed with a File Maker Pro database as a tool to help preservice students use the reflective framework. The site was designed with the intention of minimising the cognitive load on students when reflecting by using a screen design which “promotes understanding by allowing the reader to focus on new information rather than devoting time and energy to variations for format” (El-Tigi & Maribe Branch, 1997, p. 25). In addition, the web site assisted students in organizing and theorizing about their reflections to deduce a metaphor to represent an optimal learning environment. In spring semester 1999, 25 trainee teachers used the WWW site in a preservice science methods subject which lasted for 13 week in an elementary teacher training program. The students had a three hour class each week—two hours were spent with the students doing hands-on science experiments and a third hour was spent reflecting upon how they learned in the class using the web site. The three phases of the reflective framework are now described as well as features of the web site.

**Phase 1: Analysis.** After each university class students logged onto the WWW site and had to reflect upon their class experiences to identify the personal, social (teaching and peer) and situational factors which influenced his/her learning. There was a template for each category which is consistent with a constructivist perspective that views learning as an individual process of knowledge construction that is supported by social interactions with the outside world (Duffy & Cunningham, 1993). The templates were labelled according to the following four categories:

1. **personal factors** attributed to each student, such as prior knowledge, feelings, self esteem, motivation and personal learning strategies;
2. **teaching factors** attributed to the instructor/tutor, such as class organisation, teaching strategies, class organisation goals, and rapport;
3. **peer factors** attributed to other students such as how they encourage each other, share ideas and cooperate in tasks; and
4. **situational factors** attributed to the task, setting and environment.

After each class, the students identified factors which enhanced or inhibited their learning and documented these processes or strategies in the templates on the WWW site. The following is an example of a student’s weekly reflections as written in the four templates of the web site in week 2 of the subject. It should be noted that students noted a positive factor with a “+” and a negative factors with a “−” and highlighted key words using upper case:

**Personal Factors**
- I am not confident with teaching science in front of an audience therefore I feel this elective will be very rewarding as I will gain KNOWLEDGE, CONFIDENCE and UNDERSTANDING of how to teach science to a young audience.
- + I work better in an environment where I am comfortable and feel free to exchange ideas and questions without the worry/fear that others will criticize me. This style of teaching suits the way I learn.
- + As this was the first real science lesson I had no idea of what to expect from this elective so I was INTERESTED and WILLING to get involved with the debates and answer any questions thrown at me.

**Teaching Factors**
- + Today’s teaching strategies were very suited to my learning and understanding of science. I enjoy a RELAXED environment where I feel free to contribute to the class discussions.
- + It was amazing how pre-knowledge that I have gained over time was used in this lesson. I didn't realize simple experiments can make things clear.
- - Initially, I didn't feel it was necessary to write a reflection of the lesson on the internet. I prefer to share and discuss how I feel in some cases I feel it easier to talk about problems or ideas rather than writing it down.
- - I'd prefer writing on the white board to be set out more clearly and more information for each point when an idea is raised.
- + It was interesting that there is no right way to go about teaching a particular subject, everyone goes about learning differently. I enjoyed the many different styles that were discussed (the frameworks).
- + the instructor seemed to deliver the information clearly and effectively providing relevant FEEDBACK in order for us (the students) to improve.

**Peer Factors**
- - Initially, everyone in the class was a little daunted at what to expected from this science lesson.
- + From this lesson I feel confident with raising issues and asking questions. Everyone in the class was willing to accept everyone’s ideas openly and ask for any queries.
- + The class members continually gave positive ENCOURAGEMENT to those students who didn't understand the work covered. Everyone tried to help everyone understand what the lesson was about (TEAMWORK).
I enjoyed working in small groups to achieve each activity everyone had their own idea on what they thought was right.

Already I have met new friends from this lesson and together we have worked together to achieve the work set out.

**Situational Factors**

+ This class is not large therefore where the instructor was teaching or standing was always close by. There were no heads in the way, there was enough material to go round, the labs which are well lit and everyone had a great attitude to work (I suppose this was because this was the first week).
+ It was great having food and coffee provided for us which also seemed to break up the lesson.
+ As the materials were well set out it was easy to get straight into the hands-on-activities and get started.
+ Everyone in the class seemed to get on well with everyone (CO-OPERATION) therefore it was easy to reap the rewards of each activity.

**Phase 2 Synthesis.** Towards the end of the subject, students collated factors documented in their weekly reflections according to the same four categories identified in phase 1. After the students completed their collations, they used an iterative process of “constant comparative analysis” (Glasser & Strauss, 1967, p.vii) to compare, combine and synthesize factors resulting in the identification of several key factors for each of the four categories. The WWW site helped students to synthesize their reflections because it was designed to collate similar categories for all the weeks so that students could scan them to identify the most influential factors. For example, the data base within the web site linked the templates from week to week enabling each student to see the personal factors across all the weeks on one screen. This aggregation of the reflections assisted the students to identify the key factors within each category and these were summarized in a table called a “Learning Profile”. Collectively, the key factors highlighted in their Learning Profile represent a student’s identification of factors which would establish an optimal learning environment for them in a university class. It should be noted that an optimal learning environment would only be possible if all of the enhancing factors (or nearly all) were present. The following documentation represents a student’s Learning Profile which is the synthesis of key factors for each category for the duration of the subject:

**Personal**
- knowledge, confidence and understanding
- interested and willing to get involved
- preparation is necessary in order to benefit from the lesson
- motivation
- sense of achievement
- prior knowledge: you need to do the readings
- "what you put in is what your get out!"

**Teaching**
- creating a relaxed environment
- positive feedback/reinforcement for us (the students) to improve
- information given to the students is clear and concise
- providing relevant examples to explain concepts
- classroom management
- teacher involvement

**Peer**
- positive encouragement
- working as a team (teamwork).
- group dynamics
- group motivation when needed. eg. 'We can do anything, come on girls!!'

**Situational**
- all class members working together (co-operation)
- the relaxed atmosphere created by the teacher and students
- materials safe and accessible (all materials are available when needed)
- the preparation of each activity e.g. layout and materials needed
- timing of the lesson e.g. activities

**Phase 3 Theorising.** Each pre-service student considered the key enhancing factors identified in phase 2 and theorized about the relationships between them to devise a metaphor (Lakoff & Johnson, 1980) that represents an optimal learning environment for a university class. Although the students did not use the web site for designing their metaphor, it was labeled with key factors identified in their Learning Profile from phase 2. Nonetheless, the process of theorising was assisted by having the reflective data presented systematically and collectively in the templates. This thinking is consistent with (Strauss & Corbin, 1994) interpretation of a theory as “plausible relationships proposed among concepts and sets of concepts” (p. 278, italics in original). Alternatively, students
Two issues, however, became evident when preservice teachers used the web site for the reflective framework. Of the students made comments about using the web for their reflections: effectively which has reduced their cognitive load in using the framework. In an end of subject evaluation, some manually was time consuming and conceptually difficult for some students.

Patterns within the data and deduce their metaphor to represent an optimal learning environment. Students had to seek manually across many pages to synthesise the key factors for each category. Also, the students had to seek pen and paper (Hoban, 1997, 1998), this is the first time that students have documented their reflections on a

Analysis of their own experiences of learning. Although students previously used the reflective framework with theories. This means that preservice students can deduce implications for their own pedagogy based on the

To reflect on experiences by documenting, analysing and seeking patterns within the data for generating personal environments. In particular, trainee teachers often do not get the opportunity to study their own experiences as students in class to gain a first hand understanding of the relationship between teaching and learning. This is a valuable insight for trainee teachers as designing an optimal learning environment, which is the main outcome of the reflective framework, takes into account the type of teaching and the type of learning and the type of social interaction with peers. Developing such an awareness of the dynamics in any educational setting can support students in participating in reflective conversations about teaching and learning which is a useful skill for their future role as teachers.

Discussion and Conclusion

In any one year, teacher education students attend over 300 hours of formal class time at university and are exposed to a wide range of experiences across different subjects. Yet little opportunity is provided for students to reflect upon these authentic experiences to analyze how they learn in different types of learning environments. In particular, trainee teachers often do not get the opportunity to study their own experiences as students in class to gain a first hand understanding of the relationship between teaching and learning. This is a valuable insight for trainee teachers as designing an optimal learning environment, which is the main outcome of the reflective framework, takes into account the type of teaching and the type of learning and the type of social interaction with peers. Developing such an awareness of the dynamics in any educational setting can support students in participating in reflective conversations about teaching and learning which is a useful skill for their future role as teachers.

Furthermore, it is important that trainee teachers are not simply passive recipients of formal theory at university, but engage in theorising about their own experiences. This means systematically using a framework to reflect on experiences by documenting, analysing and seeking patterns within the data for generating personal theories. This means that preservice students can deduce implications for their own pedagogy based on the analysis of their own experiences of learning. Although students previously used the reflective framework with pen and paper (Hoban, 1997, 1998), this is the first time that students have documented their reflections on a World Wide Web site. Previously, students had to write their reflections each week in a journal and then scan manually across many pages to synthesise the key factors for each category. Also, the students had to seek patterns within the data and deduce their metaphor to represent an optimal learning environment. Doing this manually was time consuming and conceptually difficult for some students.

Using the WWW site has enabled the students to manage and theorize about their reflections more effectively which has reduced their cognitive load in using the framework. In an end of subject evaluation, some of the students made comments about using the web for their reflections:

1. The idea of using the web was good, it was convenient for everyone and everything was in front of you in the one place which made it easier to collate etc. I would prefer to use the web but have the option of doing it in my own time.
2. I preferred to use the web because at the end it was easier to bring everything together. I also found the reflections were more to the point and there wasn’t as much rambling on. The only negative was the inconvenience of getting onto the net whenever we needed to reflect and also when the web page was down.
3. It was better using the web. It was a great way to group the information into the different factors and it was easier to see a clear pattern of learning.

Two issues, however, became evident when preservice teachers used the web site for the reflective framework. First, initial use of the framework was conceptually difficult for preservice students as they had not reflected
upon different learning influences before and were unsure about what to look for and how to do it. For this reason, several reflective journals produced by students in previous subjects were shown at the beginning of the subject as examples of how to analyze their learning experiences. Furthermore, this needed to be revisited several times in the first few weeks with discussions about what the students were documenting. Also, towards the end of the course several students commented that this was the first course which gave them a specific framework to guide them in reflecting on their class experiences. Previously they had undertaken reflective journals in other subjects, but were not provided with a framework and students stated that in many cases they just wrote about "what the lecturer wanted to hear". It appears from the students' data that the web site made the reflective framework easier to use because it focused students in their reflections and helped them to manage the data for phases 2 and 3 of the framework.

A second issue is that I am the only person who saw all of the students' reflections on teaching and learning for the subject as I marked their journals. Certainly, the WWW site made it easier to mark the students' journals as all the data were more accessible on the web site rather than screening large hand written journals. Also, it was a valuable insight for me to understand how different students responded in different ways to the same learning experience. In some weeks, the same science activities were praised by some students and criticized by others. This highlights the problematic nature of teaching and it would be valuable for the preservice students to become more aware that people experience learning in different ways. Although students could access a summary of each student's weekly reflections on the web, they could not access the Learning Profiles or metaphors produced by other students. Perhaps the web site needs to be modified to enable more sharing of products of students' reflections, however, there are ethical issues that need to be considered as the students are documenting personal experiences. Nonetheless, it is a valuable lesson for any teacher to realize that students do not perceive the same class experience in the same way.

Abstract: A medical information system at Graz University contains three millions of diagnostic reports, which form the basis of patient care and of scientific work. Complex retrieval systems are prepared in a time consuming dialogue between clinical researchers and IS-experts. In this paper we describe the development and questions of evaluation of an intranet Web-based query/answer system with reference to aspects of human-computer interaction. The system formulates a well structured and, ideally, machine interpretable retrieval request in interaction with the user (i.e. medical professionals, bio-statistical researchers, ...) and stores it in an existing request-management-application. The user learns, incidentally, how to use the hospital information system for his needs. For optimal interpretation of the gathered information exact formulation of the questions is essential. An intelligent guidance during the dialogue is obligatory since we cannot assume any technical skill on the part of the medical users. In the near future this service will be extended to the countrywide hospital information system. By using this system, the quality of the retrieval and therefore the quality of scientific research and medical studies is raised. Less iterations mean a lower system-workload. Last but not least, we expect to lower the response time without increasing the need of human resources.

"When we write programs that "learn", it turns out that we do and they don't."

(Alan J. Perlis, Yale University)

1. Introduction

The information systems at the departments of radiology and pathology at the 2.300 bed University Hospital in Graz support activities in patient care and serve as a basis for scientific research, not only for radiology and pathology but also for all other clinical departments which refer to these systems in connection with their own patient data. Since the data are partly in standardized form (codes for examination types, organizational entities) and partly in natural language, scientific retrievals require complex strategies to yield optimal results. As will be shown below, the scope of the retrieval request is defined in an interactive discussion between a clinical researcher and an IS-expert. This procedure will be replaced as far as possible by the proposed system. The system will primarily be used by medical doctors or assistants. To improve the quality of data preparation it is necessary to provide precisely formulated questions. Since the typical user does not have detailed technical knowledge, intelligent guidance is required during the dialogue.

The user starts the dialogue with the System by stating his question in medical terminology for administrative and future purpose only. During the subsequent dialog, unconsciously he will adopt the dialogue's behavior in formulating further questions. Succeeding dialogues must always be based on information already ascertained, thus avoiding 'silly questions'. Following the indicated evaluation of criteria and features, only useful selections of data-reports should be offered. In this project the main emphasis is on 'the dialogue'. The dialogue will help the user understand and benefit from the functional possibilities of the information system. Furthermore it will help them to accept limitations and guide them to provide structured information. The high level of the system's operating
comfort aims at persuading the user not to make complicated and time consuming telephone discussions or use written inquiries to collect required information. This system provides a remarkable potential of savings in administrative expenditures by means of good integration into existing administration facilities and adding to the quality of data evaluation.

The system itself has to adapt to the user’s formulation of a question not only per session but also in the long term, thus adapting to the importance and priority of knowledge objects in general.

2. Background

The Information-System used for research and patient care was originally developed by the Institute of Medical Informatics, Statistics and Documentation (IMI) at Graz University for use in Radiology, Pathology, Neurosurgery and Pediatrics, and has been steadily refined ever since the early seventies. The IS Data Base contains approximately three million (!) medical documents, which have been gathered since 1971. Patient information, technical parameters and performance data are saved in a thoroughly structured form, anamnese, examination descriptions and diagnoses are available in free-text. Besides hundreds of simple routine retrievals for patient care, there are, on average, about one or two highly complex retrieval requests per day for scientific purposes, which requires the knowledge of an IS expert. Quite often the huge possibilities and potentialities of filtering, structuring and representing are not familiar or even known to the medical researcher. High competence by the IS expert in medical and technological fields is needed to assess the real scope of the information required by the clinical researcher for his work. The formulation of the retrieval needs are elaborated in a personal discussion between the clinician and the IS expert, a time consuming process, requiring patience and perseverance. Due to the personnel shortage and the increasing demands based on increasing standards in quality management, output documentation, health reports, etc. we consider an automation of this process is necessary to enable continued functioning in the future. The following excerpt of a conversation between an IS-expert and a client shows that several areas of knowledge are necessary to lead an intelligent dialogue:

Client: I would like to have all reports of the angiography with interventional cases from 1998 up to the present.
IS-Expert: You mean all types of examinations concerning the angiography?
Client: Yes, because the examinations are all entered with different coding abbreviations.
IS-Expert: That is clear to me. How can I identify interventions? What does the examination report say?
Client: ... well, the criteria of the contexts are ... (speaks slowly and pause for a moment) ... A.carotis, A.vertebralis, A.basilaris, embolisation, neuroembolisation, stent, balloon dilatation, PTA, ...
IS-Expert: ... hmm, that appears to be a lot to me ... if I ... for instance only look for A.carotis or A.vertebralis ... then I will find a vast amount of data-sets ... should these criteria really all combined by 'OR'?
Client: ... no, no ... I only mean neuroembolisation OR embolisation etc. with A.carotis OR A.vertebralis, ...
IS-Expert: ... ah, I see, ... well that is O.K., ... I am looking for interventions in the examination reports such as embolisation, neuroembolisation, stent, balloon dilatation and PTA and within the diagnosis for A.carotis OR A.vertebralis, OR A. basilaris
Client: yes exactly ...
IS-Expert: ... would you like to read all the documents of the interventions ... or are you primarily interested in the patience convalescence ...
Client: No, we are looking for eventual complications which might have occured later ...
IS-Expert: Ah, yes ...

It would be extremely difficult and exhaustive to put the whole special medical knowledge into the system. For instance the fact, that a balloon dilatation is already an intervention, on the other hand A. basilaris is an organ, where the intervention actually has been made. Also the knowledge about the structure of the IS (types of examinations are divided into coding abbreviations, these depict the radiological technology, but not an interventional operation) and meta-knowledge would be extremely difficult to put into the system. With the strategy mentioned above, one can find the initial intervention, but to find more about complications requires other strategies.

These problems are solved by using a combinatorial approach. Every fact, which can be appear as a filter, a classification item or as representation feature in the resulting request, is represented as an object. One method, implemented in this objects enables the dialogue with the user (e. g. a question about an examination type within a meaningful subset represented as HTML Structure). The reactions which alter the factual knowledge basis of a
particular session and that modifies the persistent user depended state of learning are important methods which are also implemented in these objects. By extending a good Meta-Data-Strategy with actions that represent semantic rules in medical context, we implement a small, dedicated part of global behavior. These actions are 'triggering questions' and 'generating answer-like facts'.

3. The system assembled as an Intelligent Tutoring System

3.1. What is an ITS?

Intelligent Tutoring Systems (ITS) are remarkable with regard to their methods and the fundamental theories used. Their origin comes from the field of Computer Assisted Learning. Generally the "Intelligence" in ITS is traced back to Carbonell in 1970. Carbonells prototyp SCHOLAR, which was actually an interactive program for computer-aided instruction based on semantic networks as the representation of knowledge, was primarily designed for learning geography. He implemented a socratic dialogue in an artificial tutor. ITS generally provides a high level of guidance and control interactive processes in great detail. Possible navigation decisions by the users are controlled by the system. There is no clear border between adaptive systems and those generally called ITS (cf. Sleeman & Brown (1982)).

Recently, ideas from both intelligent tutoring systems and from hypermedia have been brought together. This has lead to interactive and adaptive hypermedia, which we use in our system. This synthesis responds to the specific strengths and weaknesses of both approaches. A domain model representing all facts of the field to be learnt usually forms the background for a model of the learner's knowledge and knowledge acquisition.

3.2 The problematic of intelligence

Constant misuse and misinterpretation of the term "Intelligence" and in particular "Artificial Intelligence" has made it increasingly undesirable to label systems with this designation.

It is generally accepted to refer to an "Intelligent Tutoring System" if the system is able to

a) build a more or less sophisticated model of cognitive processes,
b) adapt these processes consecutively and

c) is based on these fundamentals to control an question-answer-interaction.

The basics of Intelligent Tutoring Systems are most suitable for our special purpose.

3.3 Interface and Interaction

Initially, an ITS should be able to analyze the current process of knowledge acquisition. Based on this information the ITS should be able to build instructions for the user. An ITS is generally considered to be "intelligent" if it is able to react to the process of communication in a flexible and adaptive manner. Kearsley (1987) distinguishes basically between five different types of interfaces for IT-Systems: 1) socratic dialogue, 2) coaching, 3) debugging, 4) microworlds, 5) explainable expert-systems. In our system we use the principles of the "socratic dialogue":

The system questions the user and, on the basis of the questions and answers, guides the user through a controlled interaction. A specific answer of the user is a starting point for the next question. The interaction happens close to a natural-language dialogue (cf. Kearsley (1993)).

4. The System, its features and its implementation

4.1. Prerequisites

Concerning the implementation of this system, there were several preconditions to be taken into consideration. Firstly, the system is supposed to work in cooperation with the Meta-Data strategy of existing department information systems that currently work on proprietary databases. As mentioned the information systems are about to be replaced with a countrywide information system within the next year. That means that our solution needs to provide an interface that can be easily extended or replaced.
Secondly, we had to keep in mind that we needed to find a way of implementing the system so that the result would provide as open an architecture as possible with regard to interfaces and interoperability with other systems and platforms.

Thirdly, the system should also be capable of easy expansion, e.g. additional functionality in future at very low expense.

Fourthly, in the event of migration to other hardware and/or software platforms in future, it should be easily possible to port the system without endangering the stability and/or functionality. Only minor changes or adaptations should be necessary by that time. This means that portability also had to be taken as a prerequisite.

4.2. Implementation Framework: The Java 2 Enterprise Edition

We ran across Java and the Java 2 Enterprise Edition (J2EE) pretty quickly. The J2EE provides all the functionality and tools that fulfill the preconditions of the project listed above and impresses the developer with its "write once - run anywhere" functionality. In addition, the Java Enterprise Components give us the advantage of minimum possible implementation time and low costs combined with a maximum outcome. Networking, multithreading, security and even database connectivity are available via standard APIs and do not have to be written again from scratch. Since the release of Java in 1996, a very large community of Java developers (Java Developer Connection, about 1 Mio. members) has evolved, who provide a wide variety of Servlets and Beans (reusable components) almost for free which can easily be integrated in any project without having to “reinvent the wheel”.

When considering an open system that is expected to provide as much interoperability and expandability as possible, the choice for a Multi-Tier architecture approach is obvious. Using a Multi-Tier architecture also ensures that the whole system is built to work in a distributed scalable environment, which was another prerequisite of the project.

4.3. Multi-Tier Architecture

Taking into consideration a Multi-Tiered architecture relating to the general condition explained before, we expect the following framework to meet our needs.

Presentation Layer

The user communicates with the system through an HTML - Browser that is driven by a Thin - Client Servlet. The dialogue phases should be fast and simple. In addition to the claim that the dialogue should usually be similar to a natural language dialogue, (Spada and Opwis (1985)), the possibilities of graphical user interfaces should improve the performance of the human computer interaction.

Business Layer

Here we implement all application specific components and the session management using state-full Session Beans. It is necessary to convert the stateless http-communication into a persistent, re-activateable dialogue by means of the user context. So, if the user looses the dialogue with the system for what ever reason, next time he authenticates himself to the system, he has the opportunity to continue, without loss of previous dialogue.

Technical Layer

The association of the fact-, semantic- and knowledge objects builds the didactic components in this layer. The dependency of classes from the database layer and the over all didactic strategy builds the classes.

Database Layer

Here we find the object representation of the Meta-Data in the Data-Dictionaries and their semantic meanings, as well as the user specific model, his habits, behavior, last session status and previous accesses. Also the knowledge model is represented as a class of this layer.

With respect to the manageability of all growing information components, all permanent data will be stored on database servers. Flexibility is acquired by means of using only JDBC-interfaces to the servers.
5. Research

A hospital information system provider looks ahead, hoping to gain experience in covering the complexity of huge information archives under retrieval aspects. For the cognitive scientist, the greatest advantage of that approach will consist of the feedback, that will be provided by the quality improvement for retrieval requests. During our talk at ED-MEDIA 2000 we will present some answers to questions asked in the following paragraphs.

5.1. Aspects of Informatics

5.1.1 Meta Data Dictionary (for details see http://www-ang.kfunigraz.ac.at/~holzinge/its/mdd)

The main goals during design of the Meta Data Dictionary were simplicity and extendibility, but focusing on an intelligent way of storing knowledge (actual legacy database and future SAP R/3). How can the IS-Meta-Knowledge be stored and accessed in a intelligent way to get an optimum out? What has to be prepared to be able to change the database engine itself whenever the MDD has to be moved to another platform (what about XML)?

5.1.2 Distributed System Design (for details see http://www-ang.kfunigraz.ac.at/~holzinge/its/dsd)

Thinking about a distributed application framework, it is obvious that one has to be prepared for different platforms and will result in a multi-tier architecture. The main questions in this context are: How can the system be kept portable for future platforms (JAVA Enterprise Edition)? What will happen when one component in the network cannot be reached and will not deliver an answer? What can be done to ensure good performance of the system so that the user will be satisfied?

5.1.3 Intelligent Engine (for details see http://www-ang.kfunigraz.ac.at/~holzinge/its/ite)

How should the engine decide in case of equal weighted questions (aspects of fuzzy logic)? How can the user profile be integrated as a decision criteria (adaptive behavior)?

5.2. Aspects of Human-Computer-Interaction

The knowledge representation, as a framework of objects that cover facts, semantic information and parts of common knowledge is especially important, as are the methods used to keep the users' interest, motivation and attention on the actions to keep the dialogue process alive. As an experimental design we have chosen a pre-test/post-test control-group design, assisted by qualitative analysis via interviews. The experimental sample to be examined includes 24 people: 12 experts (including MD's) and 12 novices (students of medicine). The research questions are divided into Dialogue, Usability and Learning.

5.2.1 Questions concerning the evaluation of the System (Dialogue)

How do users (experts versus novices) handle the machine-dialogue, in contrast to the human-dialogue provided by an IS-expert? How extensively do the users proceed within the dialogue? At which time do they quit the dialogue? Why do the users break off the dialogue? How often do we get useless or irrelevant information?

5.2.2 Questions concerning the evaluation of the Graphical User Interface (Usability)

How does the GUI influence the user behavior? What is the difference in handling between experts and novices? What screen contents and hints are useful for novices and experts?

5.2.3 Questions concerning the evaluation of the Intelligent Behaviour (Learning)

How big is the learning achievement by using this system? How does incidental learning (cf. Holzinger & Maurer 1999) increase the efforts of the users? How do motivation, attention and arousal directly influence the necessary actions to keep the dialogue process alive?
6. Practical Aspects

Eventually, when the IS is extended to the countrywide hospital information system, it will no longer be possible to include the whole system information in one human to human consultation call. The findings and experiences of this project will lead to a suitable knowledge representation, which provides an interactive dialogue suitable for a more complex system. Finally the quality of requests for scientific medical research can be increased by reducing the response-time and lowering the system work load through minimizing iteration cycles.

Abstract: During the period from September 1st 1998 to December 31st 1999 the first and second authors jointly managed a project funded under European Social Funding objective 2.5b and the Regional Technology Initiative entitled "Multimedia Training Materials for the Community University of the Valleys". The aim of the project was to develop learning materials, in a variety of subject areas, using a variety of media, for use in the communities of the South Wales Valleys. A variety of materials were produced and piloted by Community Tutors. The most notable successes being (1) an interactive multimedia package to teach Multimedia Principles delivered on CD-Rom and (2) a paper-based Career Planning package. A more general achievement is a wider awareness of the need for training in the use of Information and Communication Technology (ICT) in the South Wales Valleys.

Introduction

The "Multimedia Training Materials for the Community University of the Valleys" project involved the creation, delivery and evaluation of multimedia education and training materials in the areas of Multimedia, the European Computer Driving License and Employability Skills. The project is funded under European Social Funding (ESF) objective 2.5b and the Regional Technology Initiative from 1st September 1998 to 31st December 1999. The paper begins with an outline description of the CUV and a variety of its initiatives and a description of the context in which this particular project took place. It then describes the nature and structure of the materials development project and concludes with a discussion of the key lessons learned and of the ways in which the initiative could be sustained.

The Community University of the Valleys

Context

Wales is a country, part of the United Kingdom, lying West of England. The communities of the South Wales Valleys lie north of the more affluent cities in South Wales, i.e. Newport, Cardiff, and Swansea. The area is relatively deprived compared with other areas in the UK, having suffered economically from the loss of much heavy industry, particularly coal mining. The Community University of the Valleys (CUV) is a unique partnership between

476
the University of Glamorgan, the Swansea University and the Open University in Wales representing part of the regeneration strategy for valley communities in Industrial South Wales. It aims to provide for lifelong learning and widening participation in Higher Education (HE) through an active partnership of public, community, voluntary and private sectors. At Glamorgan the CUV involves a series of projects and courses, ranging from state funded delivery through to European and projects funded by Private industry. Approximately 2000 learners within the community are involved each year in various educational programmes delivered in the community by CUV tutors. The CUV project has been recognised internationally, by the European Union, and nationally in the Dearing report (NCIHE, 1997).

The CUV operates in a variety of environments but the bastions of the community provision are (i) the workplace, (ii) School and (iii) local Community Centres. Some examples of CUV provision are as follows:

**Continuing and Adult Education (CAE)**

Since 1994/95, many community centres have been used for the delivery of modular and non-accredited courses. The campus has also been used. The CUV team in partnership with FE providers is now addressing the need to define and market progression pathways into HE. Curriculum areas cover languages, arts, business, study skills, technology, social science and astronomy.

**Glamorgan Summer School**

The annual residential summer schools, (held at the Glamorgan Campus) attract between 400-600 learners. This is a stimulating and high profile activity offering valued educational opportunities to low income learners (through subsidy from the Rhondda Cynon Taff unitary authority) as well as more affluent students. The Summer School has gained a national reputation for its jazz courses.

**Compacts**

Compacts (developmental partnerships) are operating with schools in a number of Local Education Authorities and involve:

- student tutoring,
- records of achievement initiatives,
- aiming for a college education days,
- ‘A’ level master classes and
- GCSE revision sessions.

In 1998 the Compact initiative was selected by the Committee of Vice Chancellors & Principals (CVCP) as a national case study for good practice in widening access to higher education.

**Internet Simulation**

A project funded through the European Union ‘Socrates’ programme, established an internet-based journalism activity for adult learners within the Rhondda Cynon Taff area. The learners developed IT expertise as well as awareness of media issues and news values based on a newspaper editing project. This also involved students in Finland, Scotland and France. The project led to a more extensive electronic newspaper simulation involving local schools, thanks to sponsorship via the British Telecom University Development Award for 1998.

**Partnership Framework**

A University strategy on employability has been agreed by Academic Board, leading to the establishment of a Work-Based Learning Office that develops links with work based learners. The employability initiative recognises the importance of accrediting prior experience and distance learning, as well as projects within the workplace, and offers educational opportunities to employees who would not otherwise be able to attend traditionally delivered programmes on campus or in the community.
It is against this background, of an urgent need for the development of ICT (Information and Communications Technology) Skills, that this project was conceived and was successful in obtaining funding from the European Union.

Multimedia Training Materials for the CUV

Project Rationale

Nationally and internationally patterns of employment are changing, characterized by
(a) a shift away from labour intensive heavy industry to ‘information age’ organisations,
(b) a shift away from the concept of a job for life towards more short contract and part time work, and
(c) increasing numbers of female employees.

These changes are clearly applicable to the South Wales Valleys labour market. In this context the UK Government and the Welsh Assembly have recognised an urgent need to develop Information and Communications Technology (ICT) skills amongst the existing and potential work force.

Three recent publications evidence the concerns of Government.

1. The Wales Information Society report produced by the Welsh Development Agency from which the following quotation is taken.
   "If Wales is to sustain a competitive position within the increasingly information-based European and global economy, it must move towards a knowledge-based economy. The new ICTs provide the tools to enable this to happen." (Welsh Development Agency, 1998)

2. The Lifelong Learning is for Everyone (LIFE) green paper presented to Parliament in 1998. The paper provides evidence that supports the following claims for Wales:
   - there is a serious learning deficit;
   - educational achievements are lower;
   - there is a greater shortfall in basic numeracy and literacy skills;
   - barriers to learning stifle access and participation;
   - education and training are not always appropriate to the needs of the individual or the economy;
   - existing patterns of provision are not achieving the best results;
   - the nature of the qualifications framework is inflexible; and
   - there are persistent deficiencies of skill and capability in all walks of life and throughout Wales.
   (Secretary of State for Wales, 1998)

3. The Future Skills Wales report, commissioned by the largest partnership of organisations assembled in Wales including the Careers Service, CBI Wales, FEFCW and HEFCW, Wales TUC, WDA and the Welsh Office. The report indicates that in the future the following skills will be most important.
   - Basic IT
   - Understanding Customers needs
   - Ability to Learn
   - Communication
   (MORI Research and Business Strategies Wales Ltd, 1998)

With these requirements in mind, it is unfortunate that some studies have shown that many adults, particularly those from socio-economic groups D and E, are not attracted to using modern day ICT. It may also be the case that many people:
(a) do not perceive or understand the need to develop skills in these areas, and
(b) do not have the financial resources to become ICT literate.
There is thus a pressing need to extend and refocus CUV activities into these areas. The Multimedia Training Materials project is intended to begin to break down these barriers by:

- Delivering citizen-level ICT skills through the vehicle of the nationally recognised European Computer Driving License – a British Computer Society supported initiative.
- Developing a web-based collaborative learning environment providing access to a variety of new and legacy learning resources.

The European Union has recognised the needs of the South Wales Valleys by classifying the region as objective 1, but it is clear that initiatives such as the CUV need to do much more than simply developing materials and offering courses. They also need to work in partnership with schools, employers and Government agencies on changing attitudes and raising awareness of the need for lifelong learning and more specifically the need for the development of ICT skills.

Project Description

Aims and Objectives

The aim of the project itself is to deliver a variety of educational materials to community learners. The objectives are threefold:

1. To deliver specific materials to the community in the following areas:
   - Multimedia
   - European Computer Driving License
   - Employability Skills
2. To provide technology training to lecturers and community tutors
3. To develop and maintain a technical and managerial infrastructure which will enable further materials to be incorporated.

Project Structure

A Project Structure was required to facilitate the co-ordination of the various sub-activities within the project. The project steering group developed the structure described in figure 1 that distinguishes four related types of activity.

Materials Development

Some team members were mainly concerned with identifying and developing education and training materials. In the area of Multimedia a specialist team is developing a multimedia Computer-Based Learning package to teach multimedia principles and techniques. Staff at Glamorgan are collaborating with Swansea to produce web-based portfolios of materials for each of the 7 modules of the ECDL. A further team are working on portfolios in 6 Employability Skills areas including, Communications, Numeracy, Using IT, Problem Solving, Working with Others and Improving Learning and Performance.
Delivery Technology

Other team members are largely concerned with developing the web-based collaborative learning environment. This environment is accessible by registered learners and through an easy to use interface the learner builds up a Personal Academic Menu (PAM) containing all the links required for their individual programmes. A different interface to the environment is provided that allows development staff to create a standard look and feel for their materials. The efficiency, effectiveness and appropriateness of this environment is a key issue for the sustainability of the project.

Community Delivery

This is the activity the project stands or falls by. It is absolutely essential that any problems experienced, by the tutors or learners, with the materials (e.g. with inaccuracies or irrelevance) or with the delivery technology, are reported back to the project steering group for action. The key initiatives in this area are concerned with establishing reporting and feedback mechanisms to ensure that the provision works in practice.

Technology Training

The remaining team members are concerned with providing any technology training required by the members of the other teams. In Swansea the emphasis so far as CUV is concerned is on the Humanities rather than IT and thus many of the community tutors themselves have limited ICT experience. Therefore the approach will be to train lecturers and tutors in the development of flexible learning materials and the use of a variety of technologies such as video and computer conferencing. The emphasis is on providing lecturers and tutors with the technological skills to create materials for use in the community.

Lessons Learned

1. Close collaboration within and across departments and particularly between campus-based development staff and community-based tutors is critical to the success of such initiatives.
2. Developing high quality educational materials, as is already well reported (e.g. Marshall et al 1997), and based on the authors experience, is difficult and time consuming. However it became apparent that the community tutors would prefer early access to small chunks of materials for evaluation purposes, through the course of the project rather than waiting to receive finished materials.
3. Careful and close project management is required. On reflection I feel that it would have been better to begin with a much smaller portfolio of existing materials and go through the complete process in a first milestone and subsequently once the key lessons had been learned to expand the portfolio during a second milestone.

Sustaining the Initiative

Four key issues regarding sustainability have emerged.
1. Progression Pathways into Higher Education: Small cohorts of learners on non-accredited community programmes do not generate profit, clearly making them difficult to sustain. However profit can be generated if community learners eventually become full or part-time students on accredited modules and awards. So in the future we intend to focus on creating pathways into Higher Education from three sources (i) from industry via a work-based learning initiative, (ii) from schools via the University's compact scheme and (iii) from the community.
2. Focussing on Specific Economic Regeneration Needs: The key seems to be the resolution of particular local problems and the subsequent dissemination of good practice.
3. Maintaining the Efficiency, Effectiveness and Appropriateness of a Collaborative Learning Environment: In view of the perceived lack of ICT skills in South Wales it is essential to ensure that the learning environment is adding value to the learning experience rather than getting in the way.
4. Teaching Community Tutors to Develop their own Materials: It is recognised that the materials produced by campus-based academics only provide a baseline and that community tutors will augment this with materials and activities of their own in response to the idiosyncratic needs of their learners. Providing tutors with the
technical and educational skills to do this effectively (training the trainers) is another important way of developing sustainable provision.

Concluding Remarks

In the past, indigenous industry faced a responsibility to valleys communities, with organisations such as the Miners Federation acting essentially as a community college. (The Miners Federation enabled many people to successfully make the transition from mining into higher education.) Today's more mercenary hi tech industries do not face such responsibilities. These changes in the nature of the labour market combined with temporary project after temporary have not encouraged sustained education and training initiatives for valleys communities. We hope that objective 1 funding, together with emerging initiatives such as the University for Industry will enable such initiatives to flourish.

Abstract: The shift that is currently taking place within universities from teaching face-to-face to teaching online is presenting teachers in universities with the need to induct large numbers of students into learning in this new mode. It is pertinent to ask how learners themselves are experiencing this change. In a subject in human biology, an activity based on the topic on the use of statistics in the mass media was employed as a way of inducting students into online discussion. Students’ responses were monitored by focus groups before and after the exercise, by an evaluation survey and by inspection of the transcripts of the discussion. The issues that students reported included the frustration experienced in gaining sufficient access to computers, the perceived value of the task, and their comfort level in using computers in learning.

Introduction

The shift that is currently taking place within universities towards online learning is confronting teachers in universities with the need to induct large numbers of students into this mode of learning over a relatively short timeframe (Inglis et al. 1999). As students can presumably be expected to build upon the skills obtained from their first experience of online conferencing as they move on to later subjects, this need is likely to be relatively short-lived. However, as most students will have had no previous experience of anything approaching this mode of learning, their initial experience is therefore likely to colour their subsequent outlooks. It therefore behoves universities to try to come to understand the learning experience as students perceive it. In that way they can tailor introduction and delivery to meet varied students’ needs. The major hurdle is to get students off to a confident start in the first place.

In other studies it has been reported the students have found the process of learning online to be less satisfying than learning face-to-face even though this it was more effective at enabling students to attain expected learning outcomes (Benbunan-Fich and Hiltz 1999; Hiltz 1998). A number of factors may account for the stress students experience in their first encounter with online discussion in a university setting: they may have had no experience of the software used; they may not feel comfortable with using computers; they may be unfamiliar with the etiquette and conventions of computer conferencing; and they may not even see the value of interacting online when they can so easily meet face-to-face in an actual classroom or in a campus cafeteria.
Harasim et al. (1995) pointed out that inducting students into the use of computer conferencing involves two separate functions: familiarising students with the operation of the particular conferencing system that is being used, and enabling students to learn how to interact in a conferencing environment. Learning the technical skills needed to use the conferencing system obviously comes first. Harasim et al. (1995) suggested that, whenever feasible, as this gives students the opportunity to build confidence in a supportive environment rather than being thrown on their own resources. These authors suggested that a three hour session or two shorter sessions is normally sufficient for this purpose.

Inducting students into conferencing itself is quite a different task. Harasim et al. (1995) recommended that this be accomplished by use of an initial private email exchange followed by an all-group “great debate”. They pointed out that centering the debate around a controversial issue which is certain to arouse passions ensures that participants join in the discussion.

RMIT University, like many Australian universities, is expanding its use of online learning with on-campus students as well as using online learning to increase the number of students studying off-campus. The teaching staff view these trends with mixed feelings. On the one hand, there is a perception — perhaps a fear — that the administration’s drive for greater use of new technology is mainly motivated by a desire to reduce contact hours and thereby cut costs. On the other hand, they recognise that online delivery offers the possibility of improving student learning as students are afforded greater opportunities for working collaboratively while proceeding more at their own pace. However, if expectations of the value of using online learning in on-campus courses are to be achieved, then it is essential that these segments be incorporated into courses in ways that meet students needs.

The Induction Activity

In 1999 a range of online components were incorporated into the subjects in Human Biology within a Bachelor of Applied Science degree. These included lecture notes, demonstrations, web-based assignments and a discussion forum.

A task in second semester required students to summarise an instance of the use of statistics by the media (examples they chose ranged from local papers through to Rikki Lake), and comment on its accuracy and value. They were then required to respond to a minimum of two other students’ postings. Students were asked to post and comment within their practical groups which comprised approximately 20 people each. The conferencing system used was HyperNews and the groups were established within the HyperNews structure. However, due to the nature of the program, once the number of postings became significant students had difficulty identifying the first-order structure, and later posts were added in an ad hoc fashion.

This task was the ‘practical’ component of a unit which is based on Stephen Jay Gould’s ‘Mismeasure of Man’, and concludes an introduction to physical anthropology. Gould highlights some egregious examples from the history of the science where statistics have been used and abused in the scientific and, to a lesser extent, popular media. One of Gould’s points is that while data may have been generated ‘objectively’ by reputable academic researchers, when the
data are released into the public sphere, the reporting of the significance of the data is often not as objective.

The activity was scheduled for weeks 9 to 11 of a 13 week semester. It was set down as an assessed task, but was allocated a weighting of only 4% of the final mark. In the end it was decided that all students who completed the task satisfactorily should be awarded full marks. In this respect it could be classed as a 'hurdle requirement'. However, students could still pass the subject without completing the activity. Of the class of 83 students, 75 completed the activity.

Students were introduced to the web-delivered material over an extended period. Their first practical for the year was held in the Faculty computer laboratory. During this session they were introduced to the range of resources that were to be provided online. However, the conferencing system was not then functioning. A demonstration of the conferencing system was presented in a lecture in week 7 of the 13 week semester. Students were encouraged to use the discussion forum from that time onwards. Prior to the commencement of the discussion activity, the structure and operation of the discussion forum was again introduced in a lecture/demonstration.

**Evaluation Methods**

The principle method used to evaluate the success of the induction activity was the conduct of focus groups at the commencement of the activity and once the activity had been completed. We were particularly interested in observing any changes in students’ ‘before’ and ‘after’ responses to the activity.

Students were asked to volunteer for participation in the focus groups and were offered light refreshments as an incentive to participate. Two focus groups were conducted. The first focus group was held in Week 10, and the second in Week 13 of the semester. The first focus group comprised 6 students. The second focus group comprised four students from the first focus group plus three students who had not participated in the original group. The focus groups met for approximately three quarters of an hour. The discussion was guided by a series of pre-prepared questions (see Table 1). The discussion was recorded and transcribed for analysis.

<table>

<td>6b. If you were doing the subject again what would you like to be different about the way it uses online learning?</td>
</tr>
<tr>
<td>3. What do you think about the type of task you are involved in?</td>
<td>7a. How do you feel about flexible delivery in</td>
<td>7b. How would you feel about more extensive</td>
</tr>
</tbody>
</table>
The members of the focus group expressed a diverse range of
The various modes of analysis presented a broad view of the students’ perception of online learning and response to the task. Some students were familiar with computers and at ease using them

‘I like the concept of online ... I mean for people who use it you are not going to get anything better’.

Another student was resigned to the inevitable

‘Like I do everything to avoid it but its going to hit me in the face shortly so …’

‘There’s nowhere where I feel comfortable using the Internet’.

They were also perceptively critical of online material

‘It just seemed that it was that the person who had actually dished it out didn’t give a lot of thought into what had to be there’ or

‘If I wanted to study remotely I would have chosen that way’.

However, three principle issues emerged from the discussion and evaluation:

- access to computers
- the perceived significance and relevance of the task
- attitudes to online learning

Access to computers
The Bundoora campus of RMIT University is located on the northern outskirts of Melbourne. Because of this, many students travel considerable distances to and from the campus each day. Many use public transport or rely on friends. Activity on the campus therefore peaks in the middle of the day but falls away sharply in the late afternoon. As a consequence, the facilities on the campus including the general access computers are in heavy demand between the hours of eleven and three.

One might expect that having the opportunity to engage in discussion online would be an advantage by students because it allows them to undertake part of their study at home. However this was found to be only partly the case.

A survey of the class group indicated that while 80% had a computer at home, only 50% had a modem and an account with an Internet Service Provider. Therefore half of the students still needed to rely on university computer facilities to complete the task. Even students who did have a computer at home still said that they wanted to make use of computers on campus so that they could make best use of their time. Difficulty in gaining access to a computer was therefore the source of a considerable frustration for some students.

Although the Faculty of Biomedical, Health Sciences and Nursing has specialised computer laboratories on campus, the students in the focus groups expressed a preference for using the general access laboratories provided in the campus Library notwithstanding the fact that these were the busiest. The end-of-semester evaluation confirmed that most students access the conferencing system from home or from the Library. The main reasons given by members of the focus groups for preferring to use the laboratories in the Library were that these laboratories had the most up-to-date equipment and that they also had an efficient queuing system in place. However, students also commented that having to wait in the queues for a computer to become available consumed scarce time that they would otherwise have been able to spend on the activity itself.

Provision of general access to computers is a vexed issue. The cost of alleviating the shortage of computers would probably not have been much more than the equivalent of one academic staff salary for one year. Yet the cost of the provision of computers is subjected to much greater scrutiny that the cost of appointing new staff. Some staff consider that students ought to be required to provide their own computers; others believe that most students will soon have computers at home anyway. Yet all the evidence points to the likelihood that the demand will continue for the foreseeable future and that it is capable of being met a reasonable cost. The evidence provided by student’s feedback in this study is that lack of sufficient access to computers has the potential to become a fatal flaw in the strategy to build greater use of online learning into the delivery of on-campus courses.

**Perceived Significance and Relevance of Task**

While the activity had been designed to engender discussion amongst students the extent of discussion was relatively limited. Students generally logged in, posted their piece and two comments and logged out in one or two sessions. However, the reasons for their failure to go beyond the minimum level of participation turned out to be largely pragmatic rather than reflecting the value of the task.
Students explained their reasoning in terms of the perceived importance of the task. There were two aspects to this. First, the credit being given for the activity was quite modest and secondly as anatomy/physiology majors in science they did not see the exercise as particularly relevant. Therefore, given the difficulty in gaining access to computers they said that they elected to do the minimum that would satisfy the assessment requirements.

The members of the second focus group were asked what their attitude would have been to the hurdle being set higher — for example, having to provide four responses. All members of the panel said that they would have had no objection to a more substantial activity provided that it was more relevant to their course and that they had adequate access to computers. However, they emphasised that if they were required to put in more time then they would hope that the activity would receive higher weighting. Students appear to connect weighting more to the amount of work involved rather than to the relative value of the subject to their learning.

**Attitudes to online learning**

Despite the apprehensions that some students in the first focus group had expressed about the discussion activity prior to its commencement, all participants in the second focus group agreed that the task had been interesting and a worthwhile introduction to discussion forums. Typical comments included:

- It was pretty interesting a lot of it … it was pretty cool
- It sort of motivated [me]. It was interesting.

The students also enjoyed the experience of online discussion when it did occur. In the end-of-semester evaluation, comments like the following were typical:

- It was an interesting and different idea for an assignment
- allowed us to communicate with the whole group
- different perspectives
- I liked the interaction and comments between students and ideas

Some students complained that there had not been enough discussion and others complained about the formality of the system.

In the focus group there was concern about one interchange, however the overall tenor of the discussions was positive, and as one student said ‘I couldn’t really be bothered abusing anyone’.

**Issues Arising from the Activity**

The issue of relevance merits closer examination. The task around which the induction activity was centred was designed to develop the students’ critical response to the use of data and its
interpretation and presentation, as well as to foster a stronger community through discussion-based interaction. While the staff may have been clear about the particular and general value in the activity, the responses of students suggested that they had a much narrower understanding of the purpose of the activity. Nevertheless, the majority of the participants in the second focus group said that they did enjoy the exercise and that they gained benefit from it in terms of their familiarity with computers, their interaction with other students and understanding of the reporting of statistical data in the media.

The question of relevance brings up, however, a more fundamental question, which is why include online components in an on-campus program? While the distribution of lecture notes, the presentation of demonstrations and the provision of quizzes can be justified on the grounds that all of these contribute to increased flexibility, the justification for the use of discussion groups is less obvious. As one student pointed out

'I live with three other biology students anyway. So if I had a question I would just ask them'.

The educational rationale for extending the use of discussion groups to on-campus students’ needs to be better articulated. It would seem that there are two main rationales for promoting the greater use of online discussions amongst students studying on-campus. The first is that gaining the capability of being able to converse in a group online is an element of computer literacy in the life of today’s professional. The second, and more important, is that participating in academic discussion is critical for a student’s intellectual development and that online discussion has the potential to involve more students more often in this type of intellectual exchange.

Given the positive response of students to the induction activity described here, it is perhaps unfortunate that the activity was scheduled late in semester 2. As an induction task, it could perhaps have engendered much greater involvement and have led to had it been scheduled earlier in the year.

Conclusion

The results of this study show that students by-and-large adopt a pragmatic approach to becoming involved with new teaching approaches associated with online delivery. They recognise the growing importance of computers and the benefit they derive from becoming conversant with them. They will willingly participate in activities requiring the use of computers even though they might not feel entirely comfortable with computers. However, the extent of their involvement is very much governed by their cost-benefit assessment of the value of a particular activity. The contribution to grades weighing strongly as either a cost or benefit depending on the mark-value and the difficulties of gaining access to a computer. The contribution that computer-based activities make to a student’s overall workload weighs strongly as a cost.

The responses obtained from students in this study suggests that universities ought to pay close attention to contextual factors in inducting students into online learning, if they want to ensure that students’ initial experience is positive. If students are to gain the benefits from these activities, then they need to be given an effective induction to online discussion, be set tasks that they see as relevant and be given adequate on-campus access to computers.
Therefore, with Harasim et al. (1995), we would suggest that the introduction to conferencing should be through a broad debate as much through a great one. If students are aware that the relevance is as much in the process as the specific material they will respond positively, and if it is constructed as a hurdle task, they will participate.

Excellent Teaching and Early Adopters of Instructional Technology

Dr. Michele Jacobsen
Faculty of Education
University of Calgary, Calgary, Alberta, Canada
http://www.ucalgary.ca/~dmjacobs
dmjacobs@ucalgary.ca

Abstract: What can we learn from individuals who are both early adopters of instructional technology and excellent teachers? Roger's (1995) adopter categories are useful for simplifying the complexity of adoption patterns in a social system by describing a central exemplar or summarization of the early adopter and other categories. Diffusion theory and research yields global judgments and perspectives, but storytelling enables us to take the personal point of view, to understand the particular aspects of expertise and experience embodied by the unique and variable individual. This paper describes an investigation into the relationship between excellent teaching and early adoption of technology by highlighting the stories and narratives of individual adopters using Roger's (1995) innovation-decision process as a conceptual framework.

1.0 Global Characteristics versus Individual Stories

A potential limitation of considering the integration of technology using the adopter categories derived by Rogers' (1995) diffusion theory lies in their very nature as summaries of global characteristics (i.e., innovator, early adopter, early majority, late majority, and laggards). While the adopter categories are useful for simplifying the complexity of adoption patterns in a social system by describing a central exemplar or summarization of the early adopter and other categories, these "defining characteristics" also understate the uniqueness of the individual member. It is worth remembering that early adopters are unique and variable individuals who may resemble each other much less than they resemble the general subgroup characteristics. For example, one can readily appreciate that early adopters possess various and different: levels of ability and skill, beliefs and visions about the value of technology, specific personality traits, levels of risk-taking behavior, motivations to learn about technology (e.g., internal, external, environmental, opportunity), development patterns (e.g., self-taught, peer teaching, formal courses), and have implemented computers in different environments, under different conditions and with different expectations.

Sternberg (1997) profiles the views of expert professors who teach introductory psychology and have written textbooks for the course. His rationale for profiling expert teachers is that the best help comes from seasoned instructors who not only have taught for many years, but from those who have thought deeply about the course, and have come up with new and exciting ideas about how to teach it. His approach to documenting teaching excellence using narrative captured both the similarity and variability between experts, and is useful to professors across disciplines who want to improve their teaching.

Narrative stories and profiles of experts are well suited to capturing exactly those elements or details that formal models, such as theories of diffusion and adopter categories, may leave out. Personal stories, such as the profiles of expert teachers (Sternberg, 1997), capture the subjective emotions, thoughts, and beliefs of the category members. Logic generalizes, stories particularize (Norman, 1993). Diffusion theory allows one to form a global judgment and perspective, while storytelling allows one to take the personal point of view, to understand the particular aspects of expertise and experience embodied by the individual. Stories are not better than logic; logic isn’t better than stories (Norman, 1993). It is appropriate to use both in the attempt to characterize early adopters of technology on campus.

2.0 Methodology

This investigation profiled individuals who are both early adopters of instructional technology and excellent teachers. This study begins to address the need for "best help from seasoned instructors" by providing role models for faculty who want to adopt technology in their teaching. This case-by-case analysis models Sternberg’s (1997) framework by documenting instances where the adoption of technology and excellent teaching exist in the same individual. The rationale for collecting this information is based upon the value of providing descriptive accounts of
this expertise for the benefit of faculty members who wish to develop both their technology integration and teaching skills. Post-secondary instructors from across disciplines can benefit from the collective wisdom of those who have thought deeply about and taught extensively with technology for a number of years. The individual experiences represent great diversity. Faculty members profiled here represent the social and physical sciences, as well as administration and management, and they range from being enthusiastic beginners to seasoned experts at integrating technology in their teaching and research. The individuals share a passion for excellent teaching and continue to pursue new ways to integrate technology to fundamentally improve teaching and learning.

2.1 Information Collection

Semi-structured interviews were conducted with faculty members to gather more in-depth and specific information about the integration of technology for teaching and learning. The primary objective was to record, analyze and interpret the individual faculty member's experiences, opinions, and perspectives with regard to integrating technology for teaching and learning. While the interview procedure used a semi-structured format guided by specific topics, it was also open-ended in nature to be responsive to emergent topics and themes. Discussion questions were drawn from ten sub-scales of a faculty survey (Jacobsen, 1998) as well as using the following topics as guides: (a) Perceptions of value of computing skills for self and students, (b) computer use patterns and skill, (c) training and staff development (if any) & modeling from mentors, (d) motivation for using technology (instructional, personal, institutional mandate), (e) experiences with technology (early positive or negative), (f) degree to which they require technology use by students, and (g) changes in use, practices, and beliefs about computers over time.

2.2 Interpretive Analysis

Interview transcripts were analyzed using a constant comparison method, and sorted into major themes using a combination of categories derived from prior research on teaching excellence (Andrews, Garrison, and Magnusson, 1996) and from Rogers' (1995) innovation-decision process. Five categories provide a conceptual framework for the consideration of individual stories about adopting technology for teaching and learning: 1) Knowledge: values, beliefs and characteristics, as well as felt needs/problems and degree of innovativeness, 2) Persuasion: expected outcomes and benefits, as well as perceived characteristics of the innovations such as relative advantage and compatibility with existing teaching methods, 3) Decision: processes used to attain desired outcomes, and factors influencing the decision to adopt or reject the innovation, 4) Implementation: specific instructional strategies that support the processes, and 5) Confirmation: motivators and impediments to integrating computer technology, as well as descriptions of continued adoption or discontinuance.

3.0 Case Studies

The following section represents a selective summary of interview results illustrated with condensed excerpts from source transcripts. Cases are presented in no particular order, and pseudonyms are used to provide anonymity for participants.

3.1 Knowledge

The following faculty member has been awarded teaching awards at the University of Calgary, and has integrated various technologies in classroom teaching in the past few years. This individual increases their awareness about ways to integrate technology in the classroom using a variety of means. Completing the on-line survey as part of the present investigation (Jacobsen, 1998) was treated as a learning opportunity: "I found it interesting to go through the questionnaire, because it occurred to me that there was a whole lot there that I had heard of. ...I am doing stuff like that, and I am doing that, and so on..., and there was a bunch of stuff that I hadn't really thought about using for the classroom." She also described a few instructional strategies being discussed by her/his department to enhance the experience of students in large enrollment (250+) sections, including CD-ROM-based study guides produced by textbook publishers and developing web-based, self-paced instructional modules.

3.2 Persuasion

This individual brings more than two decades of experience in information technology to a consideration of the characteristics of early adopters. As such, this individual's retrospective analysis of some of the issues surrounding
the integration of technology is rich and in-depth. This individual was particularly interested in the innovators, the pioneers on the edge of their field who actually develop new technological tools to address certain problems:

“When I look at people, I consider the innovators. They've never sat around waiting for somebody to parachute in with a solution to their problems, they go out and look for it. So, I guess the first instance is the character of the innovator, the self-starter, a desire to get on with something, not just.... There are a lot of academics who, I won't say go through the motions, but there are a lot of academics who pursue the normal cycle in the normal way. They meet their classes, they write research papers, they supervise graduate students, and whether they contribute anything to the body of knowledge is questionable. But I think that most of the professoriate, certainly a significant portion of the professoriate are ... effective, competent, participants in process. The people that we are talking about are process-changers.”

This view is reminiscent of Bereiter and Scardamalia's (1993) work on competent teachers and expert teachers, and the difference between them in investing cognitive resources in progressive problem solving. Early adopters appear to be constantly pushing the edge of the problem, and as soon as it gets close to being solved, they prefer to reformulate the whole thing and start again with a new problem.

3.3 Decision

This faculty member has more than two decades of experience teaching with and about computers, has been recognized as an excellent teacher with several awards, and concentrates on technology as a major area of research. Excerpts from the interview transcript highlight some of the motivators and impediments to integrating technology for both early adopters and mainstream faculty. An individual's decision to adopt or reject technology for teaching and learning may be influenced by external factors in their research domain that take priority over an internal desire to focus on innovative teaching methods.

“Globally, the extrinsic reward systems have to be there. People at the assistant professor or associate professor level who want to get promoted or get tenure, will find very quickly that unless they are in a Faculty of Education or being sponsored by a Dean or Department Head who has a very strong commitment to quality teaching, they will not get any extrinsic rewards, such as merit pay, tenure, or promotion if they do research of this type ... in chemistry or physics or biology, the pay off is going to be in doing more basic research in their domain, such as NSERC funded research, or MRC funded research ... They make get intrinsic rewards from seeing better quality teaching in themselves, but to get that better quality teaching they have to invest a lot of time and effort, and sometimes their own money because there are no research dollars to do the things they want to do, and the payoff is quite minimal.”

The following professor has integrated technology into teaching and learning for over five years, has been awarded teaching excellence awards on campus, and currently uses the World Wide Web as a supplement to on-campus teaching. In addition to addressing workload concerns about the time needed to learn about and integrate technology, the potential threats to employment security, and the possible influence of the annual review process, this individual, who has over twenty years of experience as a member of an academic staff, discussed the possibility that some faculty are concerned about putting their lack of skill with technology on display.

“Another part of it I think is just plain competencies, old fashioned technology skill. Knowledge and skill, and sometimes an unwillingness to look stupid, I mean that is one of the things that you have to recognize when learning a new technology is you have got to become a fool for awhile. Some of my colleagues have difficulty doing that, I don't, I never have, but that is another part of the resistance.”

3.4 Implementation

The following faculty member volunteered to participate in an interview after completing the on-line survey (Jacobsen, 1998). This individual is an early adopter of technology for teaching and learning, and has past experience in the information technology industry. The discussion of this case will include attitudes and beliefs expressed by this faculty member about technology integration plans on campus and elsewhere. Even if a technology integration plan has relative advantages for the faculty, if administration attempts to force a seemingly political agenda, the plan is likely to fail. Faculty will become cynical, feel unjustifiably pressured, and not listened to. Focus will shift from the teaching and learning issues, to discussions about the perceived agenda. Faculty may
seek to undermine the innovation by actively or passively rejecting the proposal. Another constituency that will be affected by top-down decision making is the student body.

"Some students, particularly those who understand the issues, are vehemently opposed [to a lap-top acquisition requirement]. Their incensed that tuition has doubled in the last five years, and they are looking at another doubling to pay for these computers. Student leaders are very aggressive in opposition to us ... we need to deal with those concerns ... we need to deal with the fact that students have an installed base of hardware that they have bought, invested substantial amounts of time and money in, and now we are going to now say its obsolete."

3.5 Confirmation

The following faculty member has been integrating technology into classroom teaching for more than two decades and conducts both basic and applied research with computer and networking technology. In order to justify the investment of time and effort, faculty members need to be convinced that their technology integration efforts are having the desired or intended effects on student learning. This individual described some of the reinforcing messages that s/he has received from the community about the integration of technology into her/his courses.

"I have had e-mail from people in lots of places saying how they like this course. I have students who have put stuff up on the web for assignments, and then I get e-mail from industry people, people in government, hospitals, all over, who say, 'Oh, what you have been doing is exactly what I need to do for my research project'. I have to write back and say 'this was an undergraduate assignment', or 'I got that out of this textbook', or whatever. They write from all over and say, 'you are obviously a great expert on this and this and this', and it's nothing, it is just stuff I have put up along the way. So, I say to them, 'well, these are the people who have developed this, why don't you talk to them', and the students are really thrilled you know, because I mail it along to the students concerned, and I say talk to these people. ...it makes it all very authentic, because they are not just sharing it with their instructor, they are literally sharing it with other interested people in the world. And our students now do that automatically, they search for other people, and they look for list servers and newsgroups in areas that they have got an interest in, and if they have got a question, technical questions, they ask 'has anybody had this problem, or does anybody have any research material on something or other', and they get all of this stuff coming back and they make contacts."

In addition to observations and evaluations of the quality of student work throughout the course, this instructor draws upon feedback from sources beyond the institution about the relative advantage and effectiveness of using technology as an on-line publishing environment.

4.0 Discussion

The cases presented here provide some insight into the development of expertise, variable experiences, dispositions, decision making, and motivation for technology integration efforts of early adopting faculty members who are also excellent teachers. These are meant to be useful accounts of the individual experience with technology integration, as well as provide insight into the beliefs and values of individual faculty members, their expectations for outcomes and benefits from using technology for teaching and learning, and a variety of instructional strategies they use to support educational processes. There is some consistency in what the individual faculty members regard as important and valuable instructional goals, and also diversity in the characteristics of instructors and their specific instructional methods for integrating technology into teaching and learning. Readers can compare and contrast characteristics and teaching methods of a faculty member who is relatively new to technology integration and a faculty member who has used technology in teaching and learning for over twenty years. The cases present different perspectives on the administrative and cross-campus issues involved in widespread adoption of technology. A goal that was accomplished with this research was the generation of descriptive accounts that provide a means for drawing parallels and contrasts between the early adopter profiles and a faculty member's own educational practice. The cases presented here were reconstructed from interviews and depended upon the individual's retrospective analysis of their technology integration efforts and teaching philosophies. Future research that attempts to profile early adopting faculty who are excellent teachers could also employ a longitudinal observation methodology to be more informative. Although it was not a goal of the present investigation, future research of this kind may also choose to profile excellent teachers who do not integrate technology into their teaching and learning to facilitate a comparison with the early adopter cases presented here.
5.0 Conclusions

The results from interviews with early adopters suggest that there is a relationship between early adoption, motivation, and excellent teaching. The motivation to integrate technology in their teaching tends to be located in the early adopter's beliefs about excellent teaching. The faculty members described ways in which technology enables them to be a better teacher, provided enriched learning opportunities and access to information, and improved communication with students. Early adopters seem to exhibit characteristics of "expert-like learning", such as progressive problem solving, belonging to second-order environments, and flow (Bereiter & Scardamalia, 1993). They often describe or refer to their extensive experience and knowledge about the technology as a given, "it is not rocket science," which suggests they take for granted their greater literacy and fluency with computers, but might also be a sign of indifference or lack of awareness about how others struggle with the technology. However, it must also be said that most of the early adopters interviewed, who have first hand experience with the unreliability of computers and anticipate problems, demonstrate empathy for colleagues who encounter bottlenecks or problems with the technology.

Early adopters appear to regard technology knowledge and skills as one type of expertise, and pedagogical skills as another type of expertise. Some early adopters cringe at the awkward and ineffective uses of technology by their peers, and are convinced that technology cannot improve poor teaching. Early adopters interviewed in this study seem to be constantly changing teaching and learning processes, reformulating and pushing the edges of the problem, creating and designing alternate solutions, and seem to be more content with risk-taking than the status quo. Not only do early adopters appear to have the self-confidence in using technology for teaching and learning, early adopters have intrinsic motivation and a belief structure that integrating technology into their teaching is the right thing to do. An individual early adopter explained that they apply technology in their teaching because it is the solution to her/his problems, not a solution looking for a problem.

Early adopters are concerned about student evaluations of their teaching, and student access and equity issues, but many continue to integrate technology because of their enduring beliefs about the relative advantage, and the potential benefits and value of computers for students. Early adopters described some of the same impediments that other faculty highlighted, such as equipment & software failures, poorly designed classrooms, and slow and clumsy Internet connections. However, a subtle difference was that these difficulties seem to be expected, the early adopters locate the problem in the technology rather than themselves, and do not appear to be deterred by these impediments.

Because of their different levels of computer use and years of experience, each early adopter appeared to have a unique innovation-decision cycle (Rogers, 1995). For example, most of the early adopters used the WWW for demonstrations in their classroom, some of them published information to the web, and only a few required their students post work on the web. Only one described the development and delivery of a web-based course. One early adopter was convinced of the benefits of web-delivered instruction, while another only considers the web as an enhancement to face-to-face instruction. These differences are consistent with Rogers' (1995) suggestion that the same innovation may be desirable to one early adopter in one situation, but undesirable for an early adopter in another situation. Some of the early adopters described events that have lead to their current adoption patterns, and others described factors that may lead to future adoption, discontinuance, or rejection.

Current fiscal realities are impacting the early adopters as well as the mainstream. Some early adopters purchase software using personal resources, since funding is not available on campus, because they believe the application is important for instructional goals and students' learning processes. The adoption of presentation software is undesirable to some early adopters, not because of lack of skill, but because there appears to be little relative advantage; the impediments include poor lighting and unreliable equipment, and interactivity is perceived to be low.

Early adopters described their frustration with the annual review process and funding agencies that seem to undervalue their teaching and technology integration efforts. Further, for many early adopters, who are working at the edge of their fields and developing new teaching and learning environments, it is disheartening to be evaluated by department heads and peers who may not share the same belief structure and often fail to understand the significance of and motivation for their work. Early adopters also describe frustration with the "insufficient evidence" argument put forth by peers who do not share their beliefs about the benefits of this type of research and teaching. Two early adopters described the difficulty of doing experimental research on the benefits of technology.
integration with students because of equity (and ironic) concerns about the control group who does not get the technology intervention.

There were clear signals that some early adopters feel left out of the current planning and decision-making processes in their faculties or departments. Two individuals described situations in which their opinions and expertise were not been called upon by committees when major technology planning was being done and decisions were being made about the acquisition of technology for teaching and learning. One individual described a situation in which their faculty was hiring a new faculty member in the area of information and communications technology, and they were not even consulted or asked to sit on the hiring committee.

Early adopters offered some solutions for bridging the gap between themselves and mainstream faculty. One early adopter suggested providing training and support to increase the comfort level and how-to knowledge of other faculty so they can approach any piece of software and figure it out (i.e., perhaps to become more like an early adopter?). One individual called for increased standardization of hardware, software, and networking in order to make it very convenient for faculty and students to use the technology, and increase the amount of "just in time" training and support by building more critical mass technology skill and knowledge on campus. Another proposed solution from an early adopter was to give experienced faculty members course reductions so that they can invest time creating and developing technology-enhanced curricula that can be standardized throughout a department or faculty. In some cases, early adopters had strong opinions about why mainstream faculty do not adopt technology that may be inaccurate and not supported by research, such as other faculty are too old and fearful about their jobs to adopt. However, the one characteristic that all early adopters appeared to have in common was a willingness to share their knowledge and expertise in some way to encourage further adoption of technology by peers.

The interviews proved to be a valuable way to gather in-depth information from and about early adopters. Rogers (1995) calls for more diffusion research into the "why" or motivations for adopting an innovation, and interviews with early adopters extend our understanding of and provide insight into the early adopters motivation to integrate technology. A comparison of the interviews reveals that early adopters have both common and unique: (1) values, beliefs and characteristics, (2) expectations about outcomes and benefits from integrating computer technology, (3) integration processes to attain outcomes, (4) specific instructional strategies that support educational processes, and (5) motivators and impediments to integrating computer technology.

Abstract: The acceptance, use of and impact of learning resources are influenced by culture. This article presents ten design guidelines for culture-related flexibility in WWW-based course support sites and shows how they can work in practice. Two case studies, one from the University of Twente and one from the University of British Columbia, both involving WWW-based course-support sites designed for a culturally diverse group of learners, are described and related to the proposed guidelines.

Introduction: Culture and WWW-based Course-Support Sites

The WWW has the potential to make the world more global, which creates the possibility to deliver courses to students all over the world. But can you use the same course for all these students? Will they all react the same to your course? The answer to this question is most likely to be no. Earlier research has shown that the acceptance, use of, and impact of learning interventions are influenced by culture (Jin & Cortazzi, 1998; Watson, Ho & Roman, 1994). As WWW-based course-support sites are an example of such a learning intervention, their acceptance, use, and impact will be influenced by culture-related aspects (Collis, 1999). These cultural aspects can affect the reactions of the institution, the instructor, and the learners to the WWW sites. This implies that it is important for educational designers to consider the question how such sites can be designed to adapt to different expectations and learner preferences, especially those related to culture.

What are these culture-related aspects? Culture can be defined in many ways, but a pervasive view seems to be that culture involves the "beliefs, value systems, norms, mores, myths and structural elements of a given organisation, tribe or society" (Watson, Ho & Roman, 1994, p.45) that manifest itself in the shared and identifiable ways in which a group interprets and reacts to its environment. The influence of culture on the reactions to a WWW-based course-support site occurs at a number of levels: the level of society, the personal level, the organizational level, and the level of the discipline being taught. Several authors have presented analyses of the influence of different cultural levels on the acceptance, use, and impact of different types of learning support (see Collis, Vingerhoets & Moonen, 1997; Henderson, 1996; Reeves & Reeves, 1997).

However, based on the character of these efforts, Wild (1999) reaches the conclusion that research in the domain of the two-way interaction between culture and learning in distributed networks such as the Web is at an early stage of development. There seems to be a need for guidelines for the design of culturally appropriate WWW-based course-support sites (Wild & Henderson, 1997). Collis (1999) responds to this need by providing ten design guidelines for culture-related flexibility in WWW-based course support sites.
This article presents ten design guidelines for culture-related flexibility in WWW-based course support sites and shows how they can work in practice. Two case studies, one from the University and Twente and one from the University of British Columbia, both involving WWW-based course-support sites designed for a culturally diverse group of learners, are described and related to the proposed guidelines.

Guidelines for the Increase of Culture-Related Flexibility in the Design of WWW-Based Course-Support Sites

The following guidelines are a combined result of the analysis of research literature and several years of experience at the Faculty of Educational Science and Technology at the University of Twente with the use of WWW-based course support sites with a culturally diverse group of students (Collis, 1999). The ideas presented here are not only related to adapting to cultural differences, but also to adapting to learner differences in general, in other words to good instruction in general. However, in this article the comments are directly focused to cultural differences, rather than stated at a more general level, in order to assist those who are particularly working with culturally diverse student groups.

1. Plan for flexibility and adaptation right from the start (Griffiths, Heppell, Millwood, & Mladenova, 1994)
2. Design for a variety of interchangeable roles for both instructors and students and offer support for an eclectic variety of types of learning experiences (Henderson, 1996).
3. Use different media for the students in the most appropriate way. For example, use books and print materials as primary study materials, instead of expecting the students to get this information on-line if access time to a computer and/or a network are likely to be limited (Collis & DeBoer, 1998; Griffiths et al., 1994)
4. Use the site to supplement study materials and to integrate and manage student study activities, not to replace the teacher (Collis & Remmers, 1997; Collis, Vingerhoets & Moonen, 1997).
5. Emphasize student and instructor input and make use of a wide variety of learning resources (Collis, Vingerhoets, & Moonen, 1997).
6. Design for minimal technical levels: minimal levels of technical support, and of computer-related skills and competencies, both for students and instructors.
7. Limit the amount of communication, such as text and pictures, that is pre-set in the system, so that adaptations to different cultures are simplified (Griffiths et al., 1994).
8. Provide tools so that the instructor and the students can tailor communication and interactivity expectations and approaches (Collis & Remmers, 1997).
9. Design for flexibility in the organization of courses. For example, differences in length or in examination/assessment requirements (Collis, Vingerhoets & Moonen, 1997).
10. Be realistic about what instructors can and will do, in terms of time and skills (Collis, 1998).

How can these guidelines be applied in practice? The next two sections describe two examples of the design of WWW-based course-support sites planned to be appropriate for learners representing a number of different cultural backgrounds.

The TeleTOP Method: An Example from the University of Twente

The TeleTOP Method has been developed at the Faculty of Educational Science and Technology at the University of Twente in the Netherlands during 1997-1998 and is being used to redesign all of the courses in the Faculty for more flexibility. The first- and second-year courses are in full operation and the remainder of the courses, including courses for the Masters programme for international students, are in the process of re-design (Collis, 1998; see also http://teletop.edte.utwente.nl). Each first- and second-year course serves two cohorts: the regular students and what is called the "Friday" Cohort, mature students who work during the day and only come to the campus one every two weeks, on a Friday, when they attend face-to-face or practical activities with the other students in the course. The rest of the time these students participate in the course via the WWW sites. These WWW sites, however, are just as extensively used by the regular students as well; both cohorts just participate in different ways and within the cohorts students can also choose different forms of participation.
This flexibility is related to the different cultures of the students, in terms of their life experiences, educational backgrounds, ages, backgrounds, and work histories. There is also a need to provide for flexibility related to instructors and subject-area characteristics. To provide for flexible responses to these different aspects, students have the choice of different instructional methods and learning resources as well as the more-familiar flexibilities of time and place. An increasing number of the courses now are offered to combinations of students in the regular and distance groups as well as non-Dutch students in the Masters program of the Faculty and foreign-exchange students visiting the university. Eight aspects of the TeleTOP Method can be identified that provide this flexibility:

1. The instructor is extended, not replaced, to make the current practice more flexible. It is assumed that not all instructors will follow the same approach to teaching.
2. The TeleTOP technical system is based on ease of use for instructor and students.
3. The WWW-based TeleTOP Decision-Support Tools (Collis & DeBoer, 1998) assist the instructor to choose WWW-site features tailored in form and combination to his or her own setting.
4. The matrix-like course roster and the course "communication centre" are standard features of the WWW sites, but can be tailored and adapted to the instructor's wishes (Collis & DeBoer, 1998).
5. Communication and presentations that happen in face-to-face settings can be made available as asynchronous streaming video, in whatever segments the instructor or students wish, via the WWW site for use at different times and/or locations.
6. Courses are designed for "multiple use", a course is designed to teach once, adapt within for individual differences. In particular, to alter aspects related to assignments and study materials based on characteristics of groups of the students, but having all integrated within the same site.
7. Instructors are provided with an easy-to-apply analysis approach for the re-design process, based on concrete aspects of a course. They are encouraged only choose to use the WWW site when it offers added value compared to other media.
8. The TeleTOP Rapid Prototyping Method (Collis & DeBoer, 1998) involves instructors in the design and building of their own course-support sites at the same time as they develop their own skills and competencies in handling the sites.

As pointed out earlier, the TeleTOP method is being used to adapt a large number of courses, varying in instructional approaches, from project-oriented to skills training in programming, from courses focused on statistical methodologies and their applications to courses involving substantial amount of theoretical, conceptual materials. Besides this, the course-support sites include a wide diversity of WWW-based features, from very few to very many, and show a great diversity in how the instructors are using them and organizing their courses.

The Post-Graduate Certificate in Technology-Based Distributed Learning: An Example from the University of British Columbia

The post-graduate certificate in Technology-Based Distributed Learning is the result of a partnership created between the Virtual University of the Monterrey Institute of Technology (ITESM) in Mexico and the University of British Columbia (UBC) in Canada. The certificate consists of five graduate courses and was launched internationally in the fall of 1997. The five courses, on designing, developing and delivering technology-based distributed learning, are offered to several different target groups simultaneously. The first group consists of Masters students in the Educational Technology program at ITESM, originating from several Spanish-speaking countries including Mexico, Venezuela, and Chile. UBC offers the courses to UBC graduate students in the Masters in Education program as electives. In addition, international and Canadian students can take the courses as single non-credit courses or as part of the post-graduate certificate. Finally, audit status is also available. This all makes up for a diverse group of students. The first course for example had students from 27 different countries (Bates & Escamilla de los Santos, 1997; Janes, 1999; see http://itesm.cstudies.ubc.ca).
Some characteristics of this program that relate to cultural flexibility are:

1. The courses are designed for "multiple use": designed to teach once, adapt within for individual difference. In particular, the same site is used for both the ITESM side and UBC side, but for example each institution has its own discussion groups.
2. The technology used in the course is a combination of print (textbooks and selected readings), a WWW site (consisting of a study guide, original teaching materials, online discussion groups, online resources (online articles, journals, access to the extension library), a bookmark database (created mainly by students), student and instructor biographies, and assignment questions) and email. In one of the courses a purpose-designed CD-ROM is used.
3. The technical environment consists of a separate, advanced Web Server and a user-friendly WWW-based user interface developed using WebCT software.
4. The core component for each of the courses is the online discussions about key issues created in the WWW Site forums. Students are encouraged to participate actively in the discussions and course assignments are tied directly to the online discussion activity.
5. The course WWW sites share common features as mentioned in the first four points, but are tailored and adapted for each individual course. For example, the design of the discussion forums varies from course to course.
6. Students are assessed both for individual work and for (on-line) group work. International collaboration is encouraged, for example by forming small groups consisting of Canadian, Mexican, and international students.
7. Tutors play an important role. Students are divided in different tutor groups of about 15-20 students. In addition to that, each course has some internationally renowned guest tutors, often the authors of the texts or readings used. Video-conferencing sessions are organized between ITESM students and UBC tutors.
8. Communication between the participant takes place in several ways, via online discussion forums, email, and chat sessions for online group work.

The fifth and final course is being offered for the first time this fall. All the other courses have been offered at least once, and some two or three times. The first course has been evaluated as part of a two-year study entitled "Developing and applying a cost-benefit model for assessing telelearning" and showed positive results regarding meeting the needs of the different target groups (Bartolic-Zlomislic & Bates, 1999).

Relating the two case studies and the design guidelines

How culturally appropriate are these two case studies? How well do they relate to the ten proposed guidelines for the design of culture-related flexibility in WWW-based course-support sites? Table 1 shows the result of the mapping of the guidelines with the characteristics of the described cases. The numbers in the columns related to the cases correspond to the numbers in the lists of case characteristics above.

Table 1 provides different examples of how to put the ten design guidelines into practice. Besides that it indicates a good fit between the two case studies and the proposed guidelines. There are differences, however. The TeleTOP approach involves many more courses, of different types, than the set of courses in the ITESM. However, the ITESM course involves more cultural differences in terms of land of residence and language than is the case in many of the TeleTOP courses. The TeleTOP approach puts the major responsibility for cultural adaptation in the hands of the individual instructor, whereas the ITESM courses are coordinated among themselves, with a small number of course instructors and coordinators sharing the responsibility. The TeleTOP courses offer a wider variety of flexibility options, compared to the ITESM courses, which assume all students will participate in forum discussions. Despite these differences in context, both cases show how flexibility options can increase responsiveness to cultural differences among students and instructors when sharing a WWW-based course-support environment.

Conclusions

Cultural sensitivity is important in any teaching and learning situation involving participants from different backgrounds and with different life experiences. Designers and instructors should be aware of cultural differences, in what people do, how they react, to what extent they accept different reactions from different people. For example, in some cultures it is normal to criticize others and their work, in other cultures it is not. In some cultures it is normal to work in heterogeneous groups, in others not. The expectations of what comprises a good student, a good instructor, and a good learning situation vary as well. WWW-supported courses have the
potential and often the intention of reaching greater number of culturally diverse students. The key to success in
 crossing these cultural boundaries lies in the appropriate design of the online environments (Henderson, 1996).
 "It is apparent however that instructional design for Web-based learning systems cannot and does not exist
 outside of a consideration of cultural influences- both the cultural influences operating on the authors and
 instructional designers of Web-based learning materials, and similarly, those influences that impact on the
 interpretation of such materials by learners" (Wild, 1999, p. 197). We believe that increased flexibility is a
 necessary base for better cultural sensitivity in the courses. However, it is not sufficient. The skill and
 sensitivity of the course instructor or moderator remains a central variable.

Abstract

Web-based courseware is an alternative approach to provide ideal learning opportunities that empower the symbol systems and mental processing capabilities of learners. The quality of interface to courseware is a matter of vital importance to its learning effectiveness. The overall purpose of this study is to contribute to the understanding of how primary students learn in web-based courseware with respect to learners' interaction and their mental models (personal construct of interfaces) of the courseware.

This study utilized document analysis, observation, and interview methods for gaining insight into the learners' background information, their mental models of the construct of learning activities in the courseware, their actual interactive behaviors during use of web-based courseware, and the results of that use. Qualitative analysis based on learners' behaviors and their explanations of the specific learning activity frame were used to explore the nature of their interactive behaviors, their instances of mental models in web-based learning environment. A summary of the study, discussion of the conclusions, implications of the study, and recommendations for further research form the focus of this report.

Keywords: Human-computer Interaction, Mental models

Background and Purpose

Interactive Learning on the Web

Advocates of active learning, collaborative learning and authentic projects make compelling arguments, but integrating these ideas with educational technology is a challenge. Internet technologies of e-mail, listservs and the web are remarkable vehicles for thrilling educational journeys.

Human beings are information processing systems and have a huge learning potential in a dynamic and irreversible changing world. Novak (1964) suggested that exploratory oriented learning is "the set of behaviors involved in the struggle of human beings for reasonable explanations of phenomena about which they are curious." Though the learning process involves hands-on activities and learning skills, "the focus is on the active search for knowledge or understanding to satisfy a curiosity" (Haury, 1993).

To arrive at an effective learning process and result has always been an ideal for educational technology professionals with the goal of conveying knowledge efficiently and accurately. Learning is the outcome of ongoing changes in our mental frameworks while we actively make meaning out of our experiences (Osborne & Freyberg, 1985). Current theories on learning focus on the "active agent" role of learners who do not passively receive message delivered via instructional channels but who do actively explore phenomena and construct knowledge by themselves. Web-based learning environment is an option of such goal.

Learning context of web-based courseware can evoke learner's creation of analogies from previous experiences. Learners are likely to make meaning out of their interactive experiences, to interpret the verbal as well as visual information, to construct their mental frameworks, and to understand the natural facts as they work directly with virtual phenomena in the learning context.

HCI & Mental Models

Interactive learning is an emphatic concept and strategy for web-based learning; a learning party plays an active role in such process of learning. External events, learning activities on the web, might initialize or allure internal events in the learners.

Learners' perception and understandings of interfaces in terms of mental models is an important
issue in investigations of web-based courseware performance (Shackel, 1997). Learners interact with the learning activities of any instructional media/technology to construct a mental model (symbolic representation) of the specific domain and to make inferences based upon representation processing. Kozma (1991) proclaimed that "Learning with media can be thought of as a complementary process within which representations are constructed and procedures performed, sometimes by the learner and sometimes by the medium. While some learners with appropriate prior knowledge can construct and use representations on their own with information obtained from any medium, other students can not benefit from media that are capable of providing representations and performing or modeling operations on them."

The human-computer interfaces to an courseware is the only channel, a window, an agent through which a learner has access to the learning opportunities provided by the courseware in terms of information content, medium elements, interactive learning activities, and functionality. An interface might facilitate, hinder, or totally block the desired interaction between a learner and the learning context. Therefore, the quality of interface to courseware is a matter of vital importance to its learning effectiveness.

The better we understand the ways learners interact with interactive courseware, the more we can develop effective and efficient courseware (Jih & Reeves, 1992). Research on mental models can identify salient characteristics of cognitive processes and help in the development of research-based guidelines for the design of effective courseware, thus linking the technology and instruction fields together.

Research Design

The aim of this study is to explore the attributes of learners' interpretations of visual representations and their cognitive construction in a web-based learning context with respect to cognitive, affective, as well as operational aspects of mental models in order to gain a deeper insight into the interaction processes within a web-based guided-discovery courseware.

The suitable four candidates for this study were selected from two elementary schools in Taipei metropolitan by Snowball technique. The term 'suitable' pertains to 5th-graders and 6th-graders whose schedule meets with those of this study with the consent of the subjects and their parents.

The web-based courseware, named The Heart of Earth, used in this study utilizes guided-discovery environment where learner can constructs personal meaning via attempting to interpret and explain time and space concepts of Earth Science from personal exploration, experiences, and understanding. Representation medium in interfaces of the "The Heart of Earth" are designed for the following purposes (Jih & Wang, 1998): An Attention Guide, A Context Builder, An Interaction Motivator, A Record Keeper, A Visual Reasoning Anchor, The Invisible Behaviors Manifestation, and A Message/ Feedback Provider.

Accepting the suggestions by Sasse (1991), the researcher used different approaches to measure learners' mental models: observing learners interacting with the courseware, asking learners to explain the courseware to a new learner (the teach-back technique), asking learners to predict feedback of the courseware, asking learners to describe interacting with the courseware, and observing learners interacting with the courseware with a co-learner.

Information collected from subjects includes their level of prior domain knowledge, observation and video-taping on their interaction processes, in-depth interviews, teach-back results, and their audit trials. Figure 1 presents the research settings of this study.

Findings and Conclusions

Multidimensional data analysis revealed the dynamics of mental-model development as subjects learn Earth science via the courseware. This study shows that a few tasks require learners shared decision-making and mutual dependence. High motivation among learners, which is a key to participate interactive tasks actively, can be achieved by presenting a current status of each one's progress. When learners are highly motivated, competitiveness develops spontaneously among different persons in the same class.

The characteristics of learners' mental models toward interfaces included exploration, topology, pattern, preference to audio/visual elements, and pictographic representation. In each learning activity within the courseware, specific patterns emerged. The mental model of the learners can be structured in representing objects to operate on, operations (actions and their syntax), content structure, functions or features, and the courseware states.

Learning is a function of the learner's individual differences, the interaction behaviors, the
interfaces of courseware, the content to be learned, the technology issues, as well as the facilities, equipment, organizations, social context within a learning environment/organization/community (cf. Figure 2).

Learners have a variety of responses to computer interfaces, e.g., reflective, thoughtful, and changing. Learning is influenced by three dimensions of learners' mental models: (Abou Khaled et al., 1998; Ackerman, Sternberg, & Glaser, 1989; Ayersman & Reed, 1998; Iiyoshi & Hannafin, 1998; Nahl, 1998; Stark, Renkl, Gruber, & Mandl, 1998; cf., Figure 2.)

- **Cognitive factors** such as aptitude, ability, skill, prior knowledge, concepts, perspectives, educational level, experience, and learning styles.
- **Affective factors** such as values, self-esteem, motivation, attitude, preferences, expectations, and anxiety; and Facilities, Equipment, Organizations, Social context, ...
- **Psychomotor factors** such as eye-hand coordination and visual acuity.

Active participation is limited to those who are literate, those who have access to the technology and those who are able to use the technology to the maximum of value, bringing order out of chaos.

**Implications and Suggestions**

In order to increase the learner's satisfaction and performance and to create high-quality interactive courseware, the design of computer interfaces should be specific to perceptual aspects of the learner (such as visual and cognitive factors). It is argued that virtual reality environments can enhance learning environments.

Benefits of emerging virtual learning environments include new metaphors for navigation, better opportunities for knowledge construction, and better opportunities for knowledge transfer. However, future research is called for to more fully understand the potential impact of these features (Oliver, 1997).

Research issues on human-computer interaction could be broader. More studies on various factors, as shown on Figure 2, in order to further understand learners' mental models in a web-based learning environment are encouraged.

An Interactive History as Reflection Support in Hyperspace

Abstract: The main problem addressed in this paper is how to help learners reflect on knowledge that they have constructed during exploration in hyperspace. In this paper, we describe an interactive history that encourages learners to annotate and reconstruct their exploration history to reflect on what and why they have explored so far. The interactive history also generates a knowledge map proper to the annotated/reconstructed exploration history. It can be viewed as a potential support for constructive learning in hyperspace.

Introduction

Hypermedia/hypertext based learning resources generally provide learners with a hyperspace within which they can explore the domain concepts/knowledge in a self-directed way (Conklin 1988, Kashihara et al. 1997). The exploration often involves making cognitive efforts at constructing the knowledge from the contents that have been explored (Thuering, Hannemann, & Haake 1995). These cognitive efforts would enhance learning (Carroll et al. 1985). However, learners often fail in knowledge construction since what and why they have explored so far become hazy as the exploration progresses. To what extent the learning has been carried out also becomes unclear. This is a frequently experienced problem of learning in hyperspace (Nielsen 1990).

A possible resolution of this problem is to encourage learners to reflect on what they have constructed during exploration in hyperspace (Tauscher & Greenberg 1997, Thuering, Hannemann, & Haake 1995). The reflection also involves rethinking the exploration process that they have carried out since it has a great influence on their knowledge construction. In particular, exploration purposes, which mean the reasons why the learners have searched for the next node in hyperspace, play a crucial role in knowledge construction (Kashihara, Uji’i, & Toyoda 1999, Murray et al. 1999). For instance, a learner may search for the meaning of an unknown term to supplement what is learned at the current node or look for elaboration of the description given at the current node. Each exploration purpose would provide its own way to shape the knowledge structure. The reflection support accordingly needs to adapt to the exploration activities and the knowledge structure being constructed by the learners.

In this paper, we discuss a proper reflection support with a careful consideration of exploration process in hyperspace. This paper also describes an interactive history for learning with hypermedia/hypertext based learning resources on the Web. The interactive history system provides learners with their exploration history annotated with exploration purposes that have arisen during exploration. It also transforms the annotated exploration history into a visual representation called knowledge map. It spatially shows semantic relationships among WWW pages the learners have visited (Kashihara, Uji’i, & Toyoda 1999). Using the interactive history system, the learners can view and reconstruct the exploration history to rethink their exploration process that they have carried out so far. They can also view the knowledge map to reflect on what they have constructed in hyperspace. Before discussing the interactive history, let us first consider exploration process in hyperspace and how we can represent it.

Exploration in Hyperspace

In hyperspace, learners generally start exploring from one node to others by following links among the nodes with a learning purpose. The movement between the nodes is often driven by a local purpose called exploration purpose to search for the node that fulfills it. Such exploration purpose is also regarded as a sub purpose of the
learning purpose. We refer to the process of fulfilling an exploration purpose as primary exploration process, which is represented as a link from the starting node where the exploration purpose arises to the terminal node where it is fulfilled.

Table 1: Exploration Purposes and Visual Representation.

![Figure 1: An Exploration History.](image-url)
An exploration purpose may have several terminal nodes with one starting node. Exploration purpose, represented as verb, signifies how to develop or improve the domain concepts and knowledge learned at the starting node. We currently classify exploration purposes as shown in Table 1, which are not investigated exhaustively.

An exploration purpose arising from visiting a node is not always fulfilled in the immediately following node. In such case, learners need to retain the purpose until they find the appropriate terminal node/s. While searching for the fulfillment of the retained purpose, it is possible for other exploration purposes to arise. The need to retain several exploration purposes concurrently makes the knowledge construction more difficult to achieve.

The exploration process can be modeled as a number of primary exploration processes. Let us give an example where a learner uses a hyperdocument on a WWW server with the learning purpose of understanding the occurrence of earthquake. In this example, he/she explores a number of nodes (WWW documents) with various exploration purposes. Figure 1 gives the exploration history, which shows the sequence of the nodes visited and primary exploration processes. For example, he/she visited the node "Animation of the Mechanism" in order to rethink the description in the node "The Mechanism of Occurrence of Earthquake". He/she then visited the node "Seismic Wave" since he/she did not know the meaning of the term used in the previous node.

Exploring hyperspace in a self-directed way, learners construct a knowledge structure that is often different from the structure of hyperspace (Thuering, Hannemann, & Haake 1995). The knowledge structure is shaped according to primary exploration processes, especially the exploration purposes. Each exploration purpose provides its own way to shape the knowledge structure (Kashihara, Uji'i, & Toyoda 1999).

**Interactive History**

**Problems Addressed**

Let us now discuss what kind of reflection support is indicated by the above consideration. There are the following important problems to be addressed towards a proper reflection support. The first issue is how to help learners retain the primary exploration processes that they have carried out. The retention may cause cognitive overload on exploration. It is also hard for computer to infer their exploration purposes, which arise in the learners' mind. These suggest that learners should be encouraged to note down the primary exploration processes.

The second problem is how to assist learners in reconstructing their exploration process. In reflecting on their exploration process, they would not only look at it but also modify/delete the primary exploration processes and add new primary exploration processes. It is accordingly necessary to provide learners with a space where they can reconstruct their exploration process after exploring hyperspace.

The third problem is how to help learners reflect on knowledge constructed during exploration. One way to resolve this is to visually represent semantic relationships among nodes included in primary exploration processes. Such representation does not obviously show the contents included in the explored nodes. However, this would be a useful map for the learners to reflect on what they have learned. We accordingly call it knowledge map.

In order to resolve the above problems, we have developed an interactive history that helps learners reflect on their exploration process and knowledge structure by means of an exploration history annotated with primary exploration processes.

**Annotated Exploration History**

In order to help learners note down and retain primary exploration processes during exploration, the interactive history system provides them with a user interface as shown in Figure 2. They explore hyperdocuments on a WWW server with one learning purpose in the left window. When they want to set up an exploration purpose in visiting a node, they are required to click one corresponding to the purpose in the "Exploration Purpose Input" section of the right window. The clicked purpose is added to the "Exploration Purpose List" section. The node visited currently is also recorded as the starting node of the exploration purpose.

The learners can also add the object of verb describing an exploration purpose. It means what to develop/improve in the current node whereas the exploration purpose specifies how to develop/improve. When
the learners do not add this object, the system adds the title of the current node, which is the title tag in the HTML file. When the learners find a terminal node of the exploration purpose, they are required to mouse-select the exploration purpose in the "Exploration Purpose List" section, and to push the "Fulfilled" button. The node visited currently is then recorded as the terminal node of the exploration purpose.

Figure 2. User Interface.

The system also provides another support for helping learners store part of the contents of the node visited currently with Cut&Paste function in the "Contents Input" section although they may not always need this support. In hyperdocuments on WWW, in addition, the title tags of the nodes do not always represent the contents of the nodes. If the learners want to change the node titles, they can input new titles in the "Contents Input" section, which new titles should represent the contents the learners explored in the nodes.

Using the information inputted from the learners, the system generates the annotated exploration history as shown in Figure 1. In the annotated history, the nodes learners visited are sequenced in order of time. The starting node of each purpose is linked with the corresponding terminal node/s. There may be some primary exploration processes without terminal nodes since they have not been found yet. They can also click the nodes in the history to review the contents information, which they have inputted with Cut&Paste function.

Learners are not always required to input the above information whenever they visit nodes. Nevertheless, inputting the information during exploration may be troublesome for learners. On the other hand, it enables the learners to make their exploration more constructive, facilitating their exploratory learning. Without inputting, they may only browse in hyperspace.
History Manipulation

Directly manipulating the annotated exploration history, learners can reconstruct their exploration process without revisiting hyperspace. Each manipulation is done by means of mouse-clicking/dragging parts of the primary exploration processes. There are three basic manipulations: deleting and changing exploration purposes/links between starting and terminal nodes, and adding new primary exploration process.

Knowledge Map

The representation of knowledge map follows the visualization scheme shown in Table 1, which shows the correspondence of an exploration purpose to a visual representation of the relationship between the starting and terminal nodes. For example, an exploration purpose to 'Elaborate' is transformed into a set that visualizes the starting node as a total set and the terminal node as the subset. Following such correspondence, the system generates a knowledge map from the annotated exploration history. The knowledge mapping is executed on learners' demand before/after manipulating the annotated exploration history.

![Knowledge Map Image](image)

Figure 3. Knowledge Map.

Figure 3 shows an example of the knowledge map that is generated from the annotated exploration history shown in Figure 1. Viewing this map, the learner can reflect on his/her knowledge construction. For example, he/she can recall that he/she rethought the mechanism of earthquake occurrence by looking at the animation of the mechanism. He/she can also recall that he/she compared normal fault and adverse fault to elaborate the description about kind of earth faults.

Related Work

Let us next discuss the usefulness of the interactive history compared with related work on reflection support in hyperspace. As the retention support, there are several kinds of annotation systems that allow learners to take a note (Brusilovsky 1996). However, there is very little discussion of what kind of annotation should be done for the success in exploratory learning. In the interactive history, we claim that the reasons why learners search for the next nodes should be particularly noted down.

Current work on adaptive hypermedia/hypertext systems has often provided spatial maps and concept maps, which are originally used as navigational aid. Spatial maps can inform learners where they are, what they explored, and to what extent they explored (Domel 1994). However, the reasons why they visited the nodes are
not clearly shown. In addition, these maps are not very helpful since learners do not need to learn the structure of hyperspace. Concept maps are more helpful for learners who have lower capability of exploring hyperspace since the direction of knowledge construction is presented to them (Gaines & Shaw 1995). However, learners who have higher capability of exploratory learning may not always construct the same knowledge structure as the structure of domain concepts that the designers of concept maps draw. In hyperspace, learners are free to identify relationships among the domain concepts visited in a self-directed exploration, and these relationships may be different to those defined in the concept maps (Thuering, Hannemann, & Haake 1995). The interactive history, on the other hand, provides them with a more proper support since it enables self-directed exploration. In addition, the reflection support can be provided even in ill-structured domains of which concept maps cannot be defined.

Conclusions

This paper has claimed that exploratory learning in hyperspace requires learners to reflect not only what but also why they have explored, and that the reflection support needs to adapt to their exploration process and knowledge structure being constructed by them.

This paper has also demonstrated the interactive history with knowledge mapping as a proper reflection support. The interactive history encourages learners to annotate and manipulate the exploration history to rethink their exploration process. It also generates a knowledge map from the annotated exploration history, which allows the learners to reflect on what they have constructed during exploration.

In the future, we need to evaluate and refine the interactive history. We would also like to classify exploration purposes in more detail and to represent learners' exploration process and knowledge structure more precisely.

Abstract: In the medical and health sciences, a well described problem for students is the linking of discipline-based knowledge with clinical practice. The CD-Rom, An@tomedia has been developed to support a problem-based learning curriculum in undergraduate medicine. An@tomedia contains four primary perspectives, imaging, dissection, systems and regions and is intended to address a variety of student learning needs and approaches to learning. The evaluation of An@tomedia by students, tutors and lecturers is described.

Introduction

The development of problem-based learning (PBL) in medical education has, historically, focused on the whole student learning experience rather than the acquisition of content (Camp, 1996). PBL has been advocated in order to address problematic issues attributed to traditional medical courses—the creation of an arbitrary division between the basic and clinical sciences, and wasting student time in learning facts that are easily forgotten or not relevant to clinical practice (Finucane, Johnson, & Prideaux, 1998). The teaching of anatomy at The University of Melbourne over the past 10 years has integrated the structure of the human body with its clinical applications. In 1999 the medical school moved to a problem-based learning curriculum. With the advent of new computer-based technologies the development of resources to support the PBL approach included an interactive CD-Rom designed to enrich and engage the student more actively in the learning of anatomy. The software, An@tomedia, provides greater interactivity for the student by providing multiple perspectives (e.g., systemic and regional views) of anatomical knowledge linked to clinical applications in an interactive computer-facilitated learning (CFL) environment. The perspectives provide a framework for students to integrate anatomical knowledge with clinical applications and procedural knowledge. The software allows students to switch between perspectives in order to facilitate their knowledge construction, and address clinically-based problems. This paper reports the results of an extensive evaluation of the CD-Rom, including qualitative and quantitative analysis.

Student learning and An@tomedia

“When medical graduates enter the workplace, they are not faced with situations labelled ‘anatomy’, ‘microbiology’, or the like. They are faced with patients with illnesses . . .” [Bowden, 1998, p. 129].

How subject matter is experienced and how the student subsequently organises and integrates knowledge, is dependant upon the student’s perception of the learning context (Ramsden, 1984). Students may adopt a surface approach (e.g., learning by rote) or a deep approach (e.g., a holistic approach, actively searching for meaning) (Biggs, 1989; Marton & Säljö, 1984).

The learning process may be supported by appropriate learning opportunities, including the use of carefully designed computer-facilitated learning (CFL) within the context of a subject. An@tomedia is designed to enable
students to interact with anatomical knowledge and principles, from multiple perspectives. The use of multiple perspectives (and multiple pathways) in CFL has been advocated in order to:
- allow learners to access the material in a manner more suited to her or his needs (Reeves, 1992),
- support higher levels of cognition (Ramsden, 1992), and
- support a more reflective approach to learning (Laurillard, 1993).

In order to provide a richer learning environment in An@tomedia, there was a need to embed clinical, procedures, imaging, surface anatomy, and dissection components within the software, and integrate these with the more traditional systemic and regional approaches to the learning of anatomy. Figure 1 (Fig. 1) is representative of the final educational approach adopted. In Figure 1 (Fig. 1), students may deconstruct the body using Dissection and Imaging, or construct the body via Systems and Regions. An example involving the back (the first module to be completed) is highlighted. The figure shows a model of the educational design of An@tomedia in a three-dimensional space. The X-axis represents the anatomical regions (only three regions of the body are shown), the Y-axis represents anatomical systems (only four are shown), and the vertical axis represents students ability to construct or deconstruct the body by dissection or imaging. Students may move freely between perspectives, answer questions, and investigate clinical problems about the back.

Figure 1: Graphical representation of the An@tomedia perspectives

Figure 2 (Fig. 2) shows the view seen by a student examining anatomy from one perspective, dissection. The remaining 3 perspectives are listed on the lower right—reached with a simple mouse click. There are questions for the student to answer (e.g., 'Can you identify a radicular artery'), and overlays of anatomical structures that may be highlighted by the student. The student may move between specific regions by clicking on the regions on the human symbol on the lower right.

In the An@tomedia CD-Rom, there is extensive linking of anatomical details with the clinical perspective. This has been done by the use of:
- high quality images (e.g., radiographs, detailed dissection images from real human bodies, and graphics with coloured overlays highlighting key anatomical details),
- integration of clinical questions and answers, and
- the facility for the student to examine anatomical concepts from multiple perspectives using multiple pathways.

The evaluation

The evaluation of An@tomedia has adopted a case study approach. The majority of the data was generated from students, their anatomy tutors, and content experts by the use of questionnaires comprising five-point Likert questions and open-ended free text responses.
The Likert-style questions in the student questionnaire overlapped approximately 60% with that of the tutors and lecturers (TLs). Some questions were more appropriate for students (e.g., It helped me understand anatomy) or TLs (e.g., I found the four perspectives were well balanced and integrated). Anatomy tutors and lecturers also answered specific questions on how they might use the CD-Rom as part of their own teaching program. An@tomedia is not intended as a replacement for an anatomy teaching program, instead it is intended to support integration of student knowledge, the anatomical with the clinical, and systemic with regional.

Results

The evaluation results highlight the strengths and potential weaknesses of the educational design of An@tomedia. Trends in the results suggest directions for improvement as well as the educational value of the multiple perspectives. Table 1 (Tab. 1) presents the mean scores and standard deviations of students (first column) and a combined tutors and content experts (second column). Responses were completed on five point Likert scales where a score of '5' was 'strongly agree', '4' was 'agree', '3' was 'neutral', '2' was 'disagree', and '1' was 'strongly disagree'. T-Tests were also undertaken to compare and contrast the student and combined tutor/lecturer (TL) responses. There was a ceiling effect for most items and the data suggested that all respondents were overwhelmingly positive about the software. The only question to have a significantly different response between students and the TLs responses involved the locating of information. Not surprisingly, the tutors and lecturers (all qualified doctors) had significantly less difficulty than the students in locating specific information. At the time of the evaluation (but since completed), the index and search engine had not been implemented, and this is thought to have been contributing factor to the student responses.

The students were also asked how they would prefer to use the An@tomedia CD-Rom (Tab. 2). It is significant to note that while over 90% wanted their own copy, 53% indicated they would use it in study groups. The first author observed during the evaluation process, pairs of adjacent students engaged in discussion of the key aspects of the different representations of anatomical structures (e.g., one student pair may have been looking at the radiological view while the other pair, the dissection).

Students were also asked a number of open-ended questions. Student comments about the best aspects of An@tomedia included:

- Anatomical content was superb. Images (dissection, imaging etc.) were beautiful.
- Explanations are very clear and highly comprehensive.
- Love the clinical relevance and concise exam style questions.
It was simple yet complex. The diagrams to help answer the questions were fantastic and very helpful.

It was a combination of an atlas and text book which is fantastic. It saves you having to flip (between an anatomical atlas and anatomical text) ...

Table 2: Students preferred use of An@tomedia for learning: Frequency and percentage

The student comments about the aspects that needed improvement included:
- Absence of a “search” mechanism for “random access” into a particular concept or principle.
- (add an) adequate index from which to link into appropriate slides illustrating the concept or principle.

The comments from the students regarding the need for an index and search engine were expected. However, it was necessary to undertake an evaluation before the first release of the program and integration into the new PBL curriculum in order to refine and improve the initial design.

The tutors were engaged in the role of supervisors, teachers and mentors, particularly in the activities in the dissection room. Comments from tutors included:
- [the best feature was the] Combination of aspects of atlas, textbook, and clinical text in one resource.
- The radiology component was fantastic – the resolution of the images very clear. The dissections were also impressive.

Tutors were also interested in An@tomedia as a teaching resource. They perceived two potential uses for the CD-Rom—as a precursor for students prior to dissections, and access during dissection classes to clarify and illustrate anatomical relationships. The latter has implications for resources—there would be a need to install
video projection and computer facilities in the dissection laboratories and provide training for tutors to use the
equipment.
Responses from the content experts (lecturers) were more diverse, with both very positive and very negative
comments. The content experts included practitioners who were occasional lecturers, to full-time medical
educators. Some comments were very positive.
  ➢ [the best feature was the] Integration of invivo, invitro eg., dissections/imaging. Excellent dissections
  and graphics to highlight structures. Interactive format and quantity of information.
  ➢ [the best feature was the] Anatomical detail very good, especially the imaging component

Less favourable comments included:
  ➢ Everything is too static. It is a portfolio of drawings and pictures with (some) accompanying text. The
  CD is used as a filing system but under-used for constructive education.

In reflecting on the comments from content experts it is important to recall that An@tomedia is designed to be
implemented as part of a PBL curriculum—it is not intended that An@tomedia become the sole resource for the
teaching of anatomy. One outlook on teaching involves the view that a lecturer constructs learning opportunities
for students—some of which may be facilitated by a computer. The teaching methods chosen as the focus of the
learning opportunities, teacher-centred or student-centred or a mixture of both, are strongly influenced by the
educational beliefs held by the lecturer (Bain, McNaught, Mills, & Lueckenhausen, 1998). For example, in
response to the question 1(1) “Which of the factors above do you believe are the most important in influencing
student learning?”, one content expert replied:
  ➢ None of these factors are strong determinants. The cardinal determinate is what is in the exam.
  Wherefore, assuming that is what is shown is all that needs to be known, the most relevant qualities are:
  locate information, graphics clear, how much information, concise.

In all discussions with the An@tomedia development team, the need to provide a learning environment that
addressed the traditional divide between discipline-based knowledge and clinical practice was paramount.
An@tomedia has been designed to be one component within a particular educational context—one which is
student-centred, rather than teacher-centred. In Table 2, only 27.3% of students perceived that An@tomedia
would be appropriate for use in lectures—a teacher-centred learning environment. However, over 50% wished
to use the CD-Rom as part of group activities, and over 90% wanted their own copy for personal study and
revision. There may be a need in the future to include with the CD-Rom the background perspective that guided
its development, and suggestions (for students and teachers) for ways in which it might be utilised, particularly if
An@tomedia is to be used in other contexts.

Summary, conclusions and future directions

Two goals of An@tomedia were to be comprehensive and use multiple perspectives. These goals seem to have
been achieved. The comments regarding the comprehensive nature of the four perspectives, allowing the student
to move from one representation of knowledge (e.g., imaging and dissection) to the clinical applications has been
highlighted (by students and TPs) as one of the most important strengths of An@tomedia. However, there are
some students who think that there is too much information (generally, and on-screen).

In the second iteration of the software, the index has been completed to overcome the inherent difficulty of
locating specific information. In addition, an extra navigational feature in the form of sequential numbering for
each set of screens in a perspective has also been added to aid in the relocation of specific information. The
lecturers and tutors were asked specific questions that focused on the use of An@tomedia for teaching. Their
responses have highlighted the need to address the curriculum in which the CD-Rom is used. As indicated in the
discussion, there are some issues of implementation and educational perspectives to be resolved if An@tomedia
is to be used outside the context of the current PBL medical program.

While An@tomedia is focused on the content area of anatomy, the results of the evaluation indicate there are
potential lessons to be learnt from the use of multiple perspectives to link structure and application in other
subject areas, and the embedding of computer-facilitated learning in problem-based learning curricula.

Since the evaluation, the Abdomen and the Thorax (second and third modules respectively) have been completed
and a number of typographical and graphical errors rectified as well as an improved introduction and starting
screen. An@tomedia is now a pivotal part of the first year undergraduate medical program at The University of
Melbourne. In 2000, the Neck will be completed. Sample images from the CD-Rom may be viewed at

Web Raveler
An Infrastructure for Transforming Hypermedia

Andrew Kensler and Samuel A. Rebelsky
Glimmer: The Grinnell Laboratory for Interactive Multimedia Experimentation and Research
Department of Mathematics and Computer Science
Grinnell College
United States
rebelsky@grinnell.edu

Abstract: Adaptive hypermedia has the potential to change learning in an online environment. Interactive hypermedia systems, in which students can not only add their own pages and links but also modify existing pages, provide the potential to further support students. Yet the World Wide Web fails to live up to these potentials because the core Web technologies lack uniform support for adaptation or interaction.

Web Raveler is an infrastructure that supports uniform extension and adaptation of Web pages. Web Raveler mediates the dialog between Web clients and Web servers, transforming requests and responses so that, for example, faculty can make standard modifications to arbitrary pages, from adding annotation facilities to presenting pages in a form appropriate for the reader. Web Raveler is also extensible; by developing new plug-ins, faculty can add functionality to arbitrary pages.

In this paper, we discuss the architecture of Web Raveler and suggest some applications.

1. Background: Why Transform Pages?

Initial visions of hypertext emphasized a highly interactive information system, in which readers could annotate, contribute to, share, and link pages in the hypertext (Bush 1945) (Nelson 1974) (Landow 1997). Unfortunately, the World Wide Web provides a more passive model of hypertext, as most pages and browsers limit readers to scanning through pages and clicking on links. While newer technologies (e.g., Java applets, browser plug-ins, and even CGI scripts) can provide more interactivity, such interactivity is at the control of the page's original authors, and out of control of the readers. Compare this with Nelson's original description of hypertext, in which he writes "links may be artfully arranged according to meaning or relations in the subject, and possible tangents in the reader's mind" (Nelson 1974, p. DM19, emphasis ours). To support such interactivity, readers need a way to transform existing pages to add these new facilities.

Such facilities can allow students to interact with each other in a collaborative manner. An annotation system for example could let students post notes and carry out on-line discussions in the context of a course web. The instructor might post materials on-line and students would attach comments to specific points or items on the page. Other students or the instructor could then respond to them in the same manner. Students divided into groups might post notes visible only to other students in the same group. The system would customize the page for each individual who views it.

At the same time, faculty are looking for ways to use the Web to provide different perspectives on the same material, letting the Web site adapt to the needs, background, or usage patterns of their students, e.g., (Brusilovsky 1996). Computers can adapt the pages to the user, customizing them specifically to suit the person viewing the page. This can be particularly powerful in the case of education. Adaptive hypermedia is much more powerful because it can present information to the student in the way that is most effective for them and allows them to learn best. For example, an adaptive lesson might choose different examples based on knowledge of the background of the student, or suggest different resources depending on which resources students have viewed in the past.

Systems that can customize the presentation of the material for individual users can significantly improve the experience. In the case of course web sites for education, they can adapt the material to the mode of learning that best suits the student, thereby making the learning experience much more engaging.
Adaptation may also mean adapting existing pages. That is, a teacher might select portions of other pages, add comments to other pages to help students use those pages, or even tie together materials from multiple pages. As (Landow 1997) suggests, students might also engage in scholarly activity not by writing new words, but by creating new associations (links) between existing pages.

These are three somewhat different domains: adding interactive facilities to individual pages, writing pages that adapt, and adapting existing pages. However, they share some key commonalities. In each case, pages must be modified according to some rules (to add facilities; to change the page according to information on the reader or student; to change the page according to specifications from the modifier). In each case, modification requires some knowledge about the reader, some of which are tied to individual pages (desired facilities and a collection of changes made through those facilities, such as notes on the pages; browsing history, education level, other preferences; specifications for modifying pages).

The Web has the potential to provide a richer, more interactive, and more uniform environment for students and teachers. But it needs standard mechanisms for modifying pages according to information about the reader.

2. A Solution: Web Raveler

To realize this potential, we have constructed an infrastructure for transforming hypermedia. Web Raveler is a Web page modification system designed to transform hypermedia on the fly. It sits between a user’s Web browser and the Web servers on the Internet, transforming pages and resources as they go through. It supports multiple simultaneous users and keeps individual profiles so that it can customize pages differently for each user. Web Raveler runs each page through a series of plug-ins that modify the page based on the context of the page and the users profile. This transformed page is then what it returns for the browser to display to the user.

Web Raveler is also flexible in that it can be used with existing tools and course webs since it filters the pages as the travel through. Instructor can continue using whatever tools they are most comfortable with for building their course webs and easily add Web Raveler to those course webs. This system can also adapt pages outside of the domain of the course web; it can actually transform any page available over the World-Wide Web. Thus users are not restricted to a small domain but can use it to enhance students' overall experiences no matter where they are on the Web.

Furthermore, Web Raveler is transparent. There is some minor initial setup involved with configuring the Web browser to use it, but once this is done, the users can browse the Web at will using the system. Everything is accessible and there are no funny URLs to bother with. Readers can simply use the Web browser as they always do, with no extra effort beyond the initial configuration.

Finally, Web Raveler supports a plug-in architecture to provide the infrastructure for new applications. Each plug-in interacts with the Web Raveler Server through a simple interface. Web Raveler takes care of the details, from communication with the Web browser and the Web server to storing user preferences, accounts, and other information. It simply passes each page to the appropriate plug-ins along with the data on the user and allows them to modify the page freely. Thus applications are only concerned with doing their specific adaptations, leaving the mechanics of the system to the Web Raveler system.

This architecture allows the Web Raveler system to provide a wide range of services to the user, while not restricting them in any way.

3. The Architecture of Web Raveler

Three main components comprise the Web Raveler system: the Web Raveler Account Server (WRAS), the Web Raveler Server, (WRS) and a group of plug-ins. (Fig. 1) illustrates the components and their relationships.

The WRS is a standard HTTP proxy server. When the Web browser needs a page, image or other resource, it sends an HTTP request to the WRS (step 1). The WRS checks to see if the request is from a user who is already logged in. If the user is not logged in, then it sends back an authentication response that the browser interprets by requesting a user name and password of the user. Then the browser resend the request, this time...
with the request bearing the user name and password of the user. When the WRS gets this information, it then
passes it over the Internet to the WRAS (step 2). This server checks to make sure that the password is correct
for that user, and if so, sends back the data for that users account (step 3). Otherwise, it sends a response back
to the WRS indicating that the login failed, and the WRS sends back a response to the Web browser for the user
to try to log in again.

Once the user has logged in, the WRS passes along the request for the page or image to the source Web
server (step 4), which actually has the page. The Web server retrieves the requested resource from disk and
sends it back over the Internet to the WRS (step 5). Since Web Raveler uses HTTP, the standard Web
communication protocol, it can pass requests to any Web server.

After it has received the page, the WRS examines the users' settings, including specific options for each
plug-in and what groups the user belongs to. It also examines the page for any embedded instructions regarding
plug-ins. WRS then decides which of the available plug-ins should be applied the page and in what order. It
executes each of the plug-ins in turn on the page, giving them the page and the information on the user (steps
6a,7a). Each plug-in may do anything that it wants with the data, typically transforming the page and returning
the transformed page (steps 6b,7b). Each plug-in runs in turn on the page and then, after all have been
executed, the WRS returns the page in its final form to the Web Browser (step 8), which then renders it for the
user.

Note that pages (and, therefore, their authors), and not just readers, can specify which plug-ins to run. This
facility gives authors some control over what can and cannot be done to their pages (since many authors may
not want to permit some transformations to be applied to their pages). It also provides an infrastructure for
adaptive hypertext, in that authors can specify that particular adaptations be applied.

![Figure 1: The Architecture of Web Raveler.](image)

All of the components of Web Raveler were written in Perl and thus are portable to a variety of platforms,
including Unix, Linux, Windows, and Macintosh. Our current implementation is running under HP-UX, and
we are testing other platforms. We currently support Perl-based plug-ins. Perl is also a convenient language to
use because of its powerful text-manipulation capabilities and many useful Web-related libraries. These make it
easy to write plug-ins with significant capability. We are also developing a plug-in architecture based on
SATIRIC, a contextual pattern language, which was developed specifically for transforming Web pages
(Seaman et al. 2000).

3.1. Alternative Implementation Techniques

We have chosen the standard HTTP proxy server mechanism as our underlying implementation technique.
There are, of course, other mechanisms for transforming Web pages as they travel between client and server.
One might use a centralized CGI script that parses its URL and selects which server to select, as in (Becker et
al. 1999). One might rely on server plug-ins, CGI scripts, or ASP scripts, as is sometimes done in an ad-hoc fashion for pages on a single server. One might write browser plug-ins, as in the case of ThirdVoice (ThirdVoice 1999). (Tab. 1) summarizes selected issues for each technique.

<table>

</tr>
</tbody>
</table>

Table 1: Potential Implementation Strategies

While server plug-ins and scripts provide authors with extensive functionality, that functionality is typically limited to the pages on the site or sites that server serves. These scripts also leave control in the hands of authors; readers cannot decide which transformation to use. Finally, they may require cookies or strange URLs to keep track of user information.

Browser plug-ins provide more freedom, as in the case of ThirdVoice, a plug-in might be applied to any page on the Web. However, not all plug-ins run in all browsers or on all architectures, a severe disadvantage in the typically heterogeneous academic environment. For example, many plug-ins are never released for all variations of the Unix platform. Plug-ins may also be difficult to disable.

CGI proxies also provide the opportunity to transform arbitrary pages. However, they require that readers select “alternate” URLs. For example, to read the EdMedia Web page through a CGI proxy, a browser might be required to use a URL like

Such URLs can confuse novice and experienced readers alike. CGI proxies typically require cookies or even more complicated URLs to keep track of the current user.

HTTP proxies, our chosen technique, provide all of the advantages of the other techniques, with few of the drawbacks. Readers employ standard URLs. The standard proxy protocol permits the server to request a password and the browser sends account information “automatically”. Proxies support arbitrary URLs, and so allow authors to transform arbitrary pages.

4. Current Applications of Web Raveler

The Web Raveler system provides an infrastructure for the development of multiple adaptive hypermedia applications. In addition to mediating between them, it handles the details of communication over the Internet with the Web browser and the Web server. It also keeps track of the user settings and preferences. The plug-in architecture makes it trivial to develop new applications and add them to the Web Raveler system without the need to modify the Web Raveler program. Once plug-ins are placed in the appropriate directory, they automatically become active the next time the Web Raveler Server is started.

The first plug-in developed for Web Raveler was a shared Web annotation system, an update of (Luebke et al. 1999). This system allows user to attach comments to arbitrary Web pages and set different levels of access on them. This system allows students to annotate pages in a course web as well as linked external materials. Students divided into the different groups can mark their annotations as being visible only to members of their group, visible to the whole class, completely public, or private to themselves.

Another application currently under development is a trailblazing system (Glynn et al. 2000). This system allows teachers to record a series of Web pages, add notes to the pages and present them in a coherent “trail” that students can follow in the prescribed order. If a student visits a page, and that pages is on a trail the teacher has created, the system notifies the student about the availability of the trail.

A third application is a tracking system. A previous version of this was done using a CGI proxy system (Becker et al. 1999). However, Web Raveler affords many advantages for this. The tracking system will silently track where a user goes, recording how long they spend on each page, which links they follow and so forth. This information can then be collated to evaluate the effectiveness of a Web site. In an educational
context, instructors can see how the different resources on a course Web site are being used and can take advantage of this to make the course Web site more effective.

Finally, we have just begun work on the adaptation plug-in that permits authors to write pages that can take advantage of the information Web Raveler gathers.

5. Related Work

There are many other filtering systems available, written in different languages, emphasizing different transformations, or using different technologies. These include OreO (Brooks et al. 1995), GrAnT (Schickler et al. 1996), Muffin (Boyns 1998), and part of Project Clio (Becker et al. 1999). The Web Raveler system is unique in supporting user accounts and preference data, so that different readers may select different transformations. Ours is also unique in that we support author-specified transformations, in addition to reader-specified transformations.

There are also other systems available that attempt to ease the construction of interactive course webs, most notably WebCT and First Class. WebCT primarily focuses on the creation of course webs. It does have support for annotations and on-line quizzes and exams. It also provides some forms of tracking. First Class is a client/server that primarily provides services to run a threaded discussion forum. Instructors can create message areas and then students can post to these.

These systems however still lack the true power of transformational hypermedia. They are limited to their own domain and cannot customize pages outside of the course systems constructed using them. They also restrict the instructor to using their tools to construct the sites. Preferably an instructor would create course materials using whatever tool they are most comfortable with.

6. Conclusions, Future Directions, and Other Issues

Successful educational use of the Web requires more than existing tools provide; it requires uniform systems for annotating and transforming Web pages, techniques for writing adaptive pages, and systems for adapting existing resources. Web Raveler provides a uniform system for all three applications, empowering teachers to build better sites and students to interact more freely with the Web.

The Web Raveler system is currently being used as the foundation for several adaptive hypermedia systems that have been implemented as plug-ins. In the fall of 2000, the Department of Math and Computer Science at Grinnell College will begin class testing with the Web Raveler system and these plug-ins. As suggested earlier, work on a number of plug-ins has begun.

There are certainly many other issues we must consider, including a uniform language for page authors to limit and specify transformations, a more user-friendly language for writing transformations, and a language for writing adaptive pages that use Web Raveler. We have not yet measured the overhead introduced by Web Raveler and its plug-ins. We expect to report on some of these developments and experiments at a future EdMedia conference.

Developing Communication Skills
Using INSPIRE Negotiations

Abstract: INSPIRE is a web-based negotiation support system that has been used for the last three years for negotiation training and research. It has also been used in teaching written communication skills. In this paper we discuss implications of using the system in teaching English as a Second Language and English for Academic Purposes in multilingual classes and point out the benefits that this new technology offers. We also show how extending classroom boundaries to remote regions of the world add to increased students' involvement and enhance language acquisition.

Introduction

Web provides people in different locations and time zones with a communication medium that is rich in functionality and content and which offers them the ability to use previously inaccessible computational resources. While the Web is currently used as a powerful source for the dissemination of information, it is increasingly being used as a means for active communication, and remote execution and control of complete software systems, thus adding another dimensions to the value it delivers. In education, its ability to access and run remote programs and databases allows users to extend classroom and laboratory boundaries across geographical and time zones.

The InterNeg Web site and its Web-based system INSPIRE have been constructed to exploit these technologies and their use in teaching [4-6]. They aim at providing people around the world with analytical knowledge and decision support techniques within the domain of negotiations. The INSPIRE system allows participants to analyze and solve real-like decision problems and conduct negotiations with people from different cultures.

The INSPIRE system is the first Web-based negotiation support system. It is based on analytical models rooted in decision and negotiation analysis [7-8]. Developed in the context of a cross-cultural study of decision-making and negotiation, the system has been primarily used to conduct and study negotiation via the World Wide Web as well as in teaching information systems, management science, international management and English as a Second Language (ESL) [4, 9].

In this paper we discuss the use of the INSPIRE system in the context of ESL teaching, and the teacher's and students' experiences. In Section 2 the system, the available resources and the negotiation case are outlined. Section 3 discusses the context and the teaching methodology used to adapt the system for ESL purposes. The implications for teaching communication skills, and the students' and teachers' experiences are discussed in Section 4. Comments about INSPIRE's usefulness for ESL/EAP teaching and the ongoing work on new Web-based resources conclude the paper.

InterNeg site and the INSPIRE system

The InterNeg project began in 1996 with the development of a simple Web-based negotiation support system called INSPIRE (InterNeg Support Program for Intercultural Research; http://interneg.org/interneg), [6]. During
the last three years over 3,500 students used the system. The host InterNeg site offers services (see http://interneg.org), including beginners' handouts and information on how INSPIRE can be used in different university courses. Research papers, summaries, examples of students' assignments, a glossary, an extensive bibliography and information about programs and organizations involved in negotiation are also available.

INSPIRE views a negotiation as a process occurring in a particular context. The system does not act autonomously like a third party arbitrator; rather each 'copy' acts solely to support a single negotiator. It supports asynchronous negotiations, thus ameliorating the time zone problem. To facilitate this type of negotiation the system saves the current state resulting from each user's actions in a form that can be retrieved when the counterpart logs in some time later.

**INSPIRE negotiation phases**

INSPIRE negotiations follow three phases: an antecedent phase, a concurrent phase, and a consequent phase [6]. The pre-negotiation phase involves an analysis of the situation, problem and opponent, specification of preferences, reservation levels, and strategy. In this phase users read the case, formulate their preferences using simple tables to distribute scores between issues and their values, verify the utility (ratings) of selected offers that are generated by the system and fill in a pre-negotiation questionnaire. The questionnaire contains, among others, questions about the expected compromise and the worst offer that the user is willing to accept.

The negotiation phase involves exchanges of messages and offers, evaluation of offers and the assessment of the progress of the negotiation. Offers comprise the negotiated issues and their values; each offer is formulated by selecting one value for each issue. The offer rating is automatically displayed beneath the table which contains the offer. An offer may be accompanied by a message. Users may also send messages without offers; this feature is often used to prompt their counter-parts by making an additional argument. On a number of occasions users sent messages to communicate with their counter-parts about topics outside of the negotiations; in fact a number of users maintained e-mail communication with their counter-parts after the negotiations were completed.

Users have two mechanisms to assess the progress of the negotiation. They may review the complete history of their negotiations, including offers exchanged, their ratings and the messages. They can also access a graph that displays the negotiation dynamics in their utility space. The negotiation is parallel on all issues. Participants may submit the same offer many times, or keep the option of an issue unchanged, but each submitted offer contains a value for each issue.

The negotiation ends when either a compromise has been achieved, or one of the parties terminates the process, or the time runs out (at a predetermined deadline). The post-settlement phase involves the evaluation of the negotiation outcomes generated by, and after, the negotiation activity. These outcomes include the information about the compromise. If the negotiators can improve their compromise, the INSPIRE provides them with up to five Pareto-optimal offers. In this situation the users may choose to continue their negotiations. The post-settlement phase ends with filling in the post-negotiation questionnaire, which however, is not mandatory.

**Itex-Cypress Negotiations**

The negotiation problem involves two companies: Itex Manufacturing, a producer of bicycle parts and Cypress Cycles that builds bicycles. Cypress Cycles, an established manufacturer of high quality mountain bikes, is launching a new line of bikes and requires a type of component that its current suppliers cannot provide. Their first serious discussions for the supply of these components are being held with Itex Manufacturing. Itex is seeking to increase its share of the component market and would like to have the prestige that would come with supplying Cypress, should a profitable contract be signed.

There are four issues that both sides have to discuss. The issues are: the price of the components, delivery times, payment arrangements, and terms for the return of defective parts. INSPIRE users are asked to negotiate on behalf of the company rather than for themselves and told that their companies are interested in achieving a compromise. They are also informed that there are other suppliers and buyers so a breakdown in negotiations is possible, if a good deal cannot be reached. There is no further indication as to what constitutes a good deal. Each side, however, is given a clear indication as to the desirability of the options (issue values) but only in terms of the direction and not specific trade-off values. By avoiding the specification of preference values, negotiators are able to establish their own priorities within each issue.

In writing the case an effort had been made to make it as much as possible 'culture neutral'. The negotiation situation is of the type that can be encountered anywhere in the world. Also the negotiators' names (which can usually indicate their cultural background) are substituted by pseudonyms. The case is fairly simple and well struc-
tured. It describes a negotiation problem that is familiar to users from almost any country, therefore no additional explanations are necessary. Language proficiency of the users was taken into consideration too. The comprehension of the case was tested on a group of students taking Intermediate English as a Second Language for Academic Purposes course at Carleton University.

The description of the case fits one and a half pages. Generally, users find the system very easy to use, and their evaluation of the overall system is favourable. Over 75% of INSPIRE users stated that they would use a system like INSPIRE in real-life negotiations and over 85% would use such a system to prepare themselves to conduct actual negotiations. While the feedback on the INSPIRE system confirmed our expectations, the absolute levels of user acceptance of the system are surprisingly high.

EAP/ESP context

The students

INSPIRE has been used at Carleton University to teach foreign language learners communication skills. The School of Linguistics and Applied Language Studies offers two English as a Second Language Programs. In the Intensive ESL Program the majority of the student population are international students. Some are either planning to enter a regular study program at an English speaking university in North America others learn English to gain a competitive advantage at the job market in their countries. The Credit ESL Program on the other hand, is a language support program for those students who have already been accepted to Carleton on the condition that within a year they receive a B- exit grade in the advanced course of English.

There are three language proficiency levels in the Credit Program: Introductory English as a Second Language for Academic Purposes, Intermediate English as a Second Language for Academic Purposes and Advanced English for Academic Purposes. The Advanced course has two options, i.e. general EAP and English for Special Purposes (ESP) for Academic Purposes for Engineering Students. The highest level of the Intensive Program and the introductory course of the Credit Program are in fact the same course in terms of the level of language proficiency. The difference is the students' status—visa students (Intensive) versus permanent residents (Credit).

Students enrolled in both programs come from all over the world and have a variety of educational backgrounds ranging from new high school graduates to professionals. The majority of the students however, are in their twenties and have a couple of years of college or university training (particularly those in the Intensive Program).

Over the last three years, the INSPIRE system has been used with the students enrolled the writing workshop at the highest level of the Intensive Program and in the Credit Program: Intermediate English for Academic Purposes and Advanced English for Academic Purposes (both the general EAP and EAP/ESP for engineering students).

Whole language, communication and negotiations

The presented language teaching approach is embedded in the theory of whole language. It is based on the belief that development of cognitive skills is interrelated with the development of language skills; that critical thinking and analysis should constitute an integral part of learning; that we learn language to communicate with others and therefore social context is important; that the learning objectives are best achieved when there is purpose and meaning; and that students' direct engagement and experience are crucial to the learning process.

The INSPIRE system lends itself to the theory and practice of whole language. While analyzing the negotiation process the students develop both the cognitive and the language skills. The dynamic in its nature, relationship between negotiation partners provides social context for communication; the role-play which evolves around finding a solution to a conflict of interest situation gives purpose and meaning to the communication that takes place.

Negotiations require extensive use of communication skills. Although negotiations on the Web do not allow for the use of non-verbal clues (at least not yet), they stimulate the precision of expression in the written form allowing the students to work on developing their writing. The written messages can be carefully thought over and revised many times until the student feels that what he/she has written represents adequately his/her point of view. While writing these messages the students learn how to persuade, argue, convince, etc. They also learn to read, understand and follow instructions which are an integral part of the INSPIRE system. The speaking skills are developed through classroom discussions about the progress of individual negotiations, negotiating strategies and techniques. While negotiations are conducted outside of the classroom, these discussions take place during each class for the duration of negotiations.
The INSPIRE negotiations lend themselves to the thematic approach to language teaching. All the language activities evolve around the topic of negotiations, decision-making and conflict resolution. The conflict that is at the core of the negotiation keeps the students intellectually and emotionally involved. And although the negotiation case is only an assigned task, the communication that occurs is authentic.

The negotiations take about two weeks during which time the students are constantly exposed to the language of business negotiations used in a specific context for a specific purpose. The role-playing situation and the fact that there is a real person on the other side of the negotiation "table" keeps the students committed to the task. The level of difficulty of tasks and language activities grows gradually, and roughly corresponds to the three phases of the negotiation: pre-negotiation, negotiations and post-negotiation. In the pre-negotiation phase the students write and share their past personal experiences with negotiations, read the INSPIRE case and acquaint themselves with their role, read and discuss the example (this is when the vocabulary is introduced in a context), listen to a lecture on the INSPIRE system and take notes (they will need the notes later to write the introduction to their report or essay), rank the negotiation issues and options and fill in the pre-negotiation questionnaire.

During the negotiation the students are required to keep a Negotiation Journal where they record all negotiation related activities, analyze the situation, strategies, techniques and the dynamics, predict their opponent's behaviour, etc. They also share their experiences with their classmates on a regular basis, and engage in language activities such as discussing the language of e-mails, sentence combining, punctuation exercises, and play word games. This is also when the students start writing the introduction and the methodology sections of their report.

In the post-negotiation phase they fill in the post-negotiation questionnaire, evaluate their negotiations, their opponents, and themselves. Finally, they write a report or an essay in which they evaluate their negotiation experience using the information that was made available to them via the INSPIRE negotiation support system, through in-class discussions and the Negotiation Evaluation Questionnaire.

Organization

Before the negotiation begins, a brief presentation about INSPIRE is made. It is made clear at the beginning of the course that INSPIRE is an important module of the course. However, it is also stated that the final result of their negotiation (compromise or not) and its utility score are not used for grading purposes. This is important because the participants should be able to negotiate in as realistic a situation as possible and be in control of the process. Students may decide to break their negotiations with one company and initiate new negotiations with another.

A demonstration session follows the presentation and it is intended to familiarize the students with the Web, and INSPIRE. They are shown how to log on to INSPIRE, how to construct and send offers using the system, and how to incorporate changes in any of the offers or issues in subsequent visits. The session usually lasts an hour. The instructor uses hard copies of the forms used in the INSPIRE negotiation so that the participants can actually see what kinds of forms they will fill in.

During this session students log in and read the INSPIRE case. At this time they may conduct initial analytical activities: specify the relative importance of each issue and the options for the issues. This information is used to determine their subjective utilities for all possible offers. In many cases the session ends with the student making a first offer to his /her counterpart. Before the session ends, the participants are reminded that they will be notified by INSPIRE via e-mail whenever a message or offer from the counterpart is received by the system. When they receive notification the participants log into INSPIRE to read and evaluate the offer and submit a counter-offer.

Experiences

Students' experiences

Students were requested to record every activity they undertook related to their negotiation via INSPIRE. These logs were used for personal assessment of each exchange of offers/counteroffers and messages as well as for discussions. They also helped the instructor to catch and address any problems that may have occurred.

A few participants stated that INSPIRE helped them to see an intercultural point of view. A significant majority said INSPIRE did help them to refine their communication skills. They pointed out that they were more concerned with language accuracy and the appropriate level of formality than they normally are while communicating with their classmates. Those who had none or very limited experience with computer technology, were particularly appreciative of the fact that they were not only learning the language but also learning a new medium of communication. Despite the participants' limited experience with the Internet, their ability to achieve expected compro-
mises suggests that the INSPIRE system and Web-based negotiations do not introduce a significant burden or add complexity to the already complex negotiation process.

Teacher's experience

INSPIRE required different preparation, handling and conduct of the negotiations than face-to-face methods. In contrast to in-class instruction, teaching negotiation through INSPIRE required first ascertaining the level of Internet expertise of the users. Appropriate training sessions on the Internet may need to be planned before the INSPIRE session starts.

For a teacher whose class conducts a Web-based negotiation the process involves preparation and handling of three major stages: (1) introduction to the system, (2) the first exchange of offers and messages, and (3) discussion following the negotiations, and/or preparation of report or essay guidelines.

The first hands-on class has always been conducted in the computer laboratory. In this session, participants were guided through such steps as logging in, reading the case, submission of rating of issues and packages, and finally the first offer. Deft handling of varying levels of experience and expertise among the participants is of crucial importance here. We found it useful to place one skilled and a less skilled participant next to each other. The role of faculty here is one of a facilitator and his presence after the submission of the first offer, was generally not necessary.

Typical problems that may arise in running an Internet based negotiation are: (1) system problems, (2) team problems, and (3) administrative problems. System problems include both hardware and software compatibility issues (INSPIRE requires Netscape 3, Explorer 4, or later browsers) and systemic problems (including power shut-downs, and network problems), which may occur in any given time. To ensure successful completion of a negotiation through INSPIRE instructors need to plan and develop effective administrative mechanisms. These may include identifying a module coordinator from a group of participants, who could help the group stay focused and productive during the negotiation. Another possibility is pairing less computer literate students with those who feel very comfortable with the new communication technologies. Once the students have begun their negotiation on INSPIRE there is very little intervention required from the instructors.

After the completion of the negotiations, participants usually want to compare their results. The analysis of experiences can be done in many ways, i.e. informal group discussions, formal presentations followed by questions, formal reports, etc. Individual introspection proved to be most useful for the executive development programs, while post-graduate students and ESL students preferred classroom discussions.

Implications for teaching communication skills

Preparation of tasks that keep students' interest for an extended period of time and motivate them to give the best performance they can has always been one of the challenges faced by language teachers. The INSPIRE negotiations have the elements of a game and a role play and provide the students with a "real counterpart" with whom they are going to exercise their skills of persuasion and argumentation. The combination of these factors contributes to raising students' involvement and to increased awareness of the need to use appropriate and accurate language. The students themselves are responsible for initiating responses and for the outcome of the negotiations. They control their moves and actions. Therefore the communication that occurs in form of email messages is authentic. The fact that the negotiator's identity is concealed reduces the intimidation factor: racial and gender biases are eliminated. And although the negotiation may miss on spontaneity, it certainly allows for the analysis of the situations, for the preparation of strategies and tactics and for revisions of messages. Finally, some students exchange email addresses with their counterparts and keep corresponding like the traditional "pen pal" friends.

The submission of offers and counteroffers which are accompanied by written messages, the Negotiation Journal, class discussions and the use of the resources available on the Web such as questionnaires, graphs and the possibility to check the history of the negotiations creates an environment in which the language is acquired. The words whose meaning may have appeared vague at the beginning become part of the users' active vocabulary. The language of argumentation and persuasion develops because it is needed to gain concessions.

Conclusions

Systems such as INSPIRE offer an opportunity for direct participation in a negotiation and thus create a platform for experiential learning which is deeply rooted in the theory and practice of negotiation training and in the
theory of whole language. The computer is a medium of communication that fosters learners' autonomy, equality and learning skills. The opportunity to communicate not only in the class but also outside of class creates a new social dynamic [10], where the learners fully control the process and the outcomes and where race, gender and status barriers disappear. In this asynchronous negotiation the learners have the time to reflect, analyze and make as many revisions of their writing as they may find necessary. The conflict of interest embedded in the negotiation promotes richer written interaction. All this creates an environment where the cognitive and the linguistic development are interrelated [2].

The flexibility of Web based systems facilitates customization of the case material to reflect regional specifics. It is also easier to bring about a discipline-based orientation in teaching and training sessions. The systems can be tailored to reflect, say, a behavioral, decision theoretic or any other focus to suit local teaching and training needs. This is very useful for management teaching and training where different modules are often combined to reflect the particular focus of a course. Web pages are very good at representing context, and independent Web pages may be assembled by a dispatching system that determines which page to present, based on a given situation.

The successful use of INSPIRE in teaching communication skills in ESL courses prompted us to develop a dedicated Web site for this purpose (http://interneg.carleton.ca/interneg/training/esl/). The site contains a 16 hours class-time module and a detailed timeline of language activities. Over 200 students from Canada and Germany used the module. The materials available include students' handouts, examples, a glossary of terms, detailed instructor's notes, description of students' activities (e.g., examples of the Negotiation Journal, sentence combining, collaborative dictation and essay guidelines), and writing models. More information about the module, the timeline and specific activities can be found at the Web site.

Abstract: This study examines the effectiveness of a CAI system on students' academic achievement. After developing an experimental hypermedia CAI system, an experiment using this system on a group of elementary school students was performed, and the data from the experiment were then analyzed statistically.

An experimental hypermedia CAI system with an emphasis on improving reading skills was developed using Hanoi 3.0 on an IBM compatible PC. The pedagogical material for this experimental system came from the first chapter of a standard social science textbook for fifth grade students in Korea. The study involved 55 students in total, who were divided into an experimental group of 27 students and a control group of 28 students. For the final 15 minutes of a 40-minute class, the experimental group studied with the experimental hypermedia CAI system, while the control group studied in the traditional manner. This experiment was repeated for 19 class hours.

A post-test with 30 questions designed to measure academic achievement was conducted on both groups of students at the end of the experiment. The average and the standard deviation of scores for the experimental group are 25.18 and 3.43 respectively, and 22.57 and 2.96 for the control group.

In order to determine whether academic achievement for the experimental group was better than that of the control group, a t-test on the two populations was performed at the 5% level of significance. From the analysis of the t-test, it is concluded that the academic achievement for the experimental group is significantly better than that of the control group. This fact tells us that the experimental hypermedia CAI system had a positive effect on the students' academic achievement.

1. Introduction

Current computer technology makes it possible to store and retrieve information of several data types, including images, voices, and texts. Hypermedia (Conklin, 1987) is a database that consists of a collection of nodes containing unformatted multimedia data, which are interconnected by directed links and are retrieved non-linearly. There are many practical applications of hypermedia. In the field of education, computer assisted instruction (CAI) involving hypermedia technology raises the possibility of improving students' academic achievement using computers.

Many educators assume that hypermedia CAI systems stimulate students' motivation and curiosity and improve their ability to memorize new facts. However, few statistical studies have been carried out that can verify this assumption. This may be due to the fact that, while it is easy to develop a hypermedia CAI system, it is relatively difficult to carry out an experiment on a large sample of students over an extended period of time. Thus, although many researchers in the field of education are interested in measuring the effects of CAI systems on students' academic achievement, the only studies that have been carried out so far are those with small sample populations, measured over short periods of time.

Chou (1996) developed a hypermedia music CAI system and carried out an experiment to evaluate the system in an elementary school in Chungli, Taiwan. Sixty students of the sixth grade participated in the study for 40 minutes. Sixteen students were assigned to the experimental group and the rest were assigned to the control group. The experimental group studied with the hypermedia music CAI system, while the control group studied the same material in the traditional lecture format. A post-test was given to the students at the end of the
Matthew (1996) performed an experiment to compare the reading comprehension and attitudes toward reading of third grade students. The study compared students who read CD-ROM interactive storybooks with students who read traditional print storybooks. After reading, a comprehension test was assessed with open-ended questions and requests to retell the story. The results of the t-test indicate that there was no statistically significant difference in the reading comprehension of two groups but that there was a statistically significant difference in their ability to retell the story.

Like the studies just mentioned, the present study attempts to measure the effects of a hypermedia CAI system on students' academic achievement. However, the present study has the advantage of being based on an experiment that is performed over a longer period of time and with a larger sample.

2. The Experimental CAI System

An experimental hypermedia CAI system with an emphasis of improving reading skills was developed using Hanol 3.0 on an IBM compatible PC (Protectsoft, 1997). The pedagogical material for this experimental system came from the first chapter of a standard social science textbook for fifth grade students in Korea. The chapter is typically taught in 40-minute sessions over a total of 19 hours.

The characteristics of the experimental CAI system are the following. First, students interact with the system primarily using a mouse, which allows for easy mastery of the system. Secondly, the system contains a summary of the contents of the chapter being studied. Thirdly, important and difficult words in the chapter are given hyperlinks, which connect them to a glossary and which also allow users to have a sampled pronunciation of the word. Fourthly, photographs and other visual materials are included in order to stimulate students' interest and help them to understand the material. Fifthly, the system contains games and questions, which students may use to test their knowledge of the chapter. Finally, for the convenience of the user, the system contains hypermedia interfaces.

3. Test for the Evaluation of the Subjects

In order to evaluate students' academic achievement, a test was developed. The test consists of 30 questions based on the content of the relevant chapter from the text. The test was given to the students both before and after they studied the relevant chapter.

4. Subjects

Fifty-five fifth-grade students from two classes in two elementary schools in Cheonan, Korea participated in the study. They were ranked on the basis of IQ scores and school grades from the previous semester. They were divided into two groups based on this ranking, with the experimental group consisting of 27 students, and the control group consisting of 28 students. The detailed data are shown in Table 1.

5. Procedures of the Experiment

Pre-test

In order to determine whether or not there was any difference in the prior knowledge of the relevant chapter between the experimental group and the control group, the aforementioned test was given to the subjects before the experiment.

Experiment

For the first 25 minutes of a 40 minutes class, all subjects studied together in the standard manner. For the final 15 minutes, the experimental group studied using the hypermedia CAI system in a computer lab with two assistants, while the control group continued in the standard manner. This experiment was repeated for 19 class hours, 4 classes per week over 5 weeks. A summary of the classes is given in Table 2.

Table 2 Unit Class Type and Period

Post-test

In order to determine whether or not the experimental CAI system had any affect on the academic achievement of the students in the experimental group, the aforementioned test was repeated on all subjects at the end of the experiment.

6. Statistical Analysis

Data collected from both the pre-test and the post-test were analyzed using the statistics software SAS (SAS Institute Inc. 1995).

Analysis of the Pre-test

The average and the standard deviation of scores for the experimental group are 9.40 and 2.22 respectively, and for the control group 9.42 and 2.96 (full score: 30). The scores were analyzed using a t-test. Table 3 shows the results of the t-test, where N represent the sample size of each group, t the t-value, df the degree of freedom, and p the observed significance level. For a t-value of -0.0360 with degree of freedom of 53, the t-test yielded a p-value of 0.9714. This result indicates that in prior knowledge for the relevant chapter, there was no statistically significant difference between the two groups at the 5% level of significance. Therefore, one can conclude that the experimental and control groups were well constituted.

Analysis of the Post-test

In order to examine the data from the post-test, the following hypotheses were tested using a t-test.

Null hypothesis: $\mu_e = \mu_c$
The academic achievement for the experimental group is equal to that of the control group.

**Research hypothesis:** $\mu_e > \mu_c$

The academic achievement for the experimental group is better than that of the control group.

Table 3: $t$-test for the Pre-test

The average and the standard deviation of scores for the experimental group are 25.18 and 3.43 respectively, and for the control group 22.57 and 2.96 (full score: 30). The scores were analyzed using a $t$-test. Table 4 shows the result of the $t$-test. For a $t$-value of 3.039 with a degree of freedom of 53, the $t$-test yielded a $p$-value of 0.0037. Therefore the null hypothesis is rejected, and one can conclude that, at the 5% level of significance, the academic achievement for the experimental group was significantly better than that of the control group.

7. Conclusion

The question with which this study is concerned is whether or not a hypermedia CAI system can enhance or improve students' understanding of academic material. In order to answer this question, an experimental hypermedia CAI system was developed and then tested on a group of elementary school students in Korea. The data from the experiment, which were examined statistically, demonstrate that the experimental CAI system was indeed effective in improving students' understanding of academic material. This conclusion conflicts with the earlier study by Chou, who found a similar CAI system to have no effect on academic achievement. However, since the present study is based on an experiment conducted over a longer period of time and with a larger sample size, its conclusion is more credible.

One limitation of the present study is that the experiment involved a relatively homogeneous sample population: all subjects were elementary school students in Korea. Further research is therefore necessary to determine the extent to which the conclusion of this study may be generalized to students of other ages and/or cultures.

Effects of Cognitive Style on Web Search and Navigation

Kyung-Sun Kim
School of Information Science and Learning Technologies
University of Missouri – Columbia
United States
kimk@missouri.edu

Abstract: This study examined how users with different cognitive styles locate information on a university Web site, a hypermedia-based information system. A hypermedia system is considered to be capable of accommodating cognitive style differences because of its multimodal attributes. Undergraduate students with different cognitive styles (field-dependence and field-independence) participated in the study. Findings suggest that the level of users' online search experience influenced effects of cognitive style on the search and navigational behavior. Only the field-dependent users with little or no online experience seemed to have difficulties in retrieving information on the Web.

Introduction

Hypermedia is one of the recently developed information technologies equipped with attractive interface and great capacity of improving access to information. By way of the World Wide Web (Web) and other networks, hypermedia has come to include remote databases and online resources (Ayersman, 1996). Naturally, the Web, with its attractive interface and capability of connecting to a variety of different resources, has become one of the most widely used information systems in the world.

Different from more traditional information systems (e.g. books), hypermedia is intentionally nonlinear (Nielsen, 1995). It presents a new information environment with which the user may not be familiar. Hypermedia permits the user to have considerable flexibility in choosing the sequence with which to access information, rather than forcing the user to access information in a fairly linear sequence. Such linear sequencing has long been prescribed by the technology of the book and the narrative structure used by most authors. Users who have not developed skills of information-gathering in the nonlinear environment often report discomfort and experience difficulties in using hypermedia, such as “cognitive overload” and “disorientation” (Nielsen, 1995; Conklin, 1987).

Despite all these problems, early research suggests that hypermedia is promising as an information system (Gary and Shasha, 1989; Egan et al., 1989). Other studies evaluating the effectiveness of hypermedia, however, have not been uniformly successful in showing the advantage of hypermedia over other existing information systems (McKnight et al., 1990; Marchionini and Shneiderman, 1988). These inconsistent findings have led to a suspicion that there may be variables, other than system differences, influencing the effective use of hypermedia systems. To explore and identify factors influencing the effective use of hypermedia, a number of studies have been conducted. Results from the research suggest that characteristics of users and tasks may be major factors affecting the use of hypermedia systems (Qiu, 1993; Ford et al., 1994).

This study investigates how some of user variables influence the use of the Web as a hypermedia-based information system. The focus of the study is on the user’s cognitive style, and its effects on the search behavior are examined in relation to the user’s online search experience.

Background

A study analyzing usability studies of hypertext systems has revealed that four of the ten largest effects were due to users’ individual differences (Nielsen, 1989). Among different kinds of individual differences, cognitive style, especially field-dependence/field-independence (FD/FI), is one of the most frequently studied factors in the research of learning on hypermedia systems (Liu & Reed, 1994; Leader & Klein, 1996). The FD individuals who tend to be easily dominated by salient cues are more likely to be distracted in hypermedia systems where information units are presented through a variety of different, attractive media forms. In fact,
several studies have shown that the FI individuals, less likely dominated by prominent stimuli, generally perform better than the FDs in finding information on hypermedia systems. The FIs tend to search information more efficiently and arrive at desired goals more quickly than the FDs (Ellis et al., 1993; Ford et al., 1994). Each group utilize a hypermedia learning environment differently although both of the groups have equivalent learning outcomes (Fitzgerald and Semrau, 1998).

Another kind of individual difference with a strong impact on the information-seeking process includes users’ experience and expertise. Experience with online search and subject expertise have been found to influence the choice of search strategies and the search performance on information systems. Studies on linear information systems have revealed that online search experience, rather than subject expertise, plays the major role in determining the effective use of the systems (Hsieh-Yee, 1993). However, this finding is yet to be confirmed with hypermedia-based information systems.

The Study

Forty-eight volunteer students from a public university participated in this experiment. Their participation was financially compensated. All the participants were undergraduate students with different academic orientations. Fifty-four percent (n=26) of the participants were with soft science (social science, arts and humanities), and 46% (n=22) were with hard science (natural science and engineering) background. Half of the participants were male and the other half were female students.

The GEFT (Group Embedded Figures Test) and a questionnaire were used to determine the cognitive style and the level of online database search experience, respectively. Based on the results from the test (with scores ranging from 0 to 18) and questionnaire (with scores ranging from 0 to 4), participants were selected, and an individual lab session was arranged for each of the participants. Half of the participants were field-dependent (FD) and the other half were field-independent (FI): MeanFD = 8.25, MeanFI = 15.96. Also, half of them were novice and the other half were experienced online searchers; Mean NOV = 0.92, Mean EXP = 2.96. In the lab session, the participant was assigned search tasks for which he or she had to locate pertinent information within a university Web site. The Web browser used in the study was Netscape 4.0.

Independent variables for the study include users’ cognitive style (field-dependent (FD) vs. field-independent (FI)) and online database search experience (experienced (EXP) vs. novice (NOV)). On the basis of their cognitive style and online experience, participants were evenly divided into four groups (FD-NOV; FD-EXP; FI-NOV; FI-EXP). Two dependent variables were adopted to measure search performance of the participants: the average time spent and the average number of nodes visited for the completion of a task. Additionally, the number of times each navigational tool chosen was counted to examine the user’s search and navigational style.

The individual lab session started with a review of Web basics, designed to ensure that every participant was aware of the availability of different navigational/search tools and menus in the Web browser used and also general features of search engines. When the review was over, two search tasks were assigned to the participant. The same set of search tasks were used for all the participants. When the participant felt ready to start searching, he or she asked the researcher to start recording the search session. During the search session, all the screen displays consulted and keyboard/mouse inputs were recorded using Lotus ScreenCam. The participants were asked to make a bookmark of each Web page where he or she found relevant information.

Results

Average Length of Time Spent for the Completion of a Task

A two-way ANOVA was performed for the average length of time spent for the completion of a task. In this report, the level of significance was set at $p < .10$. The result indicated a significant main effect of cognitive style: $F_C (1,44) = 5.271, p < .03$. The FD individuals tended to spend more time than the FIs to find a piece of information: $Mean_{FD} = 130.3$ sec., $Mean_{FI} = 89.9$ sec. A significant main effect of online search experience was also found: $F_O (1,44) = 3.69, p < .07$. To find information on the Web, those with little or no online search experience spent more time than those with substantial online search experience: $Mean_{NOV} = 127$ sec., $Mean_{EXP} = 93.2$ sec. There was a significant interaction between the two independent variables: $F_{C,O} (1,44) = 3.859, p < 0.06$. Figure 1 shows how the cognitive style and online search experience variables interacted with each other to influence the time spent for the completion of a task.

*p < .10

For those with considerable online search experience, cognitive style seemed to have little impact: Mean _FD-EXP_ = 96.1, Mean _FI-EXP_ = 90.3. For those with little or no online experience, however, cognitive style seemed to play an important role in decreasing or increasing the length of time spent for the completion of a task. The FDs (FD-NOV) tended to spend longer time to retrieve information than the FIs (FI-NOV): Mean _FD-NOV_ = 164.6, Mean _FI-NOV_ = 89.5. Interestingly, the FDs with substantial online experience spent almost the same amount of time as the FIs (FI-NOV and FI-EXP) did for the completion of a task. It seems that, only among those with little online experience, cognitive style has an effect on the time spent for finding information.

Figure 1. Average Time Spent for the Completion of a Task (sec.): Cognitive Style by Online Search Experience

Average Number of Nodes Visited for the Completion of a Task

A two-way ANOVA was performed for the average number of nodes visited for the completion of a task. At _p_ < .07, a significant interaction between cognitive style and online experience was found: _F_ (1,44) = 3.57. As shown in Figure 2, the FI-NOV tended to visit a lower number of nodes than the FD-NOV: Mean _FD-NOV_ = 16.4, Mean _FI-NOV_ = 8.5. Among the experienced online searchers, on the other hand, little difference was found between the FIs and the FDs: Mean _FD-EXP_ = 8.5, Mean _FI-EXP_ = 7.8. The pattern was similar to what was found with the time spent for the completion of a task. No significant main effect was found, however. That is, no statistically significant difference existed between the numbers of nodes visited when the groups were compared on the participants' cognitive style or on the level of their online search experience.
Use of Navigational Tools

In order to find whether differences in search performance were reflected in the navigational tools chosen, additional sets of two-way ANOVA were carried out using the number of times different navigational tools were used (such as embedded links, Back, Home, Go, History, search engines, etc.) as the dependent variable. Significant interactions were found for the use of embedded links and the Home button: for embedded links, $F_{C \times O}(1,44) = 5.002, p < .04$, and for the Home button, $F_{C \times O}(1,44) = 3.728, p < .07$. The pattern of interactions was similar to the one found with the time spent and the number of nodes visited for the completion of a task. The FDs with little or no search experience (FD-NOV) used embedded links and the Home button significantly more frequently than the rest.

In addition to the interaction effects found in the use of embedded links and Home button, a significant main effect of online experience was found in the use of jump tools: $F_O(1,44) = 6.568, p < .02$. Here, jump tools include Go, History, Location box used for an "active" jump. The result revealed that the experienced online searchers used jump tools more frequently than the novice searchers: Mean Exp = 0.60, Mean NOV = 0.005.
Discussion

Results from this study suggest that the level of users' online search experience influences the effect of cognitive style on the search performance. That is, among those who had little or no experience with online searches, the FI individuals tend to outperform the FDs. In order to complete a search task, the FIs spent less time and needed to visit fewer nodes than the FDs. However, the difference created by participants' cognitive style disappeared in those participants who had considerable online search experience. Among the experienced online searchers, no significant difference was found between the FDs and the FIs in terms of the time spent and the number of nodes visited for the completion of a task. This implies that difficulties that the FDs face in finding information on the Web may be overcome as the FIs gain experience and develop their search strategies while using online databases. Despite presentational and structural differences between traditional “linear” online database systems and the “non-linear” Web, skills required for using online databases seem to be transferred to the use of Web sources.

With regard to the choice of navigational tools, a similar interaction effect was observed. In the group of individuals with little or no online search experience, the FDs used embedded links more frequently than the FIs. The frequent usage of embedded links can be interpreted as a linear rather than a non-linear way of navigation. It is because other tools (such as Go, History list, or a typed URL) allow the user to jump to more temporally removed point whereas embedded links do not. Findings from the study implies that the FD-NOVs navigate the Web in a more linear mode than the rest. In fact, this might be the way in which we would expect the “typical” FD would navigate. The FDs prefer a well structured set of stimuli. As they tend to be passive in learning (Witkin et al., 1977), the FDs would not enjoy imposing a structure of their own. Thus, the FDs are more likely to navigate the Web in a linear mode. Previous studies on the use of hypermedia systems found that the FDs tended to explore a hypermedia system in a linear mode, following the sequence encouraged by the system (Liu & Reed, 1994). This finding is, however, only partly supported by our study. In our study, only the FDs with little or no online experience demonstrated the linear mode of navigation. The way in which the FDs with considerable online search experience navigated the Web was different from the way in which the FDs with little online experience did. The FDs with substantial online search experience had a navigational style, reflected in their use of tools, which was rather similar to the FIs'. Their search performance, reflected in the time spent and the number of nodes visited for the completion of a task, was also comparable to the FI's.

In this study, the FDs with little or no online experience tended to use Home button more frequently than the rest. The use of Home button can be viewed as one possible indication of the user’s “getting lost,” because the Home button is often used when people wish to start over, abandoning whatever they have been doing. Based on this interpretation, the result implies that the FD-NOVs get lost more often than the rest. It is known that the FDs tend to be easily distracted in a complex field by cues that may not be relevant to the goal (Witkin et al., 1977). Hence, the FDs are expected to become easily lost through the pursuit of more dominant but possibly irrelevant cues. Again, findings from our study supports the hypothesis only partially. Among the FDs, only those with little or no online experience tended to get lost more easily than the rest, including the FDs with substantial online search experience.

The FDs, especially those with little or no experience with online databases, seem to need special attention from interface designers and those who train Web users. Interface designers may want to incorporate devices that can help the FDs be better oriented and less likely to get lost. Providing a graphical map of their search progress would be an example, and several studies have found it to be effective in terms of resolving the problem of disorientation (Chen & Rada, 1996). With the browser interface, it might also be helpful to provide a visible history list, showing all sites the user has visited and functioning like a map, at the same time. Such a list should be readily available, rather than requiring the user to make an active search for it through several pull down menu listings (which is often found in “linear” online systems). This would be useful to the FD users because the list could be used as a map showing what has been visited and also provides an easy way to return to some temporally distant, previously visited sites. Web search trainers might examine the finding that online database search experience was particularly beneficial to FD users. The exact reason is not clear, however. It may be because the heavily text-based design of both the Web and online databases appear the same to the user even though they may have very different features and intents. It may be because the Web has inherited many interface features from the traditional linear online systems. It may also be that the knowledge and skills for using online databases are useful regardless of the system used. Obviously more research is called for to investigate these potential explanations.

j.bayly@unsw.edu.au

Abstract: This paper is concerned with the four main integrated components of online learning: an administration management system; an authoring system; a learning resource catalogue; and a delivery system. The four components are set against the evolution of the concept of 'learning objects' which strongly influence how learning resources are authored and upon which a learning resource catalogue is based. Learning objects are generally small discrete chunks of learning materials that are reusable and can articulate with other learning objects to make a learning environment. Learning objects can be described in standard terms (i.e., metadata) through the use of a web application and those data can be submitted to an online searchable database to enable their use in other contexts and combinations.

Introduction

A change to educational management, funding and expectations over the last several years in numerous countries has resulted in a more technologically mediated educational environment. The use of technology to aid in the delivery of courses has resulted in a diminishing of the physical boundaries of the university while increasing the potential student pool. International and geographically removed students are increasing as a viable market for any institution as Educational delivery becomes more globally available and location is no longer such a restricting component. Professional students more and more are requiring continuing education and postgraduate qualifications while demanding that their studies fit into their existing lifestyle and work commitments. As a result access to courses has become a highly influential factor for potential students and institutions can no longer rely on academic reputation alone. Additionally, research-intensive universities are addressing the increasing time demand on their academics to be subject matter experts, lecturers and accomplished researchers. Institutions not addressing these issues will miss out on this increasing student market in the evolving consumer driven model of education.

Most institutions worldwide have made educational technology a prime emphasis as a solution to addressing these issues and tapping into the changing student needs.

The implementation of technology in education has passed through three broad phases. Each of these phases came about as a proposed solution to the primary weakness identified after the practical application of each phase.

The first phase of educational technology arose from the idea that technology could be utilised to communicate with the masses. Educational institutions adopted this notion as a strategy for increasing student markets in the evolving consumer driven model of education. In its early adoption, educational technology components were designed by academics keen to embrace this new delivery method. However the vast amount of technologies that emerged due to the boom of the Internet, quickly overwhelmed the academics whose area of expertise was not technology. Two components were identified as being essential and central to this phase's implementation of an online learning system: the authoring system and the delivery system. In its most basic form one example of this system would be an HTML editor and a web browser.
The second phase came into being to address the lack of technological expertise in the academic environment. This involved the addition of technologically trained staff to the university environment and centralised units to aid academics in developing these educational technology components. With the centralisation of specialised technological staff came a more institution-wide recognition of educational technology. It is at this stage that a new component to the online learning system was added: an administration management system. While this phase served its initial purpose, it pushed to the forefront a new issue. Although deemed beneficial, educational technology developments were proving to be highly resource intensive in terms of both time and money. Additionally, the cost effectiveness of such developments to the institution was poor as it usually only benefited a few academics and their students.

The third phase is the phase we are currently entering. The Learning Object model has been proposed as the new solution in educational technology. Loosely derived from an object-oriented programming model, it primarily aims to address the issues of reuse of materials. The learning object model is characterized by the belief that we can create independent chunks of educational content that provide an educational experience for some pedagogical purpose. These chunks are self-contained although they may contain references to other objects; and they may be combined or sequenced to form longer educational interactions (Quinn, 2000). While a learning object is not necessarily a digital object the remainder of this paper will focus on learning objects that are exclusively digital.

The new essential component for this model is a system for storing and cataloguing these learning objects, here called a learning resource catalogue. If this latest model for educational technology is to succeed, the three components identified from the earlier phases must be tightly integrated with this new, but often missing, essential fourth component.

This paper briefly examines the concept of learning objects then considers their use in the four main components (exclusive of hardware) required to facilitate online learning environments - administration and management, authoring, delivery and learning resource cataloguing. Each component is considered in sufficient detail so as to define their ingredients, complexity, scope and to identify their inter-relationships. This will enable the relevance and importance of the learning resource catalogue to be appreciated. The strength of any system or framework lies in the integration of the components.

**The learning object model**

A learning object is “any entity, digital or non digital, which can be used, reused or referenced during technology supported learning” (IEEE’s Learning and Technology Standards Committee, 2000). Learning objects are also fundamental to the IMS system (IMS, 2000).

Material that may be thought of as ‘content’, if developed as assemblages of small, discrete learning modules or ‘chunks’, may be considered to be composed of ‘learning objects’. If these learning objects are discrete enough, they may be re-used in conjunction with other learning objects in different contexts. The concept and practice of developing digital learning resources as learning objects has a profound influence on the development of learning resource catalogues (as discussed below).

The learning object model has been proposed by many in the educational community as an optimal solution to many of education’s long-standing problems with the development of educational technology materials. The main problems that the learning object model aims to address are: the time and expense involved in development of learning materials; the sharing of expertise and knowledge between academics and scholars, and the globalisation of education.

There are benefits to be gained in making and submitting learning objects to be reused by others. Such benefits could include: the prestige of having made a popular and useful resource; peer acknowledgement of teaching quality; contribution to promotion prospects; financial gain if the learning objects compete in a market economy, and a route to publication (measured by citations) without the formal publications system.

There are benefits to utilising learning objects made by others. Such benefits include: savings of time and expense; being able to compare and select teaching resources from various sources; being able to readily benchmark, and gaining teaching insights and expertise from others.

**Types of learning object**

The concept of a learning object is still evolving. A learning object can vary in size and complexity. In its simplest form a learning object is context free and may be an image, video or piece
of text such as a poem. This simple form has a very large reuse potential because it can be used in a wide range of contexts, disciplines, learning strategies and so on. From this simply beginning learning objects can grow in complexity to include context, learning objectives, pedagogy and so forth. In general, the more complex a learning object, the more limiting is its potential for reuse.

The four main components of online learning

Apart from hardware considerations, for the creation of efficient online learning environments, several components are necessary. Essentially these are: an administration management system; an authoring system; a learning resource catalogue; and a delivery system.

(1) Administration management system

The online administration management system should include facilities like student enrolment, student profiles, class lists and available courses. Fixed-cost financial transactions may also be facilitated by this system but other costs will depend upon usage of option resources at a later stage (e.g., printing and library borrowing). Such an administration management system would allow faculty members to view the student records and profiles from their desktop computer. Students would be able to view their own records, course information and class lists, for example.

An enterprise-wide online administration management system requires high-level institutional management commitment because of the associated costs and institutional changes that necessarily accompany the adoption of such an approach. Institutional commitment to this change must exist at the top as well as with faculty members. One will not work without the support of the other.

(2) Authoring system

From a digital perspective, an authoring system consists of tools that operate at two levels: firstly, the tools to create learning objects that may be thought of as 'content' and secondly, the tools to aid in the modification and sequencing of learning objects into a cohesive learning environment. As indicated above, there are many types of learning object that include 'content' as well as the activities and methods that are all part of a learning environment.

The creation of the learning objects, and their subsequent use, will depend upon the needs, educational rationales, learning objectives and delivery strategy that have been determined prior to the utilisation of any such tools. Content creation includes tools for web authoring, multimedia creation and simulations. Digital content creation may be relatively simple if it is concerned mainly with text and complex if it includes the use of several media such as video and graphics. Programming to varying extents is also usually required, particularly if several media are to operate together, and that programme itself may be considered to be a learning object that can be reused. The content may then reside in several files, databases and on different servers.

(3) Learning Resource Catalogue

In the overall picture, a learning resource catalogue (LRC) works as follows. An instructor creates a learning object, then generates a description of it (i.e., creates metadata) by describing the object using a set of standardized terms, then submits the metadata to the learning resource catalogue. Another instructor would then search the catalogue based on the same standardised terms. Upon finding a description of an object that suits a particular purpose, the instructor can contact the creator through the catalogue system and negotiate reuse of the object. It should be noted that the learning object itself is not submitted to the database; only the metadata is stored in the database. An analogy is given by a newspaper advertisement for an object – the metadata is the advertisement and the object is in the home of the owner.

Once a LRC is heavily populated, it should be possible for users to find sets of objects that suit various purposes, and thereby significantly cut down on development costs associated with content creation of learning materials.
Once learning objects have been created, they should be catalogued in a searchable database for the purposes of reuse and keeping an inventory of the organisation’s resources of learning objects. The inventory would then provide a starting point for any potential developments.

An LRC may also be known as a ‘knowledge repository’ or ‘digital resource library’. However, these terms may not be synonymous and a LRC is here defined as a database of metadata describing learning objects. Digital learning objects are noted above as being discrete with qualities that enable them to be re-used in different contexts and by other teachers and students who wish to share these resources for the sake of efficiency.

Learning object metadata (LOM) should be derived from a learning object according to a standard method because the use of standards enables consistency of usage and communication. The IMS metadata standard (IMS, 2000) is rapidly becoming the international standard for LOM, and is based on the IEEE Learning Objects Metadata standards (IEEE, 1999). The essential functionality of a LRC is that LOM should be simple to generate and submit to a database that is easily searchable.

During the creation of learning resources with various authoring tools, it is not standard practice to derive and save LOM concerning those resources because the concept of a learning object and LOM are not yet sufficiently part of the academic culture. Likewise, it is not yet standard practice to submit that LOM to a searchable database. As a consequence it is difficult for individuals to know of, and to be able to locate, desirable learning objects. From an author’s perspective, it means that many learning objects are being recreated, possibly within the same institution. This is wasteful in development time and money and also in delayed time to delivery that could have been faster had the author known of existing available learning objects. From a learner’s perspective, it means that relevant learning objects that may have aided learning could not be located.

The IMS LOM system is extensive with nearly 100 fields (at the time of writing this paper) for describing learning objects. Deriving LOM for each learning object created by an author could be an undesirable task, especially if it adds considerable time to the development process. The derivation of LOM must be simple and quick and yet still conform to the IMS standard. In a manual system, even if done on the computer through a simple interface, the process must not be onerous and must provide help on demand. Should clarity and simplicity not be part of the process of generating LOM, the adoption of the practice as a routine will not occur. At the present time, such a manual entry system is available and in increasing use. In time, it may become possible to have a system of automatic LOM generation from learning objects.

Once LOM has been generated, the metadata must be lodged in a searchable database. The digital learning object itself must reside at a fixed location if the metadata is to be useful. If the learning object is on a website then the URL must be permanent or the LOM must be editable (manually or automatically) for the new location to be entered.

A user, having discovered the location of a useful learning object (by searching the database of LOM, i.e., the LRC), may then contact the owner for permission to use that object, should any restrictions have been placed upon its usage by the owner. Ideally, usage rights of the LRC by students should be controlled by the management system.

An example of a practical application of a LRC will be demonstrated at the presentation by reference to the Universitas 21 LRC. This is a LRC developed for the Universitas 21 international consortium of universities as a means of identifying, cataloguing, finding and reusing learning objects amongst the member institutions.

(4) Delivery system

An online delivery system should include the means of enabling the learning objects to be organised by teaching staff for access by the students for specific purposes. It also includes facilities for enabling communication and dialogue interactivity between the learners and with the teacher(s). Assessment and feedback are usually also part of the delivery system. (Several delivery systems, with various features, are available off-the-shelf these days.)

The delivery system must articulate with the products of the authoring processes. The delivery system, if it is prescriptive, will determine and limit the authoring freedom. Therefore, the choice of authoring tools, and subsequent products, should take into account the constraints of the delivery system. Should the authoring products, as determined by the learning environment needs, exceed the capabilities of the delivery system, then customised delivery mechanisms need to be programmed (usually at extra cost).
Ideally, the delivery system and the administration management system should also articulate. This would enable teaching staff to incorporate class lists and provide access for those students to various appropriate learning resources and discussion groups, for example.

Conclusion

The integration of the above four components provides a framework for learning enablement. The concept of digital learning objects is evolving and is not yet part of the academic culture. Preparing learning objects as the basis for flexible teaching and learning environments will maximise their reusability and facilitate efficient production environments. The authoring of learning objects in the production environment is essential for the development and usage of learning resource catalogues. Similarly, easily accessible learning resource catalogues, at both the local and partnership levels, are essential to enable the efficient development and re-use of learning objects. Of the main components of an online learning system, learning resource catalogues are invaluable for use in an authoring and delivery system where the learning objects are available to teachers and students alike. Moreover, in any one institution, the learning resource catalogue, management system and authoring and delivery system must articulate with each other for maximum efficiency of online learning developments.

Background for designing net-based learning situations

Mika Korpi

mika.korpi@titu.jyu.fi

Abstract: In this paper I will present the main constructivist perspectives, which must be taken into account when designing learning situations in net-based learning environments (NBLE), such as TopClass. The perspectives are: constructing the knowledge, metacognition and self-directedness, and situated and meaningful learning. Then I will highlight some problems and how they could be possibly solved. The main problem is that the instructor or tutor has not enough tools to monitor the students’ net-based learning process to be able to support it intensely. A possible solution to solve the problem is to use different kinds of tools to make the processes more visual. This kind of tools could also help the learners to better understand their learning. Ideas for these tools are discussed at the end.

Introduction

When we use the new net-based learning environments (NBLE’s) it is obvious that it takes very much time and trouble to design and implement the net-based learning situations. It is thus easy to forget the constructivist principles and design the courses based on the traditional behaviorist learning paradigm (Häkkinen 1996). It is however impossible to apply the traditional models to a constructivist, learner-centered approach. In the traditional models, the goals are given from above, most of the learning paths have been determined in advance, and the learners are not able to control their own progress in the material. These models have been criticized also for their content-centeredness and surface learning. In some cases the traditional models are justified and efficient, but if deeper learning and more efficient learning skills are required, the learners’ previous experience, knowledge and skills need to be taken into account. The learners have also to be offered a chance to set their own goals and to evaluate their learning in interaction with others in as authentic contexts as possible.

After discussing some constructivist principles I will expose some problems in net-based learning environments from the instructors or tutors points of view. The problem is to keep in touch with the students and monitor their learning in net-based learning environments in order to support them. Lastly I will introduce an NBLE’s student monitoring tools and some ideas about the better tools we will test.

Constructing the knowledge

According to the constructivist view of learning, knowledge is subjective with various possible viewpoints. Knowledge is contextual and is collaboratively built. Thus it is not a ready-made and unchanging package that could be given to the learners. The learners are active processors of knowledge and central actors in the learning process. They form their own views and assimilate knowledge into their existing cognitive structures, adding to or deepening them. The constructivist conception assumes that all learners have an ability to learn. Talents are not a predestined, unchanging quality.

It is unlikely that the learners would build their own knowledge without being interested in the learning domain, or without setting their own goals in some ways. Their own activity, intentionality and emotions play a very important role in learning. This is emphasized especially in net-based learning environments. For example, frequently different kinds of technical problems during the course annoy students and decrease their studying activity.
Situated and meaningful learning

If knowledge is not a ready-made and unchanging package that could be given to the learners, then a teacher's role is more creating environments and possibilities for the learners to learn. The most effective environment for learning resembles the real life as closely as possible, replicating its typical elements and problems. Learning becomes meaningful when the learning environment has a genuine connection to the real world.

Situated learning means that learning is placed in a social and cultural context. An important part of information is meaningful only in relation to its context. From the viewpoint of learning, it is important that learning is not separated from the reality of the learner or the society. Winn (1993) argues that situational learning takes place when the learners work with authentic tasks in real-world settings. Authentic, real-life situations can simulate an expert's ways of action.

Metacognition and self-directedness

An essential part of learning and knowledge building are also the metacognitive skills. These refer to the ability of directing one's own learning. It is important to have good facilities for learning, because contemporary life constantly offers new challenges, and in the rapid increase of information it is impossible to learn everything. Thus it is important to acquire general principles, i.e. skills related to learning, thinking, co-operation and regulation of learning. Metacognition means the learner's awareness of their cognitive and emotional processes, such as remembering, knowing, thinking, and their ability to control them. On the basis of metacognitive knowledge, the learners can consciously follow and direct their own processes of learning and thinking. Metacognitive skills include, for instance, setting goals, planning learning, choosing suitable material, making consistent decisions, receiving and taking advantage of feedback, and evaluating learning. These skills help the learner to choose the right learning strategies in virtual learning environments.

When the learner has good skills in self-direction and metacognition and a deep knowledge of the domain, we can call him/her an expert learner or a specialist. He can control his learning. The opposite of an expert is a novice, whose knowledge on the subject matter is more superficial and self-direction skills are weaker than those of an expert. A novice needs guidance and support in learning and self-direction to be able to strive for expertise. The goal of a novice learner should be to become an expert.

Especially the novice-learner needs supporting e.g. for solve more complex tasks than he or she could solve alone. It is important that the learner gets support when she or he needs it and just the necessary amount to get further. This is a problem in net-based learning environments, the main problem is that the instructor has not sufficient tools to monitor the students' learning process to support it.

Supporting in NBLE

In net-based learning environments (NBLE), such as TopClass and Lotus Learning Space, the learner can be offered meaningful and authentic learning situations. It is easy for the learner to get different views to and make searches to the material but supporting is the problem. Net-based learning environments contain different kinds of discussion lists, shared workspaces, email, and chat facilities. It is also possible to create different help and hint systems. But how can the help-systems, tutors or instructors know when the student needs support if she or he does not ask for it? It is impossible or at least very hard to observe the learner closely enough and get information about his or hers emotions. Server logs are very hard to read. Learning diaries would be one chance but they are not written “online” when things happen but afterwards when the strongest feelings have passed.

For example, TopClass has some tools to monitor the students. The instructors can view the status of the courseware for any of their assigned students or classes individually, and monitor how they are progressing. Picture 1 shows the different views that the instructors are able to see. The views are quite general telling just which percentage of the material has been read or how many points have been scored.

One possibility to enhance feedback would be a “feeling console” which gathers information about the learners' feelings and difficulties in their learning sessions. The console could also be used to obtain information about the problems in the environment. The console would consist of a few buttons and it could be very easy to use. It would be easier for the tutor to support the learner with the help of this additional information.
A visual log-analyzer could be another solution. At the moment one of our projects is developing such a tool. The tool can display different views of the log file to instructor, e.g. the student's navigations, when they have sent or read e-mail. The idea is that the instructor is able to quickly view pictures or animations of the students' actions in the NBLE. Both of these tools would help the instructor to obtain quickly and easily more information about the students to support them.

**Picture 1:** Top Class student and class monitoring tools.

**Conclusions**

The learner should be offered meaningful, authentic material that relates to real-world situations and problems. The learner needs also scaffolding, so she or he will be able to effectively build knowledge and develop his or her learning skills.

The four points of Goldman et al. (1998) sum up the main constructive principles that I presented in this paper.

1. Instruction is organized around meaningful learning and appropriate goals.
2. Instruction provides scaffolds for achieving meaningful learning.
3. Instruction provides opportunities for practice with feedback, revision and reflection.
4. Instruction is arranged to promote collaboration, distributed expertise, and entry into a discourse community of learners.

Scaffolding the student is the most difficult thing to achieve in NBLE. One way to make it easier or effective is to develop tools that provide different kinds of information about the students. With this additional information it is easier to scaffold the student when she or he really needs it.

Abstract: Special education offers a challenging background for designers of educational software. One learner group are those who have deficiencies in mental programming: they have difficulties in structuring a learning task in its entirety, and organizing the plan to go through it. Understood as a crew of collaborative co-learners, agents provide promising solutions to this area, to be applied also in other educational contexts.

Motivation

Special education suffers from the lack of computer science oriented research and moderate computer expertise in existing educational software. In fact, there are only few serious efforts of exploitation of state-of-the-art computer science methods and techniques to advance special education (see Klaus et al. (1996) and Edwards et al. (1998) for the lack of examples). Besides drills, there are only basic learning programs, but challenging and truly helpful learning environments do not exist. Most of the software for special education are for visually impaired users (Eriksson et al. 1997). There are also programs for motorically and/or hearing impaired, but cognitive impairments (e.g. people with learning difficulties) are rarely addressed. It seems that in the context of special education, computers are used mainly as assistive technology to overcome communication barriers, instead of educational tools to deepen the learning process.

Can one use those numerous adaptive learning environments that have been researched and produced for non-disabled education in special education? In general, no. The reasons are threefold, related to the user interface, the content, and the processing of the content (i.e. the storyboard of the program). In addition to the need of extra-ordinary input and output (Edwards 1995), the learning content (or the topic) is usually special. There is hardly any need for a Lisp course in the special education curriculum but the need for educating children to handle everyday life is essential.

Moreover, not only the topic must differ from standard educational software. The learning style among regular learner groups is rarely similar to that of non-disabled education. For example, let us assume a person cannot formulate problem-solving strategy for a simple task. In that case, the learning environment might have to partition the task into subtasks, so that the learner is lead to the final goal step-by-step (Kurhila and Sutinen 1998). These kinds of requirements result in programming-intensive solutions: the emphasis is no more in the quantity of information, but the way it is processed and presented to the learner. In order to deal with cognitive disabilities, the agents related to the user interface, the content and its processing, must cooperate with each other and the human cognition for a consistent learning experience. The challenges are deeper than finding another way for human-computer interaction. However, fresh solutions in the area of special education can contribute in a positive manner to regular education which after all consists of diverse learners, with special needs, though often hidden.
The shortcomings of available software and the challenges of special education provide an interesting scene to observe the functionality of agents in a versatile and diverse learning environment. Our view of the applicability of agents is based on our experiences in designing a learning environment to children with problems with their mental programming (Vilkki 1995, Korkman 1988). When simplified, we can characterize mental programming as the ability to uphold the motivation, ability to compose a problem solving strategy, fluency in solving various tasks, and ability to uphold attention. Therefore, learners with problems in these fundamental skills need a targeted support from the learning environment, whether computerized or not. In a non-computerized setting, this support is seen as auxiliary personnel, such as occupational therapists and neuropsychologists. We are exploring how these various tasks can be intensified by agent technology. Therefore, our architecture is that of multi-professional agents, or a crew of specialized agents.

Intelligent tutoring systems have traditionally emphasized a method to keep the learner within a narrow optimum solution path and optimizing the time consumption to acquire a new concept. Agents are conceptually ready to support more constructive learning processes: a learner builds her knowledge freely, not necessarily along the optimum learning path but along the paths supporting that particular learner’s learning process.

A crew of Specialized Agents

Several computer-based learning environments either focus on drilling one or few skills or areas of knowledge, resulting in a biased learning process, or cover a huge amount of information, reflected as superficial learning outcomes. Contrary to these approaches, we aim at utilizing the full potential of the computer to intensify the diverse factors of the learning process. For that purpose, an agent-based architecture offers a valid platform for development: each part of the learning process can be supported by a dedicated agent.

As an example, the learner’s activities can be intensified by an agent which helps her to go through the learning material, traversing through the material in a personalized manner. At the same time, an agent supporting the teacher can recognize areas where students needs more tuition. However, a modern learning environment consists of more than the roles mentioned. A feedback agent might help teachers or administration staff to evaluate the overall learning process and its organization, with the help of other agents, a visualization agent might help the students to interpret their material in different formats, such as concept maps.

Our approach is consistent with the common definitions given for agents in the literature. For example, Russell and Norvig (1995) state an agent to be “anything that can be viewed as perceiving its environment through sensors and acting upon that environment through effectors”. A more demanding definition is formulated by Franklin and Graesser (1996). They define an agent by giving an exhaustive list of properties. An agent must fulfill at least the first four properties of their list. In other words, an agent must be reactive, autonomous, goal-oriented, and temporally continuous.

Although our agents are agents by definition, fundamental differences regarding the purpose of agents exist. The most noticeable is that our agents do not act on the behalf of the user or execute the task for the user but help the learner in conceptualizing and executing the tasks. In other words, we employ agents as an interpretation mechanism between different participants of the learning process. This means that agents – though autonomous – adapt to the human beings involved in the learning process. In a way, they are co-workers rather than auto-workers, a common emphasis in many of the prevailing agent-based frameworks.

To use an example from another context, an agent taking care of its master’s business on the web-based stock market, is an auto-worker accomplishing a specified task for an optimal solution, whereas another agent with a co-worker’s character would help its master to understand the secrets behind a long-term survival on the very same markets, and support him or her for life-long business learning.

Assistive and Adaptive Hypermedia – Ahmed

Ahmed is the first implemented prototype of the agent crew described above. Ahmed is an agent for the learner. There are no limitations regarding the content or the content presentation the agent can handle. Still, Ahmed can provide a personal learning experience to every learner. The adaptation mechanism is independent of the system, and at the same time dependent on the learning material.
A term “learning seed” or just “seed” is used throughout the following text when referring to one piece of a learning material in a learning space. This is to emphasize that the material can be more than merely an exercise, and more than a frame (a basic unit in a CAI program, as pointed out by Wenger 1987). A learning seed in Ahmed can consist of several different screens with several sequential or parallel visual, auditoria! or functional elements with temporal values. The seeds can, for example, be states of a simulated world (Kurhila and Sutinen 1999).

Overview of Functionality

The description language used in our prototype learning environment in describing the learning seeds is defined for this purpose by using XML. Compared to e.g. HTML, the description language is significantly more expressive. It includes tags for buttons, graphics, text areas, and audio clips. The functionality of the learning material is secured with tags for parallel and sequential presentation of other elements with a duration attribute. Conditioning with an if-then-else structure enhances functionality.

The learning space is n-dimensional. The dimensions are not pre-determined by any means. Instead, they are inferred from the parameters in learning-seed headings in run-time. For example, if the heading of a seed contains “Skill: 56” and “Knowledge: 49”, the seed is situated in point (56,49) in a learning space of two dimensions, called Skill and Knowledge (Fig. 1).

Every learning seed should be parameterized, since the parameters define the position of a seed in the learning space. However, not every seed needs to be located with respect to every dimension. For example, if the dimensions used in the space are “Skill” and “Knowledge”, some seeds can be defined in the “Skill” dimension only. In that case, the seeds without an explicit location in “Knowledge” would be represented as a line covering every point in the “Knowledge” dimension. This procedure ensures that a person creating the learning material does not have to assign irrelevant parameters to the material. For example, if one learning space consists of arithmetic exercises, there is no purpose to assign parameters in the “Reading comprehension” dimension to those exercises.

The dimensions and their parameters are freely selectable for the person creating the material in the sense that they can be represented with arbitrary strings. It is natural to denote the dimensions with meaningful learning objectives such as “Multiplication skill” rather than abstract ones.

An activating learning seed normally makes it possible for a learner to do something. Every action can be equipped with an effect to the learner’s position in the learning space. This is called a relative movement. For example, if the learner makes a choice which is parameterized “Skill +6” and “Knowledge +8”, the learner’s position in the learning space moves from point (56,49) to the point (62, 57) (Fig. 1). Because of the several choices the learner can make in a single learning seed, the learners are likely to follow different paths in the
In addition to the relative movement described above, there is also another way to present the next learning seed to the learner. It is possible that the multiple-choice answers have an absolute movement to another learning seed. In such a case, the learner is not taken to the next seed by calculating the parameter values relative to the learner’s profile but directly by following an absolute link. In other words, the learner is not guided in the space but in a static learning material graph (which still is a part of the learning space). The learning material can be arranged as a space of groups of static graphs, but the most common case of arranging the learning space may be to have learning seeds with only relative movements and occasional local graphs of seeds with absolute movements.

The multiple-choice answers in the learning material are not necessarily traditional “pick one from the choices”. A seed may require a learner to choose a subset of given choices. The subset can also be an ordered subset. An example of an exercise with a subset of given choices is to find a meaningful combination of objects to construct a steam engine. An example of an exercise with an ordered subset is one with a task to organize different words into a meaningful sentence.

The parameters of the choices the learner makes are used in providing the personalization of the learning experience. When the learner makes choices, her profile can be constructed by saving the information in the parameters to the learner’s profile file. While the learner is represented as a point in the n-dimensional learning space, every move of the learner in the space is saved to the learner’s profile, so that the learning path of the learner can be represented numerically or even visualized as an animation for evaluation.

In a standard situation, the dimensions of the learning space can be viewed as learning objectives, since a learner strives to achieve a higher position in every dimension. However, dimensions are not necessarily related to any objective, but they might indicate any other aspect of the learning process as well, or only those learner’s properties that a teacher wants to observe. As an example of a property to observe, we can consider “Motivation”. To enable the measurement of motivation, every learning seed can contain the button “I don’t care”. This button is equipped with an effect (relative movement) to the “Motivation” dimension. But, because none of the actual seeds is parameterized with a “Motivation” value, choosing “I don’t care” does not have an effect on the guidance of the learner in the learning space. Instead, it affects only the learner’s profile: every time the learner presses the button, the action is recorded to the learner’s profile, thus enabling the observation for the teacher.

It is also important to notice that the flexibility of the parameterization enables the use of nested or hierarchical objectives. For example, after the first answer it might be hard to assess the learning outcome whereas a series of questions gives more conclusions (e.g. concerning the type of error). A very simple example is the following. The learner is presented an exercise: 1 x 1. If the learner answers 2, it may very well be that the learner confuses adding and multiplication, or simply does not know how to multiply. However, this is hard to tell after only one answer, because it could have been a random error. By repeating learning seeds of the same kind, a correct conclusion can be made.

Other Characteristics of Ahmed

Because of the intended users, so-called single-switch input with automatic scanning of choices must be available all the time. Therefore, the login procedure and the answering to the exercises are designed to function with single-switch input. The login is conducted as follows. The learner starting the session is presented with the pictures of her class. The learner chooses a picture representing her (it can be a photo or a drawing). To ensure that none of the learners chooses the wrong picture and thus an incorrect profile, the learner has to choose her “secret picture”. This corresponds to the password. It is also possible to require a sequence of secret pictures to diminish the probability of logging in with false pretenses. The pictures are in a single directory, so that it is fairly easy for the teacher to update the pictures of learners attending her class.

The ordered subset can also be picked up by a single-switch input. Still, it is possible for the learner to correct a misprint before giving the final answer. This is important, because misprints in answers are hard to interpret correctly by a computer. In addition, it is tremendously demotivating for a learner not to be able to correct an accidental misprint.

Another feature of Ahmed is the possibility to use learning material servers to store the different learning spaces. The learner chooses the learning material space when starting a session. Technically, every space is a directory. The learning material directory can be situated in a remote Web server as well as in the local hard drive.
This enables easy networking and centralized composing of the learning material. To exploit the full potential of the schema, the learning material space should be complete, i.e. filled with learning material so that every point in the space has more than one learning seed. In practice this means that at least one thousand learning seeds should be prepared. Therefore, centralized learning material databases are a choice to consider, since composing the material is a tedious task.

To involve the teacher in the learning environment, we have implemented also a console for the teacher. If one of the learners presses the help button, a message is sent to the teacher’s computer. One has to keep in mind that the learners in this learning environment can be severely disabled, so that they cannot draw the attention of the teacher by any other means. The message is merely help, because the schema was designed to be used in a classroom with a teacher always present. Technically the help functions properly even if the learning environment is expanded to the whole Internet, since every help message comes with the IP address of the sender’s machine.

Discussion

When comparing Ahmed to the well-known and traditional four-component schema of intelligent tutoring systems (Wenger 1987), we can identify the same four concepts in Ahmed, as well. The domain knowledge in Ahmed is the contents of the seeds in a learning space. The pedagogical model corresponds to the dimensions used, the parameterisation of the seeds, and the parameterisation of the actions in the seeds. The student model is the trail (history of every visited seed and actions taken in them) of every individual learner. The interface model is the organization of the objects in seeds, since Ahmed itself is a tabula rasa if no learning material exists.

Both the strength and the weakness of this prototype is that the domain knowledge is completely isolated from the agent. The agent does not know anything about the learning material. It merely adds (or subtracts if the parameter has a negative value) the parameters together, and presents the equivalent learning seed to the learner. The advantage of this concept is that the material can truly be anything and yet the system can adapt to every learner independently. Every author of the learning material is able to create the parameters and the multiple-choice answer types based on her own experience, or some theoretical model.

The domain-independence of the system enables various possibilities. There can be exercises with right or wrong answers, but there also can be more adventurous problem solving with e.g. ethical values. An example of more adventurous problem solving could be to guide a child (or another living being the learner can relate to) to visit her Grandmother in a countryside, and there are no right or wrong answers, only different ways to cope with the problems until the final goal is achieved. Whereas an intelligent tutoring system might make the grandchild to hurry to the Grandma in the optimal time, with the minimum amount of money consumed, our system allows the child to observe the path as well, even with wolves along the route.

Because the domain knowledge is separated from the agent, the learner modeling is imperfect. The modeling can be adequate if the parameters and the content are suitable. The problem is that the person authoring the material should figure out in advance what kinds of answers the learner could choose. The parameterization of the learning material and the multiple-choice answers are not trivial either.

The impact of an computer-based educational system should always be validated empirically (Brusilovsky 1996, Brusilovsky and Eklund 1998). Although Ahmed has not yet been tested in classrooms, discussions with special teachers and other experts indicate that the idea behind Ahmed is useful and has potential. Empirical evaluation is waiting for meaningful learning material: to operate properly, Ahmed has to contain vast amount of learning seeds. For the learning material authoring, we are designing an easy-to-use tool to speed up the authoring process.

Abstract: The educational hypermedias have become indispensable tools to enrich the pedagogical value through the formation. Meanwhile the cognitive overcharging and the disorientation, the hypermedia presents another drawback: the isolation of the learner. This work presents the architecture of an hypermedia made in a way to reduce to the maximum the cognitive overcharge. This hypermedia is able to advice the disoriented learner thanks to a combination with an intelligent tutor. This tutor itself permits the learners to cooperate with each other despite the distance between them.

1. Introduction

We witness day to a exponential growth of hypermedias, to varied and multimedia content, and of their users, whose number is considerably increasing day to day, thanks to the new technologies of diffusion: CD-ROM, Internet, Intranet, etc (Chick & Daoudi 1999). Hypermedia environments become indispensable tools to enrich the educational value in the teaching and the learning (Nkambou, Isaballe, Gauthier 1998). Hence, the multiple courses of reading the hyperdocument allow everybody to organize his/her own course in order to encourage his/her understanding and his/her memorization of knowledge. The initiative of learner is the basis strategy (Bensebaa 1991).

Whereas if the use of the hypermedia reinforces the autonomy principle of the learner, it also risks to reinforce his/her isolation. If it is undeniable that this autonomy can have some positive educational effects compared with the masterly teaching, such as the respect of the rhythm, of the learning length and in certain cases to permit a plurality of learning styles, it is undeniable that this relation man to “knowledge” stocked in machine lets only small place to the mediation by another person (tutor, teacher, parents, other learners). In some methods of teaching, such as the distance teaching, this isolation is reinforced by the existed geographical gates.

However, it also appears that the teaching, the learning, have always been considered as social processes requiring a collaboration between different actors. It is sufficient to think about all approaches of the adult formation based on the group dynamics (Derycke 1991).

In addition to the learner’s isolation problem, the hypermedias have other problems. Indeed, if the aspects of learner’s interaction and participation to educative sequence can be now considered as efficient, the cognitive overload and the disorientation of the user in the hypermedia remain the major problems. It is also very current to note at the time of the use of an hypermedia, that the learner, after some minutes of navigation and research, doesn’t know its position relatively to notions to be consulted. The big freedom allowed to the user which is the principal attraction of the hypermedia becomes its principal drawback. Its pedagogical mission of knowledge construction is so compromised.

2. Proposals
2.1. Break the Isolation

Several works and in particular those of Vygotsky showed the importance of the social dimension of learning: the social interaction is an essential element of the cognitive transformation (Derycke 1991). Choplin et al. in (Choplin, Galisson, Lemarchand 1998) affirm from a didactic point of view that an activity of learning in science implies in general manner the set in motion of the student's conceptions (cognitive dimension), motivation (emotional dimension) as well as his/her relations with his/her peers and/or with the teacher (social dimension).

The survey of works or written of pioneers or visionary of hypertexts and hypermedias make appear that the dimension cooperative work was underlying since the beginning (see (Derycke 1991) for more details upon some researches on this topic).

The application of cooperation principles permits to eliminate the isolation of the learner. Therefore, cooperation depends upon a supportive community of actors who agree to help one another in activities aimed to attaining the goals of each person involved (Lewis 1996). So, cooperation consists in amplifying capacities of agents which are taken separately and to increase their performances (Ferber 1994). It is to help himself/herself by helping his/her partner (Leroux 1995).

2.2. Reduce the cognitive overload

The organization of the hypermedia separates the information from the knowledge. These are often encapsulated in the same node. Links are not structured and their conceptual values are not specified. Of where a difficulty for the author to create and to maintain an hypermedia and for the reader to navigate (Soula 1994).

2.3. Orient learner

This orientation is possible thanks to coupling the hypermedia with a tutor which is capable to judge the knowledge of the learner and also can advise, orient,..., the disorientated learner when it is solicited. For doing this, the tutor must rely on:
- the student's models,
- training objectives,
- a historic of the training session,
- an educational strategy family,
Beyond its role of orientation counselor, the tutor will inform learners upon cooperation possibilities. Those are deduced from student's models.

3. Proposed architecture

The figure 1 represents the proposed architecture of the system, we distinguish in particular:

3.1 Author interface

The organization of the hypermedia is based on the manipulation of predefined objects and on the separation between information and knowledge. So the following main characteristics (Soula 1994):
- each object in the hypermedia belongs to a specific type,
- a separation between information nodes and knowledge for the realization of links. Information corresponds to what learner wants to reach and the knowledge concerns the structure of the document that is how to reach it.

Thus, nodes and links are managed in the following manner:
1. all the nodes are instances of "typical nodes"; these "typical nodes" permit to create:
multimedia nodes,
• "exercise" nodes for the control of knowledge. The assessment of answers is assured by pondered production rules triggered in forward chaining:
If Answer Then Pedagogical-Objective (Credit, Debit)
Where Credit and Debit represent points to be added or to be subtracted to the present capital of learner for the current objective.

Figure 1: The Architecture of the system.

2. links can be:
• Explicit : managed entirely by the author, these links permit a non-linear reading of the hypermedia. They are activated by the learner by clicking on an object of the node (called hyperobjet),
• Implicit : these links are managed automatically by the system. They can be: following page, previous menu, beginning of the document, etc. These links permit the structuring of the document under hierarchical shape.

3.1.1. Hyperobjet
It is a knowledge activated by the learner by clicking on an object (elementary or composed). An hyperobjet is defined by: a name, a password identifying the owner and a list of couples: intention-action.

3.1.2. Intention-action

It is the element of an hyperobjet that defines a link. The intention carries on the reason of the link and the action on its realization. If the main feature of an hypermedia is to allow the reader a completely free course, the notion of intention-action offers information in order to permit that this course wouldn't be made "at the blind". Thus, the author associates an intention to every link that means a reason to this creation. This reason or intention represents a conceptual knowledge that may be useful to the reader. While consulting this intention, the reader will have precision on the action generated by the link and will either trigger or not the link.

3.1.3. Knowledge Base

It is structured as a set of concepts on the taught domain. These concepts are aggregated in educational objectives. An educational objective corresponds to a mental structure, an abstraction, sometimes represented by conceptual networks. It is constituted of a set of nodes. Two different objectives can share the same node. The author can create educational objectives, associate to them a difficulty level and establish prerequisite relations between them. The difficulty level can be determined according to the nature of the knowledge underlain by the educational objective (Bensebaa & Seridi 1997).

3.2. Pedagogue interface

It is through this interface that the pedagogy used by the tutor is defined. It consists to:
1. define a set of typical psychological profiles of target learners. A psychological profile is a general behavior of a learner. It is defined by assigning values to attributes representing the different psychological attitudes (weariness, attention, speed,...) that the system is capable to capture. Thus, it is possible to define several bases of different profiles corresponding to different target populations (Bensebaa & Lebbihi 1998);
2. then, associate to every typical psychological profile, an educational strategy. The utilization of this one by the tutor consists of the application of a set of educational rules in a determined order. An educational rule takes the form of a production rule:
   
   If Condition Then Action.

   Rules appear as filters in which we submit the acceptable educational objectives and that are going to eliminate those that appear too much distant of the corresponding educational principle. Thus, we have a big suppleness of the adaptation of teaching strategies (Bensebaa & Seridi 1997).

This manner to manage the pedagogy allows the system to accept different pedagogies and to adapt them according to the concerned domain and public.

3.3. Trainer interface

The person responsible of the training defines for every learner an "interval of teaching" thanks to the declaration of an initial profile (basic level of learner) and of a final profile (final objective of the teaching). A profile is a set of educational objectives.

Also, the trainer determines the student's initial psychological profile. It will permit the definition of the educational strategy to be applied. Finally, the trainer can accede to results on the evolution of the knowledge of learners, objectives that they have acquired, the difficulties which faced the learners (Bensebaa & Seridi 1997), etc.

3.4. Student's models

The student's representation is indispensable for an adaptive learning system (Ritter & Djahanguir 1991). A learner model has been considered a set of beliefs hold by the system about the learner (Ayala & Yano 1996). Learner models provide the information needed in order to support the progress of the learner and promote the opportunities of effective cooperation and learning.
In order to ensure its role of counselor for learner, the tutor is, actually, a real "spy". Indeed, all actions of learner are analyzed and are listed in his/her models so that they indicate at every time his/her level of knowledge and his/her psychological state.

3.4.1. Knowledge student's model

It is composed of a set of educational objectives. It is putting up-to-date at each end of visit of a node by the student. This up-to-date takes into account for each objective:
- the previous state,
- the CREDIT (or DEBIT) in case of an exercise node,
- ...

For each objective, the level of learner is besides matched of a tendency of short term (acquired knowledge, putting into doubt or confirmed) usable by the educational rules.

This way to manage the model permits to question the knowledge that is not possessed sufficiently or never possessed (case where the initial profile of learner declared by the trainer has been overvalued) or, what is more grave, the prerequisite objectives, in the case of a very unfavorable report. If the corresponding educational rule is active, the tutor will be able to favour the election of the node composing the deficient objectives (Bensebaa & Seridi 1997).

3.4.2. Behavioral student's model

A student's good modeling permits to put him/her in an optimal learning situation with regard to his/her mental capacities and behaviors. Behavioral model is represented by a vector constituted of n psychological attitudes. This vector is used by the tutor to deduct or to approach one of the typical psychological profiles defined by the pedagogue. The feeding of attitudes is done via sensors placed at nodes level. The given values are of a quantitative nature (number of points, percentage, etc.) (Bensebaa & Lebbihi 1998).

3.5. The tutor

It is the main piece of this architecture. It is composed of two modules: scheduling/cooperation module and psycho-pedagogical module.

3.5.1. Scheduling/cooperation module

The educational objectives (therefore nodes that compose them) represent some susceptible objects, by their visit, to enrich the knowledge of a learner. Like a production rule, an objective possesses prerequisites, that is conditions on the state of the knowledge of learner. These prerequisites translate the fact that some knowledge must be assimilated sufficiently if we want the learner fully benefits of the nodes of the objective (Bensebaa 1991).

Real educational counselor, the tutor will propose, at every time that the learner solicits it, the best node adapted according to:
- the state of the knowledge of learner (where is he/she?),
- the final profile (what must he/she learn?),
- the educational strategy (what strategy of teaching?).

At the time of this choice, the tutor takes into account the set of student’s models. It orients the learner to the node which corresponds better to her/his “knowledge state” and which represents the best opportunities of cooperation. So, it builds first the set of Pedagogical Objectives which are Candidates for orientation(POC). This set is the result of the intersection of two other sets:
- The first set is constituted of the Pedagogical Objectives that are Acquired at least by one learner (learner is concerned)(POA),
- The second one has Pedagogical objectives whose prerequisites are satisfied by the student’s model of the concerned learner (AO: Acceptable Objectives).

If the set result of the intersection is empty then POA is equal to AO.
On the POC set will be applied an educational rules sequence (inter-objectives educational rules) of the chosen strategy until to isolate one that corresponds better to the state of the learner. Another sequence of educational rules (inter-nodes rules) applies to get the node(s) to propose to the learner.

An educational rule example is favor the educational objectives which were acquired by the maximum number of learners (maximize cooperation possibilities).

The learner can solicit the tutor for obtaining potential candidates for a cooperation. After this request, the tutor responds by presenting a set of learners classified according to their similitude profiles with the demander learner (same initial and final profile, same final profile, ...). This set is constituted by all learners whose knowledge student models satisfy the current pedagogical objective prosecute by the demander learner.

3.5.2. The Psycho-pedagogical module

This module deducts the educational strategy to be applied and proposes it to the scheduling/cooperation module. This operation is done by comparing the behavioral model to the different typical profiles, in order to classify the student in the nearest profile to his/her model. For doing this, we applied a method of classification based on the Main Components Analysis (ACP: Analyse des Composantes Principales) (Bensebaa & Lebbihi 1998).

Conclusion

We notice in the first that this architecture protects totally the flexibility and the freedom which is offered by the hypermedia. Then, coupled with a tutor, the hypermedia can fulfill correctly its pedagogical mission. Finally, the problem of the isolation of the learner is eliminated. The student has the possibility to solicit the tutor at any time for obtaining orientation and cooperation advice. He/she can solicit cooperative learners indicated by the tutor.

Abstract: The design and distribution of cross-border higher education courses via global computer networks is a rapidly growing phenomenon (Davis 1998). This paper describes a recent international Web-based course and presents research that focuses on the challenge of international, cross-cultural graduate course design in education. Using quantitative and qualitative methods of inquiry, successes and failures of the effort to address cross-cultural concerns are reported. This inquiry builds on existing literature. It informs the work of teachers, researchers, course designers and program developers seeking to expand instructional horizons through international academic collaboration.

Introduction

From January through May 1999, a computer networked graduate education course connected students from the Universities of Oulu and Jyväskylä in Finland with peers from the University of Massachusetts Lowell in a shared, project-centered academic endeavor. The course, Open, Flexible & Distributed Learning (OFDL), was offered in English via the World Wide Web. It represented a joint initiative of the three participating universities. Forty students were initially enrolled: twenty-one Finnish and nineteen American. Network access for students and instructors was user password controlled.

OFDL was created and delivered by Professor LeBaron and several colleagues at the University of Oulu Faculty of Education. The course addressed issues related to distance and distributed education in schooling and in higher education. It examined principles that support open and flexible learning. In addition to examining selected theories, methods and technologies, students were asked to work as peer collaborators, and to join the instructors and tutors in content-centered research and discussion.

The technical platform for this course, called ProTo, is the product of research and development at the University of Oulu Faculty of Education. The course addressed issues related to distance and distributed education in schooling and in higher education. It examined principles that support open and flexible learning. In addition to examining selected theories, methods and technologies, students were asked to work as peer collaborators, and to join the instructors and tutors in content-centered research and discussion.

The technical platform for this course, called ProTo, is the product of research and development at the University of Oulu, headed by Research Manager, Jyrki Pulkkinen. OFDL was among the first electronically networked, academic courses formally cross-credited between Finnish and American universities. However, several earlier international courses, primarily within Europe, have been offered via ProTo.

OFDL relied on electronic distribution for all aspects of study. ProTo functioned as a server-centered database designed on a research platform that supports constructivist principles of learning; that is, that students constructed knowledge and meaning through interaction, communication, and productive collaboration with instructors, peers, and relevant materials. OFDL was simultaneously credited at three universities: one in the USA and two in Finland. A revised offering of this international course is in progress during the spring of 2000.
The Course: Open, Flexible & Distributed Learning

This course aimed to examine issues related to online open and flexible learning. In addition, the course examined other selected telecommunications technologies used in the design and execution of distributed learning environments. Students worked individually or in teams to analyze and critique contemporary practices in this field. The instructor team comprised a lead professor and a course design manager supported by three graduate student assistants (one Finnish and two American).

OFDL ran from January through May 1999. Because this was a "location independent" course, the traditional academic schedule of weekly or thrice-weekly class sessions was abandoned. Rather, students and instructors regularly and frequently "checked in" to the Web-based environment. Since the much of the responsibility for such contact rested with the student, a high degree of discipline and self-motivation was required for success (Charp 1994, in Sherry 1996).

Due to the asynchronous and "distant" nature of the course, students maintained regular communication with instructors, tutors and peers. They were also responsible for reviewing online or library-based course materials, and to reflect this research in all written communication. The discussion forums offered tools for academically focused discussion. Students worked on thematic concentrations of their choice, but were expected to show mastery of the broader substantive context.

The ProTo/OFDL online "library" pointed to a collection of resources developed or selected by the instructors, tutors, and in some cases, students. This library was divided into five major categories. The first contained pointers to "core readings," which every student was required to examine critically at the earliest possible date. This reading provided common ground for subsequent peer communication. The next three library categories divided resources into the "cornerstone" content clusters described above (pedagogy, technology, management & social organization.) The fifth category (General Resources & Information) provided glossaries, bibliographies, and other useful course reference tools. The library was rounded out with multi media virtual lectures (e.g., streamed video, PowerPoint slides.)

The communications tools built into the ProTo environment were robust and straightforward. The following tools were available for student communication:

- threaded discussion forums for scholarly discourse and problem-solving,
- an embedded Web authoring tool where student work was developed,
- a "message board" for daily information updates posted by the instructional staff,
- an e-mail distribution list, for communication to all students and instructional staff,
- "ID cards" containing photos and biographical data for students, tutors and instructor,
- a virtual "café" where course members socially "chatted" either asynchronously or in real time,
- a "private notes" utility where students could "think aloud" and store thoughts for later consideration.

Characteristics of the ProTo Learning Environment

ProTo (Project Tools for Learning) is an easy-to-use learning environment that contributes to modern open and flexible studying on the Web. It provides comprehensive communications and collaboration functions to enable the instructors and students to work cooperatively toward meaningful learning goals. The Finnish Ministry of Education has supported the development of ProTo. A newer version of this authoring-learning tool, called Learning Community Profiler, is now being prepared for public distribution in educational markets.

ProTo runs on the Internet, or on corporate or campus intranets, based on TCP/IP Web protocols. ProTo stores all information about the users and courses on a central database server. The students, instructors and administrators may access the server from anywhere on the network using a standard Web browser with commonly used plug-ins. ProTo enables bi-directional "real-time" and asynchronous communication. At the same time the application also makes it possible to access networked multimedia and hypermedia in the ProTo environment (e.g., video/audio-on-demand, real-time video streaming). ProTo's networked instructional model is based on constructivist learning principles that combine three elements (learning, technology and culture) to provide the fundamental dimensions for open and flexible learning. Students are expected to construct their knowledge and skills through personal experiences and social interaction in the learning community.
According to this model, technology is used in the learning environment differently from the traditional computer assisted learning (CAL) instructional software. Where traditional CAL technology was designed to be appropriate in terms of learning, new networked learning environment technologies should be appropriate in terms of culture (e.g., the distributed community of learners and teachers who come from different cultural backgrounds). This distinction is particularly important in international courses such as OFDL.

ProTo offers tools for learners to engage easily in structured learning on the Web, and enables teachers to create and organize open and flexible Web-based courses. The "cornerstones" of this open and flexible learning environment are threefold:

- **People** as members of a learning community (e.g., students, teachers and tutors) where the students' learning process is only one process among the others,
- **Technology** used to implement the course (which was selected considering the demands of a constructive learning process and needs of the learning community as a whole),
- **Learning culture** that supports productive collaboration in the learning community (which must be created during the course).

The ProTo technical operating environment becomes an active part of the whole learning process and is a dynamic part of learning community behavior.

The Research Agenda

Through various data collection and analysis techniques, research is examining the efficacy of efforts to build constructivist, international online learning activities. As McNabb (1995) points out, standardized assessment techniques typically fail to measure key indicators of student success in open and flexible learning situations. Rather than pursue standard research agendas that compare predefined student outcomes in networked versus non-networked environments (Wideman & Owston 1999), this agenda intends to evaluate efficacy in terms of the intentions that drove the design of OFDL in the first place.

Demographics of the Student Population

Twenty-six students completed the final course evaluation, eighteen from the USA (94.7% of active students) and eight from Finland (61.5%). This sample included thirteen male and thirteen female respondents, nine each from the USA, and four each from Finland. The mean student age of 35.5 years ranged from 25 to 56 years. All 26 (100%) had used e-mail prior to the course. Only one, an American, had never browsed the web prior to the course. Nineteen (73.1%) had never previously participated in an Internet based course. A majority of the Finns (five of eight) were experienced in the use of Internet-based learning environments. An overwhelming majority of Americans (sixteen of eighteen) were complete Internet learning neophytes.

Conclusions from this study should be considered in light of differences between Finnish and American culture and education. Few would disagree that Finns are a less voluble people than Americans. Many Finns take pride in their tendency not to talk unless they feel they have something worthwhile to say. Higher education in Finland is tuition free. Although most courses are offered during fixed semesters of time, it is quite common for students to complete work on their own personal timetables without forfeit of money or credit. Finnish students are assessed on a pass-fail basis. Thus, many of the pecuniary and scholarly pressures of American graduate work apply differently in Finland. When the student performance stakes vary so much between countries, unique challenges arise in designing tactics for international collaboration. Although a few students from both countries failed to complete the course (two American and three Finnish), an additional eight initially enrolled Finns never participated at all. (Rather than "drop outs," we might label them "never ins").
The Study

Since a major aim of the course was to foster purposeful student collaboration across national boundaries, this particular issue is addressed. The following data sources support this paper:

- a summative student evaluation anonymously and electronically submitted after grades were filed,
- comments posted by students throughout the course inside the communications tools provided by ProTo ("discussion" and "comment" forums, e-mail, the synchronous "café"),
- work actually produced by students and student teams while the course was in progress.

The final course evaluation consisted of fifty-seven questions distributed across the following categories: Background information, General overview of the course, Comparing online with traditional classroom courses, Instructional activities, Course interaction, and the ProTo environment.

A series of questions relating to a general evaluation of the course were asked. Responses were based on a four-point Likert scale numbered 1 to 4 with 1 representing "Strongly Agree," 2 "Agree," 3 "Disagree," and 4 "Strongly Disagree." To simplify analysis, the four-point scale was reduced to two points "Agree" and "Disagree." Also calculated were the P values for the independent T-test. Due to the small number of respondents, however, these values are not reported here. Of the thirty-eight Likert scale questions posed, only the following five produced significant variations in agreement between Finnish and American students:

- Mutual guidance and assistance among students promoted learning.
  17 Americans agreed, 1 disagreed; 5 Finns agreed, 3 disagreed
- You felt that you belonged to the learning community.
  (fifteen Americans agreed, three disagreed; four Finns agreed, four disagreed)
- You felt that you succeeded in the course.
  (fifteen Americans agreed, three disagreed; four Finns agreed, four disagreed)
- Compared to a typical classroom course, you worked harder.
  (eight Americans agreed, eight disagreed; three Finns agreed, five disagreed)
- Compared to a typical classroom course, you learned more.
  (twelve Americans agreed, six disagreed; four Finns agreed, four disagreed)

These disparities in perception pertain to issues of community and student success. Notwithstanding their relative lack of prior seasoning in online learning, the Americans came away from OFDL with significantly more positive reflections on their course experience in these respects than did the Finns.

Even though the following four questions show little variation between Finnish and American views, they pose distinct general challenges for future course development:

- Compared to a typical classroom course, you interacted with student peers more frequently.
  (six Americans agreed, twelve disagreed; three Finns agreed, five disagreed)
- Compared to a typical classroom course, you interacted with student peers more intelligently.
  (seven Americans agreed, eleven disagreed; five Finns agreed, three disagreed)
- Compared to a typical classroom course, you interacted with the instructional team more frequently.
  (six Americans agreed, twelve disagreed; three Finns agreed, five disagreed)
- Compared to a typical classroom course, you interacted with the instructional team more intelligently.
  (nine Americans agreed, eight disagreed; three Finns agreed, five disagreed)

Comparative US-Finnish word counts were made in three random “snapshots” of the interactive course discussion areas. In making these comparisons, Finnish results were adjusted to account for the smaller number of active students, whether or not they actually completed the course. There were nineteen “active” Americans (the same number as those initially enrolled) and thirteen “active” Finns (eight fewer than original enrollment). Since nineteen is 46.15% greater than thirteen, the Finnish contribution was multiplied by 1.4615 to arrive at an equalized count for comparative purposes. This produced the following US-Finn “talk” ratios:

- “Café” (3 separate snapshots), 3.12:1 (656 US words; 210 equalized Finnish words),
- "General discussion about course," 4.1:1 (1561 US words; 379 equalized Finnish words),

True to cultural stereotype, the American students were significantly more talkative than their Finnish peers.

Analysis of the open-ended student answers to the final course evaluation revealed some interesting Finnish-American comparisons. In response to a question asking how students defined their success in the course, for example, American comments generally focused on the mastery of external knowledge; Finns
focused more on personal performance. In roughly equal national proportions, twenty-one of the twenty-six respondents explicitly lauded the instructional team for the frequency, timeliness and quality of engagement. (This presents an interesting counterpoint to the rather dim student perceptions reported on the Likert scale questions about the “frequency” and “intelligence” of their interactions with the instructional team.)

Students were asked to describe barriers to their learning in the OFDL. Consonant with the relatively sharp lack of prior American experience in networked learning environments, fifteen US respondents mentioned problems either with their manipulation of the ProTo interface, or with the interface itself. Only one Finn did so. Finnish students seemed more concerned with the challenges of language and culture (five of eight) and a perceived lack of time to fulfill course requirements (again, five of eight). Significant numbers from both sides urged more face-to-face contact via video conferences.

Conclusions

If truly collaborative international study is to remain viable in the longer term, the relative student judgments of engagement and success must be positive and roughly equal across the participating national groups. Since Finnish perceptions about productivity, success and community were less optimistic than those of their American partners, subsequent iterations of OFDL must try to make the experience equally worthwhile for all students. Similarly, the sensing across both national groups about the questionable utility of interaction among peers and instructors bears close attention.

In this case, OFDL was the instructor's first venture not only into online course design but also into formal cross-national teaching. The time committed to all aspects of online course design, teaching and maintenance exceeded that of a very active traditional course by a factor of no less than four. Some of this may be attributable to the steep learning curve confronted in such a first-time effort. However, this factor is reduced to no better than two or three in the second iteration of the course. Under any circumstances, effective online teaching and learning is exceedingly time consuming. Administrative or professorial failure to recognize this reality will result in inferior teaching and dashed hopes for students and teachers alike.

The comparative US-Finnish word counts could be explained by the simple variation in difficulty between students communicating colloquially in their native tongues versus those struggling harder in a second language. However, the breadth of participation in the two groups produces more troubling results. The 11,709 counted US student words were spread across sixteen students (84% of the US total counted). The 3638 Finnish words were spread across six students (46% of the Finnish total counted). If active participation in the course dialogue areas was an important goal, then it seemed substantially better met for Americans than for Finns.

Whatever the study data indicate, a troubling fact cannot be escaped. Except in one case, the greatly desired cross-border project collaboration failed to materialize. Cross-cultural student discomfort may partly explain this failure, but the failure cannot be accepted. Simply enrolling in a course with peers from other nations may (or may not) marginally promote cross-border awareness, but true knowledge and sensitivity requires substantive, deep collaboration. Ironically, such collaboration occurred within the Finnish and American student communities, but not sufficiently across them. Clear, strategic, remedial thinking is needed.

The following ten lessons for the designers and teachers of international Web-based courses bear note:

1. Course designers and teachers should familiarize themselves with particular cross-border cultural and policy peculiarities before any academic offering is launched, and scale expectations accordingly.
2. Instructors and tutors must be able and willing to meet the substantial time demands of constant, supportive involvement.
3. The continuing presence of active tutorial support within the participating nations is critical to success.
4. A spirit of openness and encouragement must suffuse the instructional team membership at all times.
5. Specific activities can help to "break the cross-border ice," especially in the early stages of a course.
6. Exercises should be designed to promote substantive cross-border collaboration. (Such exercises must respect national cultural norms so that expectations are fair and realistic for both groups)
7. Quantity of student talk is less important than quality and distribution across a wide student base. (If participation is limited to a narrow subgroup within or across the national boundaries, a major course intention remains unmet.)
8. Orientation training is needed for students having had little or no prior experience in online learning.
9. No effort should be spared to humanize contact (e.g., via video conferences, audio clips, e-mail, other media and, where feasible, face-to-face communication).
10. The technical interface must be reliable, "bug free," and appropriately aligned to the speed, power and connectivity of client workstations.

The following Finnish comment poignantly illustrates the first of the above ten lessons. "Language problems and the discussion cultures in Finland and the USA are different. [It is] hard to find 'the shared language.' This doesn't mean that we should not have courses together, but students in both countries should be aware of this and take it into account."

**Limitations and Pointers to Further Research and Action**

Knowledge gained from this study cannot be generalized to other international course settings. Only one course was evaluated. The student sample size is small. The study is limited to two countries only, and to rather narrow cultural subgroups within those countries. Certain lessons, however, will assist teachers and course designers planning to launch fresh initiatives.

The analysis reported here has supported several beneficial revisions to the current iteration of OFDL, and could similarly contribute to the success of any such cross-border initiative. Future research efforts should be keyed both to the general intentions of the course, and to the unique cultural realities of the participating students. New research should be deeper and more methodologically varied. For example, qualitative interviews with randomly selected students would acutely enrich viewpoints on student perceptions, thereby arming teachers and designers with deeper perspectives for future planning and execution.

*OFDL* was made possible through a Fulbright Scholarship that assigned Professor John LeBaron to the University of Oulu Faculty of Education in 1998-99. Neither the design nor the execution of *OFDL* would have been possible without the dedicated participation of the course tutors: Patrick Scollin and Steven Tello in the USA, and Tarja Tervola in Finland.
Delivering Distance Education Using Synchronous Web Audio Technology

Daniel Y. Lee

DYL@ship.edu

Abstract: One of the key elements that is critical to the success of distance education is active collaboration between participants. "Two-way interaction with a given student and the instructor simply is not enough" (Palloff & Pratt, 1999). Online courses using the traditional Web functions lack spontaneous interactions among participants. Static Web documents and e-mail, the two most commonly used Web functions, provide only two-way interactions. Bulletin board and chat can often cause confusion and frustration. On the other hand, classroom videoconferencing is prohibitively expensive for many institutions, while desktop videoconferencing faces a serious bandwidth problem. The Web audio conferencing technology may be an efficient and affordable solution for many distance education courses that require spontaneous interactions and collaboration among participants. The purpose of this paper is to discuss the effectiveness of real-time Web audio as an ideal mode of delivery under the current state of technology and given the limited bandwidth of the Internet. Capabilities of the live Web audio technology are outlined. The comparative advantages of the Web audio technology are discussed.

Introduction

As computer-mediated distance education becomes more prevalent, some researchers have begun to voice their concerns about the effectiveness of Web-based courses. Effective learning can take place when there are active interactions between the instructor and students and among students. While the Web technology is touted as a medium to enhance such interactions, the loss of spontaneous communications among and between faculty and students can cause considerable difficulties for both teaching and learning. In particular, the most commonly used methods of delivery for distance education are subject to several limitations and/or drawbacks. Asynchronous communications such as e-mail and static Web documents do not provide sufficient interactions among participants. Even in the case of synchronous mode such as live chat can be confusing and ineffective (Hara & Kling, 1999). Classroom videoconferencing technology can overcome most of these deficiencies, but is costly to set up and maintain. Furthermore, students may have to travel some distance at certain times to take courses that are based on this technology, which defeats the purpose of distance education to some degree. Another potentially effective mode of delivery is desktop-based videoconferencing. However, for this method to work, all participants must have high bandwidth connections to the Internet, without which the picture quality would be poor and interactions ineffective. This bandwidth problem will not be solved until cable modems, DSL and ISDN connections are not only more widely available but also affordable.

The purpose of this paper is to discuss the effectiveness of real-time Web audio as an ideal mode of delivery under the current state of technology and given the limited bandwidth of the Internet. Capabilities of the live Web audio technology are outlined. The comparative advantages of the Web audio technology are discussed.

Distance Learning and Interactivity

Not surprisingly, studies find that interactivity plays a significant role for the success of a distance education course. For example, in a study of the effectiveness of corporate training, Millbank (1994) finds that an introduction of real-time interactivity increased the retention rate of the trainees considerably. "Without connectivity, distance learning degenerates into the old correspondence course model of independent study. The student becomes autonomous and isolated, procrastinates, and eventually drops out" (Sherry, 1996). In a recently released study that declares the 24
benchmarks essential to ensuring excellence in Internet-based learning, interactivity is found to be an important benchmark for teaching and learning effectiveness. “Student interaction with faculty and other students is an essential characteristic and is facilitated through a variety of ways, including voice-mail and/or e-mail” (National Education Association, 2000). However, while useful in some specific situations, the asynchronous communications such as e-mail or bulletin board don’t seem to foster informal conversations and personal interactions that play an important role in a teaching and learning environment. Even the more costly solutions such as classroom videoconferencing or telephone conferencing do not seem to be well-suited to sharing different types of information, such as slide show presentations, application sharing, or group learning processes (Navickas, 2000).

Interactions Using Live Web-Audio Conferences

One of the popular Internet conferencing software products is Microsoft NetMeeting (Figure 1). This software enables the user to communicate with both audio and video, collaborate in Windows-based programs, exchange graphics on an electronic whiteboard, transfer files, or use a text-based chat program. “Common uses of NetMeeting include real-time document collaboration, technical support in a helpdesk environment, training and distance learning, and conducting remote meetings” (Microsoft, 2000). While versatile, programs such as NetMeeting require relatively wide bandwidth. With a dial-up connection using a 28.8K modem, for example, users find that video quality tends to be poor and those with a low-end hardware frequently experience difficulty in maintaining connections.

![Figure 1. Microsoft NetMeeting](image)

![Figure 2. Centra Symposium User Interface: Application Sharing](image)
Unlike desktop videoconferencing, however, the bandwidth problem is not as serious in Web-based audio conferencing. In addition, Voice-enabled online collaboration requires no special hardware configuration beyond a typical one used for any Web-based distance education courses. A computer with multimedia capability (sound card and speaker), a microphone, and Internet connection are all that is needed. On the software side, Web-based audio conferencing software that can provide low-bandwidth transport of voice using efficient encoding is required. Such software is usually based on a client-server technology, meaning that the server software (and hardware) provides information and manages connections while client software enables the user to access the server.

The Web audio technology enables the instructor to use all the functions of the Web used in the traditional online courses including HTML documents, multimedia presentations, chat, and bulletin board. In addition, the instructor can conduct synchronous collaboration with students via live voice conference, share applications with them in real time, and administer tests or quizzes with instant feedback, to name only a few.

The use of Web-based, synchronous audio applications is still very limited (Kötter, et al., 1999). Applications such as streamed audio are usually unidirectional; no interactions take place. These applications do not take full advantage of the truly interactive nature of Web audio. The Web-based IP audio conferencing technology carries Web audio one step further to integrate high quality audio and tools for dynamic interactions among participants.

Advantages of Using Web Audio Conferencing Technology

Unlike the classroom videoconferencing technology, the Web audio conferencing technology requires no expensive rooms, equipment or transmissions. This technology is available to students with a computer with a multimedia card, microphone, and Internet connection. While this is also true for desktop videoconferencing, one important difference between the two is that the Web audio conferencing technology can be used over low-bandwidth and dial-up connections. Indeed, the bandwidth problem cannot be ignored in distance education, as long as a majority of students use dial-up connections and the costs of ISDN and cable modem lines remain high.

In addition, instructors who deliver their online courses using the Web audio conferencing technology can integrate all other Web functions into their courses, including discussion board, chat, e-mail, and, of course, HTML documents.

In particular, Centra Symposium is a leading provider of Internet solutions for live collaboration over the Internet. While the main focus of Centra is on business applications such as sales, marketing and training, it has much potential for distance education as well. Centra99 makes collaboration between instructors and students easy by providing the following capabilities (Centra, 1999):

- Intuitive controls over assigning speaking rights among students. When a student has a question, he or she can “raise” hand by clicking on an icon and the instructor can grant the speaking right to the person. This way, the instructor can avoid confusion often seen in live chat and at that same time encourage participation of all students.
- Easy administration of tests and quizzes, and instant feedback from online evaluations
- Effective management of student accounts. Scheduling, confirming, and managing student accounts are easily handled.
- Application sharing capabilities between the instructor and students for hands-on experience (Figure 2).
- Whiteboard for shared visual communications among participants.
• Support for multiple instructors for a class
• Availability of break out groups and lab environment
• Cost advantages (no transmission cost, no high priced equipment, no onsite technician and/or administrator is needed)

Recently, Centra Software launched CentraNow (www.centranow.com) that is a scaled down version of the full Symposium product. CentraNow is available for free at the time of this writing, though the number of participants who can attend a particular meeting is limited to four (Figure 3 and 4).

Overall, this voice over IP audio conferencing technology is an attractive compromise between the traditional Web technology, which lacks real-time interactions, and the classroom videoconference technology, which is too costly for many institutions and also may require students to travel a great distance. Given these limitations of various other technologies, synchronous Web audio may be an efficient and cost effective way of delivering distance education courses.

Figure 4. CentraNow User Interface Full Screen

Concluding Remarks

One of the key elements that is critical to the success of distance education is active collaboration between participants. "Two-way interaction with a given student and the instructor simply is not enough" (Palloff & Pratt, 1999). Online courses using the traditional Web functions lack spontaneous interactions among participants. Static Web documents and e-mail, the two most commonly used Web functions, provide only two-way interactions.
Bulletin board and chat can often cause confusion and frustration. On the other hand, classroom videoconferencing is prohibitively expensive for many institutions, while desktop videoconferencing faces a serious bandwidth problem. The Web audio conferencing technology may be an efficient and affordable solution for many distance education courses that require spontaneous interactions and collaboration among participants.

Web-based Foreign Language Learning in a Cooperative Environment: The Effects of Ability and Group Composition on Reading, Writing, and Listening Comprehension

Miwha Lee
Pusan National University of Education
Pusan, Korea
mlee@ns.pusan-e.ac.kr

Abstract: This study examined the effects of ability of the student and group composition on achievement in reading, writing, and listening comprehension in Web-based foreign language learning in a cooperative environment. Forty-four students were randomly assigned to heterogeneous and homogeneous groups. The results of the analysis showed that group composition as well as student ability significantly exerted differential effects on the learning outcomes. The implications of these results for Web-based small group work were discussed.

Introduction

Computer-assisted language learning (CALL) using Web-based multimedia courseware can provide a learning environment that facilitates positive interdependence and collaborative efforts among students. The students work together in small groups at the computer; their efforts are directed toward mutual, yet academically and socially beneficial, goals. In general, extensive research on cooperative learning has shown profound and positive effects on a wide range of students' cognitive and social-affective outcomes (e.g., Johnson & Johnson, 1999; Johnson et al., 1993; Sharan, 1990; 1994; Slavin, 1995). The computer as an instructional medium also has the potential for promoting interaction and collaboration among students (e.g., Cates & Goodling, 1997; Cavalier & Klein, 1998; Chen, 1995; Johnson & Johnson, 1996; Lee, 1993). During the past years, the Internet has been increasingly utilized as an effective instructional tool for language learning, since the Web can become a multimedia-based content provider with versatility and interconnectedness (Clinch, 1999; Harasim et al., 1996; Khan, 1997; McManus, 1995; Owston, 1997; Ritchie & Hoffman, 1996). For the present study, Web-based multimedia courseware was developed for computer-assisted foreign language instruction, as discussed later.

One of the key features that characterize cooperative learning settings and distinguish them from other learning settings is the increased opportunity for interaction among students of diverse ability, beliefs, and value systems in the learning process. Researchers have explored interaction as one of the mediating variables in the relationship between cooperative learning and social and academic gains (Hettinger, 1995; Huang, 1995; Lee, 1993; Webb, 1989). In a cooperative learning environment, hence, students are typically grouped heterogeneously. The rationale for heterogeneous grouping is based on the assumption that students can encounter wider diversity in heterogeneous groups than in homogeneous groups. Of particular interest in the present study are ability of the student and ability composition of the group. Although research indicates that both high- and low-ability students gain social benefits by working in heterogeneous groups, the cognitive effects of ability grouping, heterogeneous or homogeneous, have been inconclusive (e.g., Cavalier & Klein, 1998; Huang, 1995; Mevarech et al., 1991; Webb, 1989; Webb & Lewis, 1988).

The purpose of this study was to examine the effects of ability of the student and the influence of heterogeneous and homogeneous group composition on achievement in reading, writing, and listening comprehension in computer-assisted foreign language learning with Web-based multimedia courseware in a
cooperative learning environment. The achievement in reading, writing, and listening comprehension of high- and low-ability students were compared in heterogeneous and homogeneous groups featuring individual and group accountability.

Method

Subjects

The subjects were 44 undergraduate students enrolled in a required one-semester foreign language course at a national university in a metropolitan city in Korea. All the subjects had some previous experience with computers (e.g., word processing, Internet, telecommunications, games, and/or programming). All students have taken English as a first foreign language and French, German, Chinese, or Japanese as a second foreign language in middle and high schools.

Procedure

Before the study began, students were asked to complete a background survey, which was given in order to assess students' previous experience with computers and language learning and to provide a better description of the subjects. The pretest was administered to all students to identify those with high or low ability. Stratified random sampling was used to assign students to heterogeneous and homogeneous ability groups. Heterogeneous ability groups contained one high-ability student and one low-ability student. Homogeneous ability groups contained two high-ability students or two low-ability students. Students were unaware of the ability composition of the group. Students then received an overview of the courseware and instruction for cooperative work. They were instructed to work cooperatively as a group on the task, to help each other learn, and to make group decisions on the course of their actions in the learning process. Students were not assigned specific roles within a group, nor were they allowed to divide the work. Students worked for 50 minutes each day, 2 days each week, for 15 weeks, a total of 30 instructional sessions for one semester.

Web-based multimedia courseware

For the purpose of this study, Web-based multimedia courseware was designed and developed for French language learning. This courseware appears to be one of the first courseware for computer-assisted French language instruction in Korea. The courseware was designed to be adaptive to individual learning situations on a non-real time basis. Students can navigate the hyperlinked multimedia contents without a pre-ordered learning schedule. Through their exploration and navigation, they design their own instruction. The contents of the courseware are divided into two levels: beginning and intermediate. Each level consists of 15 coherent but independent lessons. Each lesson is composed of six sections: reading, writing, listening, speaking, grammar, drills, and games. These sections require either passive or active learning modes in terms of data manipulation.

The reading section shows paragraphs in a variety of styles and includes interpretations and in-depth explanations regarding morphological, lexical, syntactical and semantic-pragmatic rules and expressions used in each sentence. The writing section enables students to gain pragmatic competence in their writing skills. It provides questions related to context-based composition. The listening section presents simple expressions with immediate text feedback to improve students' listening comprehension. The speaking section is designed with an emphasis on conversational practice, based on given situations presented as a picture. Concerning the grammatical rules of the previously presented sentences, the grammar section provides charts, pictures, examples as well as explanations about those points. The game section is an additional unit designed to motivate students through games, songs, or puzzles, which may not deal with the lesson directly.

The courseware also includes the interaction facilities: help, bulletin board, announcements, and e-mail. The help component includes general instructions regarding the instructional system. The bulletin board deals with management-related interactions such as a recommended learning schedule and important dates.
The announcements show FAQ's (Frequently Asked Questions) on subject materials or technical problems. The e-mail allows for individual communications. These interaction facilities were designed to provide various types of asynchronous communications among three different user groups: teachers or tutors, students, and system administrators.

In designing and developing the user interface of the courseware, a special emphasis was placed on user-friendliness and efficiency. A simple, intuitive design with a text-based menu, rather than a complicated design, was preferred. In addition, the courseware utilizes well-designed TrueType fonts, which support unicodes such as 'Lucida Sans Unicode,' 'Berdana,' and 'Times New Roman.' The basic color of the courseware was carefully selected based on the color-effectiveness studies (Moore, 1996; Pett & Wilson, 1996; Weinman & Heavin, 1996). Considering the current access speed to the Internet via modems or LANs (Local Area Networks) in schools, a minimum level of animation was used in order not to interfere with students’ concentration level in the learning process (Jeong & Yoon, 1998). For the consistent and systematic delivery of information, the subsequent hyperlinked information is presented in the same page. To this end, the interface was developed using Active Server Page (Hillier & Mezick, 1998) and Dynamic-HTML (HyperText Markup Language) (Homer, 1997).

Research Design and Data Analysis

The study employed a 2 x 2 factorial design. The between-subjects factors included Ability (high, low) and Group Composition (heterogeneous, homogeneous). The within-subjects factor, Achievement, included Reading, Writing, and Listening Comprehension. The analysis of variance (ANOVA) was performed to determine the interaction effects as well as the main effects of ability and group composition on achievement in reading, writing, and listening comprehension. The analysis of covariance (ANCOVA) was also conducted, with students’ previous experience with computers and the pretest results serving as the covariates. The level of significance was set at .05 in this study.

Results and Discussion

The means and standard deviations for achievement in reading, writing, and listening comprehension are presented in Table 1. The results of the analysis of variance are shown in Table 2.1

Reading. Significant main effects were found for Ability, $F(1, 40) = 7.208, p < .05$, and for Group Composition, $F(1, 40) = 14.029, p < .05$, and significant interaction effects were also found for Ability and Group Composition, $F(1, 40) = 7.268, p < .05$. These results indicate that student ability and group composition exerted differential effects on achievement in the reading posttest, as shown in Tables 1 and 2. High- and low-ability students tended to achieve differentially across the groups of different composition on the reading posttest. The students in heterogeneous groups scored higher than did those in homogeneous groups. This pattern is more noticeable among low-ability students than high-ability students.

Writing. There were significant main effects for Group Composition, $F(1, 40) = 4.401, p < .05$, and significant interaction effects for Ability and Group Composition, $F(1, 40) = 3.759, p < .05$. Yet, main effects for Ability were not statistically significant. Both of high-ability and low-ability students working in heterogeneous groups tended to score higher on the writing posttest than did those working in homogeneous groups. These results indicate that the achievement of high-ability and low-ability students was dependent on the group composition in which they were working.

Listening Comprehension. No significant effects were found for Ability or Group Composition or for the interaction between Ability and Group Composition. The results indicate that the differences between the posttest means were not statistically significant, probably due to the relatively large standard deviations, as shown in Table 1. This study examined the effects of student ability and group composition on achievement in reading.

1 It should be noted that students’ previous experience with computers and the pretest results were not significantly correlated with the achievement scores. The results of ANCOVA were rarely changed. For a purpose of clarity, hence, the results of ANOVA are presented in this section.
writing, and listening comprehension in computer-assisted foreign language learning with Web-based multimedia courseware in a cooperative learning environment. The results of the analysis of variance indicate that group composition as well as student ability significantly exerted differential effects on the learning outcomes. Both high-ability and low-ability students working in heterogeneous groups showed higher achievement than did those working in homogeneous groups. These results corroborate and lend further support to the previous studies that heterogeneous group composition benefits students of both high ability and low ability (Larson et al., 1984; Webb, 1982a; 1982b; Yager, 1986). The cooperative learning methods, in non-computer settings, often call for students to be grouped heterogeneously by ability (e.g., Sharan, 1994; Slavin, 1995). The findings of this study suggest that ability grouping can also be utilized as an effective and practical method in Web-based instructional settings.

Suggestions for future research should be noted. First, a comparative study of group learning with individualized learning in Web-based instructional settings may be worth further investigation. Second, this study employed pairs; the findings may not generalize to larger groups. Some research suggested the importance of group size as well as group composition in computer-based cooperative learning (Guntermann & Tovar, 1987). Finally, this study has focused the product of group learning. Future research should also analyze the intra-group dynamics among students in the learning process.

Mt. Pleasant, MI 48859
Carl.M.Lee@cmich.edu

Abstract: This article presents a paradigm shift from the traditional curriculum model of setting goals and objectives to a new curriculum model of setting standards and responsibilities to assist instructors and students in changing from teacher-centered learning to student-centered learning in the technology era. The student-centered learning environment is diverse and allows students with different learning styles and intellectual abilities to prosper at their own pace. Teaching pedagogy and classroom learning are much behind the evolving of technology. In the advanced technology era, not only the traditional lecture and note taking approach will be seriously challenged, but also the static use of technology will be seriously challenged as well. This article addresses two fundamental obstacles in shifting from teaching-centered to learning-centered strategy in technology era at higher education. A case study is presented to illustrate how to deal with these fundamental obstacles.

Introduction

This article presents a paradigm shift from the traditional curriculum model of setting goals and objectives to a new curriculum model of setting standards and responsibilities to assist instructors and students in changing from teacher-centered learning to student-centered learning in the technology era. The use of technology in the teacher-centered learning environment is usually static, such as report writing, projects, powerpoint presentation, web material distribution and classroom demonstration. The student-centered learning environment is diverse and allows students with different learning styles and intellectual abilities to prosper at their own pace. A proper integration of technology is crucial for a successful student-centered learning model.

Background

Imagining that every student comes to the class with a laptop computer on and ready for learning. There are already universities requiring every student purchasing a laptop computer. The message is becoming clear that sophisticated computer technology will be at the fingertip for students and instructors in classrooms. The technology will soon not only be used for writing reports, doing research, or occasional class aid, but, more importantly, it will be available for class learning in every classroom. However, teaching pedagogy and classroom learning are much behind the evolving of technology. In the advanced technology era, not only the traditional lecture and note taking approach will be seriously challenged, but also the static use of technology will be seriously challenged as well. Faculty and students will have to face dramatic changes in the process of teaching and learning. Instructors will have to rethink the way of teaching and students will have to accept the role of being active learners. The concept of active learning, with instructors and students participating together as they develop the understanding of the subject matter, has received much attention in the recent decades (e.g., Lambert & McCombs, 1998; Stage, Muller, Kinzie & Simmons, 1998). In the student-centered model, students are provided with situations to deal with. Teachers are assumed responsibilities of guidance and facilitating the process of knowledge discovery, while students are involved with the process of discovering the knowledge themselves. Student-centered models are consistent with the constructivism learning theory, where both place significant emphasis on the learners' active participation and on the development of knowledge construction.

Obstacles Faced in the Paradigm Shift
Technology plays a crucial role in helping the learner-centered model more meaningful and more diverse. However, many obstacles are yet to be overcome in order to make student-centered curriculum a reality in higher education. These include

1. Instructors and students are not familiar with the concept of student-centered learning. As the consequence, instructors and students tend to think that student-centered approach means students are 'customers'. Therefore, instructors tend to resist against the approach. Students may quickly act themselves like 'customers'.

2. Student-centered learning creates many organizational problems in the development of an adequate curriculum. It takes several semesters of gradual changes to feel comfortable with. Many may choose to withdraw back to the more familiar teacher-centered approach.

3. Students are used to the step-by-step, more predictable teacher-centered learning. It is a difficult philosophical shift for students thinking they are the ones who develop their own learning and discovering knowledge themselves. A study conducted in (Lee, 1999) indicated that, although students would like cooperative learning or working on projects, the lecture and note taking is still their favorite learning style (Lee, 1998).

4. In the current higher education system, student opinion survey is the common teaching evaluation tool for tenure and promotion. Many instructors think that the change from the familiar teacher-centered and very organized approach to a diverse and unpredictable teaching environment will affect their student opinion scores.

5. The integration of technology into student-centered curriculum is a challenging task. Regardless how much technology knowledge we know, it is never fast enough to catch up with the technology evolvement. This introduces a serious obstacle for instructors to integrate technology into curriculum effectively.

Two Fundamental Issues Before Accepting the Student-Centered Learning

Research related to framework on how student learns (APA, 14 Principles, 1995; Alexander and Murphy, 1997) has suggested 14 principles to explain how learning takes place. These 14 principles can be classified into four dimensions as (1) cognitive and metacognitive dimension, (2) motivational and affective dimension, (3) developmental and social dimension, (4) individual differences. These principles shows how complex a learning process is. The success of learning is the result of all dimensions interacted together. The student-centered learning is a process that attempts to take all four dimensions into account to assist student learning. In order to accomplish all these dimensions, it is not surprising, that many obstacles need to be overcome. Literature has provided many useful framework and guidelines for creating student-centered classrooms and curriculum (e.g., Glasgow, 1997; Stage, Muller, Kinzie & Simmons, 1998). However, before accepting and implementing the model, two fundamental issues on motivation for instructors and students to accept the model seems to be overlooked. These fundamental issues are

1. What should be an adequate operational definition of 'students'? The success of education depends on how much a student is learning. Student-centered learning focuses on students and their involvement in actively constructing the knowledge themselves. Therefore, it is the first critical step to find an acceptable operational definition of 'students'.

2. How to motivate the instructor and students work together as facilitator and learners rather than teacher and student relationship? In the traditional teacher-centered learning, instructor defines the goals and objectives of the course. He/she then teaches the topics to meet these goals and objectives. If the learning outcomes are not adequate, it is often to hear from the instructor: 'students do not work hard; students are not as smart as old days'. Students often blame the instructor: 'I do not understand what he/she said; the pace is too fast!' There is usually true to certain degree for both sides. However, once such a relationship between instructor and students begins to build up, it is no longer much fun for teaching or learning. Similar blames could happen if the student-centered learning is implemented without the agreeable operational definition of 'students' and a fundamental change in rethinking the roles and the relationship between instructor and students.

Operational Definition of 'Students'

Are students 'customers'? This has been a very controversial question among different groups of individuals. It is fair to say that there is no the right answer for this question. It is not possible to define students strictly based on any
business model. The philosophy of total quality management tends to overlook the nature of feeling, attitudes, motivations and intellectual differences among students. However, some basic principles and tools are useful to help us sought out causes and effects, and to provide ways to deal with the causes. One essential step is to look for a compromised acceptable operational definition of 'students'. A closer investigation about the roles students play in the higher education environment, one begins to notice that students have several roles in the higher education. A cause and effect chart helps to identify these roles based on Deming's quality improvement philosophy (1986). Three major roles that students play in the higher education can be identified:

(1) Students are considered as customers in the service-oriented environment, including registration, financial aid, library, student life related services. The main goal for these service-oriented departments is to assist students in making their learning smoother. To these departments, students are their major customers. Therefore, the typical quality concept of 'customer satisfaction' can be defined and pursued.

(2) Students are considered as clients at the departmental level. At each departmental level, students receive advising, placement, course scheduling and so on. Students act similar to the situation where a client asks for consultation from a doctor. The client has the right to request a satisfied technical assistance, while the client must also follow doctor's direction for proper medication and so on. Students are similar to clients at the departmental level, since they receive advising and placement based on the assumption that students will continue to study and meet the curriculum requirement.

(3) Students are considered as work-in-progress at the classroom level. Students are considered similar to parts or unfinished works when they come to a class. The knowledge and skills learned from the class continue to improve the work for the ultimate customers of employers and society. In the process of building the works, quality of the work should be constantly measured. In the mean time, the facilitator's quality will also be measured based on the process of building the quality works. Therefore, in the classroom environment, students are more similar to works-in-progress. The quality is measured based on the requirement from the ultimate customers, the potential employers and society, not only based on what the instructors think about what the works ought to be.

This operational definition of students attempts to clarify confusion of the roles that students play. Any oversimplification could introduce controversy among different groups. It is important to provide quality services and quality education for our 'students'; customers, clients and works-in-progress. The above definition helps to clarify the possible causes of the obstacles discussed above. It will help instructors and students in understanding their roles in a student-centered learning environment. This operational definition is by-no-means to be exhausting in defining all of the roles students play.

Shifting Paradigm from Curriculum Goals and Objectives to Standards and Responsibilities

The second fundamental issue is about reasons for accepting the student-centered model. Most instructors were trained in the teacher-centered model. It is an approach that is predictable, and we all feel comfortable with. Students are used to the model as well. Therefore, without a profound reason, it is difficult to convince instructors and students to make such a dramatic change. This is also very important for distance learning. This fundamental issue can be dealt with by the proper shift from setting goals and objectives based on the instructor's point of view to setting standards and responsibilities for both instructor and students.

The term 'standards' in this situation is different from the 'outcomes standards', such as the standard that students graduating from a certain program must pass a certain test. In stead, it refers to 'the process standards'. That is, the process of learning, students are asked to learn each topic at a certain level of standards. These standards are determined based on the requirement of higher level courses, the preparation for career needs or society needs, depending on the types of courses and levels of courses. For an example, standards for an introductory statistics can be defined based on the courses that have the prerequisite of this course and/or the adequate knowledge and skills for understanding day-to-day information in our every day life. In order to accomplish standards defined for a course, each topic in the course should also have a set of standards for the topic. In most cases, these standards are similar to the goals. However, when setting up the goals, the instructor often relies on his/her own experience and the past understanding of the career needs. When setting up the standards, the instructor will need to communicate with the related higher-level course instructors, and some key professional fields where students are hired. If the
standards are defined adequately, it is usually easy to communicate with students with regards to reasons of setting these standards. Students are appreciative of the instructor's efforts to help them setting up these standards.

The term 'responsibilities' is not only for students, but also for instructors. It is necessary that a clear explanation of different 'responsibilities' for instructors and students are communicated with students. Once a set of standards is developed for the topic, various concepts will be covered, and therefore, students should receive a set of responsibilities for the level of understanding of each concept. In many cases, the responsibilities for students are similar to objectives. However, since they are developed to meet the standards, a rubric system for assessing the level of understanding should also be developed. One important strategy to communicate the responsibilities to students is to emphasize that these responsibilities are for both students and instructor. Students are responsible for learning the knowledge under the instructor's guidance. The instructor is responsible for designing appropriate activities and using various teaching strategies to facilitate student learning. Computer technology, cooperative learning, use of web sites and so on, in this stage, play a crucial role in helping the instructors in designing and carrying out student-centered learning activities.

A Case Study

Statistics is considered a difficult and boring subject by many college students. Lee (1997) developed a model called the PACE model for teaching introductory statistics to help student learning. P stands for Projects, A stands for Hands-on Activities, C stands for cooperative learning in a Computer classroom environment, and E stands for Exercises. A typical class begins with conducting a hands-on activity as a group project and collect data for further analysis. In the process of conducting the project and collecting data, group discussion is conducted to discuss the pros and cons of the project and the process in the data collection. Computer is used right after the data is collected for each group to conduct analysis or computer simulations, and for report presentations. The computer technology is used to help simplifying computation and understanding the concepts. Re-enforcement is carried out by exercises and projects. The PACE model is a student-learner centered strategy for teaching introductory statistics. Several studies were taken to assess the effectiveness of the model (e.g., see Lee (1998, 1999)). Noticeable difference in problem-solving strategy was found from students who were taught by the PACE model from those who were from the traditional class. The PACE model students were 'looking for similar activities and projects conducted in the classes' to solve problems; while students from traditional class were 'seeking for formulas' to solve the same problems. On the other hand, we also noticed that the motivation and expectation remained similarly low in both classes. One main reason for the similarly low motivation and expectation is hypothesized to be that students were not experienced to the stage to be able to visualize the entire picture of the benefit of basic statistical concepts in their career or in their day-to-day life activities. A fundamental change in helping students realize such a 'big picture' is necessary. This has lead me to the develop the paradigm of integrating 'standards and responsibilities' into the process of teaching and learning. Such a paradigm is becoming important in the use of advanced computer technology, since students will be more independent in their own learning. It will become extremely important to maintain students' motivation and expectation. Otherwise, higher education could easily be a place of 'diploma manufacturing'.

The paradigm of using standards and responsibilities were implemented in the Fall, 1999 PACE class. The class size was twenty eight. Students were mainly business school students. This is a course that block their way for business school, admission. Students are typical on-campus students who, generally speaking, had low expectation, little motivation, and came with rather weak mathematics background. At the beginning of each topic, students were given a sheet of standards and responsibilities, and were summarized and discussed after finishing the topic. An example of standards and responsibilities for the topic of Exploratory and Graphical Methods is given in the following:

Standard: Students will be able to summarize a real world data using proper graphical and quantitative tools so that the summary will be useful, meaningful and valid, and will be able to use computer to analyze the data, and summarize the results, and present the results in written and orally.

The corresponding responsibilities: In order to accomplish this standard, students will learn:
1) Collecting real world data properly, and explain possible sampling errors in the process of data collection.
2) Distinguishing quantitative and qualitative types of data, and the corresponding graphical methods for summarizing them.
3) Computing descriptive summaries such as mean, s.d., median, percentile, z-scores by hand and by computer.
4) Explaining the meaning of variation and giving appropriate real world cases to explain the magnitude of variation and possible factors associated with the variation.
5) Describing histogram, stem-leaf plot, box-plot, time-series plot, and explaining their differences and usages in real world applications.
6) Demonstrating empirical rule, and using the concept of rare events in real world applications.
7) Using the Z-scores to explain the concept of rare events in real world applications.
8) Demonstrating various shapes of histograms, and their relationship with mean and median.
9) Properly matching the relationship between statistical summaries, histograms, box-plot and time-plot.
10) Applying the tools learned from this topic to analyze a real world case, and presenting the report in written and orally.

A similar list for each topic was developed, and was given at the beginning of the topic. Several assessment activities were conducted throughout the semester. First, students were asked to conduct a self-assessment by rating the degree of accomplishment for each responsibility, and reasons for why they did or did not accomplish well of the specific responsibility, then, list actions that will be helpful to help them accomplish these responsibilities. Two other assessment activities were conducted at the end of the semester. One was the same self-assessment activity adding an overall assessment of the approach. The other was an assessment on the affect domain of their learning, which include attitudes, beliefs, motivations, learning styles, use of computer, and other background information.

Several observations were summarized below from the self-assessment and overall evaluation.

(1) Through out the semester, one significant difference of the interaction between instructor and students was immediately noticed: When students came for individual help during the office hours, there were no students making excuses about how difficult it was, or asking to explain the entire the topic covered in class. Students usually came with a specific question and was able to pinpoint where they did not understand. This is a reflection of the understanding of their responsibilities for each topic and willing to accept their role as active learners. As a result, students were informed, and instructor was aware of specific difficulties students encountered. This attitude has significantly changed the classroom atmosphere.

(2) Although students tended to rate their level of understanding somewhat higher than their test scores indicate, the relative level of difficulty of each responsibility, and reasons were very useful information for continuous improvement. Here are some examples from students' self-assessment for the topic Exploratory and Graphical Methods:

'The problem areas in this section are stem-leaf plot, time-series plot, their relationship and applications.
I still do not see the use of stem-leaf plot, box-plot. I think this is because we have sued histogram a lot for rare events and variation, and so on. More applications using box-plots or stem-leaf plot will be good.'

The two concepts that have been rated lower level of understanding most often were 'the use of Z-scores for interpreting rare events' and 'the relationship among summaries and various plots. This information is very valuable for continuous improvement in teaching and learning. Instructor can find out the problematic concepts and redesign strategy to help student learning.

(3) The overall assessment of the strategy was very encouraging. In the class of 28 students, everyone indicated this is helpful, especially this keeps them informed what standards they should accomplish, and how they can accomplish the standards in every topic. When asked 'is it worth of the effort to develop the standards and responsibilities for this or for other courses. Every student indicated yes for this course as well as for other courses.
Conclusion

The role of technology in education continues to evolve. Any prediction on how much technology will impact the education would be meaningless. Technology provides unlimited opportunity for instructors to create fascinating innovation to help student learning. However, since it is more and more difficult to catch up with the change of technology, the hurdle for instructors in integrating technology into curriculum becomes even larger. The success of a student-centered learning strategy relies upon, first, understanding various teaching strategies, second, accepting some strategies, third, willing to implement and assess at least a strategy, and fourth, willing to continue to improve the strategy. This process involves both students and instructors, and their understanding and accepting of the roles, respectively. In order to create an adequate atmosphere, it is important that students, instructors and administrators have a common language of the operational definition of 'students'. In addition, to create a high expectation and motivated learning environment, a shift from teacher-centered curriculum of setting goals and objectives to student-centered curriculum of standards and responsibilities provides a bridge to connect instructors and students for the common ground of pursuing high quality of education.

Professional Development through Flexible Delivery

Geraldine Lefoe
Centre for Educational Development and Interactive Resources
University of Wollongong
NSW, Australia 2522
glefoe@uow.edu.au

Abstract: This paper provides an overview of a staff development initiative at University of Wollongong, a regional university in Australia, located on the outskirts of the largest urban area in Australia with a population of approximately 500,000. It provides a model for professional development in flexible delivery through the use of video and a website. This site provides access for staff to key concepts and in depth materials on flexible delivery, identifies support services and their roles and provides up to date policies and procedures to implement the changes in teaching practice. It highlights the challenge for staff developers to "practice what we preach".

Introduction

In recent times there has been a dramatic change in technology which has seen a convergence between distance and on campus education (Walker and Walker, 1997). Technology has been used to enhance interaction between students off campus and their lecturer on campus (Agostinho, Lefoe and Hedberg, 1997, Agostinho, Hedberg and Lefoe, 1998). Technology has also been used to improve access to content both on campus and at a distance. Online learning facilities are being offered locally and by overseas institutions. Students may now be just a block away, a suburb away or on another continent. On campus students may only attend lectures two or three times a semester, if at all, but may have in depth discussions or "chat" regularly online with the subject facilitator and other students (Wills et al, 97).

Effective staff development is one of the keys to ensuring success in this dramatic move. By placing staff in the learner's shoes this project provides opportunity for teachers to actively engage in the learning environments that are being advocated for their students. Success in using these learning environments can only occur when the staff member is as comfortable in the learning environment as the student is.

Background

The University of Wollongong is located on the South Coast of NSW, Australia, strategically developed to meet the needs of students in the Illawarra region. The main campus is in Wollongong, with centres located in Sydney and Berry, and an international centre in Dubai. This has been expanded in the Year 2000 to include a campus in Nowra (one hour drive) and access centres in Batemans Bay (3 hours drive) and Bega (6 hours drive). The intention with the new campus and access centres, was to establish a South Coast Educational Network (SCEN),

"to develop a comprehensive cross-sectionally articulated plan for the delivery of effective post-compulsory education and training across university, TAFE, secondary school and other training sectors" (Illawarra Regional Information Service, 1996. P1)

The vehicle for this expansion would be a network of educational providers operating as development partners through SCEN. Within this network the University of Wollongong decided there was the need for a degree program that could be delivered flexibly. "The network would draw upon emerging educational technological developments to expand the availability of, and improve the accessibility to, relevant educational programs" (Illawarra Regional Information Service, 1996. P1)
The SCEN initiative had implications for the delivery of a large number of subjects in a different format to current traditional practice. The rapid growth of flexible delivery at University of Wollongong would require access to a variety of resources and an understanding of alternative delivery methods.

Flexible delivery, in this situation, is defined as an approach to teaching and learning which increases access to education for a wide range of students by offering greater student control over time, place and, potentially, pace of study. Technology, where appropriate, is utilised to support communication and access to information and to move towards a more student centred approach to teaching and learning. The most appropriate delivery medium, (eg a lecture, a video or a book), can be chosen to meet the learning outcome and the student's needs. Interaction, (learner-learner and teacher-learner) can be facilitated through face-to-face contact or through supporting technology such as videoconference, Internet, phone, fax. (Bell and Lefoe, 1998)

Role of development support units

From the broader perspective of the current higher education environment, both individuals and faculty units have been buckling under the combined weight of devolved responsibility for management, administration, technology implementation, professional development and a generally increased workload. Historically, many of the teaching staff developed subjects in the traditional lecture/ tutorial format on their own. The move to flexible delivery of subjects means thinking differently about this process and moving into a team based environment, especially where the development of resources is involved. Support structures are critical to ensure that this journey through chaos and confusion results in quality outcomes for all involved.

In order to be successful, the move to flexible delivery could only occur where this support infrastructure was put in place and teaching staff could tap into what they needed when they needed it. In recognition of this the university had a variety of support units, many of whom had undergone change during recent restructuring in order to meet these emerging needs (Curtis, Lefoe, Merten, Milne and Albury, 1999).

The degree support structure in the University of Wollongong includes:

* Centre for Educational Development and Interactive Resources (Includes Educational Development Lecturers, Interactive Multimedia Unit, Audio Visual Unit and Electronic Publishing) The Centre has principle responsibility for supporting faculties in their adoption and utilisation of technology within their teaching practice. It also provides a role in quality control of resources.
* Learning Development Unit (includes Lecturers in Learning Development and Tertiary Literacy officer) Their approach of providing all students with assistance in making the transition into tertiary and discipline based studies is an innovative and systemic approach to learning support (Skillen, Merten, Percy and Trivett, 1998).
* Academic Registrar's Division which has principle responsibility for student administration
* Information Technology Services provides the infrastructure for improved use of technology at all locations.
* The library provides an outreach librarian whose role is to support lecturers and students involved in flexibly delivered subjects.

The purpose of the resource

This staff development resource brings together information about the roles and responsibilities of all the support units as well as providing academic staff with experience in flexible delivery through the use of the resources. The resource models the practice of flexibly delivering professional development. It utilises various media and includes an interactive dimension in a web-based learning environment. It models the environment that will be used by academics in teaching in other locations and on campus, whilst providing access to people, policies and procedures to support development of subjects in a more flexible mode.

Description of the resource

The staff development package includes two integrated resources:

1. A video which provides case studies of teaching methods utilised by staff currently engaged in flexible delivery in a number of faculties.
A web site (http://cedir.uow.edu.au/Projects/FlexDel/) which links teaching staff to support staff for subject development as well as utilising information from an existing CDROM, Teaching at a Distance, developed by the University (in collaboration with several others) for a consortium of universities in Australia (PAGE) (Wills et al., 1998). The existing material has been redesigned to be specific to the needs of University of Wollongong teachers. An interactive dimension to the resource has been added through a discussion forum, which allows for asynchronous discussion between different people by removing the restrictions of time and place.

The website provides four levels of resources for teaching staff.

* Level 1 - Provides information about flexible delivery and its implementation at University of Wollongong and the various support teams for curriculum development including Centre for Educational Development and Interactive Resources, Library Services and Student Support Services. Images of people in their roles at University of Wollongong are used at this first level to personalise the information and introduce the topics. It defines the role of the various groups and the support for subject development that they are able to provide. Its purpose is to encourage teaching staff to consider contacting these people for support and to identify them on campus. This level also introduces a discussion forum.

* Level 2 - A detailed overview of each support area and important issues that should be considered in initial planning and design. The project also draws on other resources created by Centre for Educational Development and Interactive Resources such as the National Council Open Distance Education Flexible Learning web site.

---

Ray Stace
Robert Corderoy
Gerry Lefoe
Richard Caladine
Sandra Wills
Using the resource

This professional development initiative was designed to meet the needs of academic staff to
- highlight, through the use of the video, modes of flexible delivery that are being used on campus
- provide a learning environment which models the practice of flexible delivery
- identify in a cohesive way the support units on campus
- clarify the new roles and directions for these units
- provide interaction with other teaching staff who are engaging in this practice through the discussion forum
- support academic learning needs about flexible delivery

The resource will be used in a number of ways for professional development. At the individual level it can be used at a time or place which meets the need of the staff member. It will also be utilised at the small group level and in faculty staff development programs to support initiatives in this area. The University of Wollongong has a compulsory subject for new lecturers, Introduction to Tertiary Teaching, which has elective modules on such things as redesigning subjects for flexible delivery. This initiative provides the starting point for this module and for others related to thinking differently about teaching and learning.

Conclusion

Planning for flexible delivery has meant making drastic changes not only in thinking about curriculum development, but also in the whole infrastructure of the university from administration to information services. The University of Wollongong now has in place many structures, some of which were under utilised when implementing new ways of teaching. This resource provides a link for academic staff, not only to information about flexible delivery at many levels, but also to staff who are able to work in a team based environment to improve subject development and to provide support to staff as they make changes in their teaching practice. As the University of Wollongong expands to include other locations, professional development for teaching staff can model the changing practices for teaching and learning. "Practising what we preach" is an important component of professional development.

33101 Tampere, FINLAND
jarkko.levasma@tut.fi

Abstract: Pythagoras is one of the pilots in the Open Learning Environment (OLE) Project that develops pedagogically and technically appropriate learning environment for the net. On the Pythagoras pilot a learning environment of the same name was developed as an aid to teaching in secondary and upper secondary schools with a mission to make Pythagoras into a commercial net-product and to study its use in teaching. The Pythagoras Learning Environment comprises theory, interactive exercises, a question tool and communication tools. In the implementation of Pythagoras use was made of Java Remote Method Invocation and Servlet technologies among others, which offer a flexible and efficient way of producing WWW systems. A teaching experiment was arranged for Pythagoras to study the usability of Pythagoras and users' opinions. The students particularly enjoyed doing research using the question tool. It may be concluded on the basis of the teaching experiment that using the net as a tool for learning offers considerable advantages over conventional study.

Introduction

The article describes the Pythagoras pilot as a part of the Open Learning Environment (OLE) Project (Ruokamo, Pohjolainen 1999). On the Pythagoras pilot a learning environment in statistical mathematics was produced for the net (Pythagoras Learning Environment). The article presents the background to the pilot, the parties involved in the research, development and in the teaching experiment and the aims of the pilot. This is followed by a presentation of the functionality of the Pythagoras Learning Environment and its technical realisation. A teaching experiment was arranged with Pythagoras and the realisation and results of this are presented in the article. The article further considers the commercialization of the Pythagoras. The article concludes with some conclusions drawn on the basis of the research and development work.

Background to the pilot and co-operating parties

The first version of the Pythagoras Learning Environment was created in the Distance Learning in Multimedia Networks Project (ETAKAMU) research project on the pilot in natural sciences (Pohjolainen, Ruokamo 1999). This was carried out on the responsibility of the Hypermedia Laboratory of the Tampere University of Technology (TUT). At the time of ETAKAMU the main responsibility for the research and development work on the Pythagoras rested with Heikki J. Mäenpää, M. Sc. (Eng.). The content selected for the Pythagoras was statistical mathematics as problems in statistical mathematics lend themselves particularly well to computer presentation. The Hypermedia Laboratory has produced numerous net courses in mathematics, the latest of which is the introductory part of a course on matrix calculation (Matrix Calculus I) using a development version of the A&O Open Learning Environment (Pohjolainen, Ruokamo, Nykänen 1999). The research findings of the Pythagoras pilot and the experience gained serve as a basis for development work on A&O.

Edita Ltd has supported the OLE Project and the Pythagoras pilot in particular. A number of teachers from comprehensive and upper secondary schools in the Tampere Region have been involved in the development of Pythagoras. Among the most active members were: Jussi Kytömäki (Ylöjärvi Upper Secondary School), Päivi
Portaankorva-Koivisto (Moisio Secondary School), Riikka Uotila (Ylöjärvi Upper Secondary School) and Pauli Koivula (Teisko Secondary School and Tampere Upper Secondary School for Adults). These teachers not only participated in the development work of the learning environment but also took part in arranging the teaching experiment and in making the teacher’s guide.

Aims of the pilot

In the first year of the OLE Project the main aim of the Pythagoras pilot was to make Pythagoras into a commercial net product. This means that the technical and pedagogical features of Pythagoras were to be developed to a standard at which it would be possible to market and use it over the net. Commercialization as a whole involved many other considerations, and the main responsibility for these was with Edita Ltd. The other aims of Pythagoras were to create a learning environment that would be user-friendly, versatile, interactive and exploit the latest technologies.

Structure and functions of the Pythagoras Learning Environment

Pythagoras is a hypermedia-based learning environment. The concept learning environment subsumes certain essential characteristics compared with mere learning material, which is to be addressed later in this chapter. In management of a learning environment the main factors are the roles of the users and the rights and duties inherent in those roles. Pythagoras is used and managed over the net. There are three main user roles: student, teacher and maintenance person. A group of students and a teacher together constitute a teaching group, which Pythagoras takes as a basic unit for management purposes.

Technical framework

The basic framework of Pythagoras is a group of linked hypermedia documents. In the creation of the Pythagoras static HTML pages, as, for example, the theory of statistical mathematics, the FML publication tool developed in the Hypermedia Laboratory was used (Nykanen 1999). Some of the HTML documents in Pythagoras are dynamically created. Dynamic refers here to the fact that the content and/or the external appearance of a HTML document varies, e.g., depending on the input obtained from the user. In the realisation of Pythagoras Java Servlets were used almost exclusively in the creation of dynamic HTML pages. Servlets enable efficient and scaled server programmes operating through CGI interface and can be produced with an object-based language (Articles of Servlets).

Another prime element in the realisation of Pythagoras is the independent programmes created as Java applets that are executed in the client computer. The major advantage in using applets is getting away from the rigid page concept of WWW. In Pythagoras applets were used especially to create interactive elements. Applets were used in such a way that, e.g., instead of one large applet several smaller general-purpose applets were used on the HTML pages. Using several applets on the same page may from time to time cause technical browser problems. Some of these problems have already been solved through new browser versions, but in practice problems may still arise as there continue to be old browser programmes in general use.

Pythagoras is a distributed application. The applets store the information in the server computer, for which Remote Method Invocation (RMI) technique was mostly used. RMI is a feature included in Java language, which makes it possible to call up Java programme methods via the Internet (Articles of Remote Method Invocation). Certain problems exist in the use of RMI, especially with support from certain browser programmes and client-side firewalls. The problem concerning firewalls can be solved using Servlets (McPherson 1999). A separate RMI server is initiated for each teaching group. The advantage of this is significant scalability - Pythagoras functions without changes with both large and small user numbers.

Functionality of Pythagoras learning environment

In the planning of any net pages whatsoever one of the foremost considerations is navigation, i.e. the logic by which a user progresses from page to page. In Pythagoras an effort was made to ensure that navigation is optimally simple, and, above all, uniform. At the top of each page in Pythagoras there is a menubar for access to the four central elements of Pythagoras. These are learning material, workshop, teachers' lounge and exhibition. In addition to these four areas mention should also be made of the front page, see [Figure 1], which contains some important features.
The function of the front page of Pythagoras is to serve as the starting page of the learning environment. There is a tool for students to enrol in their teaching group. From the front page a user can log in to Pythagoras. Logging in is optional, but is makes it easier for the user to use other elements of Pythagoras later.

The learning material in Pythagoras contains elements pertaining to conventional learning: theory and practical exercises. The learning material includes examples and directions for carrying out statistical research. One of the most interesting features of Pythagoras is the interactive exercises. There are seven of these, and most offer alternatives of different degrees of difficulty. The exercises address various aspects of the theory and there are links to the appropriate theoretical sections. The individual exercise page is realised with general task elements. Some of these elements are used to present the initial information and some for the input of the solution. Every exercise page has an instruction panel on which the instructions vary according to what part of the exercise the student is currently undertaking. When the student has completed the exercise Pythagoras checks the answer. If there is something wrong in the answer Pythagoras indicates the location of the mistake and provides further prompts for the solution of the task. Each checking as well as the correct answer is registered in the database for achievements. The student can monitor his/her own achievements.

The Pythagoras workshop contains those essential features that distinguish the learning material of the learning environment. The tools to access groupwork and research are located in the workshop. Through the discussion and chat tools the Pythagoras offers its users the opportunity to communicate. The survey tool in the workshop enables Gallup-type surveys. There is also a WWW editor for students to write their research reports for the net. [Figure 2] shows an example of a research report completed through a project among students. The survey page allows students to carry our questionnaire surveys to which other students may respond. The questionnaires may consist either of multiple choice or preference questions. The material obtained from the responses can be examined and stored for later use and may be used as a baseline for several Pythagoras exercises. On the basis of the data obtained from the survey the students may write a research report. For making reports there is the WWW editor developed in co-operation with the KUOMA Pilot of the ETAKAMU Project (Leinonen 1998, Piiksi 1999). Using the WWW editor the students can write a research report, append to this the stored diagrammatic pictures and save the document in HTML format. The teacher may as his/her discretion publish the best reports in the exhibition space.

The Pythagoras teachers' lounge is an area intended for teachers only. It contains discussion and chat tools comparable to those in the workshop. There is also a tool for monitoring and managing students' achievements.

**Teaching experiment**

**General**

The first Pythagoras teaching experiment under the OLE Project was carried out in spring 1999. The purpose of the experiment was to investigate how users reacted to the new user interface and to the numerous new features. The teaching experiment was carried out in the Hypermedia Laboratory's own computer classroom that enabled us to...
collect data with various technical tools. Those participating in the experiment were students from the ninth class of the Teisko Secondary School.

Research methods

Data on the Pythagoras teaching experiment were collected by questionnaire, by video and by participative observation. Students’ background information and opinions and experiences were ascertained by the questionnaire. The questions on the questionnaire were formulated on the basis of the various elements used in the experiment. The questions were in the form of positive or negative statements to which the students responded on a scale of 1 to 5, where 5 corresponded to ‘agree entirely’ while 1 corresponded to ‘disagree entirely’. A total of 15 students responded. One computer screen was taken on video using a direct connection to the display driver card. Using the video data an attempt was made primarily to ascertain the usability of Pythagoras. A great deal of data was also obtained by interviewing course instructor Pauli Koivula.

Results of the experiment

A questionnaire was used to gather background information on the students participating in the Pythagoras teaching experiment. Most of the respondents were fairly neutral regarding the study of mathematics, but most of them considered mathematics important as a subject of study. Most of the respondents reported that they found mathematics difficult. More than half the respondents used the computer regularly and almost half made abundant use of the Internet. Most of those taking part in the experiment stated that they were glad to be involved. The usefulness of Pythagoras in the study of statistical mathematics was elicited in two questions formulated in rather different ways. The students reported that Pythagoras helped in the study of statistical mathematics compared to conventional methods. Almost all respondents reported that Pythagoras was easy to use. The most important feature to be investigated in the questionnaire was the survey tool and the production of the research report with the help of the WWW editor. The students reported that responding to questions was both easy and pleasant. While many did not consider making one’s own survey difficult and found using the WWW editor easy, several needed guidance in using these features. The respondents reported that it was pleasant to make one’s own questionnaire. Students’ opinions on the interesting nature of the Pythagoras exercises were neutral. On the average the exercises were considered difficult.

The video material gathered in the teaching experiment was of use particularly in improving the usability of Pythagoras. Examination of the recorded data revealed several different problems with the user interface. One salient feature here was that the students needed some considerable time to realise which of the tasks was baseline information and which required input on their part.

Certain technical problems emerged in the experiment; they were connected to the fact that the Netscape's Java virtual machine appeared to periodically forget the 'garbage collection', thereby causing superfluous information to accumulate in memory, culminating in the collapse of the browser. This was not a major problem as it occurred on one computer at most a couple of times in the course of the experiment.

Commercialization of Pythagoras

General

The Pythagoras pilot ended at the end of January 2000. It has been installed to the server of Edita Ltd, where it is to be marketed to various educational institutions as an educational product. In the course of the research during 1999 Pythagoras was modified to meet the needs of commercialization. We now consider commercialization from the perspective of education and software technology.

Technical considerations

The commercialization of a learning environment does not significantly differ from the commercialization of any other net environment as far as the technology is concerned. Commercialization should be taken into consideration already at the point at which the definition of the software is made. Due to the nature of the software development work, however, this is not always possible. Certain factors should nevertheless be born in mind in the planning of
any software at all. The most important of these are probably the definition of user identification and use session concepts at an early stage. It is frequently problematic and time-consuming to insert user identification into an existing environment. These concepts are the basis in planning the remunerations system.

It was decided to create the remuneration system of Pythagoras in such a way that users can purchase user rights for a specified duration. The system does not require the measurement of actual time of usage, thus there was no need for a particularly complex use session system. It was decided to base user rights on teaching groups, which is most convenient for the action model of a normal school.

It was felt desirable to create an automatic ordering system for Pythagoras to be connected to the Edita Netmarket already in use. The function of the ordering system will be to receive orders and also to create user identities, teaching groups and other technical settings for each order. In practice the system was realised in such a way that the customer completes a form in Netmarket. Netmarket sends information on this to Pythagoras, which accepts the order. Next the customer can register his/her order and select user identities and passwords in Pythagoras. This way the customer gets the identities s/he wants, which is a major aid to their memorability. The registration of the order is accomplished in such a way that it reminds several Windows users of the familiar programme installation wizard.

**Pedagogical considerations**

Commercialization also entails attention to pedagogical considerations. There is frequently far too few instructions in surprisingly many net environments. At the development stage instructions are frequently felt to be superfluous as using one’s own product generally seems fairly straightforward. At the commercialization stage the need for instructions becomes more pronounced, as the users usually lack that internalised model of the use of computer systems which is characteristic of professionals. The interface of a new system must be designed according to some familiar model, or then a new and possibly better model must be learnt. Learning the new model is best achieved through detailed instructions for use. A learning environment product also needs a teacher’s guide. A net product is something of an innovation for teachers and they need instructions as to what can be done in the learning environment and how to time the course using the learning environment. A teacher’s guide has been compiled for Pythagoras by a group of teachers (Paivi Portaankorva-Koivisto, Riikka Uotila, Pauli Koivula).

**Conclusions**

**Application of WWW technologies to the construction of teaching tools**

The construction of an interactive learning environment for the net is still a fairly technically demanding task. The cornerstone on which the technical realisation of Pythagoras principally rests is Java language, which nowadays offers all the necessary tools to produce WWW systems. The latest additions to Java, RMI and Servlets provide the more manageable technology as regards software technology for the realisation of WWW systems than systems realised with the traditionally variable script languages. The greatest stumbling block with Java technology is the browser programmes' virtual machines' poor accomplishment of the Java applets.

**Using the net as a teaching tool**

It can be stated on the basis of the results of the Pythagoras teaching experiment that using the net as a tool for study has considerable advantages over conventional study. Although several experiments with the net for teaching purposes have been fairly biased towards learning materials, it is clear that using the net is beneficial, for example, in doing groupwork. The greatest advantages of groupwork over the net are that those participating need not be in the same place, or even work at the same time. In Pythagoras the question tool is a good example, which would be difficult to arrange without the use of the net.

ADP and using the net also makes it possible for students to study with materials they themselves have produced. For example, the responses to the Pythagoras questions can be used both for research reports and as starting values for exercises.

Distance learning creates new prospects for study. It is no longer important where the studying is done; the main question is rather how to study in a manner convenient to oneself. However, although distance learning makes
individual study possible, it should be born in mind that students need interaction with the teacher and other students.

Abstract: In this paper, we lay down the foundations to produce a framework for the design of distributed collaborative environments, such as virtual laboratories. We first propose a design methodology based on a generic model of virtual laboratory and a telecommunications platform. This methodology integrates six steps corresponding to the same number of models to be generated. The generic model is founded on a hierarchy of concepts for which the terminal nodes collectively and formally define the notion of virtual laboratory. The telecommunications platform supports a series of specific virtual laboratories and provides users with transparent access to the entire environment, in spite of possible heterogeneity of the access networks. It accounts for such issues as security, interoperability, and quality of service.

Introduction

For several years, education levels have been increasing in our society. A higher proportion of the population also reaches the level of post-secondary education. There is also an increase in the demand for on-going training, caused in part by the many technological breakthroughs of recent years. However, these same technologies, those related to computing and telecommunications in particular, lower some training related constraints such as physical presence, fixed schedule, etc. (Collis 1999) Fully virtual learning institutions are starting to appear. (Finley 1999)

Problem Definition and Basic Concepts

Instructional content delivery in electronic format (Azuma 1999) as well as distant courses (Harris 1999, Takefuji et al. 1999) are applications of these technologies that are increasingly common. They are already subject to systematization effort. Design and implementation of on-line laboratory activities, however, are only starting to benefit from such an effort which involves information technologies. Such an enterprise requires a high knowledge level in these technologies as well as in cognitive sciences. As such, it is only pursued by a few privileged people, more as a craft than a science. Thus, there is a very present need for a well defined methodological approach to the design of distributed learning environment geared toward performing laboratory activities. These activities are a necessary ingredient in the pursuit of knowledge. We label as distributed virtual laboratories the subset of learning environments that enables such activities.

Several factors contribute to the use of virtual laboratories: lack of physical space, cost of real equipment, distance in terms of cost and time of travel, synchronous availability of learners and teachers, dangerous situations, etc. These factors are an incentive to share or simulate real laboratories and their resources (equipment, space, etc.).

Distributed virtual laboratories design constitutes a multidisciplinary problem which involves computer and information science, telecommunications, and cognitive sciences including instructional design. Indeed, an engineer, even with a solid knowledge base in computers and telecommunications, can not tackle this problem by himself/herself since he/she does not necessarily possess the cognitive sciences aptitudes needed for the instructional design of these learning environments. On the other hand, a simple pedagogy expert is not necessarily able to fully appreciate what is possible from a technological standpoint. This is exacerbated by the rapid advancement of the state of the art in computer science and telecommunications. Nor is he/she able to develop by himself/herself the computing environment under which the experiments and evaluations of his/her interest can be performed.
A similar line of thought can be applied to the specialists of a given discipline which is targeted by a specific laboratory, and to the designers of an environment enabling the creation of such a laboratory. Our role is that of the telecommunications and computer engineer. As such, we are primarily interested in the computer network distribution of the objects that constitute these environments, and not as much by the instructional aspects of the design of these environments. We tackle such problems as distance measurements and heterogeneous networks adaptation, in order to give other specialists access to a methodology, models, and computing tools. These enable the creation, exploitation, and evaluation of distributed virtual laboratories in a given respective disciplinary field.

State of the Art

At this point in time, we can already witness a proliferation of virtual laboratories, at least from what can be seen on the accessible part of the Internet. The real count of such laboratories must be even higher since it includes companies and militaries.

Some of these laboratories include Java applets aiming to reproduce phenomena that are of interest to students of the targeted discipline. Others aim to reproduce the very sensation of physical presence in an equivalent and real environment. Others are implemented with 3D rendering technologies such as the Virtual Reality Modeling Language (VRML, which is open) and Shockwave (which is proprietary). Others still enable distant access to real physical instruments.

The LVEST project, to which we have contributed, uses an approach which separates these concepts: the generic laboratory and the telecommunications platform. Each laboratory that uses this approach includes a specific part and a generic part. Access to the telecommunications functionalities is provided through the telecommunications platform (Kassouf et al. 1999, Pierre & Kassouf 2000), which is composed of three layers:

- the tools and functionalities adaptation layer;
- the base tools and functionalities layer;
- the network adaptation layer.

One of the objectives of this platform is to abstract the distribution and telecommunications aspects related to implementation details. This is done in order to simplify the development task for a virtual laboratory from the point of view of anyone that is not a specialist. The project itself involves a number of specialists from a host of disciplines.

Development of the generic laboratory and telecommunications platform models is done using an inductive process. This means that the initial content of these models reflects the needs of two first laboratories to have been implemented using this process (in Physics and Electrical Engineering). Each new laboratory both inherits from these models and contributes to their enrichment.

With only two laboratories, the effective definitions of "generic" and "specific" were rather trivial. They basically amounted to the idea of commonality. However, now that this project includes a third laboratory in computer engineering and that many others are planned in several domains of several disciplines, care must be taken to properly generalize these notions. If this was not done, the development of a new laboratory from a generic model would demand more effort rather than reduce it. This would be attributable to the necessary evaluation of how appropriate the use of each offered generic functionality would be. Conversely, a most restrictive definition of the word "generic", aiming to reduce the generic functionalities count, would exclude to many functionalities that are common to only a few laboratories. Such a generalization has not been tackled before.

Design Methodology

The basic principle of the design methodology consists of defining a set of attributes, tools, and functionalities shared by a variety of virtual laboratories dedicated to a variety of science and engineering disciplines. The distributed processing and access aspects of implementing the telecommunications platform imply a number of challenges related to security, interoperability, and quality of service. We now expose them.
Security

Indeed, in an open environment, users should not only benefit from the possibility to exchange information between one another, but also have the possibility to transfer and download content which is subject to a controlled usage. In such a context, securing those transfers is of a primordial importance and this should be reflected in the very process used to design virtual laboratories.

Interoperability

Likewise, there is a matter of interoperability between heterogeneous networks and communication supports that can be used to access the laboratory environment. It must be taken into account as well in the virtual laboratories design process and methodology. In our prototypes, we have investigated the use of CORBA and the capacity to support interoperability between Internet protocols and xDSL technology. We conclude that, in order to address this specific problem, a proposed design methodology must include one step dedicated to networks and supports adaptation at the level of the telecommunications platform.

Quality of Service

As for quality of service, the main concern is the delay to access, transmit, and display the (possibly multimedia) information that is exchanged in this type of environment (Campbell et al. 1994, Ren et al. 1999, Schwartz & Beaumont 1994). This aspect deserves particular attention in the context of virtual laboratories where interactive simulation, telemesure, and tele-experimentation are among the considered approaches and methods.

The three challenges we just exposed are accounted for in a distribution model. Its implementation constitutes one of the later steps in a design methodology for distributed virtual laboratories. This methodology, as well as its associated models, must be supported by software tools which reduce the design and implementation effort asked of the discipline or domain specialists. Some of these tools have already been developed as part of the LVEST project (Télé-université 1999). Other such tools are now in development and will contribute to further enrich our telecommunications platform.

Generic Model

A generic virtual laboratory model should be general enough to cover any virtual laboratory.

The set of all sciences and engineering disciplines can be considered finite. It forms a partition. A single discipline is composed of several domains, each of which is characterized by an experimentation environment that includes tools and functionalities used to define and implement laboratory sessions.

Some of these tools and functionalities are domain-specific, while others can be used universally, i.e., in several domains, even disciplines. The latter are called basic tools and functionalities.

Each domain enables experiments of various types to be performed. For a given domain, the set of experiments that can be performed can be considered finite. The set of all experiments that can be performed for a given discipline forms a partition.

Each laboratory experiment enables the practice of one or more theory elements from a given domain. These theory elements are prerequisite to performing the laboratory session. Therefore, a laboratory session can be defined as a set of experiments of various types, performed in a given environment, linked to a specific domain of a specific discipline, and forming a coherent ensemble.

For a given discipline, a virtual laboratory is defined as a distributed learning environment which enables laboratory experiments to be performed. Those experiments can eventually be grouped to form a session. They can be related to one or more domains of the discipline. In fact, we can define a laboratory as a triplet consisting of
1. the discipline specification,
2. the set of all experiments that can be performed for this discipline, and
3. a family of transformations related to the domains of the given discipline.

This family of transformations can be seen as a didactic engineering process which transforms knowledge elements of a given domain into a series of experiments.

To recapitulate, the generic model is founded on a hierarchy of concepts which terminal node is the notion of virtual laboratory. The basic concepts included in this hierarchy are: the discipline, the domain, the environment, the laboratory session, the type of experiment, the experiment, and the virtual laboratory.

Design Methodology Elements and their Respective Models

It follows that, in order to design a virtual laboratory in any sciences or engineering discipline, each of the basic concepts of the generic model must itself be modeled (Levert & Pierre 2000). They include the discipline, the domain, the environment, the laboratory session, the experiment, to which we add the concept of distribution (access, interaction, interface, interoperability, and security).

Discipline

Disciplines are located at the top of our basic concepts hierarchy since we do not intend to reassess the different discipline constellations (called knowledge fields by specialists) in use. Examples of these knowledge fields include those formed by an university’s faculties, the many contests of a grant body, etc.

The discipline modeling should produce a list of domains that is specific to it. In practice, the discipline’s evolution makes this list variable in time and possibly according to the place where it is considered. Thus, we have to explore how it will be possible to evolve this list as time passes, either by simple insertion and deletion, or by repartitioning the discipline.

Computer engineering is an example of discipline. It includes, among others, the following domains: algorithmic complexity, design and analysis of algorithms, database management, knowledge management, networking, infograpgy, multimedia, and software engineering (NSERC 1998, NSERC 1997). We can readily see that this list is not exhaustive; this shows the difficulty of producing such an exhaustive list, but it also shows the possibility of working with an incomplete list if it suffices to fill all the needs.

Domain

The domain modeling mainly includes a knowledge representation (Paquette et al. 1996). In addition to the possibility of laying them out on a learning curriculum, these elements can be classified using, for example, the cognitive levels of the Bloom taxonomy (Michalski & Stepp 1983).

The elements from this possibly structured knowledge set should lend themselves to a mapping with laboratory experiments. It does not necessarily follow that the most appropriate classification and structure for these knowledge elements will correspond to that used for the laboratory experiments (whether it is based on a laboratory session grouping or a laboratory type grouping). However, there can be a gain to forcing such a mapping. This is an open question.

Computer networking is an example of domain, in the context of the computer engineering discipline.

Environment

The environment model should account for all elements that can constitute an environment, and also for all relations that exist between those elements. This includes material resources (computers, networks, etc.), the place where they are located, as well as the human beings involved in the learning process (learners and teachers). The possible
relations between humans are represented by the availability of communication and collaboration tools, as well as by the formation of teams and the learners/teachers ratio. All others ratios between humans and material resources should be modeled. Five spaces can be defined and all elements should fall in exactly one of them: production, help, collaboration, information, and navigation spaces.

The environment is the concept which holds the tools and functionalities. Thus, it is at this conceptual level that the generalization of the genericity and specificity should be applied. This should result in a hierarchical classification of these tools and functionalities. Whether all others elements and relations found in an environment should be included in this framework is an open question. This would allow an advantageous simplification of the environment model.

Laboratory Sessions

A laboratory session is composed of a subset of experiments from the target domain. The laboratory session modeling describes the learning scenarios which are used, categorizes and plans didactical instruments and identifies where an analysis of interactions could take place (Paquette 1998).

Experiments

The experience model should specify the type of experimentation which is performed. Each experiment corresponds to some knowledge and aptitudes which should be transmitted, as described in domain modeling. An experiment takes place in a learning curriculum.

It can sometimes be advantageous to be able to record or reproduce the progress of an experiment, whether for learning evaluation or other purposes. The model must account for this since it will translate in resources needed to its implementation. The nature, moment, and requirements (e.g., temporal requirements) of the various data processing stages must be taken into account for has a strong influence on the computing distribution model which is used.

Distribution

The distribution model should first represent the different computing and networking components which are available. In particular, all aspects having to do with security, interoperability, and quality of service must be represented.

These components can be used in different possible configurations. From this information, an algorithm is devised to produce an optimal scenario for the distribution and interconnection of objects.

The very ideal of optimization implies modeling the various costs involved by the operations performed in a given configuration. They include: the cost of processing power the cost of code transmission (throughput), the cost of data copying, the cost of data transmission (throughput), the cost of configuration computation, the cost of dynamic configuration changes, the cost of data marshalling and other transformations (such as those involving security), the cost of data storage.

In practice, identifying generic characteristics among several laboratories should help reduce the complexity of the mathematical and algorithmic problems created by this modeling.

Concluding Remarks

In order to produce tools that can help develop distributed learning environments, we must first be able to determine the main axes along which their variants can be distinguished. More precisely, we must identify those characteristics that are pertinent to that goal and drop those that are not. Putting this in practice, however, is not obvious. Virtual laboratories and other learning environments developed so far form a rather disparate set from which it would be difficult to extract the principal characteristics. Rather than designing an unflexible and definite characterization from the get
go for everything that has been or will be developed, we plan to apply the conceptual clustering technique (Michalski & Stepp 1983) to existing environments and to those whose existence can be predicted.

This clustering technique can be applied to all levels (or elements) of the design methodology: from domain to individual experiments. It is used to determine if it is cost effective to make a tool generic or keep it specific. To use this technique, we must identify quality criteria for the clusters. These are used to discriminate against several possible clusters. The actual concepts that are used by one clustering reveal themselves as the technique is applied. The concepts and tools described so far are applied as they are developed to a virtual laboratory prototype in the computer engineering discipline.

A Meta-analysis of Computer Programming on Cognitive Outcomes: An Updated Synthesis

Yuen-kuang Cliff Liao
Department of Elementary Education, National Hsinchu Teachers College
521 Nan-Dah Road
Hsinchu City, Taiwan, R. O. C
yliao@mail.nhctc.edu.tw

Abstract: The improvement of higher order thinking skills continues to be an important issue in education. Over the past 10 years, two meta-analyses on the issue of computer programming and problem solving ability have been done. Yet, there is no meta-analysis conducted to clarify the issue of programming and problem-solving abilities since 1989. The purpose of this study is to continually investigate the issue of programming and problem solving ability. More specifically, this meta-analysis attempted to update the research findings from 1989 to 1999 in the area of computer programming and problem solving. The results from this study suggest that the outcomes of learning a computer language extend beyond the content of that specific computer language. Students are able to acquire some cognitive skills such as reasoning skills, logical thinking and planning skills, and general problem solving skills through computer programming activities.

Theoretical framework and purpose of study

For well over a quarter of a century there have been urgent calls for improved instruction in problem solving. There is ample evidence that the problem-solving skills of the nation's children need significant strengthening, yet existing approaches to develop and improve these skills do not seem to have worked (Casey, 1997). The link between the learning of programming language and the development of problem solving skills has been one of the most intensely argued topics in educational computing (Reed & Burton, 1988). The research findings, however, are conflicting. Some studies report significant gains in various aspects of cognitive abilities following programming experiences (Choi & Repman, 1993; Liu, 1997; Reeder, 1994). Other studies have indicated that there is little, if any, transfer of learning from the programming situation to similar non-programming tasks (Lai, 1993; Palumbo, 1993).

Over the past 10 years, two meta-analyses on the issue of computer programming and problem solving ability have been done. Liao and Bright (1991) conducted a meta-analysis on the effects of computer programming on cognitive outcomes. Their analysis covered the research published between 1969 and 1989. Sixty-five studies were included in their analysis, and the results indicated that the percentiles on students' cognitive performance were 66 for the programming group and 50 for the non-programming group; computer programming has slightly positive effects on student cognitive outcomes. Another meta-analysis conducted by Lee (1990) investigated the effectiveness of computer-assisted instruction and computer programming in the area of problem solving skills, math, and attitudes toward mathematics instruction. Seventy-two studies were included in his analysis, and the results showed that Logo was found to be more effective than BASIC in developing problem solving skills.

The improvement of higher order thinking skills continues to be an important issue in education, yet, there is no meta-analysis conducted to clarify the issue of programming and problem-solving abilities since then.

The purpose of this study is to continually investigate the issue of programming and problem solving ability. More specifically, this meta-analysis attempted to update the research findings from 1989 to 1999 in the area of computer programming and problem solving. The results from this meta-analysis will help provide clearer conclusions.

Procedures

The research method used in this study is the meta-analytic approach which was similar to that described by Glass, McGaw, & Smith (1981). Their approach requires a reviewer to (a) locate studies through objective
and replicable searches; (b) code the studies for salient features; (c) describe outcomes on a common scale; and 
(d) use statistical methods to relate study features to outcomes (Kulik, Kulik, & Bangert-Drowns, 1985).

The purpose of this study was to synthesize and analyze the research on effects of two instructional 
approaches. It is important to define these approaches to provide for proper selection of appropriate studies.

computer programming instruction -- classes using computer languages, such as Logo, BASIC, Pascal as an 
instructional tool to teach students.

non-computer-programming instruction -- classes not using any computer programming as an instructional 
tool to teach students.

Data Sources

The studies considered for use in this meta-analysis came from three major sources and published between 1989 and 1999. One large group of studies came from computer searches of Education Resources Information Center (ERIC). A second group of studies came from Comprehensive Dissertation Abstracts. A third group of 
studies was retrieved by branching from bibliographies in the documents located through review and computer 
searches. Twenty-two studies were located through these search procedures; 3 studies came from ERIC, and 19 
studies were retrieved from published journals.

Several criteria were established for inclusion of studies in the present analysis.

1. Studies had to assess the relationship between computer programming and cognitive skills such as 
   planning skills, thinking skills, reasoning skills, and metacognitive skills.

2. Studies had to take place in actual classrooms. These was no restriction on grade level.

3. Studies had to provide quantitative results from both computer-programming and non-computer-
   programming classes.

4. Studies had to be retrievable from university or college libraries by interlibrary loan or 
   from ERIC, Dissertation Abstracts International, or University Microfiche International.

There were also several criteria for eliminating studies or reports cited by other reviews: (a) studies did not 
report sufficient quantitative data in order to estimate Effect Sizes; (b) studies reported only correlation 
coefficients -- r value or Chi-square value; (c) studies could not be obtained through interlibrary loans or from 
standard clearinghouses.

Outcomes Measures

The instructional outcome measured most often in the 22 studies was student learning, as indicated on 
standard cognitive-skill tests at the end of the program of instruction. For statistical analysis, outcomes from a 
variety of different studies with a variety of different instruments had to be expressed on a common scale. The 
transformation used for this purpose was the one recommended by Glass et al. (1981); each outcome is coded as an 
Effect Size (ES), defined as the difference between the mean scores of two groups divided by the standard 
deviation of the control group. For those studies that did not report means and standard deviations, F values, t 
values, or proportion values were used to estimate the ES.

In most cases, the application of the formula given by Glass and his colleagues was quite straightforward. 
But in some cases, when more than one value was available for use in the formula of ES, the value, which 
measured outcomes most correctly, was selected.

In addition, when studies used more than one type of control group (e.g., programming vs. CAI and 
programming vs. non-programming), only the comparison of programming and non-programming was retained. 
Also, when studies contained reports of experiments where treatments were compared with each other and no 
non-computer control group was involved (e.g., programming vs. CAI), Glass et al. (1981, p.124) proposed a 
process to split the ES into two components to estimate comparisons of each treatment to a hypothetical control 
group (e.g., programming vs. non-programming and CAI vs. non-CAI). In other cases, several subscales and 
subgroups were used in measuring a single outcome (e.g., those that reported separate data by language or 
grade). In such cases, each comparison was weighted in inverse proportion to the number of comparisons within 
the study (i.e., 1/n, where n = number of comparisons in the study) so that the overweighting of ES of a study 
could be avoided (see, for example, Waxman, Wang, Anderson, & Walberg, 1985, p. 230).

Variables Studied

Seventeen variables (i.e., sample size, type of publication, year of publication, grade level, 
instrumentation, instructor bias, reliability of measure, selection bias, statistical power, statistic, type of research 
design, language studied, instructional approach, duration of treatment, type of instructional for treatment,
implementation of innovation, and type of outcome) were selected for coding each study in the present synthesis. Each variable was employed as a factor in an analysis of variance (ANOVA) to investigate whether there are significant differences within each variable on the effect size.

**Results**

The number of comparisons, target population, and the study-weighted ESs are reported in Table 1. Of the 22 studies included in the present synthesis, all of the study-weighted effect sizes were positive and favored the programming group. The range of the study-weighted effect sizes was from 0.04 to 3.7. The overall grand mean for all 22 study-weighted ESs was 0.76. When this mean ES was converted to percentiles, the percentiles on students' cognitive performance were 66 for the programming group and 50 for the non-programming group. The standard deviation of 0.78 reflects the great variability of effect sizes across studies.

Overall grand median 0.498
Overall grand SD 0.781

Note. Total N of studies = 22. Total N of comparisons = 86

*Two Separated studies reported in one article.

Among the 86 effect sizes included in the present synthesis, 74 or 86% were positive and favored the programming group, while 12 or 14% were negative and favored the non-programming group. The range of the effect sizes was from -0.17 to 1.45.

Table 2 lists the F values for the 17 variables for all study-weighted ESs in the study. For ANOVAs, two variables showed statistically significant impact. For each of these variables, a post hoc (Fisher Protected LSD) test was performed. Descriptive statistics for these variables are presented in Table 3.

Discussion

The results of this meta-analysis indicate that computer programming has moderate-to-high positive effects on student cognitive outcomes; an effect is said to be small when ES = 0.2, medium when ES = 0.5 and large when ES = 0.8 (Cohen, 1977). One hundred percent of positive study-weighted ES values and 88% of positive ESs overall confirm the effectiveness of computer-programming instruction. The overall mean ES of 0.76 was much higher than Liao and Brights' (1991) meta-analysis, in which the overall mean ES was 0.41. The great differences of ES between these two meta-analyses possibly because new programming languages such as HyperCard are easier to learn, or perhaps teachers have found more effective approaches using computer programming to enhance students' cognitive abilities.

For the analysis of coded variables, the greater ES associated with the posttest control group design was interesting. However, there were only 2 studies coded as this design, this result may be somewhat unstable.

For type of outcome, the larger ES was connected with conceptual transfer, possibly because there are some differences between conceptual transfer and other types of cognitive outcomes such as critical thinking and problem solving abilities. Yet, there were only two studies measured conceptual transfer, the result may be considered tentative.

Conclusions

The results from this study suggest that the outcomes of learning a computer language extend beyond the content of that specific computer language. Students are able to acquire some cognitive skills such as reasoning skills, logical thinking and planning skills, and general problem solving skills through computer programming activities. Since fostering students' cognitive abilities is usually part of our educational goal, the results provide to teachers a mildly effective approach for teaching students cognitive skills in the classroom setting.
unanswered is the question of whether computer programming is as efficient, or any more efficient, at developing these cognitive abilities than other possible instructional approaches that teachers might use. Studies of this question will require further clarification of the exact nature of the cognitive abilities most likely to be developed through programming. This meta-analysis points out only that improvements in cognitive outcomes are possible. That information by itself is useful.
A Meta-analysis of Gender Differences on Attitudes toward Computers for Studies Using Loyd and Gressards' CAS

Yuen-kuang Cliff Liao
Department of Elementary Education, National Hsinchu Teachers College
521 Nan-Dah Road
Hsinchu City, Taiwan R. O. C
yliao@mail.nhctc.edu.tw

Abstract: A meta-analysis was performed to synthesize gender differences on attitudes toward computers for studies using Loyd and Gressard's CAS. Twenty-eight studies were located from three sources, and their quantitative data were transformed into Effect Size (ES). The overall grand mean of the study-weighted ES for all 28 studies was 0.273. The results suggest that gender differences on attitudes toward computers exist, however, the differences are small. Left unanswered is the question of what factors truly contribute to the differences. Studies of this question will require further clarification of the exact characteristics of each type of computer attitude (i.e., anxiety, confidence, liking and usefulness) and their relationships with gender. This meta-analysis points out only that gender differences on attitudes toward computers exist. That information by itself is useful.

Theoretical framework and Purpose of Study

Computer use and skills has been portrayed in our society as more appropriate to men and boys than women and girls (Whitley, 1997). Computer games and educational software have been designed to appeal more to boys than girls (Kiesler, Spreull, & Eccles, 1985). Computer use in schools has also been linked to traditionally 'masculine' subjects such as science and mathematics but not to traditionally 'feminine' subjects such as art and literature (Hawkins, 1985). In fact, research has shown that males use computers more often (Chen, 1986; Cole, 1997; Shashaani, 1994; Sutton, 1991; Urban, 1986), in more places (Chen, 1986; Culley, 1988; Sanders, 1985; Shashaani, 1994), and for more purposes (Chen, 1986; Martinez, 1988; Riggs, 1994) than do females. Furthermore, many studies also reported that males take more classes in school in which computers are used than do their female counterparts (Chen, 1987; Cole, 1997; Shashaani, 1994; Sutton, 1991; Urban, 1986); males use computers more frequently in their recreational time (e.g., after school clubs, summer camps, and at-home use), and stay on computers for a longer time than females (Joiner, 1996; Shashaani, 1994). These gender differences in socialization and computer-related behaviors have led to the hypothesis that women and girls are more likely to hold more negative attitudes toward computers.

Although many studies have been conducted to examine the hypothesis of gender differences on computer attitudes (Campbell, 1988; 1989; Chen, 1986; Koohang, 1989; Loyd & Gressard, 1986; Meier, 1988; Wallace & Sinclair, 1995; Woodrow, 1994), the results of existing studies have reported a confusing picture. For example, Campbell (1990), Chen (1986), Colley, Gale, & Harris (1994), Jacobson (1991), Loyd & Gressard (1986), Wallace & Sinclair (1995), Whitley (1996a;1996b), and Woodrow (1994) all reported significantly higher positive computer attitudes for males than females, while Campbell (1986;1989), Cantrell (1995), Chu & Spires (1991), Francis (1994), Koohang (1987;1989), Loyd & Gressard (1985), Loyd, Loyd, & Gressard (1987), Mertens & Wong (1988), Pope-Davis & Twing, and Robertson, Calder, & Jones (1995) have indicated that there is little, if any, differences of computer attitudes between males and females. In addition, Kay (1992) based upon a meta-analysis described the results of this research as "conflicting and confusing."(p.227) Rosen and Maguire (1990) concluded on the basis of a meta-analysis that gender differences on computer attitudes were real, but small. A more recent meta-analysis on this issue conducted by Whitley (1997) also reported that the overall effects were "nonsignificant or small." (p.11)
Whitley (1997) proposed a possible explanation for the confusing picture in the computer attitude literature. He argued that many researchers treat attitudes toward computers as a unitary construct rather than multifaceted construct. The variety of computer attitudes scales that have been developed and their differing content suggest that computer-related attitudes are indeed multifaceted, including components such as anxiety about using computers, self-confidence in dealing with computers, and the positive and negative beliefs about computers and their effects on society (Whitley, 1997). Gender differences exist on one component in one computer scale may vary in another computer scale, depends on what questions are asked. Therefore, a meta-analysis synthesizes gender differences for results from studies using varied computer-related scales may not only obtain confusing picture, but also produce unexpected confounding conclusion. To avoid this, the purpose of the present meta-analysis was to synthesize the results of existing studies on gender differences toward computer attitudes using Loyd and Gressards' Computer Attitude Scale (CAS). The results of this meta-analysis may provide clearer conclusion on this issue.

Procedures

The research method used in this study is the meta-analytic approach which was similar to that suggested by Kulik, Kulik, & Bangert-Drowns (1985). Their approach requires a reviewer to (a) locate studies through objective and replicable searches; (b) code the studies for salient features; (c) describe outcomes on a common scale; and (d) use statistical methods to relate study features to outcomes (Kulik, Kulik, & Bangert-Drowns, 1985).

Data Sources

The studies considered for use in this meta-analysis came from three major sources and were published from 1986 to 1998. One large group of studies came from computer searches of Education Resources Information Center (ERIC). A second group of studies came from Comprehensive Dissertation Abstracts. A third group of studies was retrieved by branching from bibliographies in the documents located through review and computer searches. Twenty-eight studies were located through these search procedures; 8 studies came from ERIC, 16 studies were retrieved from published journals, and 4 studies were from Comprehensive Dissertation Abstracts.

Several criteria were established for inclusion of studies in the present analysis.
1. Studies had to compare the differences between males and females on attitudes toward computer.
2. Studies had to use Loyd and Gressard’s Computer Attitude Scale (CAS) as instrument.
3. Studies had to provide quantitative results from both male and female subjects.
4. Studies had to be retrievable from university or college libraries by interlibrary loan or from ERIC, Dissertation Abstracts International, or University Microfiche International.

Outcome Measures

The outcome measured most often in the 28 studies was survey data from participants, as indicated in CAS for examining participants’ attitudes toward computers. For statistical analysis, outcomes from a variety of different studies had to be expressed on a common scale. The transformation used for this purpose was the one recommended by Glass et al. (1981) and modified by others (e.g., Hunter, Schmidt, and Jackson, 1982). To reduce measurements to a common scale, each outcome was coded as an Effect Size (ES), defined as the difference between the mean scores of males and females divided by the pooled standard deviation of two groups. For those studies that did not report means and standard deviations, F values, or t values were used to estimate the ES.

Variables Studied

Nine variables were selected for coding each study in the present synthesis. These variables were nation of subject, target population, type of publication, year of publication, sample size, reliability of measure, statistical power, statistics, and type of attitude. Each variable was employed as a factor in an analysis of variance (ANOVA) to investigate whether there were significant differences within each variable on the effect size.
Results

The number of comparisons, target population, and the study-weighted ESs are reported in Table 1. Of the 28 studies included in the present synthesis, 24 or 86% of the study-weighted ESs were positive and favored the male subjects, while 4 or 14% of them were negative and favored the female subjects, indicating that males had more positive attitudes toward computers than females. The range of the study-weighted ESs was from -0.407 to 0.772. The overall grand mean for all 28 study-weighted ESs was 0.273. When this mean ES was converted to percentiles, the percentiles on computer attitudes were 61 for the male subjects and 50 for the female subjects. The standard deviation of 0.284 reflects the small variability of ESs across studies.

Table 1: Number of Comparisons and Study-weighted Effect Sizes

Table 2 lists the F values for the 9 variables for all study-weighted ESs in the study. The positive means indicate more positive attitudes toward computers favor male subjects. For ANOVA, 2 variables, sample size and type of attitude, showed statistically significant impact. Descriptive statistics for these variables are presented in Table 3.

For sample size, (\(F(3, 24) = 3.075, p<.05\)), the post hoc test showed that the mean comparison of studies with
101 – 200 participants was significantly higher than studies with 201 – 300, or over 300 participants.

The post hoc test for type of attitude, \( F(4, 76) = 4.864, P<.01 \), showed that the mean comparison of studies that measured anxiety was significantly higher than studies that measured liking. In addition, the mean comparison of studies that measured mixed attitudes was significantly higher than studies that measured other types of attitudes.

### Discussion

The results of this meta-analysis indicate that gender differences on computer attitudes exist, males have slightly positive attitudes toward computers than females; however the differences are small. An effect is said to be small when \( ES = 0.2 \), medium when \( ES = 0.5 \), and large when \( ES = 0.8 \) (Cohen, 1977). Eighty-six percent of positive study-weighted ES values and 78% of positive ESs overall also confirm the males' positive attitudes over females. The slightness of the differences must keep in mind, however; the overall study-weighted mean ES of 0.273 only indicates 11 percentile scores higher than the female subjects. The percentile scores for the overall grand mean and median were identical, possibly attributed to the small overall grand standard deviation (0.284).

The analysis of studied variables suggests some interesting trends in the accumulated research base and is
discussed in the following sections.

A comparative study of subjects from different cultures can supply valuable information, not only about the specific groups selected whose reactions toward computers, but also examine and compare the presence of computer in the context of two different cultures (Collis & Williams, 1987). The results of this synthesis indicate that studies using subjects from other countries had slightly higher ES than subjects from US. There may be some cultural bias, or difference in computer accessibility between US and other countries. The differences, however, were trivial; more cross-cultural studies need to be conducted to clarify this variable.

For the target population variable, there was no significant difference of mean ES. The fact that about 2/3 of studies conducted for college students seems to suggest that most researchers assumed that Loyd and Gressards’ CAS was more appropriate for this population. In addition, the mean ES slightly increased from K –12 to teacher/adult is not surprising. Studies have shown that, with age, males are increasingly more confident in their abilities to use computers and more positive in their attitudes toward computers than are females (Ayersman, 1996; Bunderson, 1995; Chen, 1986; Fetler, 1985; Hattie, 1987; Sackrowitz, 1995; Shashaani, 1994). The results of this meta-analysis were consistent with their findings.

Source of studies in a meta-analysis is always an important factor to be examined. The fact that more than half of studies were located from journal articles indicates that the majority of studies included in the synthesis have been critically reviewed by journal reviewers. The larger ES associated with Dissertation/thesis is atypical, however; usually the larger ES associated with published articles is typical in meta-analysis (Glass, et al., 1981, p. 227).

The year-of-publication variable in the meta-analysis allows an assessment of the effect of hypermedia over time. Although no significant difference of mean ES was found, the larger ES associated with studies published between 1995 – 1997 seems to suggest that gender differences on attitudes toward computers have become more observable recently.

The sample size for a study may significantly affect the statistical power of the study; in general, the larger the sample size, the better the statistical power. The sample sizes for about 54% of studies included in the synthesis were less than 200, and the higher mean ES was associated with these studies. For studies in which the sample size went beyond 200, the mean ES dramatically dropped to less than 0.2. This seems to suggest that the gender differences on computer attitudes may only be observed in small to medium sample size. Why the differences diminish in a larger sample size will be a critical question for researchers.

For reliability of measure, statistical power, and statistics, there was no significant difference of mean ES among them. This suggests that mean ES did not affected by the differences of characteristics of research methodology.

Gender differences in computer attitudes clearly varied as a function of type of attitude. The positive mean ESs indicate males had lower anxiety, and higher confidence, liking, and usefulness attitudes toward computers than females.

The mean ES for each subscale showed that gender differences on anxiety was higher than on liking, confidence, and usefulness, suggesting, males and females had small differences on anxiety, and trivial differences on computer liking, confidence, and usefulness. In addition, 4 studies did not report data for subscales and were coded as mixed. These studies showed highest mean ES (ES = 3.4). As a whole, he results somehow indicate that males hold more positive attitudes toward computers than females.

Conclusions

The present meta-analysis synthesized gender differences on attitudes toward computers for studies using Loyd and Gressards’ CAS so that confounding results could be avoided as stated earlier. The unique feature differs this meta-analysis from other meta-analyses on this issue. Although the results showed that the overall ES was small, the fact that the differences between males and females exist was obvious. This finding is consistent with earlier studies conducted by Rosen and Maguire (1990), and Whitley (1997). Left unanswered is the question of what factors truly contribute to the differences. Studies of this question will require further clarification of the exact characteristics of each type of computer attitude (i.e., anxiety, confidence, liking and usefulness) and their relationships with gender. This meta-analysis points out only that gender differences on attitudes toward computers exist. That information by itself is useful.

Abstract: This paper considers the impact of diverse staff development activities designed to assist faculty to integrate online media into the curriculum. An overview is given of the aims, objectives, activities and evaluation of the 1998-99 e.learning@mq project at Macquarie University. Influenced by diffusion theory and the characteristics of the early and late-majority's uptake of innovations, the author designed various activities for both local-area and university-wide settings. The patterns of participation reveal the varied activities attracted different groupings and numbers of faculty and administrative staff. At the completion of the project 91 participants self-assessed the project's impact on their understanding of the issues involved in using online media in learning and teaching. In nine specified areas of understanding 81% of the project participants have self-evaluated slight, moderate or significant improvement in awareness, knowledge and skills in using information technology and online media in their educational programs.

Introduction

Educational practices are intrinsically embedded into the prevailing dominant technologies of communication, knowledge creation and information dissemination. These tools, practices and processes are rapidly changing due to the rise of digital online media. Evermore publicity is appearing from global 'borderless' providers offering privatised and accredited educational services 'anytime anywhere'. Using 'online learning' and 'flexible delivery' these services are now available 'just-in-time' and tailored to meet your individual needs. The rhetoric exhorts that to remain relevant in an increasingly networked economy and society, education providers need to integrate online communication, activities and resources into their offerings.

To support these changes an important organisational strategy is effective staff development. This paper presents an overview of e.learning@mq, a 1998-99 project at Macquarie University that aimed to develop capacity to integrate information technology (IT) into learning and teaching. The project focused on the development of faculty, though activities were open to all Macquarie staff and interested visitors.

Influenced by diffusion theory and the characteristics of the majority's uptake of innovations, the author designed and implemented diverse activities and initiatives for local-area and university-wide settings. Diffusion theory argues that adoption of new technology and innovation starts with enthusiastic innovators and early-adopters and then moves to use by the early and late-majority when the innovation is better supported and more reliable. The characteristics of the majority to consider in the design of 'diffused' staff development include that they look to local and discipline-based ideas and practice, favour incremental change, are pragmatic and risk averse, want proven applications, and may need significant support (Rogers 1995, Geoghegan 1994).

e.learning@mq activities were designed to address these characteristics and provided staff with multifarious entry-points to engage with the issues of integrating online media into their educational programs. It was hoped the varied activities would attract different individuals and groupings of staff.

Project Aims and Objectives

Macquarie's IT Strategic Plan states that "successful integration of IT into a university environment requires radical shifts in thinking about all aspects of [its] educational vision". To support such integration the Center for Professional Development (CPD) successfully applied for an Australian Government 1998-99 CUTSD staff development grant.
The proposed project aimed to support the development and implementation of a coherent program of staff development to improve the capacity of faculty and units at the University to explore and introduce IT effectively into their educational programs. The successfully proposed objectives of the project were to;

1. raise the awareness of staff at all levels to;
   - the potential of IT to enhance and deliver educational programs across the disciplines,
   - the issues associated with the design and development of IT based curricula,
   - the issues associated with managing the development and integration of IT into the curriculum,
2. assist staff to strategically plan and set specific goals in relation to the introduction of IT,
3. assist staff to develop coordinated strategies for realising these goals,
4. assist staff to develop the knowledge and skills required to use IT in the curriculum.

Project Activities

The author's collaborative project management involved all the providers of IT support and facilities at Macquarie, together with many faculty early-adopters and invited quests, to convene and facilitate e.learning activities. In early 1998 as reference group was established with members from the CPD, the Centre for Flexible Learning (CFL) and the Macquarie Library's IT Training Unit (ITTU) to assist the development of a more cohesive approach to the project's activities.

Three co-ordinated programs of e.learning were implemented during each of the teaching semesters from August 1998 to December 1999 and included local-area and university-wide activities and initiatives. The project website at <www.cpd.mq.edu.au/e.learning> facilitated online bookings, discussion and feedback. The site includes full descriptions of all the project activities with some handouts and transcriptions from events. The site was designed to model a simple yet functional and effective online media resource.

Local-area Peer Development Projects

The successful e.learning@mq grant application proposed to establish IT peer development groups in local areas to develop discipline-specific approaches to their educational programs and to foster continuing exploration and debate. The author designed a competitive grant scheme for teams to research localized IT issues. To receive funds the team-leaders had to establish a local-area team and propose a plan to research an appropriate IT issue and then convene appropriate peer development activities for their colleagues. To provide an incentive for team-members to become involved funding was available for time-relief and other minor expenses.

In late 1998, three workshops supported the development of project proposals to include a concept, rationale, objectives, timeline and budget. A selection committee decided that nine from a total of 15 submitted proposals could be funded from the e.learning@mq grant. These nine local-area projects were implemented during 1999 and early 2000;

- 'How to use computer-mediated-communication in european languages' in the School of European Languages,
- 'Getting with IT! A structured IT core competencies program for staff' within the Macquarie Library,
- 'Using IT strategies for communication between on-campus lecturers and mentors of students' within Warawara, Macquarie's Aboriginal and Torres Straight Islander (ATSI) Centre,
- 'IT supported unit delivery facilitation' in the Institute of Early Childhood,
- 'Individualised IT support and training' in the School of Biological Sciences,
- 'How to use WebCT for creating online english language learning modules' in the National Centre for English Language Training and Research,
- 'Moving beyond the still frame -multiskill with multimedia' within the Macquarie Library,
- 'IT training for flexible courses' in the School of Asian Languages,
- 'Teacher Education website project' in the School of Education.

University-wide activities

The e.learning@mq application proposed to improve awareness, knowledge and skills about integrating IT into the curriculum with "one-off" and "short-term" activities. This prescription required
considerable elaboration and the author planned five types of university-wide activities, which were then collaboratively designed and facilitated by staff from all levels across the university;

- **Speakers** addressed the theme 'You, Macquarie & information technology' with time for questions and answers in a one-hour lunchtime format,
- **Workshops** with the theme 'Integrating e.learning into the Curriculum' with theoretical discussion and practice activities in two-hour lunchtime and some early-evening sessions,
- **Showcases** of e.learning case-studies from different disciplines and software demonstrations in a one-hour lunchtime format,
- **Short courses** requiring a time commitment to a series of activities over two to six weeks,
- **Information sessions** about IT support services and facilities at Macquarie in a one-hour lunchtime format.

Through three semester-long programs these activities were collaboratively designed, convened and facilitated together with many Macquarie staff from all levels. Descriptors of all the events and activities are found at <www.cpd.mq.edu.au/e.learning>.

**Adjunct Activities**

In collaboration with e.learning@mq, two adjunct initiatives received organisational support;

- Macquarie has established the e.studio in the Library. The facility is an independent staff and postgraduate research student IT learning facility with hardware and software often not available in local areas. Launched early in 1999, the e.studio is supported by equipment and software demonstrations by staff from ITTU and CFL and promoted in CPD’s publicity. Interesting work is emerging from this facility that would not of otherwise occurred due to a lack of local-area equipment and support.
- The CPD funded a global survey to identify and determine the quality and scope of accessible, online resources specifically designed to support the development of English language higher-education staff. A total of 385 university websites were surveyed in detail and the pdonline website at <www.cpd.mq.edu.au/pdone> has links to the 'best-of online resources found (Litchfield & Spear 1999).

**Patterns of Staff Participation**

Although I take advantage of much of what CPD offers it can be seen as something 'out there'. I think this project is the best marrying of CPD and the academic staff at the university that I have been involved in.

Comment of a local-area team member.

In Australian higher-education, staff are industrially categorised either as 'academic and research' or 'administrative and specialist support' - a 'divide' commonly described as academic and general. An emerging feature of integrating online media into learning and teaching is the blurring of these traditional categories. University work is being actively re-defined with position descriptions and selection criteria increasingly influenced by the skills, roles and team-structures needed by networked education. Concurrently many traditional academic and general staff positions are becoming redundant, and many of the e.learning@mq participants were understandably motivated and stressed by this phenomena.

**Local-area Peer Development Projects**

In late 1998, 44 staff attended three workshops convened to support the development of proposals for the e.learning local-area grants. All the ultimately successful project team-leaders attended the workshops and have stated the high-value of this support in the development of sound proposals with clear aims and objectives, time-lines and budgets. The nine funded project teams comprised 38 members (68% academic and 32% administrative staff) who worked together, and then received payment for their time, throughout 1999 and early 2000. Many of the team-leaders were in this role for the first-time and developed substantial project, team and financial management knowledge and skills.

At mini-conferences held in February, July and December 1999 the teams reported on progress and discussed issues. The mini-conferences had 72 attendances indicating a high-level of team-member participation in these support activities. The final reports from the team-leaders indicate the local-area and discipline-based
objectives were all realised often with unforeseen advances, and the peer development activities achieved very high-levels of participation. This high-level of peer involvement confirms diffusion theory's premise that the majority favour incremental change and look to local and discipline-based settings for new ideas and innovative practice.

As the main cost-item of the e.learning@mq budget, the author considers the local-area team and peer development scheme as the most effective and substantial of all the project's activities. Requiring the least amount of CPD support, significant peer development has occurred in self-selected local issues of integrating IT into educational programs.

University-wide Activities

65 e.learning university-wide activities were convened and the records indicate a total of 997 attendances from 385 individuals. The 6 speakers attracted 226 attendances, the 30 workshops 357, the 15 showcases 194 participants, the 9 short courses 170 participants and 5 IT support information sessions 50 participants. The level of participation was well-spread with only one activity needing to be cancelled due to lack of interest.

Figure One compares the staff-category of participants in each of the five university-wide activities. The attendance patterns indicate the project successfully focused on involving academic staff, who were the majority in all activity-types, particularly in the short courses, workshops, and showcases. Only slightly higher numbers of academic than general staff attended the speakers and IT support information sessions. Across all five activities an average 59% of participants were academic staff, 31% general staff, and 10% were of unknown category including the participants external to Macquarie.

University-staff in Australia are over-worked, time is valuable and clearly participants were selective about what interested them enough to attend. The author's diverse and multi-entry 'scatter-gun' strategy certainly worked as each participant averaged only 2.6 attendances. Though face-to-face 'one-off' workshops are the traditional and most-popular method of higher-education staff development, it is important to note the clear potential of short courses to attract and involve academic staff.

Activities which did not succeed included open calls to apply for funds to support relevant local-area activities. Some of the speaker's attracted low attendances, and a web-conference established to facilitate ongoing discussion of events, debates and issues received minimal staff contributions. The online feedback has not worked and even feedback sheets handed out at the conclusion of activities are difficult to garner.

Participants' Self-Assessment of the Impact of the Project

A total of 409 individuals participated in the local-area and university-wide e.learning activities. In December 1999 after the completion of all scheduled activities, these individuals were sent an email
questionnaire asking for their assessment of the impact of their participation in understanding the issues involved in integrating IT and online media into the curriculum. A follow-up paper-version of the questionnaire to facilitate anonymity was then sent to all the participants who had not responded to the email. A total of 91 valid responses were received of which a high 55 were anonymous.

In nine key areas the questionnaire asked the participants to self-assess the level of impact of their e.learning@mq involvement as significant, moderate, slight or not-at-all. The questions asked whether their participation had increased their (1) awareness, or their knowledge or skills in (2) planning, (3) strategic program planning, (4) managing, (5) designing, (6) developing, (7) implementing, (8) evaluating, or assisted them to develop (9) coordinated strategies for the use of IT in the curriculum. Figure Two compares the impact of the project in these nine key areas of understanding.

Figure Two: Participant's self-evaluation of the impact of e.learning@mq in nine key areas.

On average across the nine specified areas of understanding a total 81% of the participants assessed that the project had a positive impact. An average 18% of participants assessed the project had a significant impact, 35% a moderate impact, 28% a slight impact, and 19% assessed the project had no impact at all. These findings indicate the project has achieved its aim to raise staff's awareness and improve their knowledge and skills in the issues.

In each of the nine areas there are interesting variations in the degree of impact of the project. The strongest impact was in increased awareness of the issues, and in the knowledge and skills involved in planning, designing and implementing the use of IT in the curriculum. The project's weakest impact was in evaluating and developing coordinated strategies. The activities focusing on these issues were poorly attended and reflect the difficulties of developing coordinated strategies at the individual level, noting that in 1998 Macquarie underwent a major organisational restructure.

Conclusion

In an important strategic direction for Macquarie University, the 1998-99 e.learning@mq staff development project fulfilled its aim to increase the organization's capacity to integrate IT and online media into the curriculum. The project outcomes clearly indicate that well-funded and managed professional development activities can increase individual awareness, knowledge and skills about integrating online media into higher-education learning and teaching. The project's diverse activities, in both local-area and university-wide settings, attracted different groupings and numbers of staff, justifying the author's pluralistic approach informed by diffusion theory and the characteristics of the majority in the uptake of innovations. The different activities did appeal to different people.
Participating individual staff have self-assessed improvements in awareness of the issues involved in integrating online media into the curriculum. On average, across nine key areas of understanding, 81% of participants have self-evaluated slight, moderate or significant improvement in awareness, knowledge and skills. However it is important to note that Macquarie has a total permanent staff of some 1500 and only 409 individuals participated in the project. Overall 19% of these participants considered no change at all had occurred through the project. So a complex and ongoing issue is how to increase involvement from staff who have yet to show interest in using online media. There is a need for innovative and imaginative strategies to address this issue including improved incentives and rewards. In particular there is a clear need for strategies to maximise the number of staff getting their 'hands-on the tools' in a supportive, localised context.

The project's external funding was for 1998-99 and the project has now ceased. Macquarie has not funded an ongoing project as apparently the aims have been met and are now "embedded into the infrastructure". Better ongoing cohesion and collaboration between Macquarie's IT support structures and staff was facilitated by the project and some activities continue in different ways.

The development required to improve the organisational capacity to integrate new media into the curriculum continues to require substantial innovative, collaborative and well-designed policy, processes and activities. Issues such as improved supports for staff and students, policy developments with rigorous course review and accreditation processes, and better teaching load recognition for online development, and other incentives and rewards, are crucial initiatives that remain to be achieved.

As a local-area e.learning participant noted "it is only the tip of the iceberg - unless we can get the value of this type of skill development recognised at university level, that is with ongoing provisions for staff relief for such projects the impact will be limited".

The author hopes the activities and outcomes of the 1998-99 e.learning@mq project can assist staff developers involved in similar work. Regardless of our respective roles, with issues of IT and change we constantly need to be learning and supporting each other. Indeed facilitating professional development in using online media is emerging as a generic skill required by us all.
