Finally, as Hughes remarks, the admirable exercises in measuring job creation tell us nothing about ‘the direction of causation’: ‘finally, and perhaps most importantly, whatever may be claimed for job generation studies in terms of numbers of jobs created by size class, they are themselves merely accounting exercises and tell us nothing about the direction of causation’ (1997: p. 8). This lack of causal analysis or ‘analysis of causation’ is moreover just as harmful to the scientific approach as it is to the needs of policy guidance: ‘Why so few succeed in sustaining growth?’. The important thing in the latter is to be able to analyse and understand the factors that act in favour of the spectacular or discrete growth of some SMEs at the same time as those that prevent the others from expanding. Why should we not therefore be inter-
ested in the youngest SMEs, as advocated by Serra Peris (they grow more quickly, true, but they are more unstable and their development more risky)? On the other hand, why not promote the oldest SMEs, which are stable and survive, as Robson and Gallagher (1994) propose?

This causal relationship is the subject of a number of pieces of research which we shall now examine.

4.2 The main factors determining SME employment practice

Providing we can reconcile two literatures that are traditionally and inexorably separate (the one concerned with growth factors and the other focusing on job creation), one might in general terms distinguish between two series of factors that have been the subject of particular study with a view to explaining how SMEs behave on the labour market.

4.2.1 The traditional variables

The first 'package' would contain the work that has shown the effect of the major sociodemographic variables available in the crudest databases and which are easily objectified. We shall not return to these, since they have been amply commented on earlier in this paper. They are the size of the firm, of course, its sector, its life cycle (i.e. its age), and its legal status: independent (self-employed), integrated, in company form or family. On this latter point, it will be noted that most work shows that family SMEs ('family businesses') perform better economically and in terms of jobs than do non-family businesses (see an international survey of such research in Trouvé, 1999: pp. 31-44).

In his analysis of the specific behaviour and development of family businesses in the industrial sector in Spain during 1994 (drawing on the ESEE survey), Juan Casado (1996), after indicating that the skill structures and wages of family businesses are inferior to those of non-family businesses, shows that when the economic cycle was in a 'recovery' phase after the 1993 depression, family businesses (with less than 200 employees) created more jobs than non-family businesses (with less than 200 employees), with +3% growth compared to -0.2%, and more than family businesses with more than 200 employees, which remained stable, while non-family firms with more than 200 employees continued to shed jobs (p. 92). Nevertheless, it is true that today, in Spain as elsewhere, we are witnessing a substantial shift from the core of family funding to outside partners and capital and also an increase in foreign capital (Camisón, 1996-b, figures 18 and 19).

There are however a number of other factors, such as the mode of production or innovation capacity. According to Atkinson and Meager, who see size as the determining factor but not the only one ('employment size is clearly not the sole determinant of typical small business practices') (1994: p. 32), account must also be taken of four characteristics of the environment: the balance and tensions of supply and demand on the external labour market, the characteristics of other competitors (are they small or large enterprises? are the products they sell everyday products or not?), the political and institutional regime (favourable to SMEs or not?) and the territorial physical environment (see figure 4.3).

The second group might include work that is based either on frankly qualitative monographs or on the mobilisation of statistical classifications complemented by supplementary information.

63 Hughes is in fact right to make a strict distinction between 'business growth' and 'job generation' (1997: p. 4), since the growth of enterprises (measured by their profitability, productivity or market share) does not necessarily result in a growth in their workforce. It is nevertheless true that prosperous enterprises tend to increase in size (Baldwin, 1995), although the relationship is not automatic, since there are firms whose growth is poor in terms of jobs.

64 Apart from the Italian work already referred to, which sees the local system as a space for professional mobility (Silinas, 1982, 1996), the decentralisation taking place in most EU countries has, for example, resulted in certain institutional publications developing a regional or even subregional aspect in the light of structural fund programmes (European Commission, 1998: pp. 139-181).
segments that can be built only a posteriori from qualitative empirical studies. We believe that over the last few years this second corpus has made the greatest contribution to our knowledge of SME behaviour on the labour market. Although it is part of this kind of approach, we shall not be returning to the effect of the profile, the sociological trajectory or the career path of SME managers. This is known to be a key variable that has given rise to a number of typologies which Ivanaj and Géhin (1997) have recently tried to review for the French-speaking countries. We have already looked at that several times above.

4.2.2 The strategic behaviour variable and SME models

We are more interested in looking at what seems to us to be a new breakthrough in a field that is all the more fertile because it requires a multidisciplinary approach. We are referring here to work on the effect of competition strategies on the employment practices of SMEs. We have referred elsewhere to this as yet not very systematised approach based on a survey of the international literature (Trouvé, 1999). We shall discuss it below on the basis of three series of publications: German, British and French.

The work of Leicht and the segmentationist theories

Most German work constantly stresses that, overall, the greatest net job gains observed since the mid-1970s are found in small firms with between 5 and 19 employees (Leicht, 1995; p. 85; Leicht, Strohmeyer, 1995: chart p. 20) and this expansion took place even in the manufacturing sector, which means that, in Germany at least, it is not due only to the development of services, as is too often believed. According to the Statistisches Bundesamt [German Federal Statistical Office], between 1970 and 1987 the growth in the rate of employment and enterprises was greatest in those with up to 49 employees, while all the sizes above that stagnated or declined. On the other hand, some sources say that VSEs with 1-4 employees and SEs with 20 to 49 experienced only a modest increase (Leicht and Stockmann, 1993).

What is the reason for SEs with 5 to 19 employees being so prosperous? That is the question that these authors tackle here. They point out first of all that these small enterprises operate in quite specific branches: 'Expansion der Kleinbetriebe kommt nur in einer bestimmten 'Branchenumwelt' (Leicht, 1995: p. 178) and more particularly on markets not dominated by LEs. We are therefore back with the very old intuitions of W. Sombart, who believed that SMEs essentially occupy three specific areas: the area of individualised work, in which adaptation to the individual case is required (...); the area of localised work, i.e. work that must be carried out in a particular place, and in which a sales area of limited size serves as natural protection for the craft; the area of repair work, which is of little interest to capitalism' (Sombart, 1929: p. 27).

The specific potential of SMEs would therefore be explained by their roles as market specialists ('Marktspezialisten') and market localists ('Marktlokalisten') which enable them to retain in the long term ground that is difficult for LEs to access and which is of little interest to them. Leicht also argues that the sector is not enough to explain the expansion or decline of certain sizes of enterprises, since the true potential of SEs lies more than anything in their control of particular intra-sectoral segments that include types of production (series or to order, for example) and market. For example, in the small retailers sector we can see both the disappearance

---

65 This is the case referred to below of the German works by Leicht; Leicht, Strohmeyer; Hilbert and Sperling.

66 The authors referred to sometimes use the terms 'branch' and 'sector' without distinction, but we consider the former to be the more suitable because it specifically defines the activity (or activities) of those enterprises which, further on, we shall call the product/effective market pair(s). It is therefore closer to the enterprises’ microeconomic operation than the term 'sector', a statistical category that embraces at macroeconomic level 'all enterprises with the same principal activity' (on this point, cf. INSEE, 1997-98 or Morvan, 1985: pp. 345-347).
of 'Tante-Emma-Läden' (corner shops) and the new expansion of advanced technology centres, organic food shops, video rental shops, etc. For this reason, he proposes an approach that we shall call segmentationalist ('ein segmentspezifisches Modell') capable of differentiating SEs according to their ability to manoeuvre on the market.

He argues that the most prosperous SEs and the ones that generate the most employment occupy in particular segments where they are very close to the final customer, producing goods or services for which there is little demand or for which demand fluctuates greatly, at all events where SEs and LEs are not really in competition with each other. They also require a great deal of decentralisation and a high level of professionalism that most of the time is not conducive to rationalisation, internationalisation or standardisation. Such is the case, for example, of the building craft trades, material services ('stoffliche Dienste'), design, construction, installation, repair or maintenance activities, or technologically more modern activities (precision engineering, optics, computer assembly) and professional services to business (accountancy, consultancy) or to individuals (social and health services) that involve an ability to find tailor-made solutions to individual problems (Leicht and Strohmeyer, 1998).

Conversely, where there is direct (actual or potential) competition between SEs and LEs, the former are always under threat. Certain craft activities, for example, or branches covering inflexible basic needs (leather, clothing, food) have gradually been replaced by mass production or delocalised. SEs are therefore expanding in all activities that are remote from mass production and where Taylorist/Fordist concepts cannot apply. Contrary to the thesis put forward by Piore and Sabel (1984), however, the expansion of SEs and their production model does not, according to Leicht, presage the end of mass production, since they are not really in direct competition with LE methods of organisation. Rather, the specific nature of their field of activity makes them structural elements complementary to the production process of large organisations (Leicht, 1995: p. 179).

Alongside the work done by Leicht, we must also mention that done by Hilbert and Sperling (1993). In our opinion, these two authors go further in that they explain the strategic manoeuvres of prosperous, job-creating SEs and try to articulate them firstly with the career paths and profiles of their managers (by distinguishing between, for example, 'technical entrepreneurs' and 'managerial entrepreneurs') and, secondly, with the skill structures of their labour force. They therefore show that there is a great variety of possible developments open to SEs. They could lie anywhere on a spectrum ranging from an 'offensive productive concept' to a 'defensive productive concept', depending on their degree of dependence on the market.

- In the first concept, the SEs representing about one third of their sample practise a flexible specialisation that protects them from dependency or from competing too much with LEs. They are found mainly in the mechanical engineering, machine tools and computer industry sectors. They survive because they specialise in one market (they are 'Markt-Spezialisten'), because they are able to offer technical backup services and in particular because they have direct commercial access to the final consumer. These SEs develop a policy of having highly skilled staff, recruiting in particular young people from whom they demand a high level of commitment and flexibility. They are generally recent (appearing in the 1970s and 80s) and managed by 'technical entrepreneurs' (technischer Unternehmer), frequently engineers with several years' professional experience in their sector. This offensive production system may of course benefit from a particularly favourable regional labour market, sometimes structured by the presence of large enterprises that play a supporting role: continuing training infrastructure, availability of skilled personnel, etc.

- At the other end of the spectrum, which represents around 40% of the enterprises studied, SEs are obliged to apply a defensive concept of production, often accompanied by economic retrenchment and staff cut-backs. Most of them are small firms in
the timber or textiles/clothing industries. Mainly subcontractors (they are 'Markt-Zulieferer') dominated by their contractors and therefore insecure, one way or another they apply traditional rationalisation models: minimising costs and increasing productivity. Their flexibility is based more on a deregulation of labour relations than on new forms of organisation. They are found especially in the motor industry, mechanical engineering or furniture manufacture.

Between these two extremes, Hilbert and Sperling identify two other types of SE (1993: pp. 20 et seq.): the 'Markt-Newcomer', that is new entrants, like those that explain the American employment miracle, especially in services. A smaller number are however also found in the manufacturing trades, especially in the creation of craft businesses (Weitzel, 1986); then the 'Markt-Lokalisten' who satisfy everyday needs for goods or personal or repair services in a limited area.

SMEs may therefore move in a broad spectrum ranging from the 'poverty economy' to 'niche production' ('Zwischen Armutsökonomie und Nischenproduktion') (Hilbert and Sperling, 1993: p. 130). Like Leicht, however, Hilbert and Sperling show there is no sectoral determinism. For example, in the motor industry, where dependent subcontracting SEs predominate, we can find a 'Produktstrategie der diversifizierten Qualitätsproduktion' (production strategy of diversified quality production) (Streeck, 1986). Likewise, we can find 'Markt-Spezialisten' (market specialists) in textiles/clothing. These, it is true, are chiefly medium-sized firms that have the resources to give themselves direct access to distribution and the final consumer or to take control of design and innovation higher up the value chain.

For these authors, therefore, the business policy adopted by managers always predominates over the sectoral determinants which, for their part, do no more than define the room for manoeuvre open to the managers' strategic inspiration. This is more or less what Kotthoff and Reindl (1990) also find from their own qualitative empirical material. By focusing particularly on the machine-tool sector, which scientists often use as a model for an innovative and flexible KMU, they manage to distinguish no less than three major types of generic market strategy, analysing their links with work systems and labour relations. Thus, there are both strategic-conceptual enterprise strategies ('strategisch-konzeptionelle Unternehmenspolitik'), enterprises shifting to markets with economies of scale ('auf Massenmärkte und Skalenerträge ausweichende Unternehmenspolitik') and traditional reactive strategies ('konventionell orientierte reaktive Unternehmenspolitik'), each with very different modes of organisation, production and labour mobilisation (1990: pp. 53-72). The same also applies in the furniture industry and in textiles/clothing, where SEs whose operation is based on a great variety of competitive advantages and handicaps may exist side by side.

The competitive variables

Hence the need to pursue further the recent research into the links between competition strategies and forms of employment and labour management in SMEs. There are serious obstacles to such an approach, which by implication involves bringing together the disciplines of industrial and labour economics, the sociology of enterprises and their managers, and management, which are normally institutionally separate, even though they have in common that they have all favoured the large enterprise model. Some studies are today showing the way, however. Of these, one might mention the work by Reid (1993) and Reid et al. (1993) in Great Britain, based on surveys that are already quite old (1985-1988) of recent enterprises (average three years old) employing between 8 and 15 people. They also try to combine quantitative and qualitative methods, field approaches and statistical data, while drawing on the 'competitive advantages' model inspired by M. Porter (1980, 1985).

This train of thought developed later and more sporadically in France owing to a persistent lack of interest in employment matters on the part of managers and no less chronic disdain by sociologists and economists for categories of analysis derived from stra-
The employment and training practices of SMEs

Strategic management (Julien and Marchesnay, 1988; Mahé de Boislandelle, 1998, 1st ed. 1988; Bentabet et al., 1999; or even Moati and Pouquet, 1996). Unlike G. Reid, most of these researchers are not interested solely in SEs in the start-up phase.

For example, Julien and Marchesnay formulated 'the strong hypothesis of a causal relationship between the firm's strategic management and the practices it adopts for taking on staff and, more generally, in labour management [...]. The policies adopted in labour management may vary according to the competitive advantage sought by the firm ['manager's objectives'] (1988: pp. 242 and 251). Mahé de Boislandelle related the employment variable to the 'basis of competitiveness adopted'. Bentabet et al. ventured to study micro-firms (very often neglected, even in research on SMEs) from intersectoral monographs, trying to model the links between market strategies and labour management and training behaviour. Finally, Moati and Pouquet used an extensive database of 233 industrial sectors to show that '80% of employment flows are intra-sectoral by nature', which means that they are caused mainly by differences in performance between enterprises in the same sector. According to these authors, two factors facilitate job creation: a favourable environment (growth sector, low intensity of competition, etc.) and 'a strategic positioning conducive to differentiation or focalisation, that is non-price competitiveness, which shields them from the imperative of chasing productivity'.

Lastly, we should note a recent compilation of international literature on competitive strategies and employment practices in SMEs (Trouvé, 1999). It is concerned in particular with enterprises in a 'front-line situation', that is fast growing and job-rich SEs, world class SMEs and SMEs based on new technologies. This systematic search comes to the same conclusions: even though the variables of size and sector still seem very significant, they do not go far enough in explaining the employment practices of the SMEs considered. They have to be linked to finer segmentations – through more qualitative approaches, for example – such as the profile and career path of the managers and their positioning strategy (intentional or 'emerging') on specialised or highly differentiated segments. On the other hand, the qualitative analysis of the forms of labour management they adopt would be worth looking at in more detail, as we shall now try to suggest.

4.3 Recourse to the external market and forms of labour management

By dint of studying the contribution made by SMEs to employment on the basis of creations/destructions of enterprises, we might forget that they grow, develop and reach a cruising speed at which they interact with the labour market in a specific way. However, it is only very recently that researchers have taken an interest in this. It is true that the articulation or engaging of small firms with the external labour market, what Atkinson and Meager call 'small business engagement with the external labour market' (1994: p. 38) are very different to those of a large firm. In particular, 'for the small business ... the process is likely to be irregular, less predictable and less capable of systematisation' (idem: p. 39).

In most countries, macrostatistical corpuses are likely to tell us first of all about small firms' recruitment practices, especially of young persons being absorbed into employment, from the characteristics of the young people and the jobs they are offered. Exploitations of this kind are nevertheless not yet very widespread, especially when it comes to international, sectoral or intrasectoral comparisons. While a programme of this kind could prove very fruitful, it is still very ambitious, especially since the role of SMEs in regulating employment cannot be considered independently of the schemes that exist in most European countries for introducing people into working life and questions of initial training and the related forms of social recognition of qualifications (Lefresne, 1998, 1999).

Faced with the destabilisation of the internal markets of large enterprises and, at the same time, the proliferation of new forms of employment on the periphery of what was hitherto the dominant model (temporary, part-time or fixed-term jobs, employment-un-
employment and training-employment transitions, insecure status, etc.), might not SMEs act like a ‘transitional market’ (Gazier, 1998; Schmid, 1998), like an area of ‘intermediate positions’ between the external market and the internal market (Lefresne, 1998, p. 111) for young persons looking for a way into working life? Looking beyond young people, might not small firms play a role in transition and mobility throughout working life, becoming the preferred way back into work for ‘older workers’ who have been expelled from large organisations? On the other hand, up to what point is the labour market not nowadays segmented or polarised, with an unbridgeable gap between a relatively stable ‘primary’ sector of jobs and labour in the internal markets of large enterprises and a less stable, more externalised ‘secondary’ segment typical of small enterprises?

One thing is certain: the countless surveys of SMEs’ supposed skills needs (as of their training ‘needs’) have shown their limits. Most often commissioned by economic and political decision-makers in a hurry, most of them have resulted only in false certainties ... and in measuring the gaps between the avowed intentions and actual practices of SME managers. Conversely, the more general research into manpower management practices in small firms (including job and training management practices) have often proved to be much more illuminating (see in particular Bentabet et al., 1999).

4.3.1 A privileged role in finding young people their first jobs ... and helping ‘older’ workers back into work

Most European statistics stress the fact that there is always a higher proportion of young workers (aged 15-24) in small enterprises (with less than 50 employees), especially in commerce and hotels and catering (European Commission, 1998: pp. 102-103). For the EU countries as a whole, this would in fact represent about 26% of the persons employed (or around 13% in VSEs and the same in enterprises employing between 11 and 49 persons), compared with only 10% in enterprises employing more than fifty.

In France, even though the DMMO-EMMO surveys have not so far been used very much for this purpose and even though micro-firms (under 10 employees) remain outside their scope, they do provide a good picture of the flows of labour and jobs (entries and exits) by size of enterprise. They again show that it is the smallest establishments in the service, commerce, education/health and social sectors and in personal services that absorb the most entrants, with 18.8%, 18.4%, 13.5% and 11.7% respectively (i.e. 62.4% of entries for all these sectors together). These are however also the sectors with the most exits.

If we take SMEs to be enterprises with fewer than 200 employees, we find that they absorb nearly three-quarters of young people under the age of 25 (73.5%) and even more older workers (77%), 42.7% of them in SEs with fewer than 50 employees alone (Table 4.1).

Looking at the levels of training shown in the Employment Survey data, we find that 42.2% of young people completing vocational training of levels V and V bis are taken on by VSEs, compared with 28% for levels III, II and I, most of whom (51%) are recruited by large enterprises with over 500 employees. There seems therefore to be quite a clear break between the two groups of beginners and of enterprises: there is a larger proportion of the

---

67 According to the INSEE definition, ‘older workers’ are those over the age of 50.

68 The Monthly Return of Labour Movements (DMMO) for establishments of 50 employees and over and the Survey of Labour Movements (EMMO) for establishments of 10 to 49 employees allow us to establish, among other things, both the number and the type of contracts concluded and the reasons for cancellation or leaving by occupational categories during each month or each quarter preceding the survey.

69 The data in Table 4.1 and the figures that follow concerning the Employment Survey (Trouvé, 1996) are taken from personal processings of the DARES files (Direction de l’Animation de la Recherche, des Études et des Statistiques [Directorate for the Promotion of Research, Studies and Statistics], Ministry of Employment).

less well qualified (levels V and below, i.e. V bis and VI) in SEs, while persons with higher education (especially vocational qualifications: levels III and above, i.e. II and I) are more easily absorbed by SMEs with more than 50 employees and especially by large enterprises employing more than 500. Young entrants of level IV (that is, leaving secondary education with the equivalent of ISCED 3 (International Standard Classification of Education in the European nomenclature) are more or less equally divided between enterprises of less than 50 employees and those with more than 50, but while this level seems to be a 'floor' for the larger enterprises, it looks more like a 'ceiling' for the smaller ones.

4.3.2 Internal markets and dualisation of labour in SMEs

The opposition between large enterprises and SMEs has all too often been superimposed on the dualist segmentation of internal market and external market and, even more, associated with the primary market – secondary market split. To simplify a little, we could therefore distinguish between large enterprises providing internal stability and mobility, high wages, good working conditions and career prospects and where the organisation would contribute to training for recognised qualifications ('primary market') and small enterprises where the opposite characteristics prevail, that is making much use of the external market, paying low wages, individualising the wage relationship and neglecting working conditions and the lever of continuing training ('secondary market').

This is without counting the fact that, in theory, internal markets are not confined to the administrative unit of the enterprise (there are trade or sector internal markets in which SMEs are involved and which allow employees to pass from one establishment to another without leaving their trade or profession, as in hotels and catering or building and civil engineering) or the physical boundaries of the establishment (e.g. establishments belonging to a network or forming part of a group). True, the alternative: renewal of the workforce/internal mobility is still statistically relevant for contrasting SMEs and large enterprises at least in part (Podevin, 1990; 1994), but an over-stylised reading of dualism fails to take proper account of a number of empirical observations that reveal an internal market and indeed a dualism of labour even within SMEs (Trouvé, 1995: pp. 148-150). Thus, it is not rare, even in very small enterprises, to see the coexistence of, on the one hand, a relatively stable and generally old market segment (employees of 10 to 15 years' standing), loyal and well trained, the hard core of the workforce, and, on the other, a segment of rather young workers moving on the periphery and whom Ses have a lot of difficulty in retaining (Bentabet et al., 1999: pp. 78-79) and it is no doubt in this light that the famous 'skills needs' of SMEs ought to be examined.

This is the 'mixed market' concept advanced by Gambier and Vernières (1991) and which would seem in the end to be the most appropriate for understanding that several forms of market may exist side by side in the same SME. Thus, the enterprise's employment practices would be the articulation of two aspects – internalisation and externalisation – that could at any given moment predominate to a greater or lesser extent. Considering 'human
resources management' to be a border function on the intersection between the external and internal market, Hendry et al. (1991: pp. 37-39) are saying nothing different when they state: 'many of the SMEs possess a variety of skill groups and operate simultaneously within a number of labour markets', concluding by identifying no less than seven categories of market in their nevertheless small sample of SMEs (idem: pp. 28-36). If they are to be believed, there would be even more if a greater number of units were studied.

4.3.3 The hypothesis of SMEs as a 'transitional market'

Note also that while 22.6% of the young persons starting in VSEs in France are apprentices, no more than 3.4% are in large enterprises with more than 500 employees (Trouvé, 1996), which is also confirmed by the annual German panel surveys conducted by the IAB (jährliche Betriebsbefragung des Instituts für Arbeitsmarkt- und Berufsforschung der Bundesanstalt für Arbeit): small craft enterprises currently take on twice as many apprentices as large enterprises.

We should of course distinguish here the SMEs that take on the greatest number of young people according to the former’s sector of activity and the level of qualification of the latter. We know, for example, that vast numbers of young unskilled building and construction workers join VSEs (54.8%) or enterprises with fewer than 50 employees (74.6%). Similarly, 48% of unskilled engineering workers start out in VSEs and 61% in Ses with less than 50 employees. On the other hand, unskilled handling workers tend to join firms with more than 50 employees (68%), especially medium-sized enterprises (employing 50-499), which themselves take on 46% of unskilled handling workers. Moreover, it is SMEs that take on the most new young sales staff (69.5%), especially VSEs (47.6%), while enterprises with more than 500 employees take only 17.4%. New young hotel workers are taken on by SEs (74%) and especially VSEs (44.7%).

However, if we add the not insignificant role of SMEs in re-employing jobseekers (Leicht points out, for example, that three-quarters of unemployed persons recruited in Germany in 1994 were taken on by enterprises with less than 50 employees – 1997: p. 50), and especially that much use is made of them in employment policy (Gubian, Holcblat, 1999), that would be enough to allow us to consider SMEs a real 'transitional market' (Schmid, 1998: p. 12; Schmid and Gazier, 1999) between training and employment (including the use of assistance schemes to get young people into work), between unemployment and employment (as we have just seen), between employment and withdrawal from working life (as we saw earlier), and between domestic work and employment (see the status of home helps in the configuration of one-person businesses). Such a hypothesis would, among other things, involve articulating analysis of SMEs' behaviour on the labour market with that of their role in individuals’ career paths, not only when they first start work, but throughout their working lives.

Other French observations deserve to be mentioned and checked out for European comparison purposes. Among these one might single out that by Bruand (1991) based on Céreq career pattern surveys during the 1980s, according to which a significant proportion of young people starting out in the smallest enterprises (one third) move to a larger establishment in the first five years of their working lives. This would be in line with the DMMO and EMMO surveys already mentioned, which showed that the 'reasons for leaving' given by young persons under 25 included 18.5% 'resignations' in small enterprises compared with 8.5% in enterprises employing over 200 people, or with the comparison of first job stability rates arrived at by Céreq: 17% for VSEs and 47% for large enterprises. Which means that while SMEs play a considerable part in providing young people with their first jobs, the posts that they offer are far from being the most stable and therefore the most 'desirable' from their point of view. That is why many still regard them as 'staging posts', and the SMEs have a lot of difficulty in retaining staff. Other sources also confirm this kind of drift of young workers from small enterprises to medium-sized and large enterprises as they go through working life (Bruand, 1991).
Another finding could be stressed: despite their greater capacity to accommodate young persons with low skill levels, the pivotal role of SMEs and VSEs in particular in introducing young people to work has for some years now tended to extend to all young people, regardless of their initial level of training. Thus, Céreq's Observatoire des Entrées dans la Vie Active [Observatory of Entries into Working Life] showed that 30% of young people leaving higher education in 1992 were in 1994 working in enterprises with between 1 and 49 employees, and 13% in VSEs alone (Bentabet et al., 1999: pp. 45-46). Could this trend towards higher levels be connected with sectoral effects (development of high-value-added services), the shifting of Ses in the value chain, with, for example, the development of VSEs as part of large groups (franchising, retail chains, division into subsidiaries), the arrival of a new entrepreneurial class, or the greater loss of status of young graduates on the labour market? The work done by Dares and the Céreq's Generation 92 Survey should enable us to give a better answer to questions of this kind, but it is unfortunately not yet available.

4.3.4 The question of 'crossing thresholds'

The statistical data on the labour market and on the integration of young people into working life are not however enough to explain totally the recruitment practices observed in SMEs. If we are to understand them better, we must reintegrate them into a more general understanding of the methods of labour management in small structures. This is what we said in a recent publication (Bentabet et al., 1999) and it is supported by a number of Anglo-Saxon authors who consider the most important fields of human resources management in small enterprises still to be 'the selection and retention of staff' (Hornsby and Kuratko, 1990). That is why they are particularly interested in the required manpower characteristics, the sources used for recruitment, and the selection tools deployed by SMEs, most often comparing them with Les (Golhar, Deshpande, 1997), without for all that overlooking the 'motives', that is the representations underlying the behaviour of their managers.

A good example is given in a particularly thorough study by Atkinson and Meager (1994). Taking up an hypothesis formulated in their earlier work (Atkinson, Meager and Wilson), the two authors state that, in the course of their development, small enterprises have to cross four successive thresholds, each representing things that have to be taken into account in policies of assistance to SMEs, for example:

- The 'entry threshold', which corresponds to the decision to take on an employee, especially for a self-employed person who crosses the threshold when he engages his first employee. Most of the time, he then uses casual workers, members of the family, or works long hours. This threshold is situated at zero employees.

- The 'delegation threshold', which represents the moment when the owner-manager (the 'one man band') is no longer self-sufficient and leaves production or direct sales, for example, to concern himself with management. This threshold does not lie at a particular level of workforce, but at the time when the small firm's quantitative growth is accompanied by a qualitative change in its method of organisation.

- The 'formalisation threshold', which is the point where the organisation's complexity demands systematisation, both in order to organise the internal labour market and to have recourse to the external market. It is, for example, the moment when planned recruitment procedures appear.

- Finally, the 'functional threshold', where the activity's development demands a personnel policy based on professionals and specialists and the emergence of specialist functions. In particular, we see the appearance of formal and ongoing relations with the labour market.

According to the two authors, while the SME's workforce is the 'inescapable' variable of its specific 'labour market behaviour', it is not the only one. That is why they propose an empirical analysis grid including four other key factors (Figure 4.2).
The influence of the foregoing five variables on the behaviour of small firms is also affected by many factors reflecting the characteristics of the environment in which the enterprise moves, according to the following scheme, which is self-explanatory:

The two authors state that, contrary to what is generally believed and unlike the financial problems that remain predominant regardless of their size, the recruitment problems encountered by small firms increase regularly with their size. Thus, Very Small Enterprises have fewer difficulties on this point (since they can take on family members or relations) than firms with 10 to 50 employees, for which recruitment is the second cause of problems with the environment.

As for the players who take the recruitment decision and the procedures they follow, they are closely dependent on the 'managerial structure and practices' current in SMEs. In a survey covering 2,836 units, the intervention of the one owner-manager, who is always the majority shareholder, can nevertheless increase from 50% to 83%, depending on the size of the enterprise, its location (rural/urban) or sector. However, the demand for labour is generally quite far removed from the conventional deterministic models derived from large organisations: apart from the powerful inertia of small structures to preserve their autonomy, we note in particular the lack of planning, the predominance of short-term influences over employment decisions and the use of more informal local selection procedures in the smallest SMEs or for the least skilled manpower needs. Thus, for manual workers access to the workforce 'by word of mouth' is still going strong in large enterprises (Atkinson and Meager, 1994: p. 70) and the area of the labour market explored depends closely on the occupation of the persons recruited: whereas managers tend to be recruited from a distance, three-quarters of

---

Small rapidly growing firms are more willing to recruit managers from outside with experience of large enterprises; typical small firms tend to recruit internally, but when they do have recourse to the external market, they tend to recruit people who have worked or are working in small firms; finally, small slowly growing enterprises tend to recruit managers from within their sector because they are less likely 'to rock the boat'. On this point see also Ardenti and Vrain (1999).
4.3.5 Extending the analysis to forms of labour management

More widely, we could look at work analysing the specific forms of labour management in SMEs\(^{71}\) and including the employment (and training) practices found in them. Some authors have made this their speciality, such as Mahé de Boislandelle in France (1998 a and b), McEvoy in the United States (1984) or Pettigrew, Arthur and Hendry (1990) and again Hendry, Jones, Arthur and Pettigrew (1991) in Great Britain. In what is in the end quite a small stock of publications (at least in the opinion of Julien, 1997: p. 260), we might, with Mahé de Boislandelle (1998 b), pick out two other directions: firstly, the empirical analyses of the practices and representations of 'human resources management' (hereinafter HRM) in SMEs; and secondly, the attempts to formalise and construct theoretical concepts and frames of reference. Let us briefly look at these two groups.

Empirical studies: results tending to contradict the specificity theory

Most conventional research into HRM practices in small enterprises is essentially evolutionist, since most of the time it makes them into a smaller and incomplete model of the large enterprise. The conclusion then drawn is that there is some backwardness in their functional structure (only very rarely do they have a dedicated 'personnel management' section), inadequate planning and a failure to integrate human resources into the enterprise's strategy. A number of older authors have attributed the inefficiency or even the failure of certain SMEs to these failings (McEvoy, 1984).

Closer to our own position, on the other hand, some authors have argued for the specificity theory and have shown that there was far from being a consensus on the link between the

---

\(^{71}\) We prefer to use this term here rather than 'Human Resources Management' (HRM) used by many authors, since the latter seems to have more overtones of the rational technologies of the large enterprise.
degree of formalisation, professionalisation or differentiation of HRM and the success of SMEs (Julien, 1997)\textsuperscript{72}, since the labour characteristics and needs of small enterprises are very different from those of the large enterprises (Deshpande and Golhar, 1994). And while some researchers (e.g. Hornsby and Kuratko, 1990) have sometimes highlighted a recent coming together of personnel practices between the two types of enterprise, SMEs are likely to owe this less to their internal progression than to their increasing integration into groups, the emergence of new managers (Ardenti and Vrain, 1999) or the spread of new forms of organisation like just-in-time and Total Quality Management (Deshpande and Golhar, 1994).

The theoretical models: convergence towards a contingency model

The theoretical models are geared towards approaches of the quota type, which in the end are the only ones able to take account of the extreme diversity of forms of labour management and their present dynamics in SMEs (Fabi, Garand et al., 1994). An almost impossible multitude of factors (internal and external) are involved in their organisation, activities and HRM practices, and Julien attempts a fairly exhaustive compilation of them from the literature (1997: pp. 293-299). He mentions: organisational size; field of activity; the enterprise’s financial and material resources; organisational strategies; the sociodemo-

\textsuperscript{72} If Aragón Sánchez and Sánchez Marín (1998) are to be believed, nothing can be taken completely for granted about the relationship between methods of HRM and competitiveness, either. In an empirical study of 602 industrial SMEs in the Murcia region, they ask whether the SMEs that are the most competitive according to the resources and skills theory (technological capital, reputation, quality, size, internationalisation) have HRM practices that are significantly different from the less competitive enterprises. While some findings confirm what was expected (the most competitive SMEs are the ones that give the most training and have put in place a system of staff appraisal), others appear more paradoxical: for example, the most competitive enterprises are the ones with the highest proportion of jobs on fixed-term contracts, they do not particularly value independent working or job security, etc. This deserves to be examined in greater depth.

More or less the same idea is developed by Mahé de Boislandelle in France; he includes in his ‘social mix’ model (1998-a: pp. 113-114) personal variables concerning the manager, contextual variables (internal) of the organisation and environmental variables determining ‘the SME’s HRM system’ and which are all pointers for future empirical research (idem: p. 72).

According to all these authors, like Julien and Marchesnay (1988: pp. 70 et seq.) who already distinguished between entrepreneurs whom they designated by the letters P.I.G. (perenniarity, independence, growth) or G.A.P. (growth, autonomy, perenniality), the managers’ vision and their system of representation play a particularly determining role in the nature, complexity, diversity and degree of formalisation of HRM (Garand, 1993, and Figure 4.4). Moreover, the degree of formalisation of HRM practices seems to be a key indicator of SME development. On this point, we should not, of course, overlook ‘imported practices’ (resulting, for example, from the use of outside consultants or the subcontracting of certain HRM activities such as payroll management, employer training, the use of payroll software or training management) or ‘induced practices’ for the purpose of contractual cooperation with other SMEs, such as franchising, relations with prime contractors, or ISO 9000 certification. These are very important dynamics capable of transforming HRM practices radically (on this point see Ardenti and Vrain, 1998). This is what makes Bentabet et al. (1999) say that all the conditions are now present for the emergence, even in a VSE context, of a managerial model of rationalised or ‘modernised’ human resources management.

Like these last authors, Hendry et al. (1991) consider it essential to locate the practices of HR development in SMEs in relation to their market and competitiveness strategies. They stress the importance of these strategies and of the process of organisational development, that is the life cycle and age of the enterprises,
for understanding their skill needs. That is without a doubt an extremely fruitful avenue of research for the future if we are to gain a better understanding of the articulations between strategic behaviour, performance and methods of human resources management in SMEs.

4.4 The current outbreak of work on job quality

So far, we have looked at the contribution that SMEs make to employment only from a quantitative point of view and it must be said that most research in Europe and elsewhere has given particular precedence to this point of view. However, we have for some years now been witnessing the opening of new areas of investigation into the quality of jobs and of working conditions that are radically changing the reading of the specific contributions made by SMEs to employment. These have grown particularly in Germany, the United States, Canada and the United Kingdom, as well as in Spain, where, as we have already seen, the most ’weighty’ statistical studies (concerning the economic and financial performance of SMEs in particular) seldom overlook the data on the structure of their jobs and the skills of their workforce.

4.4.1 Comparison between small and large enterprises

We have to begin with a first set of works that try to compare the quality of jobs in small and large enterprises and that most frequently show the former at a disadvantage. Their wages are generally lower, their use of continuing training less frequent, their level of unionisation and therefore of employee protection lower, the security of the jobs they offer less evident. This was found in the United States by Brown, Hamilton and Medoff (1990), for whom ’workers in large firms have a superior employment package’.

In the case of Great Britain, Scott et al. (1989) stressed the effects of enterprise size on wage differences, and Curran and Stanworth (1981) argued with many others that job satisfaction, often presented as compensating for the lower level of wages in SMEs, in fact depends more on the sector of activity, and the age or qualifications of the workers than on the size of the enterprises. Rainnie (1989) concluded in the matter of labour relations that ’small isn’t beautiful’.

In Spain, Camisón Zornoza (1996-b) has underlined the higher percentage of temporary workers (’eventuales’) in SMEs, and the Impi for its part regularly notes a greater number of hours worked, lower wages and an overall lower skill level than in LEs (1995: p. 63). Another salient feature of SMEs that contributes directly to making employment contracts less stable is the lower seniority of the workforce. In 1995, 59.7% of workers had been there for less than 2 years and only 10.7% longer than 8 years (Para et al., 1995: pp. 29 and 64). This would seem to confirm the existence of a hard core and a periphery for jobs and labour within SMEs.
In Germany, with the exception of the work by Scheuch (1976), a great scientific defender of SMEs who, basing himself on Bundesministerium für Arbeit [Federal Ministry of Employment] surveys (1973), claimed that out of a set of 11 variables, only wages and working hours were more favourable in LEs than in SMEs, most research confirms the same findings. For example, the research by Wagner (1997) shows the ‘effects of size’ on wages, other benefits (end-of-year bonus, 13th month, profit-sharing), job security, opportunities to improve qualifications/skills, continuing training, participation, etc. Considering that most enterprises in Germany are SMEs employing a large proportion of the workforce while remaining outside the conventional joint management system, she recommends the adoption of a minimum wage and administrative barriers to dismissal rather than directly gearing public policies to improving the quality of jobs in SMEs.

4.4.2 The hypothesis of a link between job creation and job quality: ‘do more jobs mean worse jobs?’

Today, studies are tending to converge towards the idea that working conditions in SEs and large enterprises cannot be compared and that the accent should be placed on the relationship between the growth of employment in SMEs and the process of deregulating the labour markets and making them more flexible in the developed countries. This theory is supported in particular by Sengenberger (1988) and by Baldwin (1998).

Sengenberger asks whether the trend for jobs to move towards SMEs is not closely linked to the reduction in the quality of working conditions and jobs and in wages. He notes that the abolition of protection against dismissal (‘kollektiver Kündigungsschutz’) for SE employees since 1985 is likely to have perverse effects: it will now be more difficult for SMEs to find skilled staff. Another possible counterproductive effect of Government policies is that the strategy of reducing wage costs may result in lower productivity in SMEs and encourage LEs to use them as ‘cost absorbers’. This is because deregulation is built on short-term market efficiency, but neglects longer-term productive efficiency. Overall, the author does not find the policies of encouraging SMEs by making the labour market more flexible very convincing. On the other hand, a renewed efficiency in SMEs could come from improving their manpower skills and from strategies of inter-enterprise cooperation as in the example of ‘third Italy’.

Baldwin, for his part, uses a study of the manufacturing sector in Canada between 1973 and 1992 to maintain that if SMEs have absorbed most jobs in recent years, it is because the changes that have taken place in relative factor costs are more favourable to them and because they traditionally use the labour factor more than the capital factor (1998: p. 363). He then formulates the strong hypothesis that ‘to some extent, growth in the small plant segment has probably been the result of wage flexibility in this sector’ (idem: p. 363). In other words, if SMEs make such a big contribution to job creation, it is because the jobs they create are of poorer quality than in large enterprises. From the research point of view, this means that we need to articulate the quantity and quality of jobs in SMEs conceptually and empirically and to pay greater attention to industrial relations in SMEs than European work has done hitherto.

In France, authors like Grasser, Lhotel and Sacher (1999) have come close to this hypothesis. In fact, according to these authors, a parallel should be drawn between SMEs’ current success and the changes on the labour market and the increasing fragility of the wage relationship, which is more widespread in SMEs than in large enterprises, where there is still a strong internal market.

In reality, the somewhat hasty nature of these hypotheses (or rather of the interpretations we give them) overlooks a whole series of questions surrounding the methodological difficulty of precisely defining the concept of job quality, and international comparisons could be very useful for making them operational. It is these two elements that a study by Cowling and Storey (1998) attempts to tackle on behalf of the Dublin
The employment and training practices of SMEs

Foundation\textsuperscript{73}. According to these authors, \textit{job quality} cannot in fact be grasped one-dimensionally. It is in fact a composite concept, constructed empirically from a number of indicators, some of which reveal the deficiencies and others the superiority of SMEs. The question is not therefore a simple one and it no doubt calls for further investigation. They also note that international comparisons (European ones especially) are at present more of a research programme for the future than a present-day reality.

\textbf{4.4.3 The work of the Dublin Foundation}

It was in 1998 that the Dublin Foundation embarked on a programme of research into \textit{job quality} in SMEs. In this connection, it has already held two workshops (17-18 September 1998 and 22-23 April 1999) with the aim of reviewing European research in the field.

The subjects of the workshops were 'Employment conditions in EU micro-firms' and 'Jobs in EU micro-firms: a trade-off between quantity and quality?'. Still very much articulated around the debate about job creation in small enterprises, these sessions sought to define the research priorities and the instruments for collecting data (key variables) on employment conditions in SEs. Among the workshop's conclusions and recommendations, we can note:

- the urgent need for particular examination of the micro-enterprises segment of SMEs, since these account for 1/3 of jobs and 93% of establishments in the EU (including firms with no employees);

- that decision-makers often put the emphasis on pay and the length of contracts, although these two variables are not among the priorities expressed by either employees or employers;

- that in micro-firms, the employer is also a 'worker' or one of the workers. His own working and employment conditions therefore probably have an effect on the success of his business and on how he sees his employees' working conditions;

- that information on total employment and especially on net job creation is very hard to obtain because of the high staff turnover in micro-enterprises;

- that international comparisons are even more difficult because there is no harmonisation of the indicators and concepts used in the socioeconomic approach to labour and employment problems;

- that the nature (or absence) of contracts in micro-enterprises (whether or not family firms) requires specific approach methodologies for studying employment conditions. Researchers will therefore have to make a clearer link between quantitative and qualitative methods and use their imagination to identify new indicators and go beyond the limits of the databases hitherto available;

- that multidisciplinary approaches are also essential.

\textbf{4.4.4 The Cowling and Storey report (1998): from the elaboration of indicators to the difficulties of international comparison}

In their report to the Dublin Foundation, Cowling and Storey note first of all that there is at present no database capable of providing full comparative information on all the job quality variables in the 15 European countries that they analysed. The Foundation for its part tried to create a European corpus in 1996, but this does not contain any information on the wages and remuneration variable, which is probably one of the most important.

Choosing to confine their exploratory analysis to the case of Portugal, using the database compiled by the Dublin Foundation, they look in turn at the registers of the macro-economy and labour market dynamics, the demography and composition of the workforce in the market sector (by sex, age, sector of

\textsuperscript{73}European Foundation for the Improvement of Living and Working Conditions (Dublin).
activity, degrees of job stability, wages and methods of remuneration, quantities of hours worked, the relationship between training and employment, training levels, working conditions, job satisfaction, etc.), and the study of 20 job quality indicators (dependent variables) by size of enterprise.

It emerges very clearly from this study focused on one country that while SEs are at a disadvantage compared with large ones in four job quality variables, they are capable of doing better than them in four other variables. For the remainder of the 20 other variables used, however, there seems to be no significant difference between large enterprises and SMEs. It is, however, sometimes necessary to make a clear distinction between enterprises with no employees ('self-employed'), micro-enterprises (1 to 9 employees) and small firms (10 to 49 employees). Likewise, other independent variables may play a not insignificant role alongside that of size: for example, the sector of activity, the job characteristics, the personal characteristics of the employees (sex, age, level of training) and their occupational category.

In the final part of their report, Cowling and Storey nevertheless review the principal dimensions or factors that should be taken into account when measuring job quality:

- wages and other benefits: 'no doubt the most indisputable factor in measuring job quality' according to the authors;
- the ability to acquire training;
- pay structure (the measurement of performance and productivity has an effect on the variability of the compensation of employees);
- type of contract (fixed-term contracts increase employee uncertainty);
- working hours;
- job security and permanence;
- working conditions (health, safety, autonomy, involvement in decision-making, subjective well-being).

After proposing a conceptual analysis framework for examining the relations between job creation and job quality in detail (pp. 69-73), they suggest focusing on SMEs, calling for future studies of all sectors of activity (not just industry), using the series of 20 variables identified in their own work and drawing on the Dublin European Foundation's databases, the gaps in which could be plugged by national monographs, especially for the study of wages.

### 4.5 The galaxy of self-employment: alternative to unemployment or optical illusion?

Our approach to SME behaviour on the labour market would not be complete without giving special place to 'self-employment'. The interest shown in this phenomenon by both labour market policies and academic research is the result of its considerable growth over the last 20 years in many developed economies (OECD, 1998-a). Today, especially, it is considered an important source of new jobs and an alternative to paid employment. Self-employment is also seen as a possible solution both for new entrants to the labour market and for the jobless. Finally, we find that in a number of countries (France, UK, Spain) self-employment has been encouraged by policies of providing financial support and advice aimed particularly at the unemployed or persons at risk of losing their jobs.

#### 4.5.1 The contribution of international comparisons

The self-employed are generally considered to make up about 9.5% of the workforce in Europe today (that is, the number of self-employed relative to the total number of persons with a job), but with the figure differing greatly from one country to another. Thus, although the various sources do not come up with the same figures, we can distinguish between Northern Europe, where the percentage of self-employed is relatively small (Denmark, Germany, France, Netherlands, etc.) and Southern Europe (with Spain, Italy, Portugal, etc.) where it often exceeds 15%, reaching as high as 30% in Greece (see Figure 4.5). However, it must be said that the criteria for

74 The differences may in fact result either from the different definitions adopted by the various sources used, or quite simply from the difficulty of marking out the reality of self-employment statistically.
The employment and training practices of SMEs

Figure 4.5: Self-employed with no employees as a percentage of all persons with a job, 1995

![Bar chart showing self-employed with no employees as a percentage of all persons with a job, 1995. The chart includes data for EU-15, B, DK, D, EL, E, F, IRL, I, L, NL, A, P, FIN, S, and UK, with percentages ranging from 4.1% to 27.4%.]

defining self-employment differ from one country to another.

The proportion of self-employed was calculated by dividing the number of self-employed by the total number of persons with a job.

This distribution is held to reflect the enterprise size structure, and the high level of self-employment in the southern countries would be explained by the high proportion of both VSEs and agricultural activities in their economies. Moreover, the breakdown of self-employed by sector is not the same in the South and North of Europe. In the former case (Italy, Spain, Portugal), commerce, hotels and catering predominate to the extent of representing as much as 50% of the self-employed, compared with no more than one third in France and the Netherlands, one quarter in Great Britain and the United States and only one fifth in Germany (Luber, Gangl and Leicht, 1997: p. 4, Table 1).

4.5.2 Structural trends in self-employment

It is nevertheless true that in most countries the internal structure of self-employment is changing. For example, Germany has for several years now been witnessing a relative growth in ‘modern services’, knowledge services, and liberal professions (Luber, Gangl and Leicht, 1997). This internal structural trend is also noted by Granato and Leicht (1996), who stress the growth of human capital in self-employment. They say in fact that while the proportion of employees having completed university education rose from 7% to 13% of the working population between 1970 and 1993, it rose from 12% to 21% among the self-employed. They also point out that the presence of the self-employed in services (especially business services) rose from 8% to 16% between 1970 and 1993, that it remained constant in the manufacturing sector (from 24.7% to 24.1%), and that the number of female self-employed has increased, as has that of self-employed persons of foreign origin (from 2% to 7%)75.

In England, the growth in self-employment has often been seen in parallel with the drift

75 Bogenhold and Schmidt draw particular attention to the creation of businesses by foreigners on German territory: around 245 000 self-employed today offer nearly 800 000 jobs (1998). For their part, Jones, McEvoy and Barrett show that self-employment varies considerably according to ethnic group. Whereas 13% of whites could be considered self-employed in the period 1989 to 1991, the figure was 7.2% for the Guyanan working population with a job and 20% for Pakistanis and Indians.
from industry to service activities, technological progress, the break-up of large enterprises, and Government efforts to promote an enterprise culture. Between 1981 and 1991, there was also faster growth (in the region of over 80%) in the number of self-employed among the youngest population groups (aged 16 to 24) than in any other age group (Campbell and Daly, 1991).

4.5.3 Forced self-employment and 'entrepreneurial culture'

Most research also points out that the rate of self-employment has increased in the majority of OECD countries (with the exception of Japan, Luxembourg and Denmark), especially since the mid-1970s (OECD, 1992). This is more especially the case in Great Britain, Spain and Sweden, but also in Germany. Could this be the sign of the emergence of a new 'entrepreneurial spirit' bearing with it the hope of many new jobs? Not necessarily, because a high number of self-employed does not necessarily imply a greater taste for risk, or greater creativity or commitment. It could just as much be the result of the state of the labour market, processes of 'downsizing' in large enterprises and rising unemployment, all of which have magnified the phenomenon of 'forced self-employment' over recent years (Granato and Leicht, 1996). Not necessarily, either, since a person going self-employed is not necessarily accompanied by the creation of a lot of extra jobs. From this point of view, Germany and Denmark are still a case apart, since in those countries half the self-employed have been able to create other jobs, compared with only a third or even a quarter in the other Western countries. In Great Britain, there has actually been a very sharp decline in the proportion of self-employed employing other wage earners, since between 1981 and 1991 the proportion of self-employed with employees fell from 40% to 31% (Campbell and Daly, 1991).

Hence the interest of work looking at the many transitions between paid work, unemployment and self-employment. One example is Carrasco for Spain (1997). Taking as his source the Encuesta Continua de Presupuestos Familiares (Instituto Nacional de Estadística), he compares 37 000 observations of a population of men aged 21 to 65 between 1985 and 1991 and tries to see what are the factors influencing the decision to become self-employed. Is it possible to estimate the effect of unemployment on the probability of embarking on self-employment for the long term? Is it possible to distinguish between self-employment with and without employees? What reasons can be found for moving from self-employment to paid employment or from self-employment to unemployment? Two sets of interacting variables then emerge from his study: the state of the labour market (and especially job rationing) and the personal characteristics of the individuals (family situation, age, level of training, previous experience of self-employment and former status, i.e. employee or unemployed). Like Evans and Leighton (1989), he finds that an unfavourable macroeconomic situation increases the probability that low-skilled waged individuals will become self-employed. He also finds that the enterprises created by the unemployed encounter more difficulties (high percentage of failures) than those created by persons coming from a job.

Finally, and this is no doubt a crucial result, Carrasco shows that when individuals have recently experienced unemployment, if they are driven to become self-employed, especially by the withdrawal of benefits, they are more likely to abandon self-employment after a few months to return to unemployment than are self-employed persons who were previously wage earners (Carrasco, 1997: p. 29). This seems to imply that employment policies designed to encourage self-employment among the unemployed would do well to think twice before simplifying extremely complex questions.

This problem is also addressed in much recent German literature opening a very closely argued debate, both theoretical and empirical, on the culture of self-employment ("Kultur der Selbständigkeit"), which might be translated and extended to mean 'entrepreneurial culture' (Bögenhold and Schmidt, 1999). It shows that independence cannot be reduced to its legal or statistical aspects and that the enterprise spirit also has a cultural dimen-
The employment and training practices of SMEs

4.5.4 Increasingly fluid boundaries between employees and the self-employed

In France, the recent work of O. Marchand (1998) also tends towards caution and tempers the enthusiasm surrounding the growth in self-employment. The author begins by establishing that, with the exception of the United Kingdom and Sweden, employees have never been such a high proportion of the working population, approaching as much as 90% in the main industrialised countries (idem: p. 8, table 2). However much we may debate the methods of constructing the statistics, he observes in particular that the place currently held by self-employment is part of the qualitative changes affecting the structure of paid employment in the long term. From this point of view, what we are witnessing today is a blurring of the traditional split between the status of paid work and self-employment, especially with the externalisation of activities on the periphery of enterprises, subcontracting and hiving off: 'work on the margins of the paid workforce is growing, either in the form of jobs with the weakest of links with employee status... or in the form of bogus self-employment or bogus subcontracting. In the building industry, for example, firms have been very successful in encouraging certain workers to set up on their own, which may enable them to save on wage overheads by

611

The self-employed are initially defined negatively here as 'those who do not draw a wage or who pay it to themselves'.

getting around the regulations; but these new self-employed workers are in most cases completely tied to their former employer who is their only source of work' (Marchand, 1998: p. 9). On the other hand, 'some paid activities may consist of the provision of services where, conversely, certain tasks can be externalised to persons not on the payroll, while nevertheless maintaining ties of subordination between the two parties'. In other words, at the same time as the wage link is being loosened, we are seeing the appearance of new forms of dependence based on commercial contracts. Is this not the case, for example, of integrated or franchised small businesses whose wage 'independence' is paid for by economic dependence (Bentabet et al., 1999)?

5. The role of SMEs in training and in generating professional skills and status

National and European literature on initial and continuing vocational training is particularly prolific. This third section will be concerned less with mobilising this immense source than with focusing more particularly on work highlighting the relationship SMEs maintain with vocational training, either as users or as a specific forum for generating manpower skills. Special attention will be paid to examining the quantitative defining data that have recently been trying to make international comparisons, to the main factors determining SME training practices and, finally, to the main changes taking place in most European countries to make vocational training the foremost source of SME competitiveness.

We have just looked at the research into SMEs' contribution to employment and human capital formation, which is a crucial factor in competitiveness for the developed countries (Ridinger, 1997). However, we now know that the quantity of manpower alone is not the only important factor in determining the process of growth and competitiveness in an economy, but the skill level of its workers. From this point of view, as Kucera (1997: 57) notes, entrepreneurship and skilled labour
Philippe Trouvé

('Qualifiziertheit der Arbeit') go together. That is why it has become necessary to examine the role of SMEs, not only in job creation but also in the mobilisation and development of labour qualities.

The question is not new. As early as in 1986, a seminar organised by Cedefop and coordinated by I. Drexel sought to take stock of training in SMEs, and in many respects, this constitutes an excellent point of reference. The question has undoubtedly become more complex, however, given the pressing nature of the underlying issues (see the European Commission's White Paper: Enseigner et apprendre – vers la société cognitive [Teaching and learning: towards a cognitive society]) and the many national initiatives to which this has given rise in most EU countries over recent years (Aventur and Möbus, 1999).

The field of scientific research is not exempt from this complexity. First, as A. D'Iribarne (1993) points out, there are many areas of knowledge. They may, for example, be concerned with 'initial training for young people, continuing training for people of working age, whether or not in work, work itself, which allows us to relate questions of 'qualifications' and skills to those of training, staff selection by enterprises and the place of the diploma, training techniques and the cognitive processes of apprenticeship [...] and how all the above should be seen in the light of the general operation of the labour market (occupational integration, exclusion from activity, etc.).'

Moreover, when the researcher takes a transnational interest in all these phenomena, he comes up against familiar but particularly stubborn difficulties: how, for example, to achieve sufficiently reliable comparability between analytical categories that are highly marked by national contexts. What is there in common, for example, between the concept of apprenticeship in Germany and that in France? What relationship is there between a skilled worker in Italy, France or Germany when the basis of training, methods of selection, or their place in labour organisation and in career prospects or social status are not the same? How should we respond to the present instability of our main points of reference resulting from the reconfiguration of the institutional edifices of vocational training in most European countries? While it is true that statistical sources like the Labour Force Survey or the Community survey of continuing vocational training in enterprises (CVTS) have enabled tremendous progress to be made, they are still recent and in need of further development. At least, that is what emerges from the publications that deal with them.

We propose here to begin by using this corpus to distinguish between SME behaviour in the matter of initial vocational training (5.1) and then of CVT (5.2). In fact, despite the present 'easing of the separation between initial training and continuing training' noted by Aventur, Campo and Möbus (1999: 277), the distinction between these two registers, 'which together help to produce the qualifications and skills of the working population', is maintained in most of the work consulted.

Then, building on a critique of the statistical tools, we shall investigate the specifics of SME training practices (5.3). Finally, by looking at the biggest trends at work in the new forms of regulating vocational training systems in most EU countries, we shall try to interpret them as opportunities to be grasped to enable SMEs to develop their training potential in the future (5.4).

The first two sections will describe the most striking studies on the demand for vocational

It will in fact be noted that this tendency to overlapping of the initial and continuing vocational training systems is shared almost unanimously in all the countries of the EU. For example, alternating training arrangements (sandwich courses) have been available to adults in Denmark ('recurrent training') since 1992; in other countries, like Finland and the Netherlands, training systems including apprenticeship are accessible to adults. Similarly, in the new Länder of Germany, 'conventional' apprenticeship has been extended to young adults over the age of 27. In France, combined work and training contracts are financed by the Continuing Vocational Training funds, while new forms of skill validation are available both to young people and to adults in the course of their working lives (Aventur and Möbus, 1999).
training by SMEs and the use they make of it, either on the basis of their skill needs in their recruitment practices (especially relating to young people) or in terms of initiatives for the development of their existing workforce. The resulting table shows a wide variation.

It is true that in most EU countries small structures play a key role in getting young people into work and are very much involved in apprenticeship schemes. However, they are finding it increasingly difficult both to absorb and retain the most highly qualified of them and to complete their initial training. Moreover, in the southern countries in particular there is a gap between the specific skills they demand and the qualifications produced by the vocational or technical training structures (as in France, Spain and Italy, for example). Their use of Continuing Vocational Training, if not always characterised by an ‘inertia’ that leads Verdier (1991: p. 42) to describe them as ‘extras’ rather than ‘players’, at least shows a kind of deficit or withdrawal as compared to the largest enterprises when observed at European level. Behind this overall analysis, however, most research work encourages us to measure national, sectoral or size category differences very carefully, paying particular attention to the factors explaining the (small) use made of training by SMEs.

As we said earlier, from a statistical point of view comparative European research into vocational training has made some important breakthroughs in recent years. One might mention, for example, the Report by the European Commission (DG XXII), Eurostat and Cedefop (1997) concerned both with initial vocational training from an analysis of 167 programmes in 15 Member States (VET-Eurostat) and the survey of continuing vocational training within the firm, which collected information from a representative sample of 50,000 enterprises (CVTS – Eurostat). See also the supplementary dossiers of the European Commission (1999) or the University of Sheffield’s Centre for Training Policy Studies (European Commission, 1999) and the study produced by Céréq (Aventur and Möbus, 1999), which is exemplary in its depth and exhaustiveness. It is however much to be regretted that these databases, which tell us about both the structure of the initial training system in each country and enterprises’ in-house training practices, cover only enterprises with 10 or more employees and at present disregard training for jobseekers. The result is that Very Small Enterprises (VSEs), which account for the greatest number of establishments in Europe, are once again excluded from the official statistics for technical reasons.

5.1 SMEs and initial training: providing a job and/or training?

Political and economic decision-makers have for many years striven to make vocational training a major axis of the fight against unemployment among young people and to upgrade the average skills that service and craft SMEs more particularly need. If the statistical data produced on the subject at European level are to be believed, this kind of training seems in fact to be a form of protection against the difficulties of occupational integration.

5.1.1 The general effectiveness of vocational training on the labour market

In the countries of the EU, almost one third (29%) of young Europeans between the ages of 15 and 19 are today enrolled on an initial vocational training programme. This encouraging figure, however, masks major disparities between countries, since participation is very high in Austria (55%) and Belgium (45%) but less so in Ireland (17%) and Portugal (12%), the situation of young persons in the other Member States being between 20% and 40% (Figure 5.1).

Like the proportion of young persons involved in initial vocational training, the combination of general and vocational training varies enormously from one country to another. While in some countries vocational education predominates over general education (as in Germany or Austria, where 78% of pupils are engaged in vocational education at ISCED 3 level, in Italy with 73% and the Netherlands with 70%), in others it tends to be general training that prevails over vocational with the lat-

Box 5.1: The International Standard Classification of Education (ISCED)

**ISCED 0 (Pre-primary)**
- Begins between 4 and 7 years, is always compulsory and normally lasts 5 or 6 years;

**ISCED 1 (Primary)**: begins between 4 and 7 years, is always compulsory and normally lasts 5 or 6 years;

**ISCED 2 (Lower secondary)**: forms part of compulsory schooling in all EU countries. The end of this level often corresponds to the end of full-time compulsory schooling;

**ISCED 3 (Higher secondary)**: begins around the age of 14 or 15 and is either a general, a vocational or a technical education. Level required for access to higher education or end of schooling;

**ISCED 5, 6, 7 (Higher education):**
- Without university degree (5)
- First university degree (6)
- Programmes leading to a post-graduate qualification (7)

In the same publication (European Commission, Eurostat, Cedefop, 1997), we also find that, for an equal level of initial training, vocational training is more effective on the labour market than general training alone. In Europe, in fact, while 23.5% of young persons are unemployed after undergoing only general training corresponding to ISCED 0, 1 and 2, only 11.5% (one half the number) of those who also have some vocational training are jobseekers (Figure 5.2). Vocational training therefore seems to speed up integration into working life, especially for young people with

78 This nomenclature used in international comparisons at present has a few imperfections and is to be revised in the near future (European Commission et al., 1997).

79 With the exception of Sweden, however, where vocational training is institutionally independent of the production system. In this case, the school system alone is responsible for getting young people into the right jobs.
The employment and training practices of SMEs

5.1 Growing interplay between training policies and employment policies

Strictly speaking, analysis of SME behaviour in relation to the education and initial vocational training structures would involve a close articulation not only between the problems of training and occupational integration but also between training and employment and labour market policies, firstly because the absence of an internal market in SMEs means they have greater recourse to the external market than do large enterprises; and secondly because the imbalances observed on the labour market have in most EU countries resulted in the adoption of policies designed to make employment standards more flexible, especially for young people experiencing difficulties in finding work and to encourage firms to recruit them. There are generally two aspects to this ‘structural adjustment’, and they are particularly well analysed by Lefresne in a recent thesis (1999):

- Firstly, the employment status is made more flexible and/or financial incentives are introduced to encourage the integration of young persons, which are of particular advantage to SMEs;

- At the same time, vocational training needs to be developed or upgraded with the introduction of new ways of bringing school and enterprise closer together, that is of managing the training-employment transition, with particular use made of apprenticeship and alternate training.

There is no shortage of examples on both these fronts:

- For the first one might, for example, quote the case of Spain, where they have for several years been relaxing the recruitment rules by making greater use of temporary

employment contracts for getting young people into work. There is also the United Kingdom, where wage costs have been reduced by breaking the link between the wages of young persons and adults, especially through the Youth Training Scheme (cf. Box 2.2) adopted in 1982, which has enabled many enterprises, especially the smallest ones, to take on juvenile labour at lower costs. We should also mention Italy, where new rules have introduced a 'starting wage' below the collectively agreed rate of pay for new entrants to the labour market and where there are now financial incentives for enterprises to recruit young persons on a part-time basis. Or even Germany, considered exemplary so far as the training-employment transition is concerned, where, given the growing number of young people without jobs on completing their apprenticeship, the Employment Promotion Act (1985) allowed enterprises to use fixed-term employment contracts (18 months) or to offer young persons completing their apprenticeship jobs unrelated to their training specialisation. Not to mention the introduction of 'exchange programmes' allowing large enterprises, which are increasingly unwilling to retain apprentices even though they helped to train them, to make them available to craft trade enterprises (Zedler, 1994).

In the matter of bringing the educational system closer to the production system, we could highlight the development of apprenticeship and alternate training courses: in Italy with the training and employment contract (CFL) introduced by the Law of 1983; in the United Kingdom with the Youth Training scheme; in Sweden with the vocational integration courses; in Spain with the introduction of training contracts for graduate students or of the (reformed) apprenticeship proper. In all these cases, training strategies overlap with strategies for the vocational integration of young people; reforms of the education and training system go hand in hand with reforms of the labour market. Specifically, in exchange for financial assistance, enterprises agree – in theory, at least – to contribute to the training of young people. We find however that in most European countries SMEs have been expected to play a key role in these arrangements. We could go further, and say that just as training has increasingly found a place in active employment policies (as Join-Lambert et al., 1997, show for France), so the greater attention being paid to getting people into or back into work has more clearly shaped the initial or continuing training programmes for which SMEs have been the preferred vehicle.

5.1.3 The contribution of SMEs to the occupational socialisation of young people: between tradition and new deal

Despite the great diversity of national traditions, SMEs have long been making an established contribution to the occupational socialisation of young people coming out of education. Whether their contribution has formed the basis of a highly institutionalised system of career organisation (as in Germany and Austria), has been taken over and strengthened by occupational structures (as in the United Kingdom), has served to pick up those who have fallen by the wayside in a social system dominated by educational qualifications (as in Spain and especially in France), or the ground SMEs occupy has been neglected by the public player (as in Italy).

Apart from the disparities between countries (Aventur and Möbus, 1999), research reveals the importance of sectors (Curran, 1990; Curran et al., 1996; Dti, 1995), territories and local labour markets (Sperling, 1993) and the recent changes in production systems (Christe, 1998; Leicht, 1995; Campinos-Dubernet, 1999). In the rest of this chapter we shall try to show how all these factors work together.

In simple terms there could be said to be two types of national tradition in Europe as regards initial vocational training: countries where it has historically been socially discredited (as in France, the United Kingdom and also Italy and Spain) and countries where it has been highly structured and has become the centrepiece of the training system as a whole (Germany, Austria, Netherlands). A few examples will suffice:
The employment and training practices of SMEs

Box 5.2: The place of apprenticeship in French small enterprises

In France, small units are the main enterprises making use of apprenticeship contracts (72% in 1996). The rise in hirings on assisted contracts since 1987 plays an important part in raising the level of qualifications within small enterprises. Apprenticeship in particular may be a 'Trojan Horse' of the first order (Bentabet et al., 1999). Already, 24% of young persons taken on by such firms are engaged as apprentices but, in particular, this method of training under a contract of employment alternating periods of schooling with periods in the enterprise, is no longer the preserve of young persons preparing for a CAP certificate. It is also open to persons wishing to take a vocational 'baccalauréat or a higher technical certificate (brevet de technicien supérieur - BTS) and now even for some future engineers (Pérot and Simon-Zarca, 1998). Finally, apprenticeship contracts are a crucial factor in the hiring of young unskilled workers in small firms in France. Having recruited them, however, do those firms nevertheless help to train them or help them to complete their training?

In France, for example, vocational training has traditionally helped to provide workers for craft trades and large industrial firms. The modern form of apprenticeship, based on the law of 1971, recognises this as a type of initial training 'marked by a school-type diploma (issued by the Ministry of Education) and which sets all the base rules: employment contract, work in the enterprise alternating with training at the apprentice training centre (CFA)' (Aventur and Möbus, 1999: p. 195). It operated in parallel with the technical branches, which have become much more developed in recent years and which have frequently proved more appropriate for continuing studies.

Because it recruited from the lowest levels of education, vocational apprenticeship was in France long considered the 'way of failure'. For that reason, it still occupies a minority position by comparison with general education, which is considered the 'royal route' if not to social success then at least to a secure job and, above all else, to avoiding unemployment (Box 5.2).

Despite the many attempts to upgrade this type of training in recent years, we have seen a rapid growth in numbers pursuing studies beyond baccalauréat level (especially technical) and short vocational courses (DUT-BTS)80 which were originally intended as a fast route to vocational integration for young people. In other words, with the exception of long-term higher education, whenever training became vocationalised it failed in its initial task (Trouvé, 1996). At the same time, we see a rapid structural change in the populations taking apprenticeships: whilst training in preparation for the basic levels of qualification (CAP: Certificat d'Aptitude Professionnelle) is on the decline, that leading to the highest level diplomas (Bac + 2 and beyond) is growing rapidly. This trend is highly significant for our subject: while the former—sometimes after a few adjustments—was relevant to SME needs and more especially to those of the smallest among them, the latter, which may now lead to qualification as an engineer, are probably more suitable for large enterprises.

However, this SME / LE distinction is not perhaps the most relevant today, because another split—along sector lines—has appeared within the SME category. It is true that small, even very small, establishments (hotels & catering, building, small retailers, agri-food industry and car repairs) continue to dominate the sectors that take the most starters with the lowest level of initial training. There are however also small enterprise sectors that are growing and demanding higher and higher skills acquired during initial training, such as business, legal and management services, computer engineering, social work & health, tourism & leisure, education, etc.

80 Equivalent to ISCED 6 at European level.
Philippe Trouvé

There is therefore a great danger that we will see a dualism developing at the 'young' end of the labour market, not necessarily involving a distinction according to enterprise size (the smallest always taking young people with the lowest level of training), but according to their position in the production system, which would allow some SMEs in innovative growth sectors to recruit the best-qualified young people coming out of the training system. This point remains to be further considered and explored in the future on the basis of Céréq's 'Generation 92' career pattern survey of 1992-leavers polled in 1997.

In Italy, attention has only recently been paid to initial vocational training. Here, too, the young people engaging in national (at vocational institutes) or regional vocational education from the age of 14 are the ones who have failed to gain access to the general or technological streams. Vocational training course attendance rates nevertheless vary enormously from one region to another.

The alternate training system available to young people offers apprenticeship and the work-training contract ('Contratto di Formazione-Lavoro'). The former scheme is provided directly and in the majority of cases by enterprises and is 'concerned almost exclusively with training manual and non-manual workers' for SEs in the industrial sector (Margirier, 1999: p. 275): in 1994, 57.7% of apprentices were in fact in manufacturing industry, compared with 17.9% in commerce and tourism and 13.4% in construction. The latter was created in October 1984 to combat youth unemployment and offer a qualification to academic failures. It therefore acts as a 'safety net'. In most cases, training is dispensed by enterprises internally and a certificate is issued by the employer at the end, which is endorsed by the local employment agency, but it is not really a qualification. Despite its usefulness, this formula, like apprenticeship, is in decline, since 220 000 young persons were involved in 1994 compared with 530 000 in 1989. It must however be said that it is used mainly by 19-24 year olds most of whom have no more than the compulsory level of schooling and 73.3% of whom are taken on by SEs with fewer than 50 on the payroll.

At the other end of the scale from the above two countries, in Germany the apprenticeship model seems to have stood up better as a vector of vocational socialisation for young people, and SMEs have not always been 'condemned' to accepting the least-qualified young persons. It is nevertheless true that the dual system is at present undergoing a crisis because of a drop in the number of training places available and especially because young people are finding it more attractive to continue their studies (Möbus, 1999: p. 24). As in Italy, there are more young people in industry than elsewhere, but numbers are no doubt declining by comparison with the craft trades and especially the liberal professions, which are gaining ground. In this country, too, there is therefore, alongside the changes in volume, a structural change in the subjects taken, by sector.

On this point, however, it would seem that many sectors dominated by SEs are still marked by a great need for training and for highly skilled workers (Facharbeiter). Thus, all sectors taken together, Leicht (1995) notes an increase in the proportion of skilled workers as well as in the proportion of enterprises employing 50 or less. Above that, the proportion stabilises at around 26%. The proportion of unskilled workers increases in line with size, from 7.8% in SEs of 1-4 employees to 32.4% for enterprises employing more than 500 (Table 5.1). Also, according to the same author, it is SEs with between 5 and 19 employees (which have the greatest employment growth) that contribute the most to young persons' apprenticeship (10.7% of apprentices, compared to 4.8% in the over-500s). The author states that the manpower with the highest skills in relative

81 Whereas the State Vocational Institutes and the Regional Vocational Training Centres serve only a small proportion of the 14-18 and 19-25 age groups.

82 Unlike Austria, another mecca of apprenticeship, where the craft trades predominate (55%), compared with 17% in commerce and 'only' 13% in industry and 11% in tourism and transport.

* In workplaces; not including local and regional authorities, social security and PNPIs.

terms is found in an environment characterised by growing employment (craft trades, investment goods, material services). On the other hand, SEs in sectors dominated by LEs have a higher proportion of unskilled workers, which, according to him, means that the extraordinary growth of SEs is neither due entirely to a relatively lower skill level than LEs nor attributable to a ‘shift’ in unskilled activities from LEs to SEs (1995: p. 232). In some cases, therefore, the professionalism of highly skilled workers and craftsmen is indeed a prosperity potential even and especially in small enterprises, since their level of adaptability is a precondition for non-Taylorist concepts of flexible work organisation.

Like Christie (1998), Leicht puts particular stress on the sectoral and regional heterogeneity of SME situations. Hilbert and Sperling (1993), like Mendius (1988), say precisely that from their study of a sample of enterprises in the Paderborn area of Germany, noting that in Germany craft enterprises and highly structured large enterprises make the biggest contributions to apprenticeship (Table 5.2). This would mean there are sectors that do more than is strictly sufficient to meet their own needs (engineering, metal structures) and others that do less (wood, plastics, clothing). Moreover, the reason why nearly 60% of SMEs in the area studied do not train apprentices would quite simply be that they have no need for skilled labour or that they can easily recruit apprentices trained by other enterprises.

In Germany, as elsewhere, however, it is worth taking note of recent work presented by other authors. Kucera (1997), for example, comments that the craft trades are finding it increasingly difficult to get skilled manpower, because young people are abandoning apprenticeship for higher university studies. We are therefore seeing a kind of ‘negative selection’ (p. 69), now reinforced by a trend among skilled workers trained by apprenticeship to change trades (40% according to Henninges, 1994) and to move from the traditional craft trades and small firms to larger enterprises.

* Rate of apprenticeship: number of apprentices/total workforce

This calls into question the efficiency of the apprenticeship system as a whole, which is apparently confirmed by three BIBB and IAB surveys quoted by Kucera (1997: p. 71) showing that the use of initial vocational training has declined in the working population and that the gap between the content of apprenticeship and the demands of working life is widening.

It is clear from a reading of all these studies that the apprenticeship system is today facing difficulties of adjustment where the place of SMEs seems to be very much weakened, if not called into question. There are two main, convergent, reasons for this:

1. firstly, the general raising of the level of education over recent years in most EU countries, with 66% of the population aged 30-34 having in 1995 reached a level of studies equivalent to at least the second cycle of secondary education, that is ISCED 3 or above (Box 5.1). This is accompanied by a sociological change in the aspirations of young people, who are choosing either to continue their studies or to join large enterprises where working conditions are more favourable over all (on this point see Modrow-Thiel, Roßmann and Wächter, 1993).

2. Secondly, the crisis in the traditional forms of apprenticeship or, rather, in apprenticeship preparing for traditional trades, resulting from the effects of structural changes in the economy on the skills/qualifications required.

In the former case, it is to be feared that SEs will, for the best qualified young people leaving the training system, become at best a stepping stone to larger enterprises (as a number of surveys of early career paths in France have shown: Mansuy et al., 1999), or, at worst, something better than nothing and, possibly, an ‘escape hatch’ for the most resourceless among them. Such alternatives may be formulated differently depending on the national context, either, for example, because the stress is on the extreme inertia affecting recruitment in the smallest enterprises (as in Spain, for example, where they still discriminate against young people leaving vocational training, since this is not highly valued), or because of the weakness of the institutional frameworks (as in Italy, where the certificate on completion of apprenticeship is issued by the enterprise alone and there is no legal requirement governing the precise breakdown between time spent on training and on work), or as a result of the far-reaching sociological changes affecting the mentality of young people, who are increasingly being attracted to longer and more prestigious forms of training. Such is the case in Germany, for example, but also in France, where recent changes in the structure of ‘user’ enterprises and apprenticeship populations or in ‘assisted places’ in the market sector83, clearly illustrate this problem. In the case of apprenticeship, for example, while very small enterprises in the traditional user sectors are tending to decline in number, enterprises with more than 50 employees are growing the most. This must also be seen in

83 Apart from apprenticeship the French combined training and work system includes the contrat de qualification, contrat d’adaptation and contrat d’orientation. Only the first two are of interest here, being based on the conclusion of a contract between the employers and a public or private-sector educational establishment setting out how the sandwich course will be organised. While the first type are fixed-term contracts (6-24 months) for young people aged 16-25 who have been unable to acquire a qualification during their schooling or whose qualifications do not provide access to employment, the second type are fixed-term or permanent contracts (6-12 months) for young persons aged 16-25 leaving the education system after completing a full cycle of initial training that needs to be complemented by general, vocational and technological education.
The employment and training practices of SMEs

The light of the trend in the educational attainment of apprentices: while the lowest levels of training are static, the higher levels of education are growing (Sanchez, 1999-a). As for combined training and work, that is so-called 'assisted' jobs in the market sector in the French terminology, they seem to be going the same way. While in 1998 most such contracts were still being signed in establishments with less than 50 employees (72% of contrats de qualification and 49% of contrats d'adaptation)84, they are making particular headway in units with more than 50 employees and are of interest to populations of increasingly skilled young people (Sanchez, 1999-b).

The analysis of the structural changes to systems of production in turn leads to a variety of possible developments, almost all of which may exist side by side. It explains, for example, the increasing difficulties encountered by SMEs in continuing to play a preferential role in training and vocational integration and an increasingly evident dualisation between small enterprises in the traditional sectors (sometimes condemned to be the only place where the least qualified young people can find their first jobs or where people in difficulty can get (back) into work) and small enterprises in high-technology sectors or intellectually sophisticated services with the highest skill needs. On the first point, the detailed investigations made by Campinos-Dubernet in France (1999) are highly illuminating: while SMEs take 80% of young secondary-school leavers (Levels V and IV)85, they are less and less able to provide the additional training in practical skills in some sectors of activity (mechanical engineering, plastics technology) where know-how is inductive, that is building on in-depth theoretical knowledge already obtained. According to this author, the incompleteness of the professionalisation profiles produced by the school system obliges some SMEs to take responsibility for completing young people's education. However, the constraints of competition and the growth of subcontracting are now making them less able to do so, especially given the risk that the young people they train will then be recruited by other enterprises. Hence the development of the use of intermediate formulae to test young people's abilities before taking them on (interim, apprenticeship, assisted contracts with the cost of the vocational apprenticeship recovered from the public authorities).

5.2 SME use of CVT: low use of formalised training

The greatest paradoxes of SMEs are well known: while characterised by less favourable skill structures than LEs, they seem to make less use than LEs of structured continuing vocational training programmes. While they apparently play a key role in getting young people into work, especially those with low skill levels (see above), most of them seem to be incapable of developing their skills and improving their long-term employability. 'Although owner / manager attitudes to vocational education and training are largely positive, its actual provision fails significantly to keep pace with the perceived needs of small firms' (Matlay, 1997: p. 587)86. We have already seen that most present-day research seeks to complicate the most unequivocal opinions about initial vocational training. So what about continuing vocational training? Can any useful conclusions be drawn, not only from national studies but also from those on a European scale?

According to D'Iribarne (1988), the basic 'ingredients' of continuing training systems are similar from one country to another (players with their roles and objectives, intervention structures, operational structures, instruments and levels of intervention), but they are

84 It is interesting to note that in addition to training/employment schemes, some measures taken to help jobseekers aged over 25, such as Employment Initiative Contracts, have also been used on a massive scale by VSEs with 1-5 employees (44.4% of persons recruited in 1995) and SEs with less than 50 employees (83% of persons in the same period) (Charpail and Zilberman, 1999).

85 That is the equivalent if ISCED 2 and 3 at European level (cf. Box 5.1).

86 At least, this is what appears from a survey conducted by the author of over 2 000 SMEs.
often very strangely combined, with strong coherences peculiar to each country, since they are generally 'heavy social constructs'. For example, the articulation between initial training and continuing training at the employer's initiative often proves highly discriminating.

5.2.1 The articulation between initial and continuing training: great differences between countries

The use made of CT is in fact the result not only of the extent to which it is institutionalised in each country, but also of the links between CT and the initial education system and the labour market. In other words, the practices of continuing training at the employer's instigation have to be placed in the context of how initial vocational training is organised in the country concerned. That, at least, is the hypothesis advanced by Aventur, Campo and Möbus (1999).

Several situations can then be distinguished (Figure 5.3). Roughly speaking, the first case is where enterprises invest heavily in continuing training in addition to initial vocational training focused on apprenticeships and academic qualifications. Here, CT is seen as a way of 'catching up' or a 'second chance'. That is the route taken by France, and also by Sweden, where, for other reasons (there being no apprenticeship), employers need to initiate the individual into the specific knowledge/skills of an enterprise or branch.

The second case is that of Germany. Here, enterprises are very much involved in initial training (by way of apprenticeship) and invest less in continuing vocational training (on this point see also Gehin and Méhaut, 1993). The picture is much the same in Austria and, to a lesser extent, the Netherlands.

The third situation is that found in Italy, Spain, Portugal and Greece. In these countries there is a progressive complementarity between the efforts to structure initial vocational training and the emergence of rules for the organisation of continuing training.

Looked at in this light, Denmark's position seems unique, since apprenticeship and employer's initiative continuing training exist on an equal footing, the two types of training being considered very much complementary.

Other work, however, (see in particular European Commission et al., 1997 or European Commission, 1999), based on the findings of the Continuing Vocational Training Survey (CVTS) covering 12 Member States of the EU, stresses the inequalities of access to continuing vocational training between different sizes of enterprise.
5.2.2 European work on inequalities of access to CVT

According to this research, while more than one half (57%) of enterprises with more than 10 employees organise continuing vocational training courses for their employees (representing a participation rate of about one third: 28%), this figure masks great differences between enterprises according to their size (Figure 5.4). In fact, in those with more than 1 000 employees, almost one in two employees has the benefit of a vocational training course during the year. On the other hand, in the smallest enterprises (between 10 and 50 employees), only one in ten has that opportunity.

Of course, the use made of CVT also varies considerably from one sector to another. Thus, the rate of staff participation is approaching 60% in enterprises in sectors that have experienced rapid organisational and technological change over recent years (energy, posts and telecommunications, banking and insurance). In hotels and catering, construction, retailing and repairs, on the other hand, sectors where small enterprises predominate, the participation rates are only 23%, 14.7% and 27% respectively.

We shall see below that courses are the preferred type of CVT offered by enterprises, even in the smallest of them (Table 5.3). But it is worth asking whether the survey methods used (administrative survey, questionnaires, etc.) do not favour this configuration. It is true that training 'in work situation' accounts for a significant proportion and that the use enterprises make of training increases with their size, regardless of its type. In other words, contrary to what is commonly believed, apprenticeship on the job operates less as a substitute than as a complement to formalised training in all enterprise categories.

Moreover, there is a marked distinction between the rate of participation (volume of training received by employees) in enterprises offering CT courses and in enterprises as a whole. For this reason, not only are employees of small enterprises less likely to be employed by one that offers training, but even where training is provided, they have less chance of taking part than do employees of large enterprises.

On a qualitative level, finally, SEs make less effort than LEs to assess their manpower and skill needs (European Commission, 1999: p. 53) and fewer of them have staff specialising in training management (only 15% of enterprises with 10 to 499 employees against 93% for enterprises with more than 2 000 employ-

Moreover, they are less likely to have a training plan or a training budget (idem: p. 55). However, where they do have a training plan, SEs (10-49) have almost the same participation rate as large enterprises (44% compared with 49%). There is therefore probably a link of cause and effect between the existence of a training plan and the level of development of CT practices (idem: p. 60).

The French data, which are quite precise on the subject, complete the picture of CVT 'deficits' in SEs. They show in particular that the two national objectives set by the 1971 law for equalising opportunities for both enterprises and individuals have not been met. The two registers are moreover closely linked, and the size of the enterprise in fact plays an important part in the disparities in training access between occupational categories.

1. On the one hand, SEs have difficulty in raising themselves above the statutory threshold (1.5% of the payroll) and participation by enterprises with 2 000 employees and over is three times greater than by those employing 10-19 (Table 5.4); the gap between the proportion of employees with access to VT in small enterprises and in the largest ones has tended to grow despite a higher growth in the rate of financial participation of the smallest enter-

prises by comparison with the largest in the long term (Table 5.5).

2. On the other hand, not only does enterprise size affect the disparity between socioprofessional categories (for example, an unskilled manual worker in an enterprise of 2 000+ employees has in fact twice as much chance of access to training as an executive in a small enterprise), but in particular, socioprofessional inequalities in the end appear greater in small enterprises than in large ones: for example, the difference between the rates of access of executives and unskilled manual workers was 5.6 in 1993 for enterprises with 10-19 employees, as against 1.9 for enterprises with 2 000+ employees (Bentabet et al., 1999). In other words, in the French context, SEs are more elitist than LEs.

There seems therefore to be a broad consensus at European level around two findings based on statistical data: overall, SMEs make less and different use of continuing training than do large enterprises for developing or renewing their employees’ skills. While the latter tend to favour organised training, the former prefer on the job training and make greater use of new staff recruitment. Over all, they recruit more than they train (Aventur et al., 1998).

5.2.3 Two interpretations of the deficiencies of formalised training in SMEs

Two interpretative approaches are generally encountered to these two findings: the one tries to put the emphasis on the inadequacy of the supply of continuing training in the respective national context; the other gives more priority to the specific nature of the demand for training in SMEs and the more or less spontaneous adjustments of which they are capable. We shall now look at these two aspects and try to stylise them.

1. The first interpretation harks back to the failure of normative models: SMEs’ deficiencies in continuing training are explained by the chronic inadequacy of the institutional structures. This is the problem discussed by such authors as Verdier in France or the British analysts, who on this point have voiced the same criticism of both the old system of vocational training (corporatist regulation) and the new institutional framework of VET and the new institutional framework of VET (see Chapter 2.2 of this paper, which is devoted to this point).

In the case of France, whether the law of 16 July 1971 is seen as ‘a statist institutional edifice’ (Santelmann, 1999) or the product of a ‘negotiated legislative’ path (Verdier, 1999: p. 11), most authors agree that in its excessive formalism it is far removed from the specific needs of SMEs. It is a common thread throughout Verdier’s successive studies: there is a contradiction between the formalised nature of the law, whose model remains the course disconnected from production and work, and the specific characteristics of SMEs. By introducing an obligation to spend money on continuing training for all enterprises employing 10 persons or more without distinction, it has merely reproduced the gap
between enterprises that already trained their employees and those that were clearly lagging behind. It has also proved incapable of dismantling the structural inequalities between SMEs and LEs, most of which are nowadays almost always above the statutory minimum (Verdier, 1991).

The same author also highlights 'the relative failure of the intermediate institutions' responsible for mutualising the funding intended for CT (joint bodies or employers' trade associations) that were initially supposed to act as interfaces 'between the central norms' and the specific needs of enterprises. In most cases, they were unable to avoid transfers benefiting larger enterprises. Bentabet et al. (1999) reiterated this diagnosis, focusing more particularly on the extension of the norms to very small enterprises (law of December 1991). Despite the statistical data being less precise than for enterprises with more than 10 employees and covering a smaller field, they showed that mutualisation was of particular benefit to VSEs in certain sectors, such as business services, because of their greater ability to decipher a supply system that had become increasingly opaque and complex as time went on.

There is another possible interpretation: faced with the deficiencies in the official schemes or in parallel with them, SMEs may be capable of generating dynamic adaptive behaviour like any player on the labour market. If that is the case, they do not necessarily train less than large enterprises. Bentabet et al. (1999) reiterated this diagnosis, focusing more particularly on the extension of the norms to very small enterprises (law of December 1991). Despite the statistical data being less precise than for enterprises with more than 10 employees and covering a smaller field, they showed that mutualisation was of particular benefit to VSEs in certain sectors, such as business services, because of their greater ability to decipher a supply system that had become increasingly opaque and complex as time went on.

This thesis of SME adaptability is also developed by some German researchers, however. Büchter (1998), for example, believes that, contrary to what is said in public, few SMEs are complaining of skill problems. The only ones to do so are those that need and already have a highly skilled workforce, especially in the high-tech sectors. But, he argues, most have shown a remarkable adaptability thanks to 'muddling through' and to existing skill reserves built up piecemeal over a long period. In an institutionally and socially stable context, moreover, they are able to 'count on their employees' to adapt ('learning by doing') and on cooperation between suppliers and manufacturers.

5.2.4 The main factors determining demand for training

More generally, a lot of European research tries to answer the question of the main factors determining training practice in SMEs. A few examples will be mentioned here.

5.2.4.1 The key variables

Curran et al. (1996) stress the importance of size, sector, market conditions and the legal and institutional framework. The size of the enterprise is certainly important in that it determines the material resources available and the likelihood that the training effort will pay for itself (the enterprise's 'internal market'). The effect is not the same in every country, however. In Denmark, for example, the link between enterprise size and the amount of use made of continuing training is not as clear as elsewhere and this 'atypical' situa-
tion deserves further analysis. Also, while the split between small and large enterprises is particularly acute in the south of Europe (France, Italy, Spain, Greece and Portugal), the same does not apply in the northern countries.

Looking at VSEs, other authors (Bentabet et al., 1999) add to the list the legal status of the enterprises (independent, company form, subsidiary) or their place in the value chains, the methods of access to the profession (closed/open)\(^{87}\) and the sociological profile of their managers, not to mention the local or territorial contexts in which small firms operate, and their strategic behaviour (that is the product-service/market pairs). The researchers mentioned consider this a key variable, e.g. Verdier (1990-b: p. 299), for whom ‘recourse to continuing training is linked to the enterprises’ position and that of their activities in the production chain. It also depends on the characteristics of the resources deployed in the productive combination’. Drawing on a study of professional electronics, this author in fact notes with Grando that the capital intensity, the technical nature of the products and the job structures, which favour the best qualified levels, entail a massive use of continuing training (Grando and Verdier, 1988). Therefore, taking into account the heterogeneous nature of production structures in the French context, it is not so much the prescriptive nature of the statutory provisions that makes them particularly difficult to apply to SMEs as their excessively homogeneous nature (Box 5.3).

On the basis of a consultation of experts, Gil S., Allesch J., Preiß-Allesch D. (1993) for their part make a systematic analysis of the barriers separating heads of small firms from the world of training. They identify no less than 70 factors most commonly mentioned in specialist literature, dividing them into three categories: factors relating to demand (like the lack of training infrastructures in sector associations, the small entrepreneur’s rejection of ‘traditional’ training), those concerned with the supply (excessive cost of training, inappropriate training methods, lack of pedagogical skills and especially insufficient knowledge of SMEs on the part of trainers), and, lastly, those connected with the environment (excessive red tape involved when SMEs apply for official assistance, lack of LE/SME cooperation for training heads of SMEs, etc.)\(^{88}\).

All these factors are inextricably linked. The authors describe them as a ‘jigsaw puzzle’ and they try to complete it on the basis of 36 examples of ‘good practice’ and 11 sets of recommendations.

Looking more specifically at the obstacles to the use of formalised training in SMEs, Grasser et al. (1999: p. 26) summarise in this way the obstacles ‘tirelessly recorded and repeated’ in the literature: ‘inadequate own resources for training their employees themselves; a relatively limited temporal economic perspective preventing SMEs from implementing a proper training policy; difficulties in ‘releasing’ staff because they cannot be replaced temporarily; the impossibility of offering career prospects and internal promotion and the fear that, once trained, staff will leave, making it difficult to encourage training or to get employees to value it’. The authors say that financial incentives have no effect on these last points.

**Inadequate supply ... and the impasse of needs analysis**

Inadequacy of supply has also been suggested as a barrier to the development of CT in SMEs and an ignorance of SMEs’ true needs has often been blamed for this. Hence, enterprises have for some years now been the subject of a growing number of studies seeking to clarify their ‘skill needs’ and to give decision-makers concrete answers. However, most of these analyses have proved extremely disappointing in use. One reason for this has been methodological difficulties following the necessary

---

87 In some branches of the craft trades, for example, the possession of a certificate of competency is for the manager both an operating permit and a protected way in for exercising his profession.

88 This factor should not be underrated. In France it has in fact been the subject of a position paper containing 37 administrative simplification measures recommended by the State Secretary for SMEs.
Box 5.3: Market constraint, industrial strategies, type of qualification required and training practices in SMEs

**The example of professional electronics**

- subcontractors dependent on short-term orders from their clients are not able to make long-term investments in training:
  - Enterprises of this kind are often involved in bottom-of-the-range products and prefer qualities like 'dexterity or tenacity' which have little to do with formalised training;
  - a subcontractor who becomes his backers' 'partner' has to meet quality standards that result in formalising and/or raising the enterprise's skill levels:
- Less dependent on prices and with a longer-term outlook, he is also able to invest in training, making it part of an industrial strategy;
  - a designer of specific products meeting his clients' particular demands combines great technical knowledge with skills built up over a period of time, often on the job:
  - Use of courses will be only ad hoc, motivated by the desire to familiarise his employees with a new process, for example; these will then pass the knowledge on to their colleagues;
  - designers who themselves place orders with subcontractors in order to concentrate use of their high skills on product design, assembly techniques and marketing. The corresponding technicians, engineers and sales staff are however often active on an inter-enterprise job market and their employer is exposed to periodic external mobility:
  - The return on training is not therefore guaranteed, and these enterprises sometimes confine themselves to ad hoc training; building staff loyalty or constructing an internal market determine the enterprise's reliability in the medium term.

abandonment of normative models based on the large enterprise (on this point see a whole gamut of German literature, including: Stockman and V. Bardeleben, 1993, Kailer, 1992; Paulsen 1992, Kramer, 1995), and they have also proved disappointing when it comes to implementing new training practices more tailored to the needs expressed.

Some empirical research in Germany has shown that, unlike the technocratic concept developed in regional, national or European institutions, SMEs seldom consider skills an essential part of their strategy (Höfkes and Beyer, 1995). A simple cost-benefit calculation is enough to make them reject formal, planned CT as not applicable and in the end to prefer ad hoc adjustments that are closer to the needs of a small enterprise. According to the authors, this has been encouraged by the lack of a law on CVT in Germany.

As for the famous and countless 'needs analyses', either the information collected is too vague and too general to be of any practical use, introspection in the matter of skill and training needs not being an SME speciality, especially for the smallest of them (Lehmann, Speckmann, 1993), or the demands expressed are so specific that they would require tailor-made training, of necessity expensive, for every enterprise or group of enterprises with identical interests. Finally, even if the CT available were highly adjusted and differentiated according to the enterprises or regions concerned, that would not mean that it became a strategic part of enterprises' consideration of their future reorganisation (Modrow-Thiel, Roßmann, Wächter, 1993). Hence, some researchers say it would be better to stop looking at needs that are often artificially wrung out of SME managers and instead to use empirical studies to look more closely at how they manage their manpower (Bentabet et al., 1999).

Another point of view is taken by Hyland and Matlay (1997), who use an extensive survey of 2 000 independent small enterprises in five different sectors of activity in the West Mid-
lands as a basis for in-depth interviews with 246 of their managers. We find here a mixture of internal and external factors like the enterprise's stance on the market of products or services, the prevailing economic and institutional climate, which are described as the most important at the same time as 'the lack of training schemes relevant to their specific needs' (87% and 81% for respondents from industry and services respectively), while the availability and cost of training and the 'inevitable time constraints' are mentioned only half as often. As to the more 'personal' or 'secondary' factors affecting SME bosses' attitudes to training, the authors consider that 'by far the most important was the previous education and training experiences of the individuals concerned' (1997: p. 133). That is why it is interesting to think about manager training.

5.2.5 The importance of manager training

Special attention has always been paid to 'management resources' (Manz, 1993) as a factor explaining SMEs' continuing training practices. In general, two registers can be distinguished concerning either the initial training of the managers themselves or their continuing training. The first has been studied especially from a sociological point of view and concerns significant determinants over which decision-makers have little control. We looked at them ourselves in the context of a localised production system, examining 'the social construction of entrepreneurial behaviours' (Trouvé, 1989). The second may either be linked to the experience of the managers – by way of concepts of self-examination as developed by Le Meur (1993), of sociology of action as in Perrien (1994), or of previous career paths as in Ardenti and Vrain (1998, 1999) –, or be considered a preferred lever of policies to stimulate training in SMEs by way of formal training for their managers or for enterprise creators (Education Permanente, 1993; Melis et al., 1993).

In this latter field, some international literature does indeed look at the links between 'management training' for managers and owner-managers and SME performance in terms of survival, profitability and turnover and employment growth (e.g. Bell et al., 1992; Hewitt, 1993; Kinsella et al., 1994). Nevertheless, it is 'rather sparse' according to Westhead and Storey (1996), or fails to take direct account of access to training as an explained variable. In every case it tends to be the SMEs' economic performance that is examined and the findings seem fairly inconclusive. For example, while Cosh, Duncan and Hughes (1998) do find a correlation between formal manager training and growth in turnover and employment from a survey of 1 640 SMEs employing less than 500 people over two different periods in the United Kingdom (1987-90 and 1990-95), they fail to check it against the profit level. At the same time, they develop a finely shaded opinion, suggesting that formal training affects the survival and performance of SMEs of a particular size or during some periods but not others. Kitching (1998) comments: 'in itself, this constitutes an advance over previous thinking that training necessarily leads to increased chances of survival or improved business performance for small enterprise owner-managers and suggests that policy-makers may better employ public resources by targeting training at specific kinds of small enterprise'.

Westhead and Storey (1996) go further. In a remarkably well-documented article that sets out to examine the European and non-European literature on the subject (Canada, US, Australia), they show that the link between management training for managers and the economic performance of SMEs is very 'weak' and that training in management is less relevant in SMEs than in LEs. They take up the argument adduced by Baldwin et al. (1994) for Canada, according to whom 'business success was not associated with training alone'. In an earlier publication, they had already found this to be due primarily to the methodological failings of the studies claiming to establish a relationship (Storey and Westhead, 1994). Considering on the one hand that the main characteristic of SMEs in relation to LEs is the 'external' uncertainty to which they are subject and which causes them to take a short-term view incompatible with investment in training, even in management, they think the same reason explains the low
demand from managers who are not owners and consider there to be an urgent need for ‘additional carefully conducted research’ in the field.

Here we have findings (or rather a lack of them) that contradict the certainties of those who defend training and HRM and that ought to be seriously considered by future research. What should we say, then, of the empirical work of Baldwin et al. (1994), who show, in general terms, that ‘the most successful businesses tended to train fewer workers than a less successful group of firms. In addition, the more successful firms were more likely to provide formal training and less likely to undertake informal training’? True, these authors add that ‘The results for training might disappoint the advocates of the importance of training. This should not be so. The results do not mean that training is counter-productive. They only indicate that the more successful do no more training than the less-successful firms’ (1998: p. 78). Clearly, a distinction would have to be made according to the extent of the training (generalised to all staff or targeted on a subpopulation) and the differences between the formal and informal nature of training better identified. Most of the European research that we shall look at now has in fact been concerned with this latter opposition.

5.3 The ambiguities of ‘Training on the Job’

As we have seen, for most of the research concerned with statistical data, SMEs make less use of training than do large organisations, especially in the most structured form, and they make inadequate use of the skills available in their environment. This is what causes Perrien (1994) to say that ‘the trainer remains on the SME’s doorstep’. Most of the time, therefore, it remains for qualitative monographs to show that, in small firms, the deficit would be offset by a wider use of informal or implicit training in the work situation.

Care should however be taken with this overworked argument. While it would be absurd to deny that large enterprises have any ability to provide on-the-job apprenticeships, neither can SMEs be held to be definitely unsuitable for formalised training. This would explain why taking account of the relative importance of informal practices does not necessarily narrow the gap between SEs and LEs, as is shown by the work by Serfaty and Delame (1991) for France or the European data presented in Table 5.3. True, for the former, on-the-job training always carries more weight than official training in SEs (about three times more), but it still represents about 1/3 of the financial effort of large enterprises with more than 1 000 employees and the importance of undeclared courses increases with size. So what is the real picture?

5.3.1 The inadequacy of the tools for measuring SME involvement in vocational training

Firstly, it should be pointed out that the deficit thesis is concerned at least in part with the inadequacy of today’s tools for measuring, observing and comparing continuing vocational training practices, either for comparing SMEs with LEs or for international comparison purposes.

To begin with, most national statistical systems use a restrictive definition of training and find it hard to record the informal training practices that predominate in SMEs. However, the same applies to the theories on human capital formation, which more often than not look only at the number of years’ schooling or the completion of a level of education as capital-forming activities (OECD, 1998: p. 88). Among the many studies that all come to this conclusion, one might mention those by Hendry et al., 1991, Goss and Jones, 1992, Vickerstaff, 1992, Nove et al., 1995 and Bentabet et al., 1999. That is why a lot of the research is given over to a criticism of the statistical sources and to defining the concept and the various types of training (Box 5.4).

89 On the other hand, Curran et al. (1996) note that ‘a wide definition of ‘training’ covers both in-house and informal training as well as external training including that leading to formal qualifications’ (p. 17).
Box 5.4: Training typologies

1. **Formal Off-the-Job Training**: all forms of instruction that take place away from the workplace and which are designed to increase knowledge and skills in relation to the job. Such training may be provided by public-sector institutions (i.e. colleges of further education) or private-sector bodies. Such training may - but not necessarily - lead to a recognised qualification.

2. **Formal On-the-Job Training**: training geared directly to the acquisition of a level of qualification necessary for the job held but which takes place separately from production activities. This training is often provided by private-sector bodies, such as equipment suppliers, to ensure that employees know how to use the equipment better.

3. **Informal On-the-Job Training**: any activity that increases the knowledge and skills of individuals in relation to the tasks they have to perform, but not requiring more than very short periods of time away from production activities. For example, new employees or the less skilled may be 'mentored' by more experienced or better-trained ones who advise them if they encounter problems.

4. **Informal Off-the-Job Training**: Activities that develop individual skills but which are intermittent and of limited duration and do not necessarily lead to clearly defined qualifications. It may mean, for example, attending trade shows, taking part in seminars or workshops, visiting suppliers or other enterprises in the sector, studying work-related documents in their own time.

We can also distinguish:

- **initial training** (formal or informal) accompanying 'induction into the job role' or for new or recently promoted employees starting their jobs.
- **continuing training** (formal or informal) designed to enable the firm’s present employees to maintain or enhance their skills or acquire new ones.

Finally, the training process may be described in terms of three dimensions:

- **duration**: may vary from less than an hour to several years, be continuous or broken down into several periods, sometimes planned in advance according to precise objectives.
- **intensity**: may vary regardless of the degree of formalisation of the training. The length, complexity and stratification of the training required depends on the standard of competence defined and required by the employers (cf. the national system of vocational qualifications - NVQs in England and SVQs in Scotland). Similar distinctions may also operate in some informal training.
- **scope**: this may be divided on the basis of whether the skills acquired are easy or difficult to measure. The 'informal' label is generally applied in the latter case. However, the least well-defined and least measurable training may be of prime importance, as in the case of economic activities involving the production and handling of intangible goods.

Comparative data on the subject at European level are even more difficult to come by. Felstead et al. (1998) warn us that 'the interpretation of statistics on training at European level is full of pitfalls and must be undertaken with the utmost care'. The issue here is not only the divergent national concepts of training (Campanelli et al., 1994) but also the data collection techniques and the breaks in time series that occur despite the 'harmonisation and synchronisation' work done by Eurostat in particular since 1960 (1992: p. 53).
5.3.2 Uses and limitations of the cottage industry paradigm

The on-the-job training argument is very often used to relativise or qualify the apparently irrevocable verdict on SME handicaps in the matter of training. Such is the case of the many qualitative analyses of practices, which have at least shown all the complexity of apprenticeships in the work situation. The upshot of such investigations is most often that SMEs not only contribute less to skills formation, be it because of their different arrangements more integrated into daily production activity or by concentrating their training in particular moments in their development, such as on their creation, when making new investments, when they change hands, or when quality policies are introduced. Moreover, the skills that they create or maintain are not the same as those acquired by formal, codified apprenticeship, either. From this point of view, they are more suited to passing on initial or 'elementary knowledge and skills', just as they are 'a more favourable landscape for practical apprenticeships', or at least less abstract than large enterprises (Drexel et al., 1986).

What we are marking out here is the paradigm of the craft trades, whose advantages many researchers are trying to identify in order to see whether they might be extended to all small enterprises, whether the accent is on the particular forms of socialisation to which they give rise (Zarca, 1986; Combes, 1988; Bentabet et al., 1999), or they are trying to think in terms of their contribution to general human capital formation. This is what Kucera (1997) does in particular, drawing on the German example which shows that apprenticeship and continuing vocational training in a craft trade situation have significant advantages: on the one hand, they allow the product and the skills of the apprentice ('Auszubildende') to be produced simultaneously ('Kuppelproduktion') for a net cost (that is, the gross cost less the advantages brought by the apprentice) that increases with size; on the other, they offer a proximity to working practice that college apprenticeships cannot provide; finally, their integration into production activities makes for greater versatility.

The positive external effects of on-the-job apprenticeships are therefore considerable, and all the more so since a major proportion of the individuals trained by apprenticeship, especially in the craft trades, are able either to create their own enterprises or to go for a complete change of career, often moving to larger enterprises. Such is the case, for example, in France (Bruand, ...) and Germany, where nearly 40% of craft workers change their trade (Henninges, 1994). Should we see these processes of mobility, especially at the start of a career, as an imperfection in the training-employment relationship and a poor use of the initial vocational training, or should we, as we did above (cf. Chapter 4.3), consider VSEs to be acting as a place of transition on the labour market?

Nevertheless, it would be wrong to reduce the SME training model to that of informal apprenticeships, contrasting it without qualification with the essentially more formalised model of the large enterprise (Verdier 1990-b: p. 303), because, for one thing, large enterprises are not unaware of the processes by which skills are passed on at the workplace and, for another, small enterprises are not chronically unsuited to formal external training. What needs to be rethought are the ways in which different forms of training are articulated, so as to avoid 'courses' becoming so disconnected from the actual performance of work as to be far removed from the realities of SMEs, while at the same time preventing apprenticeship from becoming so closely adapted to the job in hand as to preclude any kind of inter-enterprise transfer or mobility.

5.3.3 SEs are not unsuited to codified training or to using outside training

Several situations are adduced in the literature to explain that the prospects for developing structured external training in SMEs are not zero, even in the smallest of them.

First of all because of the heterogeneity of the field of SMEs: highlighting three major configurations of SMEs / VSEs, Bentabet et al. (1999) stress their greater or lesser reservations about institutionalised arrangements for training. Represented in the first of these
by the most widespread traditional small firms, 'family firms' and the self-employed, where the employment relationship between the head of the enterprise and the employee is the most personalised and where the building of skills depends very little on formal qualifications and formal continuing training, enterprises find it most difficult to provide training in the form of 'courses' outside the work situation. The second configuration, described as 'ideal-typical', involves 'managerial, integrated or modernised VSEs/SMEs' at the opposite end of the spectrum. They are extremely sensitive to the market through their involvement in various networks (franchise, branch, part of a group) and the methods of human resources management are much more formalised than before with vocational diplomas being required and significant use made of external formal continuing training. Employees can be assumed to have wide access to training in this situation. The third configuration is indicative of practices half way between the previous two. It embraces 'entrepreneurial VSEs/SMEs' where the pattern of activity is marked by breaks and innovations enabling the enterprise to differentiate its products or services, where employment relationships are in the process of being formalised and where the skills required are both the product of a technical culture and the result of experience in a particular field. Here, continuing training is marked rather by a hybridisation between the two previous models: both external and formal, but also 'on the job' and most often provided by other employees through a 'trickle-down effect'.

Training practices must therefore be examined in the light of this extreme differentiation of the SME fabric as it appears in most of the most recent work. The targets and possible expansions of training in SMEs should be designed on the basis of this differentiation.

Then, training practices can also be differentiated according to the time span and life cycle of SMEs. Looking at the supply of training and the regulatory abilities contributed by the intermediate players (consular bodies, trade associations, public or private consultancies), we find that a number of - at least partial - responses to small enterprises' training needs involve identifying specific moments and publics that facilitate investment in training in those enterprises. Thus, the transfer of an enterprise, the purchase of new equipment and its corollary the expansion of activity, as well as changes in product-market pairs, improvements in quality or the tightening of management constraints (delivery times, just-in-time) are important moments that very often open a wider breach into management problems which in turn call for training. As for the publics concerned, young people and especially husband and wife teams, they also help to structure the training supply. Thus, in the report by the European Commission, Eurostat and Cedefop (1997), based on data derived from the Labour Force Survey, a chapter is devoted to CT for the self-employed as compared to employees. Among other things, they state that, among the self-employed (with no employees) women undertake the most continuing vocational training (almost 4% of them, compared with just over 2% for men).

Finally, observation of innovating SMEs in the field of training could be a very great help, especially since it would enable us to understand why some small enterprises are able to adopt 'atypical' behaviours, that is training policies that are not normally very widespread in similar firms. An example of this type of approach is given in the work of Bel and Rosanvallon (1990) and Rosanvallon (1990). These authors begin by pointing out that new training policies in SMEs do not come about by chance but are very much based on internal factors or external management mechanisms that facilitate them.

For the former, note will be taken of the enterprise's history, the manager's personality and his ability to set a strategy ('in 2/3 of units studied, training innovation goes hand in hand with the arrival of a new manager'). Analysing innovating initiatives in SMEs in the Rhône-Alpes region, they in turn recognise that, far from ruling each other out, formalised training and training incorporated into the work situation are complementary, since innovation is an expression of the abil-
ity to formalise needs and of the specific methods of implementation: 'the most innovative enterprises recognise the limits of training on the job, especially its ability to ensure mastery of new, more complex working situations. They make greater use of formal training in the form of courses with a theoretical content' (Bel and Rosanvallon, 1990: p. 65). It is true, the authors add, that measuring the training effort in terms of courses shown in official returns (e.g. the famous 24.83 in France) does not make for a complete appraisal of the training effort, but the small amount of formal training generally shown for SMEs in national and European statistics 'is revealing of real or potential major imbalances between the content of the training policies deployed and what is needed to cope with the changes that are taking place' (p. 42).

So far as external factors are concerned, Rosanvallon (1990), like many others, puts particular stress on the emergence of a large number of 'new players and training skill networks', including local authorities, private companies providing consultancy and assistance with training, sundry agencies, etc. In this sense, 'the emergence of innovating training practices forms part of a wider process of integrating SMEs-SMIs into external skills networks providing aid and assistance, particularly in training', which must be seen alongside 'the rise and development of new profiles of entrepreneurs, the recruitment or arrival of engineers and managers who remain in contact with their old networks' and also alongside the current trends in the ways SMEs-SMIs articulate with large industrial groups (Bel and Rosanvallon, 1990: p. 82).

Finally, it is clear that 'the establishment of new systems of apprenticeship and skill production' cannot be reduced to ad hoc interventions targeted on enterprises alone. Innovatory schemes are of necessity complex and need to deploy a larger number of players using more diverse methods of training. Without a doubt, 'such many-sided and varied reshaping' is, potentially at least, more appropriate to the specific nature of SMEs-SMIs because of its modular nature and greater integration 'between the organisation of courses and experimentation with new working methods, between training and needs analysis, between training and production within the enterprise...' (Bel and Rosanvallon, 1990: p. 85), but it also requires overall consideration to be given to the institutional machinery of vocational training, as can at present be seen in most EU countries.

5.4 Towards new forms of regulation...

It is not our purpose here to go back over the many examples of the reform of national continuing vocational training structures examined in detail in outstanding publications (e.g. Cedefop, 1983, for the structure of the systems, and Aventur and Möbus, 1999, for a study of their recent dynamics). It seems to us more interesting to bring out the main trends and current changes of course that may augur well for the future development of vocational training in SMEs. We shall look here at three in particular: firstly, the present swing of enterprises towards skill mobilisation; secondly, the ways of identifying, validating and accrediting informal apprenticeships; thirdly, the debates on technological and organisational innovation for a training appropriate for SMEs.

5.4.1 The shift towards a 'skills' logic: between individualisation and institutionalisation

For a number of years now, there has been a marked trend in most European countries to build enterprises' competitiveness on the 'mobilisation of skills'. Clearly, this is not something unique to SMEs. One might even say that it is inspired more by the technologies of Human Resources Management common in large enterprises. But the notion of 'skill' carries with it three ideas that are very close to the models of professional competence and status validation currently encountered in SMEs.

Following the skills logic, first of all, the specific command of work situations takes priority over both the trade-related systems of recognition that are structured by professional relationships (as in the old British corporatist tradition), over diplomas and theoretical knowledge (as in the French-style institu-
The employment and training practices of SMEs

tional, statist control), over the jobs or positions held (as in bureaucratic organisations) or over socially incorporated knowledge (as in the Italian forms of local regulation).

Secondly, looking at training, as A. Vinokur notes, the skills logic corresponds to a requirement for ‘downstream piloting’ of apprenticeship systems, a piloting ‘characterised by a separation of the skill transmission function from the certification function’ (quoted by V. Merle, 1997: p. 49). From this point of view, the process of apprenticeship is less important than the result, that is the command of work situations in all their complexity. However, SME managers and especially VSE managers who are their caricature are saying nothing different: ‘training takes place in the enterprise itself’ and the use of professional know-how can be validated without any formal training or instruction or even diplomas (Bentabet et al., 1999). Moreover, in the British NVQ system, often held up as an example of the ‘skills’ approach, apprenticeship courses and their content are not specified.

Thirdly, the recent theoretical widening of the concept of skill to include social and relational know-how may be applied to SMEs in traditional commerce and service activities (sales, catering, accommodation, etc.).

Some critical analysts have said that the rise in the concept of ‘skill’ should be seen in parallel with the weakening of the ‘qualification paradigm’ (Rainbird, 1995: p. 246), which was based on strong professional, institutional or societal regulation (on the British, French or German models)90. In fact, it appears at a time when the traditional collective regulations in the field of work and training are in crisis and the small enterprise model is, according to some, becoming established as an organisational alternative to the rigid professional relations of the Fordist era. In plain terms, in an area where trade unions are so little involved and where SMEs have such reservations about initiatives taken by the State, the skills logic could be all the more important for assuming a weakening of the wage relationship and its conventional framework and an individualisation of training.91 There is a whole series of articulations here that need to be studied and debated, while not forgetting the dangers that V. Merle refers to as ‘tendential in the European Commission’s White Paper (1995), those of a ‘free market in skills [where] only the individual and his skill remain’ (1997: p. 42) with no other form of regulation than the short-term needs of enterprises.

In this extreme case, there would be the risk of excessive individualisation resulting in desocialisation, that is a failure to take into account the collective contexts in which vocational skills are acquired and, ultimately, quite simply a return to elitist mechanisms (exclusion of individuals from the labour market, aggravation of the rifts between SEs and LEs, dualisation within the SME sector). That is why we must be attentive to the new compromises built in each country between the various players on the labour and training markets, since the adoption of a skills logic would paradoxically require the adoption of strong institutional norms, be they inspired by the State or regional institutions (as in the United Kingdom, France or Spain) or born out of collective bargaining between the social partners (as in Germany).

This is how we must understand the gradual hybridisation of the new CVT systems being built in most EU countries. In the United Kingdom, for example, where the edifice of TECs and LECs inspired by a liberal, decentralised concept and powered by the market

91 Such individualisation of training can in fact already be seen in the concept of ‘co-investment’ that is emerging in several EU countries and which involves a financial sharing between the individuals in training and their enterprise or the State to adjust to new forms of employment (training partly in leisure time in Denmark and Germany, ‘Youth Credit’ in the United Kingdom). It is also explicitly suggested in the concept of ‘individual right to training’, which would operate as a system of credit throughout working life, as recently proposed by J. Delors (1999: p. 5) as part of the reform of the French CVT system.
Philippe Trouvé

('market-led training system': Parker, Vickerstaff, 1996: p. 251) may be combined with a highly voluntaristic action by the State resulting in a kind of 'organised laissez-faire' (Bouder, 1999: 387). Similarly, the guidance and organisation of NVQs at national level can adapt to programmes of support for individuals (Youth Credit, Career Development Loans) or for enterprises to enable them to invest in human resources (Investors in People). Likewise, too, the leadership of large local enterprises on TECs can coexist with the quest for new balances that will allow the specific nature of SME needs to be recognised by the establishment of ad hoc committees and even a programme adopted in 1995 (Skills for Small Business). In France, where the skills approach is not really institutionalised as a tool for human resources management, but is recognised as an individual right ('skill balances'), the Ministry of Education (Education Nationale) is still the dominant player for certification. The establishment of machinery for validating vocational experience and of Vocational Skill Certificates (Certificats de Qualifications Professionnelles – CQP) have however helped to get the training role of enterprises recognised and the power to oversee and evaluate employment and training reference systems opened up to other players (on this point see Feutrié, 1997). There are many other examples of new combinations of players accompanying the progressive diversification of systems of qualification and forms of certification.

5.4.2 Recognition and validation of professional or informal experience

Another movement is emerging that could prove favourable to the development of training in SMEs. We are referring to the policies adopted by the EU, in particular through the Leonardo da Vinci programme and illustrated by the White Paper (European Commission, 1995) concerning systems for the identification, validation and recognition of informal experience for improving transparency and skill transfer92. It is not our place here to go into the methodological and epistemological debates to which such a set of measures has given rise, or even to list the current studies or international comparisons on the subject. These are all described and discussed at length by Bjørnåvold (1997-a; -b; -c; -d).

While not adopting a specifically SME-centred stance, he reviews the context that encouraged the emergence at European level of measures for the validation of skills acquired outside the formal education and training system alongside the traditional certification procedures based on formal education. He refers both to the calling into question of the social and professional value of qualifications in rapidly changing production systems, 'the emergence of new organisational perspectives and practices in enterprises, requiring a more diversified approach to questions of apprenticeship and skill formation', the development of training throughout life, and especially the changes that have taken place in the operation of labour markets where internal recruitment practices (which presuppose at least a relative transparency of professional experience) have weakened while the strategic importance to enterprises of looking to external markets has increased, which implies taking a closer interest in the formal and especially the informal or 'invisible' skills of candidates for recruitment (Bjørnåvold, 1997-c, pp. 5-6).

We can see here that the first and fourth arguments are the ones most in line with the SME issue, firstly because SMEs (especially the smallest among them and in some national contexts more than others) are always quick to question the value of qualifications produced by school systems, and secondly because more intensive use is made of external markets in SEs than in LEs. While the approaches to the validation of non-formal experience are appropriate to the ideas of SMEs, they are nevertheless limited, not only

92 A number of benchmarks may be quoted in the European Commission’s guidelines for identifying and validating existing and/or informal experience: the project launched in 1993 for an 'individual skills portfolio' (Individual Portfolio Project), the idea of a Personal Skills Card put forward in the Livre Blanc (1995), the EU Skills Accreditation system and the 'Euro-validation project' conducted in five countries as part of the Leonardo programme (on this point see Bjørnåvold, 1997-c, Chapter 4).
by their ability to formalise implicit skills, but especially by their sociology, that is the cultural norms they carry. In other words, going back to the three aspects suggested by Bjørnávold (1997-d), while the identification of non-formal skills is going well methodologically and scientifically, and while their validation requires top-level decision-making authorities at European level, their recognition depends for its part on social values at national level and in the enterprise.

As Bjørnávold (1997-d) suggests, a discussion of instrumental approaches (their ‘validity’ and ‘reliability’) must not neglect the questions of their acceptability and credibility, which are sociological in nature. In a way, ‘creating a system for recognising non-formal experience is tantamount to changing the social definition of skills’ (idem: p. 43). We know in fact that any national or European system of this kind adopted may very well not be followed by SMEs, either because they lack the means to do so or out of ideological reluctance: despite making much of their specific contribution to the construction of skills, they generally rely on the legitimacy conferred by official certification arrangements. Moreover, they have historically been kept away from the legitimization authorities (whether or not central). This, at any rate, is what emerges not only from a historical analysis of CVT systems in most European countries, but also from how they have developed, leaving SMEs little say in the most socially recognised certification and validation processes. Hence the dilemma, never completely resolved, in the various national or European political guidelines, between a centralised strategy that seeks to make systems for the recognition of skills homogeneous and give them greater credibility, but which runs the risk of being far removed from specific SME practice, and a decentralised strategy (‘from the bottom up’) which, while offering pragmatic solutions and a degree of flexibility, risks lacking legitimacy and being too piecemeal.

Despite these reservations, SMEs could well be a crucial arena today as well as a potential laboratory for experimentation and for building public policies for the recognition of non-formal skills.

5.4.3 Technological and organisational innovations: mirages or a way to make SME training practices more dynamic?

While considering the questions raised above, we should not at the same time overlook the many pedagogical innovation and experimentation schemes aimed at making continuing vocational training more appropriate for small enterprises, be it by using the new distance learning technologies or by organising training in networks or enterprise or businessmen’s clubs on a regional or branch basis. This is a vast new field for the systematic observation of ‘best practice’, so we shall merely mention it here.

5.4.3.1 Use of new education technologies: hopes and open questions

Subject to the distinction between employee training and manager training, the application to SMEs of new education technologies (modular, individualised, multimedia, assisted self-instruction, ‘open and distance’ learning) has already been widely discussed in the European literature. Some see their flexibility and accessibility as helping to spell the end of the traditional model and therefore as being better geared to SMEs’ needs. However, this new multifaceted paradigm, which already has its monographs, its Netherlands-based European Federation (FFFOD), its ‘abundance of local initiatives’, its websites, etc. (Actualité de la Formation Permanente, 1998) is still far from being sta-
Box 5.5: Commitments to Develop Vocational Training in France (EDDFs - Engagements de Développement de la Formation en France) in France

Created in 1984, the EDDFs are intended for enterprises that are under a statutory obligation to take part in the development of vocational training and which increase the quantity and quality of their training effort as part of a programme extending over several years. The aim is to support projects to raise the level of employees’ qualifications and skills as required by technological and economic change.

Aid is granted in particular to small and medium-sized enterprises (be they self-employed, or group subsidiaries). Thus, 90% of enterprises involved in EDDFs have fewer than 50 employees. Two thirds of trainees are manual and non-manual workers.

Enterprises’ training plans must form part of a development strategy. They are for the most part negotiated at the level of occupational branches, where problems of modernisation and competitiveness can be raised globally and coherently; they also cover a period of several years so that training schemes can take a medium-term view. They can also be decided on a territorial basis, with interprofessional organisations, for example, for local development purposes. For the most part, EDDF framework agreements are negotiated between the State and one or more trade organisations; however, employee representatives ensure they are properly implemented through their involvement in supervisory committees.

This scheme is currently under review. It could be improved in three ways: by giving greater place to local initiatives (30% of credits are still managed at national level) while preserving the benefits of branch-level negotiation; by expanding the scope of EDDFs to include experiments in e.g. internal training and skills validation; and by simplifying procedures so as to extend the scheme to enterprises normally bypassed by public intervention, especially small enterprises that are not group subsidiaries.

5.4.3.2 ‘Networks': genuine alternative, magic formula or additive?

The findings of research into the effects of inter-enterprise organisations on their training dynamics seem less uncertain. Hence, political decision-makers have come to think that the best way to influence SME training behaviour would be to apply pressure to the existing forms of cooperation, be they in the form of customer/supplier relations, partnerships, groupings, associations, clubs or various kinds of interrelating networks. That is the lesson to be drawn, for example, from observation of Italian-style industrial districts or French-style localised production systems, but which is also provided by some evaluation work on the United Kingdom’s TECs and LECs. Many of these aspects have already been mentioned (Chapters 2.1, 2.2, 2.3 and this fifth section). We shall now concentrate
The employment and training practices of SMEs

on the essentials, always remembering that these selected configurations are not all based on the same rationale: some are the product of a historical heritage, others are constructs or artefacts born of changing production systems and a political or entrepreneurial desire to modernise SMEs.

In Italy, local systems of inter-enterprise cooperation and competition have a training role for SME employees and bosses at the same time as collectively incorporated vocational training operates as an engine of entrepreneurial dynamics (Capecchi, 1995), and the recent development of external networks (Castaldi, 1999) or the present CVT reforms (Treu, 1997) must be analysed in the light of this initial model, either as challenging it or as continuing it with adjustments.

In the French example, the work on local development and localised production systems must be mobilised, such as the work by Laget (1994) with his ‘small enterprise’, ‘local’ and ‘training’ triplet, or that by Bel (1992) which, taking the mythical example of the Arve Valley, shows how the relations between the different players help to develop the skills of the workforce in a system of SMEs specialising in screw-cutting.

Another example is the in-depth appraisals of TECs and LECs made by Vickerstaff and Parker (1995). They stress the importance of inter-enterprise networks or of existing forms of cooperation between enterprises and local, regional and professional bodies in getting LECs to make greater headway with SMEs.

However, enterprise networks and the externalisation of training into networks are not a panacea for SMEs. In Germany, for example, Lehmann and Speckmann (1993) show how difficult it is to make a success of ‘artificial’ projects for networks of cooperation between small enterprises and public and private sector institutions.

Inter-enterprise relationships may, it is true, help to loosen the constraints on enterprises; agreements may, in part at least, take the place of market forces and widen SMEs’ temporal horizons: investment in manpower and training can then be seen as a medium-term thing (Verdier, 1990-b: p. 300).

There are however other possibilities, involving adjustments or improvements to institutional arrangements, following different national traditions that are at least as important as the major European trends and convergences described earlier. Such is the case, for example, of the French Government’s contract-based training and employment assistance schemes like the Engagements de Développement de la Formation Professionnelle (EDDFs) (Commitments to develop vocational training in France) that have in many cases enabled the priority targeting of public action on small enterprises and the reality of their situations to be reconciled with branch and/or regional negotiations and provided a strong incentive to incorporate training into a medium-term strategy (Box 5.5).

But does such an exemplary arrangement not always favour those enterprises that are the best equipped to find ‘a compromise between public norms and SME practices?’ Verdier (1990-b: p. 309) asks. The institutional arrangements to encourage training have no more succeeded in reducing the inequalities of SME access to training up until now than the networks themselves manufacture training within SMEs.

6. Conclusions

The stance adopted in this concluding chapter is not entirely prescriptive: firstly because the breadth and complexity of the ground explored defies all simplification; secondly because we are strangely lacking in perspective and lucidity as we emerge from this bibliographical confusion; and thirdly because the purpose of this dossier was not so much to analyse employment and training policies in the EU and to make recommendations as to examine the research into SME employment and training practices. The political dimension has not been forgotten for all that, especially when the subject is broached by the work quoted, but also because we are trying here to present the findings that appear to us
to be the most significant and the most useful to decision-makers without stepping into their shoes ourselves.

Dealing with the question of SMEs at European level is in many ways a challenge. Despite the Community being unanimous in its sensitivity to the decisive role they play in economic growth and competitiveness, small enterprises are still approached in a great variety of ways in different countries, both as regards industrial, employment and training policy, and in the field of research. On the one hand, their very definition, not to mention their economic weight, varies considerably from one country to another. On the other, their unequal place in national traditions means that research work must always be contextualised. Finally, with the exception of Germany and Italy, SMEs have almost never been a scientific subject in their own right for the academic world.

Despite these three difficulties, we know that SMEs have in recent years become a preferred focus for transnational policies that have not been content with designing funding programmes for enterprise creation, plant modernisation, research and development and technological innovation, but have sought to draw up guidelines for investment in human resources, now considered the major source of competitiveness. At the same time, they have become a new field of research, with a large quantity of empirical work, national or comparative, theoretical or geared to decision-making.

We shall not go back over the reasons for this relatively recent interest in SMEs. Mostly, they have to do with their expansion in service economies, the reconfiguration of production systems marked by the crisis in large productive concentrations and by the simultaneous redeployment of small structures that are more agile and more capable of meeting a demand that is increasingly unstable and diversified. Let us not forget, either, the persistence of unemployment in Europe that has made SMEs 'harbingers of hope'.

These developments are however heteronomous, and even if the generic model of the small independent family enterprise is still in the majority (especially in the countries of Southern Europe), it is tending to diminish in favour of small structures caught up in networks of dependency or multiple interdependency with other small enterprises or large groups. These changes must be the starting point for tackling the employment and training behaviour of SMEs, which is what most European research generally does.

6.1 The employment practices of SMEs

On the first field of investigation ('SMEs and employment'), research work into the relationship between enterprise creation and job creation is the first to be mobilised. Contrary to what is commonly thought, it shows very convincingly that such a relationship is not obvious, firstly because the proportion of newly created enterprises surviving for more than five years does not generally exceed 50%. Secondly, the rapid growth in those enterprises' workforce is a relatively marginal phenomenon subject to a number of conditions that the defenders of enterprise creation often overlook. These include the sector or branch, the territorial bonds, the creator's previous career path, the strategic stance adopted (cf. Box 3.1), and, above all, the size of the enterprise when first created (the potential of newly created enterprises to create jobs increases with the number of employees on start-up). There is also some uncertainty about the number and quality of the jobs created by small 'high-tech' firms. In short, in France at least, while there are more pure creations than resumptions or transfers of activity, they also create fewer jobs. Finally, enterprise creation does not appear to create more jobs than existing small firms do.

Hence the dilemmas surrounding political intervention to encourage or accompany enterprise creation: apart from administrative simplification ('one-stop shops') (ENSR, 1997: p. 102), should we be arguing for undifferentiated aid for all enterprise creation (by creating an 'enterprise culture', for example), or rather for measures targeted on particular small enterprises? In that case, what would be the criteria for targeting? 'Assisting employment through growth, or rather assist-
ing enterprise growth through skilled labour' (Semlinger, 1995: p. 2)? We now know that financial aid to creation alone is not enough, but that it must be accompanied by management support to avoid creators starting out with too small a workforce. In the end, should we be assisting enterprise creation or 'caring for the stock of existing SMEs' by making more counselling available, since paying attention to SE creation is justified less by their employment potential (which is frankly uncertain) than by the problems resulting from their being too small and the obstacles to their development (Semlinger, 1995: p. 21)? And to round off, should we remain with these dilemmas or construct complementarities between all these options?

Another widely held opinion that was to be tested scientifically and in the end proved more difficult and more complex to substantiate than expected was the claim that 'SMEs create the most jobs in our societies'. More difficult because the speed of the changes taking place in production systems today makes it increasingly hard to identify the specific contribution SMEs make to the creation and growth of employment. More complex, too, because the concepts of 'creation' and especially 'job/employment' are themselves being called into question. On this point, there seems at present to be a tremendous distance between the certainties of common thought (for which there is no doubt that half of Europe's working population with a job are currently employed in SMEs) and the barrenness of the methodological debates that inevitably follow when this is contrasted with the research. The overall movement of the latter is relatively clear, however:

It is true that the proportion of jobs in SMEs has been on an upward trend in most EU countries for a number of years. One might for all that question the specific role of SMEs in generating new jobs, especially since the accounting methods used to make the transition from 'stocks' to 'flows', from static to dynamic or longitudinal data, are unreliable and controversial. The main question raised here is whether the job creations observed are endogenous or exogenous. Should they be counted as creations or as the fruit of internal growth within small enterprises? Must they not rather be interpreted, at least in part, as a consequence of the restructuring taking place in large enterprises? What emerges from all this in any case is that the behaviour of SMEs as regards employment cannot be studied in isolation from an observation of what is happening in large enterprises.

Moreover, while SMEs create jobs, they also destroy a lot, and this is not without significance. The example of the 'American job-creation machine' and the phenomenon of 'creative destruction' invoked by Schumpeter have often made people think they were right to consider job turnover an essential feature of a dynamic economy, a contribution to structural change and the responsiveness of the labour economy. There is, however, also a suspicion that, at a high level, job turnover generates and amplifies processes whereby the labour force, especially the frailest sections of it, becomes more insecure. It may also prevent small enterprises and workers from making the best investment in training, the former giving priority to outside recruitment (flexibility) instead of stabilising their workforce and using internal flexibility, the latter by withdrawing from vocational training and work, sometimes at the cost of exclusion, and instead going for longer and more 'noble' forms of training or towards enterprises with more stable jobs, sometimes at the risk of being overqualified.

Then, not all SMEs create employment, only a small number do so. Hence the crucial question: which ones create the most jobs and, more generally, what are the key factors determining employment behaviour in the specific case of SMEs? On this point, research shows that the size variable is not the most important, but that it would benefit from being combined with other variables such as sector, the sociological profile of the managers, and, more important still, the competitiveness strategies adopted by the managers. This is the line taken by a series of recent studies in France, the United Kingdom and Germany in particular.

In most cases, SME performance in the field of employment is then associated with
product-service/market pairs based on differentiation or even specialisation. It may however also be associated with a particular positioning of small enterprises in the value chains, enabling them, for example, to avoid being too dependent on distribution circuits or having to fight competitively on mass markets, seeking instead direct contact with the final customer. From a scientific point of view, the advantage of such approaches is that they encourage a transdisciplinary stance combining industrial economics, management and sociology. From a methodological point of view, they are based on the quest for complementarities between purely statistical studies and more empirical, qualitative investigations and monographs, the former offering possibilities for generalisation and framework data useful to decision-makers, the latter yielding models closer to reality but less easy to use because of their complexity. They may nevertheless serve to improve the former.

Other approaches again allow this analytical segmentation of the variables to be avoided by integrating employment practices into the productive combination as a whole by means of '(holistic) enterprise' or 'labour management models'.

I:3 Over the last few years, however, another question has come to the fore in the relationship between SMEs and employment, that the issue is not only the number of jobs but also the forms of employment created in SMEs. What, in particular, about their durability, their stability and their content? Again, such approaches require articulations between disciplines concerned with employment and those focusing on work. Bringing these disciplines together is more than mere scientific debate. It opens the door to questions that might renew aid policies for the creation and development of employment in SMEs by making a connection with issues of job and manpower quality, that is qualifications and the construction of skills. This is the second subject tackled by our report.

6.2 SMEs and vocational training

Like the examination of research about employment, examination of that on SMEs and vocational training inevitably has a methodological prerequisite. The difficulty here has to do first of all with the impossibility of getting an overall picture at European level when there is such diversity of both institutions and practices rooted in 'heavy structures' and deeply anchored national cultures, and secondly with the complexity of the recent changes that have taken place in the education and vocational training systems of most EU countries. The lack of perspective here is obvious, especially with the main thrust of research in this field lying in attempts to assess the impact of the changes on SME training practices. Hence the impression that tracing the 'best practices' in both national and transnational policies and in enterprises themselves is sometimes substituted for the establishment of a corpus of scientific data that is sufficiently generalisable or reliable to guide decision-makers. From a methodological point of view, we also find a permanent tension between attempts to establish a statistical corpus, especially one where data can be compared at European level, and monographic investigations, which are more qualitative and more intensive but much less open to generalisation. Finally, the main contribution of research in this field seems to reside less in immediate and unambiguous answers to the questions put by decision-makers than in an effort to relativise what are sometimes over-sharp judgements on SME training practices.

What are the most significant points that emerge from all the work consulted?

First of all, while most research now tries to show up strong articulations (especially institutional ones) between initial vocational training and continuing vocational training, this distinction still seems very relevant for sounding out SME training behaviour. While in the former register they may be considered a key player in training and especially in getting young people into work95, in the second they are more like 'extras'.

95 It will be recalled that, with the exception of Denmark, Ireland, Finland, Sweden and the United Kingdom, small enterprises employ a higher proportion of young people (aged 15-24) than large enterprises (European Commission, 1998: pp. 102-103).
The employment and training practices of SMEs

In the first case, it is not surprising to see research taking an interest both in the links between vocational training and the emergence of new types of employment and in the various attempts to bring school and (small) enterprises closer together. However, the training function of SMEs and their role in vocational integration now seem to be marking time in most EU countries, both because of the changes to the production apparatus and because of young persons’ sociological development. There is then a great danger that we shall see a rift developing not only between SEs and LEs, but within the SE sector itself, a dualism between those capable of absorbing young people with medium to high qualification levels and the rest, the most numerous, that would be condemned to take on the most insecure people. That is why the role of public policies is absolutely central here in organising the labour market and rethinking the patterns of initial vocational training.

So far as continuing vocational training is concerned, most of the statistical data compiled at European level show what little use SMEs make of the most formalised forms of training. This deficit is moreover closely linked to the articulations between initial and continuing training in the various countries. It also shows that the training available and the normative models adopted most of the time by public policy or training intermediaries are inadequately matched, even though it is they who are responsible for making the link between enterprises’ needs and institutional guidelines.

A lot of work then tries to identify the main factors determining SME demand for continuing training. It again emerges that, contrary to the interpretations given by statistical corpuses, the effects of size and sector must not be given too much weight. Other factors are involved, like strategic guidance and modes of production, or the sociological profile and previous career path of the managers. Other research tries to demonstrate SMEs’ ability to adapt outside the formal models of continuing training. Not only do these allow the measurement tools traditionally used to be put into perspective, but they also show that there are many different forms of apprenticeship and that it is now high time account was taken of them. Hence the current work on the recognition and validation of occupational or non-formal experience converging with the processes of individualisation of training, the development of skills logics, the rediscovery of the notion of ‘trade’ (especially in craft activities) and the many experiments in new teaching technologies and networking as a way of disseminating CVT in SMEs. In any case, not all SMEs are incapable of appropriating the most codified forms of training. Some even turn out to be providing at least as much training as large enterprises (this is true of the SEs and especially the inserted or integrated VSEs analysed by Bentabet et al., 1999)96, if not more (on this point see Lange and Gros, 1987).

In the field of public CVT policies, we have for several years been seeing a clear concentration on the needs of SMEs. New ways of structuring the field are appearing in most countries, generally based on a variety of combinations of several levers, depending on the national tradition, summarised by Aventur and Möbus (1999) as follows:

- a necessary arbitration between a statutory funding obligation on employers (as in France) and a laisser-faire where the employer is free to choose (as in the United Kingdom, but also in Germany, Austria, Luxembourg, Sweden and Portugal), with a whole series of ‘intermediate’ regulations involving limited constraints, flanked by collective agreements (as in Italy, the Netherlands or Denmark) or tripartite accords (as in Spain);

- the adoption of public financial incentives to enterprises in the form of subsidies and tax credits in about half the countries of the EU, including: France (with the EDDFs, see Box 5.5), but also Germany, the Netherlands and even the United Kingdom and Ireland. In Sweden and Denmark in particular, these aids allow a jobseeker to be recruited and trained to replace an employee who has gone away for training;

96 The same reasoning may also be applied to the employment policies of ‘integrated’ SEs and VSEs.
Philippe Trouvé

subsidies to support and structure the supply of training (especially in the Nordic countries), but also and especially incentives to improve the quality of training (ISO 9000 standards) and regulation through the introduction of vocational certificates like the NVQ in the United Kingdom, directories of vocational certificates in Spain, Portugal, etc.

finally, the establishment of organisations created specifically to mediate between (small) enterprises, the public authorities and employees, such as the United Kingdom's TECs or the Organismes Paritaires Collecteurs Agréés in France.

True, none of these schemes and arrangements will solve every problem, especially the main paradox of SMEs when it comes to continuing vocational training: those that have most need of it seek it the least. Hence the importance of increasing empirical research into the factors that make 'reaching SMEs' easier (Vickerstaff and Parker, 1995) upstream of training actions and counselling. Hence the interest shown, too, in regionalisation (German researchers refer to the 'Regionalisierung der Regionalpolitik' and 'Regionalpolitik von unten' – Büchter, 1998), and in the diversification and transversality of actions (combining, for example, technological and/or organisational modernisation with training).

Nevertheless, we should not forget, either, that outside enterprise practice, continuing training ('throughout life') is also a matter of individual projects and that it could therefore be the subject of new research into 'employability'. This would have the merit of being deliberately at the crossroads between training, employment and mobility, between individuals and enterprises. A new field of inquiry could then be opened into the role of SMEs in the individual's career path, not only at the stage of initial training or starting the first job, but also in occupational change and mobility 'throughout working life'. But let us not try the reader's patience.

Human resource development in Europe – at the crossroads

Barry Nyhan

Abstract
This paper examines the concept and practice of human resource development (HRD) from a European perspective. It locates HRD, which is seen to refer specifically to learning, training and development activities, within the context of underlying people management theories (human resource management – HRM) or what can be termed as 'industrial or working life cultures'. The paper contrasts two theories of HRD derived from different ways of conceiving human resource management. The one that has more in common with classical European industrial values is the humanistic-developmental tradition. The competing model, which it is argued is growing in prominence in Europe, is the instrumental-utilitarian way of looking at human resources. The paper concludes that Europe is at the crossroads at the moment in its search for a signpost leading it to human resource management practices that are socially sustainable.

1. Introduction

The term 'human resource development' (HRD) refers to educational training and development activities related to working life. Although it is often used in a very wide sense to refer to all work related learning activities, more accurately, it relates to development and learning activities of those who are at work and have completed their basic vocational or professional education and training. These activities are often referred to also as continuing vocational training (CVT). However, HRD is not a stand-alone concept, but is derived from theories of 'human resource management' (HRM; see Box 1 for notes on key terms used in this paper).

This paper firstly looks at the emergence of 'human resource management' strategies in the context of the challenges facing European companies. It traces the origins of the internationally influential Harvard 'Human Resource Management model' which espouses humanistic-development principles. This model gives a high priority to generative human development and learning activities as a prerequisite for long term business success. In raising the question – is there a distinctive European HRD model – the paper examines the values and policies underlying what can be loosely called a European industrial/working life and vocational education training culture in relation to the above international model. The effects of the emergence of a competing utilitarian and instrumental model of HRM radically challenging the one above, are then examined. This latter model of HRM inspired by neo-tayloristic work organisation principles and neo liberal economics portrays 'human resource development' as a contingent activity shaped mainly by environmental factors. The paper concludes by discussing the future direction of HRD strategies in the context of building a socially sustainable industrial/working life society in Europe.

2. New ways of organising work

Over the last fifteen or so years European companies have had to radically revise their attitudes to work organisation – 'human resource management' – in order to respond to the dramatic changes taking place in both the global and European business environments. These challenges have been outlined in countless publications, but just to recall them, four of the major change factors are briefly summarised here.

1. Firstly, world business has witnessed a major decrease in markets for mass produced goods and a significant increase in demand for more customised 'high quality' goods;

2. secondly, the globalisation of world trade has threatened the competitiveness of European industries;

3. thirdly the creation of the Single European Market on the one hand, and the opening up of a market economy in the eastern parts of Europe on the other hand, have forced all European companies to rethink their work organisation strategies;

4. fourthly advances in Information and Communication Technologies have raised questions about investment in and use of these technologies and the work organisation implications in introducing them.

In response to these new challenges companies began to adopt new more 'flexible' (both internal and external) types of work organisation which are reflected in new forms of a workforce management strategies and became known as 'human resource management' strategies (see Sparrow and Hiltrop 1994; Miles and Snow 1984). These theories of HRM entailed the abandonment of centralised bureaucratic work production strategies – according to which everyone had a clearly designed function, suited to an age of sustained mass production – and the adoption of a new organic workforce model which devolved wider responsibilities (both vertically and horizontally) to employees, although excluding financial control which tended to continue to be centralised. This entailed putting a heavy emphasis on HRD practices such as team building, multi-
Box 1: Notes on key terms

The terms elaborated below are interpreted by authors in many different ways. The practice often determines the theory. Below, these terms are described as they are used in this paper.

**Industrial/working life cultural traditions**

This refers to the guiding principles and assumptions according to which a society or a company/institution designs its work organisation and work management systems (Taylorism, for example, forms an industrial/working life cultural tradition.

**Personnel management**

This term which is now giving way more and more to 'human resource management' (HRM) refers to a specialist function or department within companies (or workplaces) dealing with the building of efficient and satisfactory (just) working systems from the human perspective. Initially 'personnel management' had more of a reformist purpose counterbalancing the excesses introduced by mass industrialisation. Beginning with a concern for promoting social welfare and fair employment practices, it took on board 'scientific management' practices and 'human relations' concepts.

*Typical activities undertaken are:*

- Recruitment and selection, training and development, performance appraisal, industrial relations, compensation and benefits and health and safety.

**Human resource management (HRM)**

This represents a transformation of the 'personnel management' function from being an ancillary service to senior management to that of a strategic influencing role under the responsibility of a director who is a co-equal board member. Instead of being a separate and specialist (and often a kind of occasional) function the management of human resources becomes an embedded company strategy and the concern of all line management who must carry out activities formerly passed on to personnel management.

**Human resources development (HRD)**

This can be interpreted in a wide or in a narrow sense. For some commentators HRD is almost synonymous with HRM. More commonly however, HRD refers to learning and competence development actions, although these are integrated with other HRM actions and have an organisational learning and developmental form as much as an individualistic one.

**Continuing vocational training (CVT)**

This is another term used which is closely related to HRD but can have a wide or a narrow meaning. Ant et al. (1996) adopt a non restrictive definition in their review of continuing vocational training in Europe taking it to cover more or less the same ground as HRD. A narrow interpretation of CVT restricts it to training activities at craft or worker level excluding management development and organisational learning actions.
skilling, work based learning in order to promote greater degrees of functional flexibility (OECD 1999, p. 183).

2.1 Humanistic-developmental tradition

One of the most influential models of ‘Human Resource Management’ which has had a major impact on the European and the wider international business and research (Hollinstead 1995) is the ‘humanistic-developmental’ model devised by Beer et al (1984, 1985) at the Harvard Business School. The strength of this model is that it attempts to align the goals of a company’s effectiveness with those of individual well being and positive benefits for society.

It is in the interconnected triangular dimension of the Harvard model that the notion of stakeholder interests is introduced. All of those with a stake in the company have a role in influencing company policy. This includes employees, trade unions, the community, government, as well as the traditional company controlling groups of shareholders and management.

From an employee work relations perspective the model represents a radical departure from the ‘tayloristic’ scientific management (instrumental) view based on tight control of employees in an atmosphere of mistrust, towards one based on winning their commitment in a context of mutuality of purpose. It also lays great emphasis on intensive HRD in generating high levels of employee competence. The other expected outcomes of this HRM philosophy which are seen as justifying the risk in moving from a ‘control’ to a ‘commitment’ based approach are:

- greater loyalty to one’s organisation and on the part of individuals a greater sense of self-worth and a sense of belonging;
- cost effectiveness in relation to turnover of staff, low rates of absenteeism as well as societal and individual costs;
- greater congruence between management and employees, between different groups of employees, and between employees and their families and society as a whole (Beer et al. 1984).

2.2 From a ‘personnel management’ to a ‘human resource management’ perspective

One of the main implications of adopting this ‘Human Resource Management’ model is that external flexibility such as outsourcing and internal flexibility based on devolved management and autonomous work groups. One of the hypotheses postulated in the OECD report (1999) is that these changes represent a pendulum swing from management philosophies based on ‘tight management control’ to ones based on ‘employee commitment’. This paper argues that these represent two competing HRM philosophies, the one being instrumental and utilitarian and the other humanistic and developmental. Further material on this issue is to be found in the section of this paper entitled ‘level of implementation’ and in the papers of J. Dejonckheere and G. v. Hootegem in this report.

1 The extent to which, what are termed, flexible work organisation practices have been introduced in firms is discussed in an OECD report (1999). According to that report the position is far from clear as it is difficult to separate empirical changes from ‘management fads’. According to Ellström’s review of international research in this area, including OECD studies, about 25 to 50 per cent of companies have adopted ‘transformed work systems’ to some extent (Ellström 1999). However, a complication in estimating the degree of implementation of these practices is the lack of a clear definition of what is meant by flexible work organisation approaches. Authors often fail to differentiate between.
human resource policies are integrated with all activities of the company. This is illustrated by the fact that the implementation of 'people related' policies is devolved to frontline supervisory management levels. Because this entails a shift from a compartmentalised view of the management of 'people related issues', under the responsibility of a specialised 'personnel department', to an integrated notion, the overall change has been described in terms of a movement from a 'personnel management' to a HRM perspective. The demise of the 'personnel management' approach was due to the fact that as a specialist function it failed to place human resource policies as a strategic issue in the company. In the era of HRM, a very senior management person who is normally a member of the board (a director of human resources) ensures that enlightened 'people policies' are embedded in a systemic manner throughout the organisation.

The overall effect of the adoption of this human resource strategy is that the 'human factor' is assigned a key influencing role with regard to the shape of the company's business, organisational and technological parameters. This entails involving all employees in company change and development actions. A prerequisite for this is the continuous building of broad competence levels through formal and non-formal learning initiatives.

This HRM model, therefore, has given a great impetus to HRD activities as one of the key objectives to be addressed in an integrated HRM policy closely linked to the issues of recruitment; career management; organisational development; work design; pay and benefits and employee relations² (Sparrow and Hiltrop 1994; McLagan 1999). Regarding the boundaries between HRM and HRD in reality, some authors such as McLagan argue for more integration seeing the distinction between them as too fine (McLagan, ibid.).

3. HRD and competence development

In line with the theory presented above, 'Human Resource Development' objectives are focused on developing the 'competence' of employees. The notion of 'competence development', within a HRD framework, lays the emphasis on a comprehensive programme for all employees including intermediate and frontline workers as well as management. This is in contrast to a development approach that is biased towards enhancing management's skills.

The term 'competence' refers to a person's ability to carry out a series of actions (or a whole complex action) in an autonomous or independent manner. Competence gives one the ability to be able to perform in a highly proficient manner in a variety of social contexts, generalising know how and transferring it from one context or situation to another, be it related to work or personal life. According to Docherty and Marking (1997; see also Docherty and Dilschmann 1992) 'competence' relates to an individual's ability to execute tasks to meet external demands and is based on the understanding of the individual as an interpreting, acting and problem solving human being. This notion of competence is closely related to the concept of 'core competences' which entail generalist knowledge allied to a capacity for deliberation, judgement and action (Nyhan 1993). Competence gives one the ability to make connections between theoretical knowledge, practical knowledge gained from experience, constantly building up one's 'practical knowledge' to use in the different situations of one's life.

3.1 Learning organisation

This contextual/situated and 'high transfer value' notion of 'competence' has generated theories and promoted 'social innovations' related to the integration of learning and working and individual with organisational learning agendas. Senge (1990, 1997) who is one of the foremost exponents of the concept of a learning organisation as offering possibilities for professional as well as personal growth, asks why is it not possible for people to at-

² In a HRM context the term 'employee relations' is preferred to 'industrial relations'.
Human resource development in Europe at the crossroads

tain company goals 'in a work environment that is close to the things that workers really value in life' (Senge 1997, p. 144).

For Senge all significant learning for action is social and collective by nature. A prerequisite for learning is the development of 'a sense of connectedness, a sense of working together in a system and an understanding of how each part of the system is affected or being affected by other parts and where the whole is greater than the sum of the parts' (p. 129). Learning is about sharing knowledge and this occurs when people are genuinely interested in helping one another develop new capacities for action.

A learning organisation can be described as 'an institution which involves all its members in increasing organisational and individual competence, through continuously reflecting on how strategic and everyday tasks are handled' (Nyhan 1999). These two dimensions, organisational effectiveness and individual competence are seen as interdependent factors. Organisational effectiveness provides an impetus for individual learning, while the latter in turn contributes to an increase in organisational effectiveness. If this model is implemented in an idealised situation, line workers are learning as a result of being assigned challenging tasks and through being assisted to continuously reflect on those tasks, so as to learn from them. The work content therefore becomes the learning content, as work and learning become part of a constant improvement spiral having an impact on the competence level of individual workers, the collective learning of work groups and the total organisation (Nyhan 1999; Stahl et al. 1993).

3.2 Level of implementation

As regards the degree to which these 'Human Resource Development' or competence development measures are being implemented, even though sufficient research has not been carried out, and as already stated in footnote 1, according to Ellström’s review of the recent findings, somewhere between 25 to 50 percent of companies have adopted them, at least to some degree (Ellström 1999). In the study of Cressey and Kelleher (1999), undertaken in the auspices of the European Commission’s Leonardo da Vinci programme, it was found that there was a great degree of consensus among employer and employee representatives (the ‘social partners’) in large companies in the car manufacturing, telecommunications and banking sectors in the UK, Germany and Sweden about the need to adopt these new HRD models. A different rather sceptical view about the impact of this new models, however, is that the interest by the management and academic community in these concepts is perhaps more due to their attractive presentation by management gurus rather than solid research evidence (OECD 1999). Méhaut and Delcourt (1997, p. 30) argue that neither on the European nor global stage do we see convergence towards a uniform model of new forms of work and learning organisations away from the ‘old’ ‘tayloristic’ control model. According to Poell (1998, p. 6) instead of understanding the changes in work organisation in terms of the replacement of one dominant ‘tayloristic’ model by a new dominant one we should pay attention to the diverse ways in which work and learning is organised.

In any assessment of the implementation of these strategies, it must be acknowledged that the adoption of radical transformative learning approaches is a complex process. There is often a big difference between what people say they are doing (or perhaps what they would like to do) and what they are actually doing. First impressions can be deceptive. One has to deeply analyse companies to see the extent of the changes achieved. In one intensive study of a eleven European companies, that claimed to have introduced radical learning organisation principles (and at first sight seemed to have done so) it was found that many of the changes had an impact only of introducing new learning methodologies at the frontline (shop floor) level.

---

3 Prahalad (1993) uses the term ‘core competence’ in a similar way to Senge although in a different sense to the way it was used earlier, to mean the ‘collective competence’ or ‘collective learning’ of an organisation, in particular referring to the ability to co-ordinate and integrate different skills and technologies.
or at a level of management structure without any transformation in a company’s values/vision/culture (Docherty and Nyhan 1997; Nyhan 1999; Nyhan forthcoming). A genuine transformative level of change, internally driven and built on radical new insights about the contribution which employees can make to the company, was achieved by only five of the eleven companies examined. This entailed radical change at all levels of the organisation in relation to values, structures and work processes. This required the following elements – visionary leadership from the chief executive, the development of a ‘shared vision’ generated by everyone in the company, risk taking by management and employees, the development of a long term strategic programme and a commitment to follow it through in all its time consuming practical steps. What is more, the study also showed how fragile human resource innovation can be. Opportunities to change can so easily be let pass by, and major gains made, often after the expenditure of enormous effort in terms of time and finances, can be lost overnight (Nyhan 1999, p. 20).

4. HRD in Europe

4.1 European industrial/working life cultural traditions

Historically, within Europe, more particularly northern continental and Nordic Europe, one finds many different versions of what can loosely be called a European industrial development/working life model based on common threads running through national and sectoral traditions and common problems encountered in the different historical paths and choices taken on the road towards industrialisation. European industrial/working life cultural traditions differ from those in the US in that they place much greater emphasis on the role of skilled workers rather than managers (in particular in small and medium sized companies), on the role of social partners in the employment relationship and envisage an intervening role by Government (see Brewster et al. 1993; Guest 1990; Pieper 1990). Albert in his book ‘Capitalism Against Capitalism’ (1993) contrasts the European continental economic and industrial model, what he terms the ‘Rhine Model’ with that of the ‘Anglo-American’ one. According to the ‘Rhine Model’, management and trade unions loosely ‘share’ power (in Germany ‘co-determine’ policies) with the state playing a major role in areas like initial vocational education and training and providing a safety net for those who lose their jobs. This model has existed for nearly a century in Germany, the Netherlands and France and in many respects, although taking a different form, in the Nordic countries. The ‘Anglo-American’ model, which mainly applies to the US (but also to the UK in many respects) gives a greater reign to market capitalism, stressing the state’s subordination to the economy and business activities, with a consequent lesser focus on government intervention. Some of the European traditions outlined above have been enshrined in European Union legislation or agreements such as the Social Charter (in 1989) the European Works Council Directive (in 1994) and the European Confidence Pact for Employment (in 1996). Of course this is not to deny the fact that the manner in which these agreements are applied differs in line with national Member State traditions and legislative frameworks. Thus the ‘principle of subsidiarity’ which was enshrined in the European Union Maastricht Treaty strikes a balance between the ‘unifying’ policy making role of the EU and the diverse autonomous positions of the Member States.4

Within a common European heritage, of course, significant cultural differences exist between the different countries which affect how issues surrounding work and learning are understood and related policies and strategies implemented.

Trompenaer (1993) carried out an extensive worldwide survey of people in the business world to find out the corporate cultural fac-

4 Art. 127 of the EU Treaty is a good example of how this works out in practice regarding the implementation of vocational education and training policies.
Box 2: Different ‘national corporate cultures’

‘Power oriented’ corporate culture
A leader in this hierarchical but person oriented culture can be seen as a caring ‘patron’, who knows better than his subordinates what is good for them and in appealing to their deepest feelings, directs them on how things should be done. This form of leadership can be referred to as ‘management by subjectives’. The ways of thinking and learning in such cultures tend to be intuitive, holistic, lateral and error correcting, and according to Trompenaar are typical of Spain and to a lesser degree France and Belgium.

‘Role oriented’ corporate culture
This is based on a bureaucratic division of labour with the various rules and functions prescribed in advance. When each role is performed in accordance with the overall system then tasks are effectively completed. The approach to thinking and learning in this culture, which according to Trompenaar is typical of Germany and to a lesser extent Denmark and Netherlands is logical, analytical, vertical and rational.

‘Project oriented’ corporate culture
This third category differs from the power and role oriented cultures in being egalitarian. Even though it resembles the role-oriented model in being impersonal and task oriented, it differs from it in that the jobs people do are not fixed in advance. The UK (and the US) are seen as having many examples of these kinds of companies where thinking and learning patterns are problem centred, practical and cross-disciplinary.

‘Fulfilment oriented’ corporate culture
This is based on the notion that organisations are secondary to the fulfilment of individuals. These kinds of organisations which operate in an environment of intense emotional commitment are, according to Trompenaar, typical of Sweden. The approaches to thinking and learning in these organisations are creative, ad hoc and inspirational (one has to question the rhetoric as opposed to the reality!).

tors influencing how they perceive and design work organisation. He developed a fourfold typology – ‘power oriented’, ‘role oriented’, ‘project oriented’ and ‘fulfilment oriented’ corporate culture. A resume of how these four types apply in a European context is provided in Box 2.

4.2 Europe and humanistic-developmental HRD

Despite the American origin of the Harvard human resources model described earlier, it can be argued that its ‘humanistic-developmental’ perspective and in particular its effort to align company objectives with those of the needs of the individual and society as a whole, complement mainstream European industrial and working life traditions. The adoption, or at least the application of its underlying principle of embedding ‘open’ and developmental ‘people management’ and learning activities in all aspects of a company’s activities, by many large European countries in the late 1980s and 1990s had a positive impact in revitalising practices that were often being implemented in a rather regimental (and Tayloristic) fashion. The dynamic and integrated organisational perspective also challenged the rather compartmentalised and rigid thinking of those in charge of vocational education and training institutes. It certainly improved the status of ‘personnel’ and ‘training and development’ functions within enterprises and gave rise to new University and Business School courses in this area.
Perhaps one of the most noteworthy effects of the HRM movement was the modernisation of peripheral countries and regions in Europe which did not have a well developed industrial development tradition. So, for example, for a country like Ireland coming late to industrialisation and cut off from progressive continental European industrial/working life traditions, the investment by American and European multinational companies with sophisticated and enlightened modern management systems, many of them with humanistic-development approaches, had an impact not only on the economic development of the country, but also offered illustrated lessons on how to design organisations that promote human systems for development and learning.

The humanistic-developmental HRM model also can be seen to share some common underlying principles with European originated innovation movements. The ‘sociotechnical’ systems thinking tradition is one of them. The original work in this area was undertaken by the Tavistock Institute in the UK in the 1950s and implemented in particular in the Nordic countries (e.g. the Norwegian ‘Work Democracy Programme’ in the 1960s) and also in the Netherlands. The work organisation design, put forward by the ‘sociotechnical’ school, centering on the notion of ‘semi-autonomous groups’, stressed the benefits to be derived (in relation to efficiency and worker satisfaction perspectives) from workers having control over and shaping their work and technological environment. There is emphasis on introducing the latest technology but designed in a way to fully harness workers’ skills and motivation. The benefits to be derived from such a ‘sociotechnical’ tradition are seen to be superior productivity and work performance as well as a more fulfilling work environment in the form of challenging work that also offers opportunities for learning and development.

The relationship between the ‘humanistic’ human resource management tradition and the concept of ‘social shaping of technology and work’, which came from the German tradition is also worth commenting on (see Rauner 1988; Heidegger 1997). According to this concept a high degree of control (‘influence’ or ‘shaping’ – in German ‘Gestaltung’) by the workforce of the work environment is essential to ensure productivity and create an environment in which people learn continuously. This concept has similarities with ‘sociotechnical’ thinking but differs from it in that it is derived from the discipline of vocational education and training rather than a top down ‘systems design’ approach. It also gives an active role to workers in continuously modifying and developing new work processes. Through this, they are also developing ‘practical expert knowledge’, called ‘work process knowledge’ which can only be learned in an experiential (bottom up) fashion. In relation to technology, this means that the knowhow and the competence in the workers’ heads must be superior to the ‘software know how’ embedded in the technology. This concept is based on the notion that the cornerstone of effective production systems is the expertise or ‘work process knowledge’ of the human being and not the technology. According to a related concept of ‘anthropocentric technology’ (or ‘human centred technology’) – ‘it is only when the technologies allow the development of human capabilities and skills that they become optimally productive’ (Wobbe 1990, p. 11).

This emphasis on the centrality of the skilled worker (intermediate level profession or craft/trade level) who has a high degree of discretion, authority and responsibility can be seen as one of the hallmarks of the more highly developed indigenous human resource policies in Europe. This gives them a clear stakeholder role within the company – reflected in the wages offered. This role is strengthened by an occupational identity through membership of a professional group and in the extended society by what has been termed an ‘industrial citizenship’. Referring back to the German context, Hendry (1991) states that it is not a platitude to say that Germany’s greatest asset is her people. While the German concept of HRM differs from the US originated humanistic model, both of them concur in recognising the need for a highly motivated, flexible and trained workforce. HRM, therefore, should not be considered a new or alien concept for German organisations.
5. A competing human resource strategy

A recent study of HRD trends within seven European countries (Ter Horst et al. 1999) concluded that in the face of globalisation, there appears to be a tendency towards convergence in the human resource policies of Europe, the United States and Japan. According to the study, the common aspects of human resource policies between large companies in the three most powerful global trading blocks are seen to be more significant than the differences. This conclusion is drawn on the basis that the globalisation of business is forcing all companies, who wish to compete in world markets, to adopt human resource policies focused on meeting companies' immediate business performance objectives. This emphasis on more or less short term performance objectives gives rise to a contingent and situational view of human resources along the lines of Trompenaar's 'project based' corporate business culture outlined above.

In line with this, many companies today see themselves more like loose 'market led networks' rather than organisations. These networks are constantly redefining their structures offering project based work opportunities for people in a dynamic market environment. We live in the age of the contingent worker in which jobs are being replaced by 'projects'. In the United Kingdom, Brown and Keep (1999) make the point that 'taylorism' and 'neo-taylorism' still offer a powerful model of competitive advantage, in particular within the service sector. In a large study of British manufacturing companies, Acroyd and Proctor (1998, p. 171, cit. in Brown and Keep 1999) conclude that profitability is not secured through 'the acquisition of a highly trained 'core' labour force but by a combination of relatively unskilled labour and a willingness to utilise external sources of production'.

In France, on the same day that the Michelin tyre manufacturing company announced a net profit of EUR 292 million for the first half of 1999, up 17 percent from a year ago, the company also announced that it would cut its workforce in Europe by 7,500 over the next three years. This news received a euphoric reception in the Paris Bourse. The new finance director justified the cost cutting exercise by stating that: 'Our principal rivals have clearly announced firm intentions to target Europe. We want to react before anything happens' (International Herald Tribune, September 11-12, 1999, p. 11). This newspaper report went on to note that while 'the family controlled company has traditionally been considered as paternalistic towards employees and unresponsive to shareholders, three months after taking over as president, however, Eduoard Michelin, 36, appears eager to break away from the old school management style of his father, François, and introduce business practices he learned in the United States.'

This is an example of growth in 'shareholder power' in European companies which according to an article in The Economist (2000) promises to remake European capitalism. German critics of the Mannesmann hostile take over of Vodafone in early 2000 see this as the first severe blow to the country's well found Rhineland capitalism model built on consensus and close ties between bankers, business, employers, trade unions and the government. This article goes on to state that behind this trend towards shareholder power is a new generation of managers who believe that 'firms belong to shareholders, not bosses or 'society'. Germany is singled out here because it is a stronghold of the classical European social market economy, but taking Europe as a whole there has been a merger boom in response to shareholder pressures in recent years. The values of mergers and acquisitions in Europe for 1999 was 1,200 billion dollars, an increase of 50 percent over 1998 and 700 per cent over 1994 (source cited in The Economist, 2000 – Thompson, Financial Securities Data).

In line with the above trend, HRM policies are driven principally by the situational context in the external market environment. This entails adapting human resource policies to fit in with the corporate business strategy. Companies 'upskill' or 'downskill' as the market demands. Brought to its logical conclusion, human resources are a contingent, instrumental factor with no inherent value in
their own right. Accordingly, HRD as a distinct activity may or may not be a part of the HRM policy, but based on the principle of 'external flexibility', human resource stocks can be renewed more effectively through a process of short term 'project based' recruitment, outsourcing products and services, downsizing staff etc. The concept of 'business process engineering' (see Hammer and Champy 1993) entailing an overnight reshaping of one's organisation, and indeed the whole supply and sales chains with an emphasis on cost cutting and downsizing the number of employees, offers a way of implementing this form of 'Human Resource Management'.

This is referred to as the 'hard' model of human resources derived from tayloristic and neo-tayloristic/neoliberal thinking. It is contrasted with the 'soft' 'humanistic' model which attempts to match company needs with individual career development and wider societal effects. The 'hard model' is based on the 'external flexibility' (or 'numerical flexibility') of the outside labour market (the classical free market 'hire and fire' approach) as distinct from the 'internal flexibility' (or 'functional flexibility') of the workforce within the company, which is cultivated through continuously developing people's competence and capacity for change. The difference between these two strategies is that one entails a 'redundancy of parts (people)' approach in which people are constantly replaced in accordance with the tasks that need to be undertaken, while the other implies a 'redundancy of function' approach (Morgan 1986, pp. 98-100) according to which, even though jobs may change, the company sees it to be in its long term interests to retain people, within the firm, sufficiently well skilled (or being restrained) to take over new tasks. The dominance of neoliberal policies across the world is strengthening the position of those putting forward this 'redundancy of parts' view and is strongly challenging the 'humanistic-developmental' model of human resources.

While in an earlier book Handy (1989) portrayed the arrival of a flexible labour market with its flexible companies (or as he also called them 'shamrock companies') as offering people (with their portfolio of skills) liberation from rigid employment patterns and providing them with opportunities for choice and personal fulfilment, he changed his mind later on, saying that although this situation may be in the interests of the elite highly skilled professionals – the 'symbolic analysts' who comprise a small percentage of the workforce – it was not really enhancing the quality of working life for the average person (Handy 1994).

According to Sennett: 'in attacking rigid bureaucracy and emphasising risk, it is claimed, flexibility gives people more freedom to shape their lives. In fact the new order substitutes new controls rather than simply abolishing the rules of the past – but these new controls are also hard to understand' and represent 'an illegible regime of power' (Sennett 1998, p. 10). In addressing the question The HRM organisation – rhetoric or reality? Sisson (1994, p. 15) contrasts the 'rhetoric' of certain HRM slogans with their 'reality' counterpoints – 'flexibility' often means that 'management can do what it wants'; 'lean production' can in fact be 'mean production' and 'team working' can mean 'reducing the individual's discretion'.

Adler and Cole (1993) attempt to resolve the polarisation of the 'instrumental' with the 'humanistic' type of work organisation. The result is the concept of 'democratic taylorism' which seeks to integrate the characteristics of efficient bureaucracy along neo-tayloristic lines with a genuine humanising environment (characterised by good working conditions and training opportunities). They see this as an 'enabling' formal system rather

---

5 A human resource director of a major international firm, shedding much of its workforce in a restructuring exercise, facetiously referred to his job title as 'human remains' director.

6 This a kind of 'third way' work organisation version of Giddens' political and societal 'third way' concept that attempts to go beyond the two dominant political philosophies – social democracy (which is rooted in Keynesian demand-management, interventionist government, the welfare state and egalitarianism) and neo-liberalism/market fundamentalism (Giddens 1998).
than a 'coercive' one. They argue that it is romantic nonsense to talk about the notion of a workplace characterised by autonomous workgroups and see the 'humanised lean production' plant of NUMMI – a joint venture between Toyota and General motors in the US – as offering a model that can be implemented in practice. The NUMMI plant, according to Adler and Cole, represents a good balance between the exigencies of efficiency and satisfying work, making what they term a 'humanised' work environment. This environment has a good layout, is ergonomically well designed and has good worker support facilities. It combines features of 'lean production' systems with classical Fordist ones, with workers having responsibility for quality assurance and routine maintenance (see Cressey and Kelleher 1999; Ellström 1999).

6. Future direction for HRD in Europe

This raises the question about the future role of the 'Human Resource Development' policies in a European context.

In discussing the challenge of globalisation from a European point of view, Lundvall and Borrás (1997) in their report 'The Globalising Learning Economy: Implications for Innovation Policy' argue for wide transformative social innovations, laying an emphasis on building societal frameworks focusing on new forms of interorganisational cooperation and alliances between enterprises and knowledge producers. They talk of the need to build 'learning economies' which enhance the learning capability of individuals, firms regions and countries. What is more, Lundvall developed this notion further at the European Socio-Economic Research Conference, in 1999, when he spoke about creating a 'socially sustainable learning economy'. This approach appears to be in continuity with the wider implications of 'sociotechnical systems theory', which addressed the issue of building strong institutions in turbulent social environments. This means according to Emery and Trist (1965) that interconnected organisations must contribute to the creation of shared value systems that have meaning for all of them and so guide their actions.

For Lundvall and Borrás the neoliberal solution and the neo-protectionist solution must give way to the 'new new deal' which focuses in particular on the learning capability of the weak learners, people and regions (Lundvall and Borrás 1997, p. 38). In this regard the regional territorial dimension become important because 'territory and proximity play a central role in the genesis of tacit knowledge and the capacity to exploit it. The region is increasingly the level at which innovation is produced through regional networks of innovators, local clusters and the cross-fertilising effects of research institutes.' (ibid. p.39) The concept of the 'learning region' is put forward as a model for mobilising all of the actors in a region to build inclusive innovation policies addressing integrated economic and social development goals (see Nyhan et al. 2000).

The central message of Lundvall and Borrás is very relevant to the debate about the future direction of HRD policies within industries for the reason that companies cannot survive without learning from and contributing to their environment. However, to do so, innovation at the level of the company is called for. Coriat (1995) refers to organisational innovation as being the missing link in European competitiveness. He calls for new organisational models to be developed in a research process which is concurrent with experimentation by enterprises. This means research imbedded in practice that will provide practical knowledge for a new genera-

---

7 In this publication, which is an analysis and synthesis of the findings of seven major European socio-economic research projects, covering many disciplines, supported by the European Commission's Fourth Framework Targeted Socio-Economic Programme, Lundvall and Borrás have attempted to provide policy makers with an overview of the implications of these studies for innovation policies and identify the direction of further research.

8 This conference, organised by the European Commission, took place in Brussels on April 28-30, 1999.
tion of managers and professionals within firms.

Returning to the question of ‘humanistic’ versus ‘instrumental’ models, the need to have a more business-led focus of HRD was put forward by Harrison (1999), a European keynote speaker at the Academy of Human Resources Development Conference at Washington in 1999. To the contrary, McLagan (1999), a leading American keynote speaker at the same event, criticised the ‘mechanistic, more authoritarian worldview’ in which people are seen as ‘resources in the sense of being optimised and even exploited’. She pointed out the ‘dichotomy between this utilitarian view which is based on behaviourism with the generative view which is based on humanistic philosophy’. She went on to ask the question: should the HRD specialist become a performance engineer and systems consultant or focus on unleashing the capacity of people so that they can work for themselves? (p. 17)

In responding to the above question, it would appear to be an abdication of the role of the HRD professionals were they to adjust themselves or merely submit to the dictates of those espousing the utilitarian view of human resources, which is derived from perspectives and values outside of the ‘human resource development’ one. Having overcome most of the inefficiencies and lack of competitiveness which became apparent in European companies in the 1997s and 1980s, particularly in the face of superior Japanese innovativeness and productivity, surely the challenge now is to devise innovative solutions which look beyond the present situation and can contribute to building a ‘socially sustainable learning economy’.

Perhaps the reflection of the ‘business guru’ Handy (1994, p. 1) should be kept in mind by the HRD research and practitioner community in building a future model: ‘In the pursuit of these goals (economic growth and efficiency) we can be tempted to forget that it is we, we individual men and women, who should be the measure of all things, not made to measure for something else. It is easy to lose oneself in efficiency, to treat that efficiency as an end in itself and not as a means to other ends’.

Abstract
Human capital encapsulates individuals’ attributes of use in the labour market, while reporting on human capital, on the other hand, is primarily associated with the enterprise level. This apparent paradox is partly due to the fact that the identification of an individual’s knowledge, competences and skills as well as their acquisition, maintenance and upgrading, i.e. the input side to human capital, is only rarely related to the output, i.e. human capital, irrespective of the former being the very substance in the latter. This lack of interconnection is primarily due to different traditions where human capital is considered in purely economic terms whereas the individual’s acquisition of knowledge is primarily related to the pedagogical, sociological and psychological fields. One reason for this being, of course, that the notion of human capital does originate from within economy and, further, that economists still relate human capital primarily to the enterprise level and/or at macro-economic level while generally neglecting the individual’s level.

In this paper human capital is defined as ‘the knowledge, skills, competences and other attributes embodied in individuals or groups of individuals acquired during their life and used to produce goods, services or ideas in market circumstances’.¹

The paper will focus on the enterprise level and primarily with an economic perspective, but, as indicated above, other levels and dimensions will play a significant role throughout the paper. This is particularly the case when it comes to reporting on human capital, and when it comes to an analysis of the interests of the main stakeholders.

¹ For discussion of the definition, please refer to the chapter on theoretical and methodological considerations.

1. The socio-economic context

Technological, commercial and organisational developments have changed the labour market. Shorter life cycles of goods and services, increased and globalised competition, the growing importance of intangible assets at all stages in production cycles and new forms of work organisation have transformed both the workplace and the skills required to perform a given task. This requires new qualifications from employees and a new perception of the workforce and work organisation from employers in that ‘traditional’ instrumental skills are no longer viewed as sufficient to maintain competitiveness; flexibility, responsibility and involvement of the workforce must be added as well as new dimensions to the management and organisation of work.

The strict distinction between knowledge workers, skilled workers and unskilled workers is thus diminishing following the more horizontal organisation of work which leads to higher utilisation of knowledge found in all employees at all levels and not necessarily limited to the employees’ core work. The enterprises’ knowledge base is not only identified in special units such as the management group, the R&D department or the sales division, it is increasingly being diversified covering the entire workforce.

Achieving a competitive edge for individuals, enterprises and societies alike is increasingly becoming synonymous with the notion of human capital. This is partly justified by the growing importance of intangible assets in enterprises, of which human capital constitutes a major element and by the emphasis from both public and private bodies on human capital as a saviour of competitiveness, reduction of unemployment and expansion of economic wealth.

Human capital has therefore become the focal point for theoretical and methodological considerations, and analyses as well as for numerous pilot projects initiated by practitioners, researchers and policy-makers alike. Further, and irrespective of its economic origin at enterprise level, human capital is now subject to various levels and dimensions, as illustrated in Table 1.12.

Levels and especially dimensions are to a great extent interrelated with many overlaps. This must be kept in mind while working with human capital in general and reporting on it in particular. It is therefore critical to have a clear understanding of the various stakeholders’ interests as well as the specific objectives for concrete methods when also keeping in mind related levels and dimensions while exploring possibilities and limitations on the notion of human capital and the reporting of it.

1.1 Macro-economy and human capital: the endogenous growth theory

Human capital is related to the economic interaction of the labour market and it is the human knowledge as a production factor, which is of interest as opposed to, for instance, social or cultural interactions. It is thus the human capital’s contribution to economic development which is looked into. As such, human capital is closely related to physical and financial capital though it must be treated differently, both theoretically and in practice due to its intangible nature.

Although being acknowledged theoretically, human capital has tended to be hidden under residual factors in economic growth theory, primarily due to the difficulties in the measurement of human capital and other intangible values. However, the exogenous fac-

---

3 The notion ‘social capital’ refers to the influence of the social setting for the development of human capital. As such, social capital can be seen as going beyond the scientifically established boundaries between the social and economic spheres of life. See Goleman 1996, Fukuyama 1995, Putnam 1995, World Bank 1999.

4 A classic example is the Solow residual, i.e. the part of growth which is not explained within his growth model that is based on the growth of labour and capital.

NB: Different levels as well as different dimensions may have identical objectives. The examples given must, therefore, be treated as indicative rather than exhaustive.

tors, i.e. the growth of (homogeneous) labour, investment and general technical progress has become less and less sufficient to explain growth, development and productivity, both at micro and at macro levels. Mainly because intangible input into the economy has grown and may even have exceeded investments in physical capital. Consequently, endogenous growth theory has gained momentum in recent years by opposing the classical notion of exogenous factors determining growth. Instead, they include explicitly endogenous factors, foremost the accumulation of human capital to explain growth and growth differentials between States. The production of human capital in terms of the allocation of resources to the formation of knowledge in the labour force is thus being internalised rather than just being a 'residual' factor.

While macro economic theory has begun to include human capital as a decisive, endogenous growth factor, actual knowledge is still sparse. The most widespread method used for examining the influence of human capital on economic growth, is investment in education relative to national wealth. However, these are very crude measures and often only refer to school attainment and, thereby, neglect training outside the formal education system, for instance vocational training not leading to formal qualifications or informal training. Further, they do not include the quality of the output.

This perspective conflicts with the demand from governments for international comparisons of national educational achievements, which focus on the quality of the output. While this perspective focuses predominantly on the formal education system and primarily the general education segment, it is not directly related to economic growth. Benchmarking has taken place for a long time, for example through surveys by IEA.

As Steedman phrases it: 'growth economists are concerned principally with human capital as an input, that is, one among a number of independent variables influencing economic growth. Until now, they have had little interest in how (efficiently or inefficiently) those inputs have been produced. Governments and policy-makers view stocks of human capital as outputs of educational provision – that is, as a dependant variable – and their questions

largely concern relative efficiency in the way resources devoted to education are used.\(^{10}\)

Bearing in mind the practical and methodological limitations to both approaches, it is still a long way to go before the creation of human capital outside the formal educational system will affect macro-economic thinking and be visible to wealth creation at macro level. This is to a certain degree paradoxical to the intense promotion of investments in human capital formation outside formal systems notably through the notion of lifelong learning, which has taken place since the mid-1990s.

1.2 Micro-economy and human capital: the returns to human capital

As opposed to the macro level, calculating costs and returns on human capital at micro economic level has a long history which dates back to at least the Roman times and includes calculations on slaves, soldiers and workers. However, it was in the 1960s that the human capital theory in its present meaning was introduced. The theory was originally based on the assumption that investments in human capital do pay off because the correlation between years of schooling or on-the-job training and income demonstrates that there is a positive rate of return\(^{11}\). This correlation was soon questioned both from a theoretical perspective as well as from empirical findings. Nevertheless, it is still the dominant method used to indicate returns on investments in human capital to individuals although supplemented by screening and signalling theories\(^{12}\).

Still, returns to individuals are fairly easily captured through the correlation of education and life earnings at an aggregate level. There are serious limitations, though. Methods do not, generally, provide any indication of the returns on investments in education and training outside the formal education and training structures, such as continuing vocational training, training supplementing initial vocational training, etc. This is particularly important for decisions on further investments by individuals, since the return on such investments may be invisible or even non-existent, especially in money terms. Theoretically, a higher level of human capital embodied in individuals, i.e. the increased level of labour market relevant knowledge obtained through additional training, should be reflected in the income. However, just as an increase in income does not necessarily stem from increased productivity, increased knowledge does not necessarily result in higher income.

Above all, the human capital theory does not identify the stock of human capital but merely the correlation between input of education and the return. At enterprise level, this is inadequate since their primary objective is the operational utilisation of human capital; hence, generalisations and abstract correlation between measures are of relatively little use.

This leads to the most underdeveloped research area: the meso-economic or enterprise level, where the same uncertainty regarding returns on investments can be identified. While the input side or the investments in maintaining or upgrading the human capital in enterprises is fairly easy to identify through measuring the direct and indirect costs, little is known about the output side and especially the returns on such investments\(^{13}\). Even if this is not a new problem, no reliable evaluation method has so far been developed\(^{14}\). Human resource accounting which originated as a response to this 'black spot' has not yet provided an adequate response.

More limited approaches, such as utility analyses on the cost and benefits of employ-

\(^{10}\) Steedman 1996.

\(^{11}\) Refer to Blaug 1985, Flamholtz 1985 and Schultz 1961 for further details on the roots of the human capital theory.

\(^{12}\) For screening and signalling theories, see Weiss 1995. One serious attempt to expand the human capital theory can be found in OECD 1996, p. 19-23.

\(^{13}\) See Barrett, Hövels, den Boer and Kraayvanger 1998.

\(^{14}\) See for instance, Kirkpatrick 1959, one of the founding fathers of modern evaluation methods.
ment strategies and of health and security policies, have, however, developed into standard practice in many enterprises. Although these elements play important parts in current thinking on reporting on or accounting for human capital, they too do not measure the stock of human capital. However, they do provide an input-output relation in specific areas related to human capital; that is, the costs and benefit of maintaining a good safety and health environment and by outlining the costs and benefits of strategies where enterprises rely on a high staff turnover. This is information of direct relevance to enterprises and although human capital cannot be reduced to a technical issue about cost and benefit alone, it does provide an easily understood and relatively simple method of evaluation.

Nevertheless, utility analyses, despite their practicability, do little to capture the maintenance and upgrading or a specification of the enterprises’ stock of human capital. In other words, equivalent methods for measuring the stock of human capital or returns on investments in training have not been developed.

The increasing use of benchmarking is therefore partly the cause for the lack of information on the return side, in that they primarily focus on investments/processes or the input side rather than the output side. Hence, benchmarking will only compare the enterprises’ input to human capital formation and not how these investments are capitalised. However, benchmarking does provide the tool for providing information on the correlation between, say investments in training and net profits. Hence, some indirect measures on the returns of investments can be established through benchmarking.

Benchmarking does not, however, provide a method for measuring directly the returns to training investments in enterprises.

Proposing increased investments in continuous or lifelong learning by policy-makers, researchers and some practitioners is therefore based on a high level of uncertainty and lack of actual knowledge. This is even more the case when discussing the cost distribution between individuals, enterprises and the public sector and, further, how to find additional funding for the perceived need for an increase in the total level of investments in human capital.

Lack of reliable and precise information on the return side of investments in human capital formation is one of the basic reasons why indicators other than financial ones are being used to capture the positive returns. This is also the reason why, ultimately, non-financial reporting methods and benchmarking are being utilised as proxy measures.

### 1.3 The abstraction of human capital within economic theory

As mentioned in the introduction, human capital cannot be captured in economic terms alone. The fact that human capital, and especially its acquisition, maintenance and upgrading can only be measured indirectly is not satisfactory from economists’ points of view. Especially, since the return on investments is only captured indirectly, as exemplified in Table 1.2 below.

The ongoing sophistication of methods does overcome some of the weaknesses in using proxy indicators. However, to capture fully the notion of human capital, a more stringent theoretical and methodological framework must be established and for the enterprise level in particular, standard methods for reporting on human capital must be developed both for the input and the output sides.

2. The theoretical and methodological context

2.1 Defining human capital

Human capital can be defined strictly within an economic context, i.e. as a production factor, or it can have a more universal meaning. Treating human beings as economic entities in a purely market-related context often causes some confusion and opposition since it is viewed as a simplification of human values. It is, however, necessary to differentiate between different sets of perspectives and objectives. This can be illustrated with the distinction between general and vocational education: general education provides the individual with knowledge in order to participate in society, i.e. the social, cultural, economic, etc. life spheres, whereas vocational education is targeted entirely at the demands of labour markets, i.e. the economic sphere only.

As indicated in Chapter 1, human capital will be defined within an economic context; further, human capital is embodied in both individuals and in organisations, and the acquisition of human capital is a process which also has a fixed value albeit not necessarily in economic figures.

Given these considerations, human capital is defined as 'the knowledge, skills, competences and other attributes embodied in individuals or groups of individuals acquired during their life and used to produce goods, services or ideas in market circumstances'.

This is the basic understanding of human capital being formed around the formation and utilisation of knowledge, be it in individuals or in organisations. A third level can also be identified, i.e. the societal level, which in effect is the crude accumulation of individuals' and organisations' human capital.

2.2 A theoretical framework for reporting on human capital at enterprise level

Since human capital at enterprise level is relatively underdeveloped within economic theory building and at the same time emphasis for reporting on human capital at enterprise level is growing, it seems necessary to go beyond economic theories to explain this development. This can partly be captured by the emerging distinction between managers' perception of enterprises' relations with the surrounding world.

Three approaches can be identified:

- the shareholder approach;
- the enlightened stakeholder approach;
- the stakeholder approach.

2.2.1 The shareholder approach

The shareholder approach equates the traditional identification of the management of a company with the shareholders of an enterprise. The approach follows the logic of enterprises being established and managed for the benefit of shareholders and for the benefit of actual and potential creditors.

Following this logic, accounting and disclosures are provided both for shareholders to exercise and maintain full control over the enterprise and for actual and potential creditors.

---

16 This definition is based on OECD (1996) and OECD (1998) with two important deviations; collective human capital has been included whereas the non-market relation has been excluded. See also Gröjer and Johanson (1996) and Bullen, Flamholtz and Sackman (1989).

17 See the discussion in 1.1 above, or refer to Rouhesmaa and Bjurström from the Finnish Ministry of Labour 1996, Serageldin from the World Bank 1996, the European Commission 1996 and OECD 1996.

18 The following part is primarily based on a consultation document from the Company Law Review Steering Group under the British Department for Trade and Industry 1999.
Given that shareholders are identified as those having an actual or potential economic interest in the enterprise, disclosures are primarily if not entirely related to the economic performance of the enterprise reported by means of figures.

Shareholder values thus reflect that it is the owners (and to a certain degree also the creditors) of an enterprise that exclusively define the objectives of the enterprise within the limits of public regulations and that the ultimate objective is to secure the maximum value for shareholders.

2.2.2 The enlightened shareholder approach

The enlightened shareholder approach also recognises that the ultimate objective of an enterprise is to secure the maximum value for shareholders; however, the means to achieve this end differ. This approach emphasises that an exclusive focus on the short-term financial bottom line may result in a suboptimum result for shareholders since sound long-term investments and, hence, long-term gains will not be sought.

This approach emphasises long-term relationships with employees, subcontractors, customers and others who may affect the long-term objectives of the enterprise. Further, they will respond proactively to trends and developments in society and to public regulations.

Still, the shareholders decide on the objectives of the enterprise.

2.2.3 The stakeholder approach

A contradictory argument summarised as the stakeholder approach, is that the ultimate objective of maximising shareholder value will not achieve maximum prosperity and welfare for neither shareholders nor other stakeholders or society as a whole.

This approach overrides the notion of shareholders as the sole and ultimate stakeholder of an enterprise. Rather, other stakeholders such as employees, subcontractors and perhaps even customers should provide equally relevant input into the formation of the enterprise's objectives and its management. It follows that companies cannot be identified through their shareholders alone. Instead, enterprises are identified as entities in society with their own ethos which management of the enterprise must comply with.

It follows from the three approaches that it depends on the management perspective of the company, the interests of the company as well as the best means to achieve these objectives, whether non-statutory reports and accounts will be developed and utilised.

Growth in non-compulsory reporting at enterprise level suggests, however, that the traditional shareholder approach is diminishing in importance, and that the enlightened shareholder and the stakeholder approaches are growing in importance. This is reflected in many analyses of enterprises' roles in societies as well as in enterprise and government initiated initiatives focusing on the roles of enterprises outside those of money generation and provider of workplaces.

2.3 Reporting on human capital

Reporting on human capital is one of the means used by enterprises to address the dual aims of maintaining traditional shareholder values and also complying with the interests of stakeholders. As indicated in Figure 2.1 below, reporting on human capital can take place at three levels.

However, following the different approaches to enterprises, as discussed in 2.2 above, reporting on human capital is gradually changing its focus. Newly developed approaches link reporting on human capital within broader issues, such as internal management or external information provision, rather than focusing on accounting frameworks. The shift can be illustrated by saying that reporting is now becoming the means rather than the objective. This also implies that the notion 'reporting' must be interpreted in its widest meaning, i.e. a systematised disclosure of information rather than being associated only with financial statements.
Clear cut demarcations between different approaches cannot be made, since most approaches tend to overlap. Nevertheless, even a primitive division of main approaches, as provided in Table 2.1, indicates the gradual shift of orientation.

This broad overview must be broken down to each level presented in Table 1.1 to understand recent developments better.

2.2.1 Reporting at individual level

Reporting on human capital does already take place at individual level, both formally and informally, by means of diplomas, certificates, written statements, curricula vitae, etc. Much work is currently taking place to provide even better reporting mechanisms for individuals' knowledge, for instance the European Union's promotion of the cross-national Europass for apprenticeships. Other initiatives include the identification, assessment and recognition of non-formal learning. Complementary to individual human capital is collective human capital, the latter reflecting knowledge obtained in groups of individuals, be it in organisations or outside, which accumulates in individuals and perhaps also in organisations. Some researchers and practitioners refer to intellectual capital as the total of human, organisational and customer capitals. They define intellectual capital as follows: 'human capital is the knowledge that each individual has and generates; organisational capital is that knowledge that has been captured/institutionalised within the structure, processes and culture of an organisation; and customer capital is the perception of value obtained by a customer from doing business with a supplier of goods and/or services.'

While organisational capital relates to the enterprise level alone, it does not encompass collective human capital formed outside the organisation. Inclusion of the organisation's culture is, however, interesting and may have connotations to other intangible assets, such as...

as goodwill. Still, it is outside the notion of human capital.

2.2.2 Reporting at enterprise level

Reporting at enterprise level is, as already stated, gradually moving from accounting to management principles and beyond. Four stages are thus observable, as indicated in Table 2.2.

Originally, the ambition was to put value on human capital within an accounting framework, i.e. to put a value on human capital and
include it as an asset in financial statements. While this element is still being debated among scholars, it is largely being deemed unrealistic, simply because the measurement problems seem unlikely to be overcome and, further, even if they were to be overcome, human capital does not generally qualify as an asset within accounting standards\textsuperscript{21}. Though some methods and approaches still consider this to be a viable path, the notion of enlarging financial statements with human capital assets is quickly fading away. The economic dimension still plays a dominant role, though.

The first stage is predominantly based on accounting principles, while the second stage is initiated from a management perspective focusing on the optimised use of human capital as a means to gain a competitive edge. The third stage operates with a global perspective, i.e. the enterprise and, consequently its human capital, interacting with the surrounding world. Human capital is a dominant element upon which strategies are formulated and implemented and forms a major input to the assessment of enterprises’ total value.

The fourth stage combines basic information on investments in human capital with human capital strategies and evaluation of returns. At the current standing, this approach is fairly less ambitious than for instance the Balanced Scorecard and other advanced management approaches identified at Stage 3. On the other hand, the more pragmatic approach seems to gain more momentum in that it can be a useful instrument internally and be used to benchmark enterprises within and across sectors as well as across countries. As such, it seems to be more applicable than other methods and, further, is more readily comparable to quality management systems and other alternative reporting mechanisms.

However, methods to be identified with the fourth stage leave out some of the black spots, which other methods have tried to respond to. Consequently, the fourth stage does not provide a solution to all relevant information needs related to the growing dominance of intangible inputs to production. The fourth stage must therefore be considered to be a pragmatic but also an incomplete solution to the demand for improved information on human capital at enterprise level, seen from the perspective of researchers and policy-makers. However, growing utilisation of audit systems and participation in benchmark programmes by enterprises indicates that the methods have a practical usability, which overrides theoretical and methodological concerns.

2.2.3 Reporting at society level

Estimations on the stock of human capital at society level is primarily done by measuring educational attainment – the highest level of education completed – of members of the adult population. As mentioned under 1.1, this method tends to overlook other important inputs to human capital not visible through formal education, such as work experience, non-formal learning, etc. Another more reliable method is to test individuals for certain abilities. However, this is possible only as spot which is difficult to attribute at national level.

Most reporting on the stock of human capital at society level has been linked with the societal returns on investments in education, i.e. human capital is defined as education or an input factor\textsuperscript{22}. Consequently, these surveys do not provide a measure on the totality of human capital stock in societies, they merely reflect the societal investment level in formal education.

As was the case at enterprise level, incomplete proxy indicators and benchmarking rather than output measures are utilised to estimate and report on the stock of human capital at society level. However, some have started to push forward the need for a more sophisticated human capital account at national level, such as the Federation of Danish Trade Unions\textsuperscript{23}. Further, the regional level is being introduced, among others by the World Bank.

\textsuperscript{21}See International Accounting Standards Committee 1998.

\textsuperscript{22}See Psacharopoulos 1994 and 1995.

\textsuperscript{23}See Federation of Danish Trade Unions 1999.
2.3 Methodological considerations

From the previous sections it has become apparent that many weaknesses of reporting methods originate from lack of adequate measuring techniques. This relates primarily to identification of human capital and especially how to measure it.

2.3.1 Identification of human capital

Identification of human capital can be stratified into three elements: first, a consistent framework must be established which captures both the definition of the term itself and the levels and dimensions related to the term, e.g. as outlined in Table 1. Second, identification of the processes related to the acquisition, maintenance and development of knowledge at individual level must be established, since it is at individual level that knowledge is acquired, maintained and developed through learning, be it formal, informal or non-formal learning, and work experience. Third, one must differentiate between individual and collective human capital. Collective human capital encompasses work organisation and processes, information networks and other forms of intangible, non-visible knowledge embedded in a group of persons rather than in individuals. It can to some degree be defined as knowledge that remains in the organisation even if individuals are replaced.

Identification of human capital and the various forms it takes to acquire, maintain and develop it have undergone considerable research in recent years, notably within the informal and non-formal segments of learning. Even though some theoretical and methodological difficulties are still present, it is justifiable to conclude with Hartog that '...the main problem is not so much how to define human capital as how to measure it'.

2.3.2 Measuring human capital

Identification of human capital does not in itself imply that it will be measured. Given the intangible nature of human capital and the difficulties in establishing reliable measuring techniques, crude proxy indicators such as market value over booked value or costs of input over output activities at enterprise level have been used rather than actual measurements.

Essentially, two different methods can be identified, one used to measure the stock of human capital and one used to measure the costs related to acquire, maintain and develop the stock of capital.

Non-economic measurement methods can be linked either to formal or to real human capital. Formal human capital will be measured through proxy indicators, such as educational attainment, years of schooling and/or other indicators such as job positions, number of years in job positions, etc. This is primarily related to individual and society levels. Real human capital can be measured directly at individual level by means of interviews, tests and/or examinations.

Economic measurement methods are related to the costs and benefits of acquiring, main-

---

25 Scandia, a Swedish insurance company, has been one of the pioneers within organisational intellectual and structural capitals. For further details, see Edvinsson and Malone (1997). It must be noted that collective and organisational human/intellectual capitals do not merge totally, although for simplicity it is presented as such in this paper.

26 See also Bjørnávold 1997, European Commission 1997, Bjørnávold and Sellin 1998, Frederiksen and Westphalen 1998. It should be noted that the focus on informal and non-formal learning should not be overemphasised given that the dominant feature on the labour market and related to competitiveness at individual, enterprise and society levels is still the level of skills identified through formal learning. Formal learning is thus also likely in the future to be the guiding determinant for competitiveness and job creation as illustrated by Pfeiffer (1997).

28 See Ernst & Young and OECD 1997.

The inability to establish reliable and verifiable measurement systems is the biggest challenge for reporting on human capital. However, despite the shortcomings so far in establishing a coherent measurement methodology, less technical hindrances also add to the reasons why such methods are not better developed, at least when it comes to measuring returns on any given investment in training:

- the cost-effectiveness of the training may be so obvious that formal evaluation is unnecessary;
- it may be impossible or prohibitively expensive to obtain the data necessary for a formal evaluation of training.

Identification of the stock of human capital may therefore to some degree be sufficient to identify future needs and demands, be it at individual, organisation or society levels. However, this leaves the economic dimension unexposed, and without measuring the economic consequences, over- and under-investment in human capital is less easy to detect as is choosing between alternative strategies related to human capital and, not least, the distribution of costs between different stakeholders.

3. Political considerations and the stakeholders

There are ultimately two paths for introducing reporting on enterprises' human capital on a large scale; public regulation or market forces. If both fail, i.e. if there is not sufficient political support or not enough market incentives, reporting on human capital will remain a technical exercise at macro-economic level and a description of knowledge, competences and skills at individual level.

In this process, the interests and dedication of the main stakeholders become vital.

3.1 The stakeholders

A stakeholder is defined as an individual, private organisation or public body having a direct interest in or being able to influence the widespread use of human capital reports. Table 3.1 provides an overview of stakeholders at various levels.

---

31 See Frederiksen and Westphalen 1998 for an in-depth stakeholder analysis. Table 3.1 is partly copied from this report, p. 24.
3.1.1 International state organisations

*International state organisations* are generally very active within the area of human capital. But even though the OECD has promoted investments in and to a certain degree reporting on human capital, it has so far abstained from clear recommendations and has not provided specific frameworks. The European Commission favours treating capital investment and investment in training on an equal basis. In this respect, the European Commission proposes that support structures be established at European level for the measurement of investment in education and training and promotion of investment in human resources. However, the European Commission too, has abstained from specifically influencing development, i.e. they have not provided or supported specific frameworks.

3.1.2 Governments

*Governments*' interests can be summarised as a concern for efficiency of educational provision, cost sharing on further development of society's stock of human capital and internal optimisation of its own stock of human capital. Consequently, they have a self-interest as well as a societal concern for establishing reporting mechanisms on human capital. Governments may, therefore, be a driving force for popularising human capital reports or, ultimately, installing regulation for compulsory reporting at enterprise level. The Danish government has summarised as follows: 'We have to contribute to creating a basis for companies', consultants' and investors' use of intellectual capital accounts in Denmark by actively participating in international development of guidelines.' Until now, however, it is primarily Scandinavian governments and the Netherlands, which have supported pilot studies on how to report on human capital, both in private enterprises and public organisations.

3.1.3 Trade unions

Generally, trade unions are not deeply involved in reporting on human capital. Still, concerns on the approach to human relations at enterprise level have been raised. For instance, ILO has, in the context of the crisis of trade unions globally, stated that 'The inherent risk is one of focusing attention on a purely economic – even econometric – approach to human relations' (ILO 1997, p. 222).

Exceptions to this observation are, again, to be found in Scandinavian countries where trade unions have developed policies on reporting on human capital as well as participated in the development of framework models and the testing of them. LO, the Danish Confederation of Trade Unions, has been involved because: 'LO has certain reservations about tying employee development too closely to technical principles of accounting; and for that very reason, one of the critical points in the knowledge account will be whether we can manage to include the right things.' Further, LO sees reporting on human capital as a means not only to fulfil economic requirements but also to meet social and ethical objectives and, furthermore, see it in connection with lifelong learning and the learning organisation, i.e. as a means to improve the workplace.

To secure maximum influence for its members, LO has developed a participatory strategy, i.e. it has developed information and training material so that members can influence the development of a HCA system. Still, it is important to note that this approach is based on the common interests of both enter-

35 See for instance www.efs.dk (English version exists on the site) for information on the Danish government's project. See also Dutch Ministry of Economic Affairs 1999.

36 See foreword to LO, 1998. Knowledge account is the name of a human resource accounting system developed by Jan Mouritsen, Professor, for the Agency for the Promotion of Trade and Industry under the Danish Ministry of Commerce.
prise and employees. The cornerstone of this strategy is that employees be directly involved in and exert influence on enterprises’ training and development programmes through informed discussions of the outcome of such programmes. The outcome is divided into work efficiency, creativity, staff turnover and absenteeism, which reflect both the enterprises’ need for profitability and the employees’ interest in a good working environment.

3.1.4 Investors

The investors’ perspective has been the focal point for most of the work initiated by the OECD in this area. The reason has been the focus on measuring the real value of enterprises given that financial statements do not fully capture the intangible assets in enterprises, notably the knowledge of employees in high-tech sectors. However, until now investors have shown relatively little interest in such information.

The empirical findings in the Danish project further underline that enterprises do not have investors in mind as the primary target for producing human capital reports (see Chapter 3.1.5 below).

3.1.5 Enterprises

Reasons for enterprises to start reporting on human capital generally come from a belief in management that it will improve performance. Still, external pressures exerted by investors, trade unions or governments, or internal pressures exerted by trade unions or individuals may also influence the decision. Nevertheless, the decision to start reporting on human capital is taken by management of the enterprise and ambitions differ accordingly. Skandia, for instance, a Swedish international insurance company, considers new indicators and collects new data for their human capital reports, while the Danish Environmental Protection Agency bases their human capital report on existing human resource data.

Most commonly, enterprises introduce reports on human capital to obtain:

- an external information system to attract investors;
- an internal information system on human resource issues;
- a cost-benefit analysis of investments in human resources;
- improvement in human resource management.

However, many pilot projects indicate that other objectives besides the officially stated ones play an increasingly decisive role. These include:

- maintain or improve enterprise image in society;
- indicate social responsibility and ethical values to the outside world;
- improve marketing to present and potential customers;
- benchmark human resource management and development;
- attract qualified labour force;
- retain qualified labour force.

A Danish project initiated by the Ministry of Business supports the theory that enterprises give a high ranking to human resource development in HCA. Of the 10 Danish and Swedish enterprises included in the project, nine list human resource development as the main objective in having an HCA. Only three enterprises include customers and only one enterprise lists investors and external reporting, respectively, in their objectives for HCA.

---

37 See Frederiksen and Westphalen 1998, the case studies.

However, when enterprises estimate the effects of their HRA, investors' and external stakeholders play a role almost equal to human resource development, productivity effects and creation of an enterprise spirit. This indicates that a non-stated objective behind much HCA is actually to acquire information directed towards investors and external stakeholders.

A more recent study provides more detailed information on the reasons behind enterprises producing human capital reports. Results of the study are presented in Chapter 4.2, Table 4.3.

Finally, it must be emphasised that use of HCA is already widespread in some countries. In a survey of human resource managers in companies with more than 200 employees located in Stockholm, Sweden, 70% of the respondents said they were applying HCA in some way. Most organisations had started at the beginning of the 1990s. An investigation conducted by the Swedish Association of Local Authorities found that 22% of the 276 respondents had decided to use HCA. Only from 5% to 15% of the personnel, accounting and financial managers asserted they were not interested in HCA.

3.1.6 Employees

Employees are listed as main stakeholders since they are the core element in any reporting mechanism being introduced and, further, reporting on human capital can be viewed as an instrument 'to create a new contract between company and employee. The individual takes responsibility for his or her own training. We are trying to create key figures for the new contract. The employee undertakes to seek knowledge and education, while the company undertakes to make the employee suitable for employment... This can lead to an "every man for himself" attitude'. On the other hand, as expressed by a shop steward in an enterprise developing human capital accounts: 'There is nothing wrong with being measured and weighed, as long as it is done fairly.'

Still, employees generally are not particularly interested until after it has been introduced by management.

In summing up; generally, stakeholders do not formulate policies or strategies concerning reporting on enterprises' human capital. Exceptions come from relatively few, isolated pilot projects at enterprise level formulated by dedicated management and, notably, from Scandinavian countries where both social partners and governments are actively involved. However, not even these countries or otherwise active international organisations have formulated clear policies and most work/support is still dedicated to testing and/or theorising rather than decision-making or active promotion of reporting frameworks.

3.2 Market forces or public regulation

Despite interest in reporting on enterprises' human capital, a clear strategy for popularising reporting on a large scale has not yet emerged. The core elements for a wider dissemination are thus related to relevance, applicability and promotion.

The relevance is not generally disputed by insiders. Most researchers, policy-makers and practitioners see the importance of reporting on human capital as a means to improve overall performance of enterprises. But, as indicated above, relevance has many faces following stakeholders' different objectives. Consequently, it remains questionable whether all objectives, insofar as they are being formulated by a small group of experts, dedicated practitioners or in general political statements, can be captured in one framework.

It follows that if the importance of reporting on enterprises' human capital is only captured by insiders and their judgement is correct,

---

40 See Gröjer and Johanson, 1996. N.B. Johansson refers to the use of HRCA, which is one specific form of HRA.

</tr>
</tbody>
</table>

NB: Since there is a lack of examples directly related to human capital, examples related to alternative reporting and quality standards are used.

Four ways can be identified for promoting such a reporting framework, as outlined in Table 3.3.

The unstructured, voluntary market-based method has prevailed until now. This could be seen as an experimental phase where different methods and approaches are being tested. However, after almost 10 years of testing, the position is still not clear. Continuation of pilot tests indicates that either no reliable method has emerged, no consensus can be reached or that stakeholders are reluctant to commit themselves to a given standard.

Some would argue that this is also an indication that reporting on human capital will remain an internal management procedure or be part of an enterprise's external promotion catalogue with little general interest nor support. However, the Investors in People award programme, discussed in detail in Chapter 4, as well as the growing use of benchmark programmes suggest there is widespread interest in reporting on human capital when the framework for doing so is within practical reach at enterprise level.

Inevitably, wider dissemination depends on the establishment of a reporting framework, deemed both relevant, relatively easy to apply at enterprise level and subject to external audit. Further, reporting must be promoted and become available as well as attractive to a wider range of enterprises than have hitherto shown interest.

---

Signals of market preferences for specific methods are thus emerging and a market standard within human capital reporting may be on its way. In contrast, there is little sign of public authorities at national or international levels, willing to commit themselves to promotion activities regarding voluntary rewarding mechanisms as is the case within other spheres of enterprise issues. It is surprising that since the European year of lifelong learning in 1996, despite governments and international organisations advocating strongly for increased investment in human capital, none — with the notable exception of the United Kingdom — have provided an awarding mechanism for reporting on such investments. The European Union, in particular, having introduced awarding mechanisms or supporting such mechanisms within environmental friendly production, quality promotion and, most recently, a European label for innovative projects in language learning, should feel an obligation to introduce such a scheme within reporting on human capital. Especially since it would supplement policies on lifelong learning which the European Union reintroduced in 1996.

Consequently, it seems unlikely that public authorities are going to issue any form of regulation in the near future. Therefore, if a standardised framework for reporting on human capital is to emerge on a similar scale as ISO standards or TQM within quality management, it must be market initiated.

4. Current reporting frameworks

The development of an advanced framework, which can capture the full range of human capital and report within reliable reporting mechanisms and be subject to standard auditing control systems, seems not to be a realistic option at the moment. Instead, current reporting frameworks concentrate on elements of the stock of human capital in enterprises, be it depreciation, formation or utilisation of human capital. Some, if not the majority, would not, however, classify themselves as human capital reporting tools. Rather, they are identified as management tools, cost and benefit analyses or quality training standards. This indicates that at enterprise level, reporting on human capital has to be related to practice, i.e. its usability should be clear for management. The best way of securing this is either through financial indicators, i.e. showing the relation between a given procedure and the costs and benefits or through improved management, i.e. showing that the policies introduced clearly improve overall performance.

There follows a description of approaches aiming at providing frameworks for developing some sort of human capital reports. The examples presented will only include approaches, which have already gained certain popularity or are likely to become widespread relatively quickly. Consequently, some examples are very limited in scope and may not rightfully qualify as a human capital account instrument, such as the Investors in People programme. They are included, none the less, because they do provide us with tools, indispensable in human capital accounts and because they highlight that financial indicators and overall performance are not necessarily the only reasons for undertaking investment in human resources.

4.1 Intellectual capital accounts, Denmark

The Danish Ministry of Business and Industry is testing a framework model for human capital accounts. The project started in 1997 and should be finalised in 2000 with a fully developed human capital account. Due to the time framework, there is a lack of details on specific guidelines to be developed from individual experiences. It is therefore not possible to present a human capital account framework, as such, but merely to present some mid-term experiences.

According to the Danish minister at the time, Mr Jan Trøjborg, the project should 'give an

NB: the survey is based on interviews with managers in 23 companies participating in the Danish project.
Source: Bukh, Larsen and Mørtsen 1999.

An overview of the factors that create development within the company: the people working for it, their qualifications and the way in which they carry out their work... If things are not in order and are not consistent with the market or the strategy the company is following, this will become apparent in the intellectual accounts'.

The Danish ministry stresses the need for a broad interpretation of knowledge and provides some examples of figures which could be included in an intellectual capital account:

- costs of training,
- IT skills,
- the seniority value of each employee,
- running-in time for new organisational units,
- employee satisfaction,
- costs per process,
- customer satisfaction.

In 1999, the first report on the mid-term experiences of the project was published. Each participating enterprise is developing a highly individualised human capital account and, consequently, experiences are individualised. Generalisation and guidelines will be developed by the end of 2000. Consequently, the experiences gained are not systematised other than the following rough indications of the enterprises' approaches:

- some companies work with databases of employee competences;
- others work with systems for formalisation and sharing the company's experience re-

---

47 See Danish Ministry of Business and Industry, 1999. See also www.efs.dk.

garding products, customers, technology and processes relating to knowledge of the different company and innovation processes, intellectual property rights, etc.;

- many companies have introduced employee and customer satisfaction analyses and thus view knowledge as more ‘implicit’ relations between persons;

- some companies focus on the description of organisational procedures regarding information technology, casework and other factors. Companies view knowledge as the mechanisms binding people, technologies and processes together.

A survey tried, however, to research the reasons why companies get involved in developing human capital accounts.

Based on this relatively small sample, it is clear that presentation of the company as a knowledge intensive enterprise to attract employees and customers and as support for overall business strategies are of overall importance. In contrast, that human capital reports are conceived for or aimed at investors and suppliers is of relatively little importance. This clearly indicates that human capital reports are used as much as external reporting tools as they are for internal management purposes.

The Danish government’s interest in intellectual capital accounts must be seen in the macro perspective of maintaining the competitiveness of Danish enterprises. Further, they also see the testing of a framework for intellectual capital accounts as a means of establishing a common intellectual capital account internationally, thus expressing the role of governments to provide regulation.

4.2 The Finnish model

The Finnish Ministry of Finance established a project on human resource accounting in 1995 aimed at the public sector but attributable to private enterprises as well. Based on a working paper developed by the Finnish government together with its social partners, an HRA system with the following main categories was tested in the public sector:

- a) current personnel resources:
  - amount and structure,
  - use of the working time,
  - labour costs,
  - travel expenses;

- b) future need for personnel resources:
  - demand and supply of the personnel;

- c) development and support of HR:
  - Motivation and ability to work:
    - work satisfaction,
    - competence,
    - absence due to illness,
    - absence due to occupational accidents,
    - personnel turnover;
  - Personnel investments:
    - development and support of work satisfaction and work ability,
    - training and educational activities,
    - occupational health services,
    - replacement costs of the personnel;

- d) HR output and productivity:
  - financial indicators,
  - customer satisfaction,
  - job requirements, performance, merit pay;

- e) financial HCA information:
  - Cost and income calculation:
    - balance sheet calculation,

The data gathered provides information on:

- how cost-effectively human resources are managed, so that the organisation benefits from its human capital as much as possible;

- how the organisation has taken care of its personnel, so that they have both quanti-
tatively and qualitatively adequate human resources;

- how the quality of work and working conditions, personnel resources, efficiency and personnel wellbeing has been handled.

According to a survey in 1998, HRA is implemented by 28% of respondents in the public sector\(^{51}\). However, the Finnish model seems closer to the French social accounts than to the Danish project on human capital accounts and the trend seems to be more and more towards broader intellectual capital accounting. Both private and public organisations are searching for alternatives to HRA and purely financial metrics and indicators\(^{52}\). Still, the HCA forms a solid background on statistical indicators for further development of the tool, be it for individual human capital reporting or supporting generic management tools.

4.3 Social accounts in France

Since 1977, enterprises have been required by law to provide social accounts in France (more than 300 employees from 1982). The social accounts are entirely for internal reasons and primarily aimed at providing information for the benefit of the employees' bargaining position towards management.

Social accounts provide a richness of detailed information on employees, education and training, etc. The number of indicators is counted in hundreds following specific descriptions and definitions. It is by far the most detailed compulsory reporting mechanism on employees that enterprises have to develop. This indicates the administrative and organisational burden on enterprises and, consequently, the problems in viewing social accounts as useful for management purposes.

Even if social accounts are not perceived as a human capital reporting method they are closely related. Presently, discussions are going on in France to improve the social accounts so they can be used for management purposes\(^{53}\). If successful, experiences from the social accounts will provide valuable information on definitions, gathering techniques, etc.

4.4 Investors in People, the United Kingdom

Investors in People (IiP) is a standard on training investments developed in the United Kingdom which has been in operation since 1991. In early 1999, more than 33,000 organisations (which include enterprises, schools, public and private organisations, etc.) covering 33% of the total workforce in UK were committed to the standard (according to statistics from DfEE). The standard has been introduced in other countries, albeit until now unsuccessfully.

The standard is a relatively simple training needs analysis within a larger framework oriented towards implementing structured training methods. The standard includes four principles (and 24 indicators) within an action line, as described in Figure 4.1 below. The standard is based on a common framework but with a high degree of flexibility within each indicator. Further, some indicators are policy- rather than process-oriented, such as management commitment. Of the four principles, one is solely devoted to commitment of management and awareness of employees.

The relatively broad framework does imply that each IiP plan is highly individualised according to the need and wishes of the individual organisation. From a standardisation point of view this is a weakness but from a usability point of view, i.e. the organisation itself, it is a strength which optimises use of the framework.

Once an organisation has been rewarded the investors award, it has to be renewed on a yearly basis. From year to year between 85 and 95% of awarded organisations want to maintain the award. The reasons are listed in Table 4.1 below based on a survey from 1995.

\(^{51}\) See Eronen and Ahonen 1999, p. 7.

\(^{52}\) See Eronen and Ahonen 1999, p. 3.

\(^{53}\) See Fruleux 1999.
It is clear from Table 4.1 that organisations generally value the award albeit most of the reasons only indirectly relate to overall performance. This highlights the perspectives for new enterprise statements as well as the irrelevance for having such information tied into traditional financial statements; reporting on human capital via the IiP focus on training and training processes is simply operating on a different level. This is underlined by the anticipated benefits realised from organisations involved in IiP, as described in Table 4.2 below.

Again, the benefits are highly visible but it is meaningless to try to present this within the framework of a traditional financial statement. The problem is whether it can be reliably reported annually at organisational level with a satisfactory degree of comparability. And whether this is relevant as long as the relevance of using the IiP is obvious for the organisation itself!

4.5 ISO quality management – Guidelines for training; ISO/DIS 10015

The ISO standard on training was planned to come into force late in 1999 and forms part of the standards on quality assurance and quality management. The standard as such is not markedly different from other methods within the area of training needs’ analyses but has the advantage of being an international standard. More importantly, it gradually builds up a database of the competences of employees in the enterprise having chosen the ISO standard which – eventually – can be easily adopted as a means to report on human capital.

Consequently, the interesting aspect of the ISO model, presented in Figure 4.2 below, is

not the model as such but the perspectives for enterprises over time while using the standard. The standard will gradually build up a comprehensive database in each enterprise; a database which will provide a detailed overview of the competences and qualifications of the workforce, i.e. the enterprise’s human capital.

It is the requirement to identify systematically the competences needed compared to the existing competence of its personnel. The ISO standard will provide a tool for standardising the information and, hence, the opportunity to store the information for future uses. It is specified that: ‘the organisation should identify the competence needed for each task that affects the quality of products, assess the competence of the employees to perform the task, and develop plans to close any gaps’.

This provides the ultimate tool for mapping the present stock of human capital at enterprise level and constantly upgrade this information. Further, if used properly the standard will also provide information on the flow of human capital, both actual stocks and required stock, over time!

From this perspective, the ISO standard has the potential of paving the way for reporting on human capital.

4.6 The current standing on human capital reporting frameworks

Human capital reports have been developed over the past 10 to 15 years. If human resource accounting and social reports count as human capital reports, reports have existed for the past 30 to 35 years. Still, reports combining measuring and managing human capital for both external and internal reasons are a recent phenomenon.

Even more recent are attempts to systematise the development of standardised human capital report frameworks. Currently, such attempts exist in Denmark, the Netherlands and in the international Meritum project under the European Union’s TSER programme. In the latter participate Denmark, Finland, Norway, Sweden, Spain and France thus underlining that structured impulses are coming from the Scandinavian countries in particular. To this must be added numerous methods developed by consultant companies most of which, however, seem to be biased towards internal management objectives. This renders them incomplete if judged from the experiences of the Danish project and from the stakeholder analysis in Chapter 3. This is why the Dutch experiment has not been described in greater detail, because they formed a project by inviting four consultant companies to develop a human capital framework, which, in its initial stages seems to suffer from traditional consultancy weaknesses.

Finally, the individual enterprise approaches

suffer from their very individual styles and lack of generalisation.

Consequently, the examples present the current state of the art outside individual attempts and consultant companies’ methods. This may not look promising for the future of human capital reporting!

5. Research findings: from theoretical intentions to applicable methods

The first question is whether standard reporting tools can be developed? On the one hand, they do already exist but at such a low abstraction level that they only barely qualify as being a human capital reporting tool. On the other hand, the very problem is whether standards in an area where the process is deemed as important as the end result, i.e. the report, can be developed and made operational.

One way of solving the dilemma is establishing a minimum set of standard indicators, which will satisfy the need for reliability and comparability while still leaving room for manoeuvre taking individual requirements and perspectives into account. This is the approach guiding the Danish project although the framework as such is not yet developed.

The next question is whether reporting on human capital should be compulsory or voluntarily. This question is not yet answered definitively but it seems that public authorities are reluctant to force a reporting method on enterprises. Further, the French experience does not seem to support the idea of regulation. Having said that, it must be underlined that the intention behind the French’ social accounts was to provide employees with a tool to strengthen their bargaining power against management. This approach will naturally hamper any perception of this being a tool for mutual benefit. Therefore, the French example is not of much relevance today and seems more to be an anachronism from an earlier era than being related to modern management and reporting ideas.

The final question is who is to ensure that human capital reports become widely used? Governments trying to steer development by incentives rather than by laws may pursue establishing one or the other variation of human capital reporting as a policy programme. It indicates that governments do commit themselves by supporting a specific framework but leave it to market forces supported by incentives to make it become widespread. This may be a very successful approach as in the UK case of Investors in People and is likely to be the approach adopted by the Danish government once their pilot project is finalised in 2000 and can be implemented.

But government regulation or steering is not the only way for reporting on human capital to become widespread as market forces may create their own momentum. This has been the case with quality and environmental standards, etc. Presently, different forms of human capital reporting, together with intellectual capital management, social accounts, ethical accounts, etc., are becoming inevitable elements in consultant companies toolboxes. This may be a first indication of things being set in motion. However, it is still not clear in which direction.

The ISO 10015 on quality management of training, as well as the Investors in People programme, are examples of a minimalist approach to human capital reporting although training and related areas constitute a major element within reporting on human capital. Business Excellence, the Balanced Scorecard and other generic management approaches are at first sight all embracing. However, a closer look reveals that they are limited in three perspectives: first, they seem to operate on a high abstraction level. They do not provide tools or indicators, which can transform them into an operational tool at enterprise level. Notwithstanding their usefulness at a strategic level they remain theoretical tools. Second, and as a consequence of the first, these tools are of relatively little use in the day-to-day running of an organisation.

55 See for instance KPMG, Ernst & Young, Arthur Andersen, ICM, etc. Accountancy organisations are also exploring opportunities.
unless they are transformed into specific tools. This requires for instance a human capital reporting mechanism. Third, the need for providing reliable and valid information externally can never be fulfilled by these tools since they remain management tools.

Consequently, between the minimalist and generic approach specific tools are necessary, which can address the specific needs at enterprise level for gathering information as well as providing the framework for external reporting. This is the reason why experimentation is ongoing. Further, different stakeholders will have different orientation points and, hence, focus on different aspects. An inherent risk, unless governments are involved, may be that only incomplete reporting tools with fragmented or highly individualised frameworks will be developed. Frameworks that will not satisfy the full range of needs and demands, as expressed by a full range of stakeholders, will fail to become more than a short-lived fad.

6. Conclusion; recent trends and likely future of reporting on human capital

Human capital is about measuring and reporting fixed values and processes related to gathering, developing and disseminating knowledge. From this very broad framework, a new approach which combines reporting on and management of enterprises' human capital is emerging. The methods being developed focus either on specific elements or on the totality of elements constituting human capital and the utilisation of it.

With the increasing dominance of intangible assets, first and foremost knowledge in production, reporting on human capital seems to be a method on which future estimates on enterprise performance as well as future strategies can more efficiently be made. This is the advantage over other reporting methods, notably financial statements, and is the constituent factor in most strategic management tools developed in recent years. The benefits of human capital reports in this connection are that they include specific measurement elements on which most management theories fall short.

Potentially, human capital reports are therefore a complex form of measuring, reporting and acting at the same time which may overcome the barriers between static measuring and active managing. However, there are substantial problems to overcome before the potential will be realised.

6.1 Society level

Reporting on human capital is still surrounded by a high degree of indecisiveness regarding its direction, as indicated in Figure 6.1 below. Although human capital is becoming part of mainstream macroeconomics and statistics, it still falls short of being used in a coherent manner. Rather, human capital is replacing the black holes in macroeconomic theory, which used to be covered under the notion of externalities or residual factors and, further, within macrostatistics, human capital has become synonymous with education alone.

This is primarily due to methodological problems deriving from the intangible nature of human capital indicating that direct measurement seems unlikely to appear in the near future. Instead, proxy indicators linked to factors feeding into the creation of human capital will prevail, and proxy measures related to output will remain on the level of comparisons. This may be in the form of benchmarking or through statistical observations of the correlation between input investments in human capital and output performance of economies, be it at micro or macro level.

It must not be neglected, however, that proxy indicators may be satisfactory for a number of purposes, although they may not provide a complete description. Indeed, the balance between full knowledge and operational measures does inevitably lead to imperfect information provision but also leads to constant improvements and refinements if only the scope changes. The very notion of reporting

56 See Larsen, Bukh and Mouritsen 1999.
on human capital can thus be seen as a shift in orientation among economists, statisticians and other research areas on the one hand and policy-makers and other stakeholders on the other. The notion of human capital has resulted in inclusion of the enterprise level as a focal point for measuring investments in and returns on human capital formation in enterprises, which was relatively neglected by researchers and policy-makers for a long time.

6.2 Enterprise level

Enterprises are gradually showing more interest in reporting on human capital. There are a number of reasons for this development. The shift of responsibilities between the private and public spheres have made enterprises increasingly willing or under pressure to take on social responsibilities. Further, the emergence of the political consumer will force enterprises to respond to market pressures beyond the actual product being produced (e.g. working conditions, environmental protection and production methods). This has already led to pressure for reporting on human capital in some cases, e.g. as a minimum to document that child labour is not being exploited. Furthermore, in the light of a rapidly ageing population, which will make the labour force with the right qualifications scarce, enterprises are trying to find new means to attract and retain labour. Finally, the decentralised and individualised bargaining pattern will contribute to the mobility of the – well-qualified – labour force, thus intensifying the need for policies to retain the workforce.

Within the area of internal reporting and management tools at enterprise level, certain developments utilising human capital as defined in this paper have arisen. Although still primarily occupied with the input side, some programmes like Investors in People in the UK and various benchmarking programmes, do evaluate the return side based on a standardised framework.

Ambitious human capital report frameworks like the Danish project try to incorporate various elements while servicing both internal management as well as external reporting needs, as presented in Figure 6.1. Gradually, it appears that financial indicators become relatively less important while indicators related to human resource management, work environment and development and dissemination of knowledge gain momentum.

It is thus important to maintain focus on human capital reporting as a response to societal and industrial changes, leading to more transparent enterprises and organisations. Further, the development of new products, production methods and work organi-

---

sation, both internally and across companies, has created the knowledge society, which requires fundamentally different management and reporting tools from those of the industrial age.

The question is whether human capital will develop out of economic theories into a new reporting framework for enterprises with all its consequences. And if so, whether this framework will lead to a fixed set of standards relative to those within management and quality control. Another possibility—supported by the initial phases of the Dutch and Danish governments' pilot projects—may simply be government programmes for supporting and strengthening enterprises' use of human capital!

6.3 The future of reporting on human capital: the quest for indicators

Actual development of a standard reporting framework will depend on whether stakeholders will start formulating clear policies on human capital; if not, they may find themselves overtaken by consultants and practitioners developing their own brands. Eventually, one or a few of these will become market leaders, such as at the current stage of the Balanced Scorecard or the Investors in People programme in the UK. The risk, if considered to be a risk, may be that focus will be on short-term internal management needs and thus remain in the traditional shareholder perspective, and not incorporate the need for external reporting expressed by stakeholders. If this dissemination strategy prevails, human capital reporting is likely to be short-lived, never to become widespread, since consultancy methods are too limited in focus.

On further dissemination of reporting tools and having at least some standardisation, international organisations have, until now, been dragging their feet to avoid taking a clear standpoint despite expressing strong, general support. Scandinavian governments and social partners and the Dutch government have begun to position themselves, generally along a stakeholder approach. It seems likely that human capital reporting frameworks with a minimum of standardised indicators will emerge. They will not become compulsory, at least in the short term, but will be promoted through financial, consultative and/or political incentives.

Enterprises are increasingly operating with alternative internal and external reporting systems, from financial statements over green accounts to ethical accounts with human capital reporting being only one (sub)system. Thus, given that a single human capital reporting method has not manifested itself qualitatively nor quantitatively so far, relatively few enterprises are utilising human capital reporting. Instead, widespread management approaches like the Balanced Scorecard, the learning organisation and business excellence prevail and are often, misleadingly, believed to encompass human capital reporting, although they would greatly benefit from doing so.

Unless general approaches are developed supported by governments and/or international organisations, human capital reporting is likely to focus increasingly on the management perspective only while neglecting the measurement and reporting elements. If this is the future, other benefits of human capital reporting, such as attracting qualified employees, will not be fulfilled.

On the other hand, if a set of minimum indicators is established, which is the likely outcome of the Danish project, the potential of human capital reporting is likely to be reached for the benefit of not only management but also for other stakeholders. The Danish project has from mid-1999 become a Scandinavian project, which further underlines that human capital reporting is gaining momentum!

Reporting on human capital; objectives and trends

Federation of Danish Trade Unions, 1999. The national human capital accounts, Copenhagen.

Abstract
Reliable information on trends in labour market demand and enterprises' skills requirements is increasingly of interest not only to those researching the labour market and occupations but also to the labour market players themselves. However, as yet only inadequate information on establishments and enterprises is available. One result of this is that research activities are concentrating on the supply side of the labour market.

The presentation of empirical studies based on establishment and enterprise data demonstrates the potential that research of this kind offers for vocational training research. This report therefore covers the skills requirements arising in the context of enterprises' increasing flexibility, in-company vocational training and the employment of trainees on completion of their training, and the trends discernible in the field of continuing in-company training. In this context, matched employer-employee data records are also discussed. With data records of this kind, it will in future be possible to analyse labour market demand and supply jointly.

The advantages, but also the disadvantages, of longitudinal surveys as opposed to cross-sectional surveys are also brought out. The advantages of longitudinal surveys lie in the survey, i.e. the fieldwork, the sampling and the questionnaire design. Longitudinal analysis, as opposed to cross-sectional analysis, offers other advantages in the shape of the allowances made for the heterogeneity of individual businesses, and consideration of the links between cause and effect and of processes of adjustment. Certain questions can be analysed only by means of panel data. The increased significance of measurement errors and selectivity problems can be regarded as a disadvantage of longitudinal data, including the panel mortality caused by various factors. As a rule, the collection of longitudinal data is considerably more costly and time-consuming, and it also takes a few years before evaluations of them can be presented.

1. Introduction

Politicians, scientists and employers themselves have an increasing interest in reliable information on trends in labour market demand and companies' skills requirements. The main reasons for this are the persistently high level of unemployment and the associated under-utilisation of human resources, and reinforcement of the quality of locations via investment in human capital. The OECD's Jobs Study (1996), for example, cited lack of flexibility on the part of companies as one of the main reasons for the European employment problem.

However, in comparison with the data available on the supply side of the labour market, the data available on the demand side is inadequate. Hitherto, various public bodies and research institutes have concentrated on surveying individuals. Establishment and enterprise data is systematically collected, but seldom with regard to employment and skills aspects and the variables determining these.

In order to be able to analyse and possibly reduce the continuing problems in the context of the labour market and training, there is a need for reliable data on the demand side of the labour market. Hamermesh (1993, p. 400) has also drawn attention to the interdependence of research activities and data availability thus addressed.

Naturally, vocational training issues are among the most important subjects that can be researched using establishment and enterprise data (cf. e.g. Lynch 1998, p. 54).

This report will therefore describe the potential which analysis of establishment and enterprise surveys holds for vocational training research. This will be done in several stages.

The next section presents a review of research dealing with issues relating to vocational training and continuing training and to company skills requirements on the basis of establishment and enterprise data. The review includes both studies with particularly high-quality data records, in particular panel data records, and studies with particularly interesting but non-representative data records. Panel data records are preferable to one-off cross-sectional surveys, not only owing to the more interesting evaluation options they offer, but also for technical reasons associated with surveys and questionnaires.

Section 3 therefore systematically compares the advantages and disadvantages of these two methods of gathering data.

Section 4 contains conclusions in the form of recommendations for structuring and evaluating company and enterprise surveys focusing on vocational training and continuing training.

2. Vocational training studies based on establishment and enterprise data

2.1 Introduction

In the field of vocational training research, there are very many questions which can really only be adequately analysed by using and combining both personal and company/enterprise data. In addition to the trend in the skills structure and skills requirements and questions relating to recruitment and the quest for staff, they include any problems arising with particular skills groups and with employment under-utilising skills (over-education), and also the increasingly important evaluation of publicly subsidised training and continuing training.

These are, of course, interesting and important topics, but are mentioned only in passing in this report, which concentrates on the following topics: skills requirements generated in the context of increased flexibility in companies, in-company vocational training and employment of trainees on completion of training (so-called second threshold), and the development trends discernible in the field of in-company continuing training. Not only do these topics cover major fields of debate, but they are also particularly suitable for demonstrating the potential of establishment and
enterprise surveys for vocational training analysis.

2.2 Promotion of flexibility in companies

The European Commission has emphasised the link between external and internal flexibility and their significance for economic growth, competitiveness and employment. In a world of increasing competition, companies are endeavouring to structure work organisation more flexibly in order to be able to respond more appropriately to external challenges and opportunities (cf. European Commission 1993). In the process, it has been acknowledged that workforce flexibility is the key to entrepreneurial success. A particularly crucial part is played by the capacity of employees to adapt in line with business needs by acquiring new knowledge and skills.

2.2.1 Business process re-engineering

Since the early 1990s, in management practice all sectors have adopted a management concept rightly described as a 'megatrend' and by some as a 'management revolution'. Lean production, lean management, lean enterprise and lean company are terms in common use. The more wide-ranging term 'lean management', or 'business process re-engineering', is superseding 'lean production', because the aim is to structure not just the plant or factory but the company as a whole in accordance with lean principles (cf. Hammer and Champy 1994).

'Lean' organisation structures differ markedly from Taylorist forms of organisation, which produce significant 'organisational waste' in the form of job and interface ballast. All reorganisations are aimed at making better use of the potential skills and motivation of on-site employees (cf. e.g. Frieling 1992). To this end, powers and responsibility are consistently decentralised.

The current range of reorganisation measures includes, in particular:

- flattening of hierarchies (hierarchical levels, management spreads);
- segmentation by creating autonomous and autarkic 'centres' (integration of functions, holding structures, new independence for parts of the company in their locations, fractal plant, manufacturing islands, companies within companies);
- learning organisation in the sense of transferring improvement processes from central staff departments to specialist departments (continuous improvement process);
- intensification of teamwork (semi-autonomous teams, project teams, work circles, coordination bodies);
- and total quality control (TQM), i.e. monitoring and maintenance of quality at all business and production levels.

Brewster, Hegewisch and Mayne (1994) criticise the fact that labour market flexibility has usually been measured and regarded as a problem not from the corporate point of view, but indirectly via staffing increases and decreases (numerical flexibility), atypical and also precarious employment relationships, part-time work, fixed-term contracts, seasonal employment and labour-law regulations. It is true that the distinction between core and marginal workforces leads back to company level, whether it be under the segmentation theories of the 1970s (cf. Doeringer and Piore 1971, Sengenberger 1975) or Atkinson's (1985) concept of the flexible company, but it remains blurred, with little empirical foundation and strategically unclear, since it is not possible to verify that companies form and use core and marginal workforces as part of their personnel strategy.

In any case, the combination of the two arguments led to the finding that labour market flexibility outside companies is closely linked to flexibility within them. If external flexibility is too high or too common, this can have a negative impact on per capita productivity, the business commitment to efficient workforces, recruitment, and the necessary job rotation within the enterprise. There is no in-company training or continuing training for temporary staff, employees with fixed-term contracts, persons in seasonal employment, persons in...
Vocational training research on the basis of enterprise surveys

insignificant employment, part-time workers, marginal workforces, etc., one reason being that it is not economic.

This means that functional flexibility in companies and for all personnel is crucial to the ability to tackle external requirements necessitating adaptation strategically, in the sense of a company policy decision geared to the long term. Thus productivity advances must be organised, work organisation must be adapted in line with market, customer and production requirements, collectively agreed and individually desired working hours must be balanced out with the longer operating times required, and in-company skills training and participation of employees must be extended.

The slimming down of large private companies, whose depth of production has been reduced in the context of lean management concepts, has also led to hiving off of service areas and the emergence of service enterprises close to the means of production. The effect of these developments on the capacities, skills and competences required in enterprises of different sizes is therefore at the top of the research agenda.

2.2.2 Case studies

Looked at empirically, human resources management practice has been the subject of company case studies in many European countries, such as the Price Waterhouse Cranfield study (cf. Brewster et al. 1994), and studies by Hutchinson and Brewster (1994) and Doherty and Nyhan (1997). It is also interesting to compare trends in these companies and US companies, and such a comparison definitely indicates that they are converging (cf. Nyhan 1999). Case studies have also given rise to work on intellectual capital accounts (cf. Westphalen 1999, Danish Agency for Trade and Industry, Ministry of Business and Industry 1999).

Given the arguments put forward, it is not surprising that there is a widespread view that the focus on labour market flexibility is too narrow and a broader perspective based on organisation theory should be chosen. The Swedish NUTEK study (1996) defines flexible organisations on the basis of four characteristics: organised improvement of knowledge and capacities, delegation of responsibility, flat organisation structures and individualised pay systems. From this perspective, the key interest lies in findings on the structure of the organisation as a whole, its human resources and strategy, and not simply in the way in which workers are used.

2.2.3 Studies based on the IAB establishment panel

As with the NUTEK study (1996, esp. Chapter 4), therefore, the empirical analysis in the study by Bellmann et al. (1996) focuses on the distribution of flexible organisations. Thus the authors do not simply provide an overview of increased flexibility of working hours and business processes and flexible wages, but also report on product and process innovations, research and development, and the position in respect of training and continuing training. On the basis of the employment statistics of the Federal Institute for Employment, information was also provided on the significance of newly created and altered employment structures.

There is still great scientific interest in the impact on employment – including individual skills groups – when flexible forms of organisation are introduced and extended. Bellmann (1999) investigated the impact on employment of innovative processes and organisational change for individual groups of employees with the IAB [Institute of labour market and vocational research – Institut für Arbeitsmarkt- und Berufsforschung] establishment panel. The IAB establishment panel (cf.Box 1) is a survey of establishments carried out annually in Germany since 1993, which provides a representative view of all establishment size classes and sectors.

Since 1996, the survey has also been carried out in the new Länder and East Berlin, so that in 1998 approximately 10000 establishments were involved in the panel. In order that new establishment creations and establishment closures can be included, every year new establishments entering the market are incorporated into the panel. Survey units are
Box 1: IAB establishment panel

Oral survey, annual, from 1993 onwards in West Germany and from 1996 onwards in East Germany too.

Questionnaire: standard element and changing focal points
Scope of survey: 9200 (1998) establishments
Sampling based on the establishment file in the employee statistics of the Federal Institute for Employment.
Topics in the IAB establishment panel:
- Number of persons employed and employment trend
- Skills and employee structure
- Business policy, business planning and investment
- Training places
- In-company training and continuing training (1997 and 1999)
- Wages and salaries
- Working and business hours (1999)
- Public support via wage and investment subsidies
- Contact with the employment office (1995)
- Works council and collective agreements

Sources: Bellmann (1997); Bellmann et al. (1998).

drawn from it on the basis of the employment statistics of the Federal Employment service, which are also used to weight the data collected (cf. Bender et al. 1996).

The employment trend in the period from 1993 to 1996 in the old Länder shows a decrease in workers without vocational training, while the other skills groups have increased. This applies particularly markedly to graduates. The findings of the IAB establishment panel also show that the employment trend is more favourable in establishments in the manufacturing industry and in closely associated services implementing innovative processes. This affects skilled blue- and white-collar workers in particular. Organisational changes (such as teamwork, flattening of hierarchies, downward transfer of responsibility, combined departments, institution of units calculating costs and profits themselves, introduction of just-in-time production) reduce the number of employees, at least in the short term.

In the longer term, however, in the wake of organisational changes an increase ensues in the employment of individual skills groups, e.g. skilled workers. There is a great potential for organisational change in small and medium-sized enterprises (SMEs) in particular in the next few years, since there is empirical evidence that here flexible forms of organisation are much less common than in larger enterprises. It is also apparent that improvements in technical status and organisational changes have a negative effect on the trend in part-time employment.

2.3 In-company vocational training and employment of trainees on completion of training

2.3.1 Overview

This section reports on studies by Dietrich and Bellmann (1998) and Bellmann and Neubäumer (1999a, 1999b) based on the IAB establishment panel, on the subject of determinants of company training intensity and participation in training and of employment of trainees by the companies providing training on completion of training. It goes on to describe the 'early recognition system for skills trends', in which a total of nine research institutes in Germany are involved. Last but not least, it reports on the research of Bardeleben et al. (1995) on the costs and benefits of in-company vocational training.
2.3.2 Company training intensity and participation in training

Using the data from the IAB establishment panel, Dietrich and Bellmann (1998) and Bellmann and Neubäumer (1999a) investigated the attitude to training in companies in West and East Germany. The studies cited contain representative findings on enterprise participation in training, measured as the number of establishments in relation to all establishments (training company ratio) and as the number of trainees in relation to employees liable to contribute to social security (training ratio), in both cases by sector of the economy and establishment size. The determinants of the training company ratio and the training ratio are also analysed.

This shows that SMEs provide an above-average amount of training. The ratio falls with establishment size. This means that when SMEs provide training, they train a relatively large number of young people in proportion to their number of employees. As many very small enterprises provide no training whatsoever, the training company ratio rises with the size of the company. These two overlapping trends mean that in West and East Germany, more than 50% of all trainees are found in establishments with fewer than 50 employees.

In a multi-variant analysis, the number of trainees is treated as a dependent variable and possible reasons determining this as an independent variable. All data available for the years 1993-1997 is used (this means, for example, that enterprises repeatedly involved in the survey are taken into account more than once). This leads to a substantial increase in the number of cases to be incorporated into the analysis.

This analysis of the attitude of establishments to training results in the following finding: in addition to the general trend of a reduction in the number of establishments in West Germany providing training between 1993 and 1997, the sector, size and anticipated turnover of the enterprise and the proportion of skilled workers and women in its workforce, as well as the type of region (city, surrounding countryside or other) in which it is located prove to be the determinants helping to explain ongoing training activities in an enterprise. The sectoral comparison possible on the basis of the IAB establishment panel shows above-average training activity in establishments in the production sectors of the chemicals industry, iron and steel production and vehicle manufacture, while there is below-average participation in dual training by the production-oriented service sectors.

Bellmann and Lahner (1998b) also investigated, again on the basis of the IAB establishment panel, why establishments do not provide training. Questions were asked about the possible lack of the necessary preconditions in establishments (justifiability of training), but also about training costs, later employment of trainees who successfully complete their training, and the lack of suitable applicants, as reasons why enterprises are less willing to provide training. A question was also asked about the involvement of employment offices in arranging training places.

Lastly, establishments were also asked if they wished to extend or restrict their training activities. This information can, for example, be compared with the anticipated employment trend (cf. Bellmann and Lahner 1998a). This shows that, on average, establishment training provision in the establishments surveyed has not decreased to the same extent as employment.

2.3.3 Employment of trainees in the training company on completion of training

In principle, the transition from school-based forms of training in dual training into employment is still a relatively smooth one for young skilled workers. Here, the fact that companies are involved in training is advantageous. However, the difficult situation on the labour market also affects the entry into working life of those starting out on completion of training.

Bellmann and Neubäumer (1999b) investigated employment by the training company of trainees who successfully complete their training, on the basis of the IAB establishment panel.
The study discusses the influence of the relevant sector, establishment size, the anticipated trend in employment and turnover and the technical status of machinery and plant, the proportion of turnover used for product innovations and improvements, and variables in respect of whether the establishment does its own research and development and/or market research. It also takes account of variables relating to the establishment structure, such as the proportions of white-collar workers, woman and skilled workers in the workforce and the proportion of employees with fixed-term contracts, the extent of pressure of competition, the staff turnover rate, capital intensity, and variables in respect of whether the establishment is independent and whether it is bound by collective agreements.

The empirical findings show that establishments are trying to cover their own need for skilled workers themselves in the long term, via vocational training. The wishes of those completing training correspond to this concern, since they want the training establishment to give them permanent jobs. However, if there is a short-term fall in profits or the business situation worsens, the establishment is unable to take on trainees on completion of training. The arrangements laid down in collective agreements for employment of trainees on completion of training are also important, but they often govern only fixed-term contracts and part-time employment.

2.3.4 Early recognition system for skills trends

Since 1998, Germany has had a network known as the early recognition system for skills trends (cf. Alex and Bau 1998, Kloas 1999 for a brief description), involving a total of nine institutes\(^1\). Not only does this network apply a very interesting mix of different methods, but it also draws on various data sources for analysis.

The activities of three of the institutes focus on surveys of establishments and enterprises. The Federal Institute for Vocational Training (BiBB – Bundesinstitut für Berufsbildung) has developed a system of some 1500 reference enterprises willing to take part in short-term representative surveys of topical training and continuing training issues. For example, they are asked questions about changes ensuing in the wake of product and process innovations and organisational changes, changes arising in skills, or changes in existing training arrangements required from the enterprises’ point of view.

INFAS (Institut für angewandte Sozialwissenschaft – Institute of applied social science) studies the skills trend in the service sector, using as a tool regional case studies on the skills required by SMEs in particularly dynamic markets such as software development and sales, Internet service providers, advertising and specialised trade for information and communication technology.

The Institute of structural policy and economic research (ISW – Institut für Sozialpolitik und Wirtschaftsförderung Halle-Leipzig e.V.) investigates 'fashionable skills', in order to use them as a basis for early identification of skills requirements. Interviews are conducted with companies which play a trend-setting role in their sector or region or as regards their products, and therefore detect new skills requirements much earlier than their competitors. It is also important to identify skills requirements ensuing from the use of trend-setting technologies.

---

\(^1\) The following institutes are involved in this network: Bundesinstitut für Berufsbildung (BiBB), [Federal Institute for Vocational Training], Fraunhofer Institut für Arbeitswirtschaft und Organisation [Fraunhofer Institute for the work-based economy and organisation], Institut für Arbeitsmarkt- und Berufsforschung (IAB) [Institute of labour market and vocational research], INFAS (Institut für angewandte Sozialwissenschaft – Institute of applied social science), Institut für Sozialpolitik und Wirtschaftsförderung Halle-Leipzig e.V. (ISW) [Institute of social policy and promotion of economic development], Infratest Burke Sozialforschung, Kuratorium der Deutschen Wirtschaft für Berufsbildung [Board of trustees of German trade and industry for vocational training], and the Wissenschaftszentrum Berlin [Scientific Centre of Berlin].
2.3.5 Costs and benefits of in-company vocational training

The Federal Institute for Vocational Training (BiBB) carried out a series of company surveys to identify the costs and benefits of in-company vocational training (cf. Bardeleben et al. 1995, 1997; Kau 1994)\(^2\). These were supplemented by case studies. It proved to be easier to identify the costs of vocational training than the benefits. The companies were also asked the reasons why they trained their skilled workers themselves instead of recruiting them externally from the labour market. The argument put forward was that skilled workers are only available by means of vocational training, since they are not available on the external labour market. Within the framework of the company's own vocational training, it is possible to identify the employees with the best skills and knowledge. In-company vocational training increases loyalty to the company and thus also reduces the staff turnover rate.

2.4 The trend in in-company continuing training

2.4.1 Overview

This section summarises empirical studies with differing structures on in-company continuing training, based on enterprise and company data.\(^3\) It begins with German/British studies from the 1980s, the studies of Holzer et al. (1993), Bartel (1994), Bishop (1994), Lynch and Black (1995), and Black and Lynch (1996, 1997), which are ambitious in their evaluation methods and use econometric methods to investigate the returns from continuing training. They assume a broad definition and take these as proxies for the returns from continuing training.

The section goes on to describe the studies of Gerlach and Jirjahn (1998) and Dull and Bellmann (1998, 1999), which also use econometric methods to investigate in-company continuing training provision and continuing training intensity – including considering men and women and differently skilled employees separately. Lastly, it presents special surveys on the subject of in-company continuing training by the institute of German trade and industry [Institut der deutschen Wirtschaft] (cf. Weiβ 1990, 1994, 1997), Eurostat (cf.European Commission 1998a), and the American Society for Training and Development (ASTD) (cf. Bassi and McMurrer 1998, 1999; Bassi and Van Buren 1999a, 1999b).

2.4.2 Studies on the returns from in-company continuing training

Prais (1987), Prais and Wagner (1988), Prais et al. (1989), and Steedman and Wagner (1987, 1989) investigated the effects on productivity of various vocational training systems in a whole series of publications based on company data from Japan, the UK and Germany. They attributed the higher level of productivity in Germany to better-skilled workers, owing to a better vocational training system and to the work organisation, while taking account of differences in real capital.

On the basis of a survey of 171/250 companies in the manufacturing sector in the US State of Michigan, Holzer et al. (1993) investigated whether allocation of training subsidies has a positive effect on the company's productivity. The reject rate was used as the figure for measuring productivity. A comparison of the trend in companies which had received a training subsidy with that in companies whose applications were rejected shows that the training subsidy reduces the reject rate by 7%.

Lynch and Black (1995) and Black and Lynch (1996, 1997) carried out cross-sectional evaluations based on the Workforce National Employers Survey (NES) of the National Center on Educational Quality of the Workforce, a telephone survey of 2,945 com-
panies, and longitudinal evaluations based on a database generated via interplay between the NES and the Longitudinal Research Database of the US Bureau of Census. In the cross-sectional analyses, although not in the longitudinal analyses, they established that productivity was influenced by the proportion of participants in continuing training. They put this finding down to relatively poor recording of in-company continuing training. Interestingly, their study shows that organisational change has a significant effect. This needs to be examined further. On the basis of a comparable survey of 654 (1993) and 215 (1997) companies in Ireland, Barrett and O'Connell (1999) were able to ask very specific questions about enterprise-specific and general continuing training. They were able to establish that general, but not enterprise-specific, accumulation of human capital had a positive and significant effect. These studies are closely aligned with the increasingly important evaluation studies in the field of publicly funded continuing training.

Supplementing the questions also asked in the other surveys, in the data records used in the study of Frazis et al. (1998), companies were asked for more precise information on training and continuing training, pay levels and productivity in relation to two employees selected at random. This procedure is intended to reduce the problems arising from the great heterogeneity of the employees in an individual company. The most important finding is the greater involvement of larger enterprises in in-company continuing training and the stronger fostering of skilled employees.

Action-oriented approaches can be regarded as an alternative to the above approaches, which sometimes involve very sophisticated econometrics. The question also arises of whether a partnership is possible between companies and scientists in evaluating continuing training measures, also in the sense of monitoring training. The way in which this could work and the conditions that would need to be met are also discussed by Büchter (1999), Krekel and Beicht (1998) and Barrett et al. (1998, p.36).

2.4.3 Determinants of in-company continuing training

Gerlach and Jirjahn (1998) research the question of the fundamental factors influencing in-company continuing training on the basis of a panel data record generated in 1993, 1994 and 1995 covering 1,022 (1993), 849 (1994) and 721 (1995) manufacturing companies in Lower Saxony. The authors show that the factors promoting in-company continuing training activities include the skills structure of the workforce, increasing enterprise size, integration with other enterprises, modern work organisation, employee participation, performance incentives within the enterprise, the existence of a works council, and a company strategy based on research and development.

The growing number of enterprises with continuing training in line with the proportion of graduates and skilled workers in the workforce is seen by the authors as evidence of a business calculation leading to greater willingness to invest in the human capital of workers from whom returns can be expected. There appears to be little likelihood that enterprises will make a greater investment in continuing training for employees with skills deficits and hence indirectly improve their labour market prospects. Against the background of this finding, one also has to take a sceptical view of the willingness of enterprises to take on the long-term unemployed, even on a trial basis, as long as they can call on jobseekers lacking the stigma of a lengthy break in employment.

Following on from the study by Gerlach and Jirjahn (1998), the IAB also carried out research into company-subsidised continuing training, adopting a similar approach. The authors take their basic data from the information in the 1997 IAB establishment panel survey, which focused on in-company continuing training. Dull and Bellmann (1998) research the determinants both of in-company continuing training provision and of the intensity of continuing training in establishments. An enterprise is subsidising continuing training if it has financed a continuing training measure for at least one employee in the first
Vocational training research on the basis of enterprise surveys

six months of the survey year; by bearing costs or releasing employees for participation in measures. The intensity of the establishment's use of continuing training is given by the proportion of participants in continuing training in the establishment's overall workforce.

The descriptive evaluations presented clearly show a heterogeneous picture for continuing training activities in establishments. An average of four in ten establishments in both East and West Germany undertook continuing training activities in the first six months of 1997. While in the smallest establishments (up to nine employees), only three in ten establishments offer any continuing training measures at all, in enterprises with up to 49 employees the figure rises to more than 50%. Virtually all establishments with 1,000 or more employees implement continuing training measures. The increasing readiness of establishments to offer continuing training as their size increases applies equally to establishments in the old and new Länder. A similarly differentiated picture emerges if establishments are classified by sector. Skills training measures for employees are most frequently implemented by enterprises in the following sectors: mining/energy and water supply, banking and insurance, the health sector, education/publishing and the public sector (local authorities/social security system). They are least often implemented by establishments in the agriculture sector and in the hotel and restaurant industry and the cleaning sector. This again applies equally to West and East Germany. Taken together, these findings show that there are considerable variations in continuing training provision according to sector and establishment size.

In multi-variant analyses, the most important factors are the skills structure of the workforce, the proportion of industrial workers, the proportion of trainees, investment in modernisation in the form of EDP, and the proportion of employees working overtime. These are the key factors determining both funding and the extent of the continuing training options offered by the establishment, i.e. the intensity of continuing training in the establishment. Thus the authors demonstrate that establishment decisions on promoting continuing training are linked in particular to technical modernisation and a skills bottleneck which cannot be resolved by taking on new staff.

In another study, Dull and Bellmann (1999) move beyond their original questions in order to determine the likelihood of continuing training for a skills group on the basis of the proportion of participants in continuing training from this group in all employees with this level of skills.

In the old Länder, the likelihood that these employees will participate in in-company continuing training varies according to their level of skills: skilled workers are most likely to receive continuing training, and unskilled and semi-skilled workers are the least likely. This applies to both the manufacturing sector and the private service sector. In the new Länder, the likelihood of continuing training essentially follows the same pattern, but in a comparison of different establishment sizes, the intensity of continuing training of skilled workers is higher in smaller establishments, while on the other hand it is higher for unskilled and semi-skilled workers in large establishments. In in-company continuing training, selection can be linked to the corporate framework conditions and to the application of specific staff deployment and work organisation concepts. It may be supposed that enterprises with their own personnel management system are more likely to implement systematic personnel work in the form of continuous in-service and continuing training, while establishments with no separation of functions of this kind are more likely to tend to make adhoc adjustments in line with current needs.

The authors also offer some evidence of the relationship between training and continuing training within establishments. The higher
the proportion of trainees in the establishment, the more likely skilled workers are to participate in in-company continuing training. In large enterprises, unskilled and semi-skilled workers also tend to be included in in-company continuing training. As the establishment size falls, however, in-company continuing training activities decrease. While large enterprises tend to have a strategy of supplementing knowledge acquired in vocational training with job-specific special knowledge in additional continuing training stages, in SMEs’ ‘dual’ training strategies of this kind appear to founder owing to the question of costs. The findings available suggest that large establishments implement a complementary strategy in relation to vocational training and continuing training, in which job-related continuing training supplements the vocational training of junior staff. Owing to the human and financial resources required, smaller establishments do not implement systematic continuing training of their employees. Here, initial vocational training is the only pillar of the efforts made to impart vocational skills. Responsibility for continuing training lies with employees themselves (although in some cases networks of SMEs arrange continuing training, or there are linked systems).

2.4.4 Continuing training surveys by the Institute of German trade and industry

The distinguishing feature of the written company survey implemented by the Institute of German trade and industry in West and East Germany (cf. Box 2) is the fact that it uses a largely unchanged questionnaire, to make time-based comparisons possible. Questions were asked about the following:

- the number of participants and the amount of time involved for them;
- the range of in-company continuing training activities (on the job learning, self-regulated learning, internal/external lectures, internal/external information events, retraining measures);
- the timing of continuing training;
- the level of expenditure per employee;
- developments in continuing training;
- the problems involved in releasing employees, and;
- trends in the regulation of continuing training.

It can be seen that enterprises prefer shorter events, organised in-house. In the author’s view, it all amounts to organising continuing training in a time-saving and just-in-time manner (cf. Weiss 1997, p.9). The breakthrough with regard to the ‘new’ media that keeps being signalled has not yet come about. A look at future trends shows the greatest growth taking place in on the job learning and self-regulated learning. Two thirds of enterprises see a need to intensify monitoring of success, and almost as many want to improve the cost-effectiveness of continuing training (cf. Weiss 1997).

2.4.5 Eurostat (Statistical Office of the European Communities) Continuing Vocational Training Survey (CVTS)

In the years from 1991 to 1994, the European Commission addressed itself to companies in the private sector in the individual Member States with the FORCE action programme.
(Formation continue en Europe), in order to support companies’ efforts in the field of continuing vocational training. Interviews were carried out with 50,000 representatives of companies with 10 or more employees. However, important sectors of the economy like agriculture, education and health care and the civil service were not included in the survey. In the context of this action programme, surveys on continuing vocational training were carried out in 12 Member States with the aim of acquiring data facilitating a comparison of the quality and quantity of actual continuing training activities in companies in the individual Member States.

In Germany, a two-stage survey concept was developed, consisting of a preliminary survey and a main survey. The main purpose of the preliminary survey was to obtain initial findings on continuing vocational training provision in companies. In the main survey which followed, these findings were consolidated and supplemented by further content. This stage of the survey covered all companies that had responded in the preliminary survey and had not expressly indicated that they did not wish to participate in the main survey. This was designed to ensure that it was not only companies active in continuing training that participated in the survey.

Selected findings were published by the European Commission (1998a) and the European Commission, Eurostat and Cedefop (1997, 1999, forthcoming). The CVTS contains international comparative data on

- the number of companies offering continuing vocational training by size and sector of the economy;
- the number of participants in continuing training/external courses, in-house courses (continuing training on the job), participation in lectures, specialist meetings, trade fair events, job rotation and self-regulated learning.

In addition,

- in in-house and external courses, participants are broken down according to sex, occupational activity (managers and scientists, engineers, office and sales staff and blue-collar workers), sector of the economy, duration of course, content of continuing training, type of supplier and costs (including in relation to overall labour costs);
- the time spent on participation in courses and the continuing training intensity are measured in relation to working hours and the number of participants.

For countries which provided Eurostat with micro-data records, i.e. all countries except Germany and the Netherlands,

- the assessment of companies’ future skills requirements was analysed;
- the participation of certain groups in continuing training events was also described;
- the trend in forms of continuing training was assessed; and
- the reasons why some enterprises implemented no continuing training measures were analysed.

Apart from the fact that in 1994 there were (still) some differences in the data collection methods used by the countries concerned (cf. European Commission 1998a, pp. 12f.), the CVTS offers an extremely valuable potential for analysis. Above all, country-specific differences in the willingness of companies to offer employees skills training and in the intensity of continuing training can be investigated. At the same time, differences between the countries as regards sector and enterprise size structures can also be included, as can differences in types of supplier. It would also be interesting to indicate lines of development, although the topicality and relevance of the findings are impaired by delays in provision.

5 In Cedefop’s first report on vocational training research in Europe (Tessaring 1998), the Continuing Vocational Training Survey (CVTS) is discussed in Part 3, Chapter 4.4.

6 The corresponding findings for Germany can be found in Schmidt (1995) and Grünewald and Moraal (1996).
Since the survey and hence also the questionnaire are specifically tailored to the field of in-company continuing training, however, it is not possible to take account of important company determinants of willingness to provide continuing training and continuing training intensity, such as investment activity, the company's technical status and the existence of a works council, as included by Düll and Bellmann (1998, 1999). Admittedly the works council is not involved in the everyday life of the enterprise, but only in the event of major rationalisation, as shown in the study by Sadowski and Pull (1997).

2.4.6 Benchmarking by the American Society for Training and Development (ASTD)

Since 1997, the American Society for Training and Development (ASTD) has carried out an annual written survey of member companies on a voluntary basis.

The companies were of all sizes and came from all sectors of the economy. The questions related to

- expenditure on training and continuing training;
- the proportion of participants in continuing training measures;
- the use of external continuing training providers;
- the use of modern learning technologies;

and

- the significance of training in the field of technical knowledge and skills; and
- the introduction of innovative forms of training, work and remuneration.

The success of and return on investment in training and continuing training was evaluated by creating sub-samples and comparative groups. For example, Bassi and McMurrer (1998, 1999) compared companies whose per capita investment in training and continuing training was above the mean sum for all companies with those below the mean, firstly in terms of value added per employee, secondly as regards gross returns per employee, and thirdly as regards the relationship between market value and book value. More favourable findings are obtained for companies investing relatively more strongly in training and continuing training. It should, however, be noted that it was only possible to include 40 companies in these analyses, since in some cases reference had to be made to published data in the public domain.

The fact that small numbers of companies took part in both surveys considerably limits the meaningfulness of the studies. There are procedures for correcting possible distortions in selection, but with very small samples they are of very limited use (cf. Huselid and Becker 1996).

Bassi and Van Buren (1999a) report on the findings of an analysis comparing 55 companies selected, with the aid of a cluster analysis, as leading edge companies with the remaining companies. The same authors have also compared the leading edge companies and all companies participating in benchmarking with regard to expenditure on training and continuing training and the returns achieved. One criticism must be made, namely that only 85 of 754 companies in the 'other companies' group surveyed in 1998 were able to provide details in respect of the same company unit as for 1997. Interestingly, the empirical results obtained clearly supported a positive connection between training and continuing training on the one hand and company operating efficiency on the other. However, the association cannot necessarily be interpreted as a causal one, since more efficient companies also have

---

more financial resources available for training and continuing training than do less successful companies. In other words, the direction of the association cannot be derived from the correlations identified.

In addition, there was also a positive association with the introduction of innovative forms of training, work and remuneration. In this respect, this finding confirms research by Kling (1995) and Ichniowski et al. (1997). Admittedly the latter obtained, on the basis of only a small panel survey of 26 steelworks in the USA, the finding that utilisation of individual personnel policy measures has a lesser effect than a combined approach. OECD (1999) reviews similar studies.

2.5 Matched employer-employee data records

Willis (1986, p.598), in his contribution to the Handbook of Labor Economics, indicated that the development of matched employer-employee data records was crucial to the progress of research in the fields of pay structure theory and human capital theory.

In their contribution to the new Handbook of Labor Economics, Abowd and Kramarz (1999a) cite some 100 studies from 15 countries, most of which have been produced only in the past five years, many as yet only in the form of discussion papers. Thus this is a research field that is developing very fast.

Provisional estimates of the future trend in the number of applicants for training places in the dual system are confronted by the problem that applicants for training places take account of the trend in training place provision. Fewer people apply for training places when there is a shortage of them than at times when there is a glut. In this respect, extrapolation of rates of transition between different class stages, types of school or education systems (general education versus vocational training) is dependent on provision of vocational training places (cf. Behringer and Ulrich 1997).

In-company training rates and rates of employment of successful trainees, as well as the intensity of in-company continuing training, continue to be determined not only by the structural characteristics of companies, but also by the range of vocational activities in the enterprise and changes in this. Conversely, an analysis of individual career paths, e.g. based on employee surveys, should also, of course, include factors relating to enterprise structure.

For studies of this kind, it is necessary to develop data records in which employers and employees are matched. As far as I know, however, no research of this kind is as yet available on the subjects of company flexibility and in-company training and continuing training, as covered in sections 2.2, 2.3 and 2.4. To date, the only studies available are in the field of pay structure and labour market demand. These will be discussed below.

A supplementary questionnaire in the French 1987 employee survey contained detailed questions on the use of new technologies. Kramarz (1994) and Entorf and Kramarz (1997, 1998) matched this data with the company data available for 1978-1987. In the context of a multi-variant approach, the authors examined the question of whether employees using new technologies earn better because they have better knowledge and skills than other employees or because new technologies increase productivity. The authors come to the conclusion that technologies based on the use of new information technologies have a relatively minor direct effect. Instead, these technologies are used by better-qualified employees, who also become more productive when they have acquired experience with these new technologies. Goux and Maurin (1997) also matched data from an employee survey and a company survey, in order to examine participation in in-company continuing training and the effects of continuing training on individual incomes and dismissal patterns. Troske (1999) and Bayard and Troske (1999) use similarly structured data records from the US Bureau of Census and conclude that large enterprises are in a better position to recruit skilled employees, and can organise them into teams and use them in combination with a high-quality capital stock. Schone (1999) uses Norwegian data to analyse the effect of continuing training measures on pay.
Bellmann et al. (1999) examined the flexibility of the skills structure on the basis of matched data records from the IAB establishment panel and the employment statistics of the Federal Institute for Employment. The employee statistics contain, inter alia, individual details of the pay subject to social security contributions of employees liable to pay such contributions (cf. Bender et al. 1996). On this basis, it was possible to estimate a translog cost system for six skills groups (blue- and white-collar workers each divided into unskilled/semi-skilled, skilled and highly skilled employees) in the manufacturing sector in West Germany in 1995. The substitution options ensuing from the company cost function for groups with different skills were examined. The substitution relationships identified within the individual blue-collar groups are very similar to those within the individual white-collar groups: skilled and, to a lesser extent, highly skilled employees prove to be substitutes for unskilled/semi-skilled employees. This finding could go at least some way towards explaining the increase in unemployment among the unskilled and semi-skilled.

At this point, mention should be made of the labour market supply and demand panels drawn up at two-yearly intervals since 1993 by the Dutch Organisatie voor Strategisch Arbeidsmarktonderzoek (OSA - Organisation for strategic labour market research) (cf. Allaart 1996), and of the possibility that arises, with very large data records of individuals (e.g. social security data), of aggregating the resulting personal information under the relevant enterprise number. Another good example of this is the study by Laaksonen and Vainiomäki (1997). This offers further opportunities for combining supply- and demand-side data. However, to date these have not been applied to vocational training research issues. Haltiwanger (1998) regards the possibility of surveying, in enterprise surveys, not only representatives and enterprise management, but also individual employees, as a critical one, because it involves a selection problem. The studies by Frazis et al. (1998) and Krebs et al. (1998) constitute examples of such a procedure. In the study by Frazis et al., two selected employees per enterprise were surveyed, and in that by Krebs et al., six or seven, depending on the company size.

Another advantage of matched employer-employee data records lies in the associated opportunity to carry out consistency checks (cf. Hamermesh 1999).

Hildreth and Pudney (1999) and Abowd and Kramarz (1999b) review the econometric problems arising in the context of analysis of matched employer-employee data records and the solution to them.

2.6 Establishments or enterprises as survey units

An important question for empirical analyses is that of the suitable survey unit. In official statistics, the ‘establishment’ is understood as being the local unit in which a company’s activities, i.e. the production of goods or services, are actually carried out. The ‘establishment’ survey concept is also preferred to the enterprise level in other panel studies in the Federal Republic of Germany (the Hannover Firm panel and the NIFA panel in the mechanical engineering sector) (cf. Brand and Carstensen 1995, pp. 2f.; Hauptmanns and Ostendorf 1994, pp. 3f.), even if, in the context of individual questions on labour market policy or company policy, individual players are surveyed who are not themselves among those responsible for decision-making at company level. The ‘establishment’ is normally the suitable survey unit for the questions to the IAB establishment panel, as the unit in which employment and personnel policy and their determinants manifest themselves in the form of the corresponding business sizes or personnel structures. In the context of company reorganisations and organisational change, as discussed in section 2.2 of this article, a link is apparent between enterprises employment and personnel policy and organisation of local performance, i.e. the establishments. At the same time, business statistics such as turnover, working hours, wages and salaries and others are directly available for establishments. A similar argument can be put forward in the case of vocational training research. Interestingly, it was also apparent in the context of the 1993 CVTS

Survey that in-company continuing training data was often not available at enterprise level and therefore had to be collected in a decentralised way (cf. Federal Statistical Office 1996, p.4). However, certain information on business activity such as the ownership, funding and marketing structures can be collected only at enterprise level (cf. Licht and Stahl 1995), so that it is likely to be extremely difficult to determine the influence they exert on vocational training variables, if this information is not available (in full) at establishment level.

2.7 Interim summary

In the field of vocational training research, many topics can really only be adequately covered by means of personal, enterprise and establishment data. Box 3 gives another summary of the most important enterprise and establishment surveys from various countries. The European Commission (1998b) reviews...

The second subject covered in this section was in-company vocational training and employment of trainees on completion of training, in the training company. Research into participation in in-company training was presented, with participation being measured, for instance, as the number of trainees in relation to the number of employees liable for social security contributions and to the reasons for non-participation in in-company vocational training, by means of the IAB establishment panel (cf. Table 1 for a summary of selected results). Differences as regards specific enterprise sizes and sectors were also discussed, as were development trends. Studies on employment of trainees on completion of training show that establishments implementing long-term planning and investment employ more trainees, comparatively speaking, but that current problems in the establishment definitely exert an influence. The section also mentioned the 'early recognition system for skills trends' network, in which a total of nine institutes in Germany are involved, and in which a very interesting mix of different methods is employed. Since 1995, the Federal...
Institute for Vocational Training has been researching the costs and benefits of in-company vocational training.

The third area covered was the development trends discernible in the field of in-company continuing training on the basis of establishment and enterprise data. From the methodological point of view, studies examining the returns and above all the effect of continuing training measures on productivity, using panel-based analytical methods and establishment and enterprise data, are comparatively ambitious. These studies have much in common with studies evaluating publicly funded continuing training measures, which my report did not cover.

Other studies examine in-company continuing training provision and the intensity of in-company continuing training, including for individual skills groups. On the basis of data from the IAB establishment panel (again, cf. Table 1 for a summary of selected results), it is apparent that skilled employees are most likely to be given opportunities for continuing training, and unskilled and semi-skilled employees are the least likely. The Continuing Vocational Training Survey (CVTS) carried out by Eurostat in the years 1991-1994 is probably the largest investigation ever carried out in the field of vocational training research, in terms of data collection. Questions are asked on the form of continuing training offered, the group of people involved, the time involved for participants, future skills requirements and the estimated development of forms of continuing training. Enterprises not offering their employees continuing training are asked about their reasons for this. Another strength of these data records is the opportunity to carry out international comparisons. Improvements are required in the area of coordination of the questionnaire in the countries involved (as yet a standardised questionnaire has not been used), in the surveying of important determinants of decisions on continuing training, and in the area of the time span between data collection and publication of the results.

In addition to this most important research in the field of in-company continuing training, I have covered the research of the Institute of German trade and industry, since this facilitates time-based comparisons. Since 1997, the American Society for Training and Development (ASTD) has been carrying out surveys involving company-related questions as well as continuing training questions. The development of matched employer-employee data records is also likely to continue to offer interesting prospects for the further development of vocational training research. However, as yet there has been no research on this basis in the field of training and continuing training. Lastly, the question of the suitable survey unit was addressed. In vocational training topics, surveys of establishments offer the advantage that at this level the necessary data is directly available.

3. Advantages and disadvantages of longitudinal as opposed to cross-sectional studies

3.1 Overview

The previous section clearly showed the importance and potential of broad-based empirical studies using establishment and enterprise data for many areas of vocational training and skills research. This section will bring out the advantages, but also the disadvantages, of longitudinal research as opposed to cross-sectional research. In this context, a distinction must be made between advantages and disadvantages in respect of data collection and in respect of evaluation of data or interpretation of the results.

With the exception of the IAB establishment panel, the previous section described only surveys designed as cross-sectional studies. It must also be mentioned that the longitudinal data records cited were not usually evaluated as such. In other words, to date in most cases only the data from individual survey waves has been evaluated, and the longitudinal information has not yet been used. Thus, as yet, not all the advantages offered by longitudinal data records have been utilised, but only the technical advantages as regards the survey.
The structure of the IAB establishment panel can be used as an example demonstrating the specific advantages of repeated surveying of the same establishment unit, as well as the problems, in comparison with a survey of different establishment units in different years. The sampling, the fieldwork and then the questionnaire design will be discussed.

3.2 Sampling

In the IAB establishment panel, sampling is done in accordance with the principles of the so-called optimum sample (Pflanzagl 1978, pp. 162ff.), divided into 16 sectors of the economy and ten establishment size classes. Table 2 shows the enterprise size classes, the number of establishments surveyed, the selection probabilities and the response rates in the individual establishment size classes.

It is apparent that the number of establishments responding and the probability of selection increase steadily with the establishment size, measured as the number of employees (e.g. in class 1, up to 4 employees, probability of selection is 0.1%, whereas in the class with 5,000 or more employees, this rises to 91.27%). In the lower classes, the margin between the sizes of the smallest and largest establishment is much smaller than in the higher classes. Hence the establishments in the lower classes are much less heterogeneous than those in the higher classes. In order to compensate for these differences in heterogeneity, an effort is made to survey a larger number of establishments in the higher classes than in the lower classes. The number of cases suitable for evaluation is based on the establishment response rate in relation to specific establishment sizes and sectors of the economy. While this concludes the sampling procedure for the first survey wave, as from the second wave an additional sample is drawn from newly created establishments. This ensures that the data record constitutes a representative cross-section, via appropriate projections. Without the additional sample, establishments founded or employing, for the first time, workers liable for social security contributions after the first sampling procedure (also known as the basic sample) would have no opportunity to be included in the sample.

This sampling procedure gives rise to two important aspects as regards assessing the advantages and disadvantages of longitudinal as opposed to cross-sectional surveys of establishments. Firstly, with larger establishments the probability of selection is so high that in the case of most establishments with over 1,000 employees it is de facto impossible to abstain from repeated surveying of the same enterprise unit, because almost all the establishments actually available for survey in the higher establishment size classes have already been covered in the basic survey. For according to Table 2, the probability of selection is 87.65% in enterprises with between 1,000 and 5,000 employees and as high as 91.27% in enterprises with over 5,000 employees. In West Germany, just under one quarter of the establishments covered by the sampling belong to these two size classes.

Secondly, with newly founded establishments the probability of survival is much lower than it is with long-established ones. Consequently panel mortality is higher for these establishments than for long-established ones, even if enterprise representatives in the two groups are equally willing to respond. Therefore, in the IAB establishment panel, a disproportionately large number of newly founded establishments are included in the sample. With a cross-sectional survey, there would be no need for this so-called over-sampling, which takes account of future panel mortality owing to possible establishment closures.

9 Unlike other enterprise surveys, such as the Hanover firm panel (cf. Brand and Carstensen 1995) and Eurostat's Continuing Vocational Training Survey (CVTS) (cf. section 2.4.5 of this report), the IAB establishment panel survey is not restricted to individual sectors of the economy or establishment sizes. The only condition is that the enterprise should employ at least one worker liable for social security contributions (in the private households sector, at least five workers liable for social security contributions must be employed).

10 In the CVTS, as from a company size of 1,000 employees every third company is surveyed (cf. European Commission 1998a, p. 12).
### 3.3 Fieldwork

The IAB establishment panel imposes particularly stringent requirements as regards data quality. This can be assured firstly by the high-quality sample based on establishments’ statistical data in respect of employees, which establishments with employees liable for social security contributions have a statutory obligation to notify, and secondly by a high response rate (60-70% of enterprises surveyed for the first time, 80% of enterprises in subsequent surveys). In addition, *Infratest Burke Sozialforschung* subjects interviewers’ data to a relatively intensive process of checking for completeness, consistency and plausibility, including follow-up telephone calls to the establishments surveyed. With longitudinal surveys, previous values can also be taken into account in checking data.

In the long term, the personal contact between respondents and interviewers also has a positive effect on willingness to participate. As Table 3 shows, everywhere where it has been possible to use the same interviewer as in the previous year, the response rates are markedly higher than where there has been a change of interviewer.

### 3.4 Questionnaire design

In the IAB establishment panel, the questionnaire is designed using a modular approach (cf. Bellmann et al. 1999). In repeat surveys, the questionnaire can be shorter if certain details of establishments do not constantly change and questions about these are therefore asked only in the initial survey and at certain intervals. The various waves also focus on different aspects.

When the same establishment units are surveyed regularly, with an establishment panel as the instrument, extensive comparability of the questions asked in each wave is assured. Since the proportion of enterprises participating in the survey also depends on the length of the questionnaire, a modular questionnaire structure was selected in the IAB establishment panel. Hence the questions in certain parts of the questionnaire are asked only every two to three years.

### 3.5 Evaluation

The first advantage of longitudinal data as opposed to cross-sectional data is the possibility of taking into account the heterogene-

ity of the establishments and the consideration of the relationship between cause and effect (cf. Baltagi 1995). More complex and hence more sophisticated behaviour models can be formulated on the basis of longitudinal data. Establishments' behaviour as regards adaptation can be investigated much better with longitudinal data than with cross-sectional data. There are also certain questions that can be analysed only by means of panel data. There is an increase in the number of cases and of degrees of freedom, a reduction in problems as regards multi-collinearity, and an increase in the efficiency of estimates of regression. Disadvantages are the greater significance of measuring errors and selectivity problems, including the panel mortality caused by various factors. These advantages and disadvantages of longitudinal data as opposed to cross-sectional data will be discussed in more detail below.

A regression model is specified by defining variables. Distorted results are obtained from the assessment of regression coefficients if influential variables are suppressed. This is a serious problem, to which a solution unfortunately cannot always be found, since influential variables often escape notice or at least are not included in the data records available. One of these is the individual heterogeneity of enterprises. However, when panel data is used, this is not a problem if its influence does not change over time and the regression model is formulated in terms of first differences, not size levels. The influence of this variable, which is unobserved but does not change over time, is 'cancelled' out by means of first differences. With longitudinal data, cause/effect relationships can be analysed, as information provided at different times is available and effects cannot precede causes.

Adjustments in line with new balances on the labour market are of great interest for economic policy, since different economic policy measures must be judged differently in terms of the time required for the intended aims to be achieved. The reason for delayed reactions is the costs arising when employee numbers change. These adjustment-related costs may extend over more than one time period (cf. Hamermesh 1993). Dynamic adjustment models therefore need to be evaluated. This can only be done by means of panel data.

Certain issues can be examined only via longitudinal data. These include the question of whether training companies simply do not train during individual time periods, or whether they make a lasting decision to institute their own in-company vocational training.

Thus it is easier to research developments over time on the basis of repeated surveys of the same business units than if different units are surveyed. In this way, it is easier to make a distinction between changes in the behaviour of the same business units and changes based on changes in the composition of the aggregate under consideration. For example, the decline in provision of training places in Germany is caused both by a display of cau-

Nevertheless, foreseeable changes can be anticipated, which means that chains of causality can be identified to only a limited extent.
tion on the part of training companies and by the increasing importance of enterprises with no connection with training, which as yet, therefore, do not provide training, e.g. service centres, temping companies, young entrepreneurs or foreign companies. The latter are endeavouring to establish themselves on the market and are less concerned about their own possible future need for workers.

If the results of different survey waves can be evaluated in summarised form in longitudinal analyses, higher case figures ensue, so that the number of degrees of freedom increases. Thus at a given level of test statistics, it becomes easier to draw statistical conclusions. Admittedly it must be possible to pool the data records, but this is a property that can be tested for. Problems of multicollinearity are reduced, because the level of variance contained in the explanatory variables increases. This means that the results are more reliable. Measurement errors are generated by incorrect delimitations, inaccurate answers, or the efficiency of estimates and sampling errors. Incorrect information arises as a result of unclear questions, inaccurate memories (especially if questions are asked about events some time in the past), deliberate misinformation (e.g. prestige bias), information from incompetent persons, interviewer effects and processing errors (cf. Kalton, Kasprzyk and McMillen 1989).

The decision on continued participation in a survey may be dependent on the same factors whose influence on in-company training and continuing training is to be investigated, such as the answers to questions about business returns, the anticipated employment trend, the anticipated trend in in-company vocational training or the quest for staff. The ensuing selectivity represents a major problem for the modelling and interpretation of results. Kalton, Kasprzyk and McMillen (1989) examined several panels from the point of view of panel mortality and concluded that it increases from wave to wave - but at a decreasing rate. However, the research of Hartmann and Kohaut (1999) in the context of the IAB establishment panel showed that panel mortality has only a minimal influence on the results obtained.

3.6 Interim summary

To summarise, it can be stated that longitudinal surveys are more time-consuming and costly than cross-sectional surveys, but offer important advantages. This also applies, at least in part, to repeated cross-sectional surveys.

I have been able to use the example of the IAB establishment panel to show that there is no difference between longitudinal surveys and repeated cross-sectional surveys with regard to the selection group in the context of the larger establishments surveyed, because larger establishments were intended to be taken into account to a disproportionate extent in the sample. In the case of the IAB establishment panel, Infratest Burke Sozialforschung, which is responsible for collecting the data, subjects interviewers' data to a relatively intensive process of checking for completeness, consistency and plausibility. At the same time, owing to the longitudinal nature of the survey, previous values can be taken into account and follow-up telephone calls can be made to collect further information. In addition, the personal contact between interviewer and establishment is the most important precondition for high participation rates. In longitudinal surveys, the questionnaire can be designed using a modular approach. Therefore the questionnaire can be shorter, as in the case of certain details of establishments, which do not constantly change, questions only need to be asked in the initial survey and at certain intervals.

In the context of evaluation, the main advantages of longitudinal data as opposed to cross-sectional data lie in the possibility of taking into account the heterogeneity of establishments and the consideration of the relationship between cause and effect. More complex and hence more sophisticated behaviour models can be formulated on the basis of longitudinal data. Enterprises' behaviour as regards adaptation can be investigated much better with longitudinal data than with cross-sectional data. There are also certain topics that can be investigated only by means of panel data. However, statistical advantages are also offset by the selectivity problems occurring.
in longitudinal research, including those caused by panel mortality.

4. Conclusions

The selected studies on company flexibility and in-company training and continuing training discussed have shown that in future establishment and company surveys will be an essential instrument for vocational training research. What do the ideal data records look like in this context? Similarly to the IAB establishment panel, questions should be asked about the intensity of in-company training and continuing training, as well as the skills structure and skills requirements.

A list of questions about various aspects of company personnel and employment policy must be asked, in order to cover influencing factors that are important from the point of view of vocational training research, e.g. factors influencing the intensity of in-company training and continuing training and skills development. The survey should be carried out annually on the basis of a panel, since this gives rise to major technical advantages as regards the survey, the questionnaire and evaluation. In addition, it would be productive to interview a representative group of employees in the companies participating in the survey and to build up matched employer-employee data records.

If questions of continuing training actually implemented or financed within the enterprise are also addressed, it would not be sufficient to use (only) data such as the social security data in the employee statistics of the Federal Institute for Employment in Germany. Admittedly the selection problem arising in a survey of workforce members would have to be solved. In this respect, administrative data offers advantages as it relates to the majority of employees in the enterprises covered. In this context, it would also be of great interest to include surveys of employee representatives at establishment level in the establishment and enterprise units surveyed (cf. the works council and staff council surveys carried out by the Institute of economic and social science (Wirtschafts- und Sozialwissenschaftlichen Institut, WSI) in Germany and the British Workplace and Industrial Relations Survey (WIRS). Last but not least, it is very important to resolve data protection problems, since in future both research into the demand for labour and vocational training research based on establishment and enterprise data will have greater weight only if the data collected can be evaluated not only by employees of the institutions collecting it, but also by other scientists (cf. Bender, Brand and Kohaut 1999).

In evaluating establishment and enterprise surveys, which I argue should be available in longitudinal form, the greatest potential lies in using panel econometric methods of analysis. It is necessary to include a number of questions on various aspects of company personnel and employment policy because when econometric procedures are used, the most important factors influencing in-company training and continuing training, for example, can be identified. In addition, the use of matched employer-employee data records has the advantage that supply-side influencing factors can be taken into account as well as demand-side factors. If matched employer-employee data records are built up on the basis of administrative data, no selection problem arises as regards surveying of employees, but fewer variables are available. However, the social security data in the employee statistics of the Federal Institute for Employment includes information on employees' qualifications, their occupations and their pay, in longitudinal form.

An important potential for analysis ensues if similar data records are generated in different countries, so that international comparisons are possible. Although institutions are of very great importance in vocational training, their positive or negative influence on vocational training cannot be determined in national studies alone, if they are national institutions. Ideally, data collection should be coordinated in the countries concerned, as in Eurostat's Continuing Vocational Training Survey (CVTS). The first steps in this direction have already been taken in the field of research into continuing training and company flexibility. As yet, however, little re-
Vocational training research on the basis of enterprise surveys

search is available into questions of initial vocational training, skills requirements, recruitment and other important issues in vocational training research. Since it is likely to be at least very difficult to determine the factors influencing in-company training and continuing training, for example, in different countries, strict limits are set for the use of econometric methods. On the basis of a good register of establishments and enterprises, however, projected results for countries as a whole can be compared with one another.

5. Summary

Politicians, scientists and employers themselves have an increasing interest in reliable information on trends in labour market demand and companies' skills requirements. The main reasons for this are the persistently high level of unemployment and the associated under-utilisation of human resources, and reinforcement of the quality of locations via investment in human capital. However, in comparison with the data available on the supply side of the labour market, the data available on the demand side is inadequate. Hitherto various public bodies and research institutes have concentrated on surveying individuals. Company and enterprise data is systematically collected, but seldom with regard to employment and skills aspects and the variables determining these. In order to be able to analyse and possibly reduce the continuing problems in the context of the labour market and training, there is a need for reliable data on the company side of the labour market.

Many topics in the field of vocational training research can be adequately covered only by means of personal, establishment and enterprise data. This report has shown the potential which analysis of company and enterprise data offers in respect of three important subject areas.

Firstly, additional skills requirements arise in the context of enterprise measures to increase flexibility. Organisational changes such as teamwork, flattening of hierarchies, the downward transfer of responsibility, depart-mental mergers, the institution of units which calculate their own costs and results, and the introduction of just-in-time production tend to increase demand for employees with vocational training qualifications. The slimming down of large companies leads to hiving off of service areas and the emergence of service enterprises close to the means of production. The effects of these trends on requirements as regards capacities, skills and competences in enterprises are also on the research agenda. Here, the key concern is again to obtain insight into the structure of the organisation as a whole, its human resources and strategy, and not simply the utilisation and deployment of employees.

The second subject covered in this section was in-company vocational training and employment of trainees on completion of training, in the training enterprise. Research into participation in in-company training was reviewed, with participation being measured, for instance, as the number of trainees in relation to the number of employees liable for social security contributions, and to the reasons for non-participation in in-company vocational training. Differences as regards specific enterprise sizes and sectors were also discussed, as were development trends. Studies on employment of trainees on completion of training show that establishments implementing long-term planning and investment employ more trainees, relatively speaking, but that current problems in the establishment definitely exert an influence. This section also discussed the 'early recognition system for skills trends' network, in which a total of nine institutes in Germany are involved, and in which a very interesting mix of different methods is employed. Since 1995, the Federal Institute for Vocational Training has been researching the costs and benefits of in-company vocational training.

The third area covered was the development trends discernible in the field of in-company continuing training on the basis of establishment and enterprise data. From the methodological point of view, studies examining the returns and above all the effect of continuing training measures on productivity, using panel-based analytical methods and estab-
lishment and enterprise data, are comparatively ambitious. These studies are closely aligned with studies evaluating publicly funded continuing training measures, which my report did not cover.

A fundamentally different path is followed by approaches involving action-oriented evaluation, e.g. in the context of monitoring of continuing training. Other studies examine in-company continuing training provision and the intensity of in-company continuing training, including for individual skills groups. It is apparent from these that skilled employees are most likely to be given opportunities for continuing training and unskilled and semi-skilled employees are the least likely. The Continuing Vocational Training Survey (CVTS) carried out by Eurostat in the years 1991-1994 is probably the largest investigation ever carried out in the field of vocational training research, in terms of data collection. Questions are asked on the form of continuing training offered, the group of people involved, the time involved for participants, future skills requirements and the estimated development of forms of continuing training. Enterprises not offering their employees continuing training are asked about their reasons for this. Another strength of these data records is the opportunity to carry out international comparisons. Improvements are required in the area of coordination of the questionnaire in the countries involved (as yet a standardised questionnaire has not been used), in the surveying of important determinants of decisions on continuing training, and in the area of the time span between data collection and publication of the results.

In addition to this most important research in the field of in-company continuing training, I have covered the research of the Institute of German trade and industry, since this facilitates time-based comparisons. Since 1997, the American Society for Training and Development (ASTD) has been carrying out surveys involving company-related questions as well as continuing training questions. The development of matched employer-employee data records is also likely to continue to offer interesting prospects for the further development of vocational training research. However, as yet there has been no research on this basis in the field of training and continuing training. Lastly, the question of the suitable survey unit was addressed. In vocational training topics, surveys of enterprises offer the advantage that at this level the necessary data is directly available.

Longitudinal surveys are much more time-consuming and costly than cross-sectional surveys, but offer important advantages. I have been able to use the example of the IAB establishment panel to show that there are only partial differences between longitudinal surveys and repeated cross-sectional surveys with regard to the selection group in the context of the establishments surveyed, because larger establishments were designed to be taken into account to a disproportionate extent in the sample, and therefore virtually all of them have to be surveyed. In the case of the IAB establishment panel, Infratest Burke Sozialforschung, which is responsible for collecting the data, subjects interviewers' data to a relatively intensive process of checking for completeness, consistency and plausibility. At the same time, owing to the longitudinal nature of the survey, previous values can be taken into account and follow-up telephone calls can be made to collect further information. In addition, the personal contact between interviewer and establishment is the most important precondition for high participation rates. In longitudinal surveys, the questionnaire can be designed using a modular approach. Therefore the questionnaire can be shorter, as in the case of certain details of establishments, which do not constantly change, questions only need to be asked in the initial survey and at certain intervals.

In the context of evaluation, the main advantages of longitudinal data as opposed to cross-sectional data lie in the possibility of taking into account the heterogeneity of establishments and the consideration of the relationship between cause and effect. More complex and hence more sophisticated behaviour models can be formulated on the basis of longitudinal data. Establishments’ behaviour as regards adaptation can be investigated much better with longitudinal data than with cross-sectional data. There are also certain topics
that can be investigated only by means of panel data. However, statistical advantages are also offset by the selectivity problems occurring in longitudinal research, including those caused by panel mortality.

Lastly, it is recommended that company and enterprise surveys be developed and evaluated, focusing on vocational training and continuing training. Similarly to the IAB establishment panel, questions should be asked about the intensity of in-company training and continuing training, as well as the skills structure and skills requirements. A list of questions about various aspects of company personnel and employment policy must be asked, in order to cover influencing factors that are important from the point of view of vocational training research, e.g. factors influencing the intensity of in-company training and continuing training and skills development. The survey should be carried out annually on the basis of a panel, since this gives rise to major technical advantages as regards the survey, the questionnaire and the evaluation. In addition, it would be productive to interview a representative group of employees in the companies participating in the survey and to build up matched employer-employee data records.

The greatest potential offered by establishment and enterprise surveys lies in using econometric analysis methods. It is necessary to include a number of questions on various aspects of company personnel and employment policy because when econometric procedures are used, the most important factors influencing in-company training and continuing training, for example, can be identified. In addition, the use of matched employer-employee data records has the advantage that supply-side influencing factors can be taken into account as well as demand-side factors.

An important potential for analysis ensues if similar data records are generated in different countries, so that international comparisons are possible. Although institutions are of very great importance in vocational training, their positive or negative influence on vocational training cannot be determined in national studies alone, if they are national institutions. Ideally, data collection should be coordinated in the countries concerned, as in Eurostat's Continuing Vocational Training Survey (CVTS). The first steps in this direction have already been taken in the field of research into continuing training and company flexibility. As yet, however, little research is available into questions of initial vocational training, skills requirements, recruitment and other important issues in vocational training research. Since it is likely to be at least very difficult to determine the factors influencing in-company training and continuing training, for example, in different countries, strict limits are set for the use of econometric methods. On the basis of a good register of establishments and enterprises, however, projected results for countries as a whole can be compared with one another.

Employment, economic performance and skill mismatch
The skills market: dynamics and regulation

Abstract

This report deals with the dynamics of the balance between the supply of and the demand for skills in the labour market in developed countries, especially those of the European Union. In a context of radical changes in the demand for labour, which have resulted primarily from the development of international trade and technological progress, the transformation of the nature and content of work is forcing the productive system to adapt to new skills within a very short period of time, which often bears no relation to the traditional timescale for the acquisition of qualifications. At the same time, as the average number of years of study per head of population in Europe continues to rise, generations of increasingly highly qualified young people are finding it no easier to obtain employment. On the basis of this twofold observation, the aim of our research is to examine the way in which adjustments are made in the skills market and the role of initial and further-training systems in the regulation of that market.

We have tried to distance ourselves from traditional methods of analysing the relationship between training and employment, which often boil down to an appraisal of the relevance of formal qualifications to the demands of the workplace. These methods tend to present the problem in terms of a functional relationship between a customer (the productive system) and a supplier (the education system). For our part, we intend to study the relationship between skills and employment. This amounts to confirming the hypothesis that human productive capacity is divisible into a number of components that may be acquired in various places, at various times and by various means. If this hypothesis is true, the relationship between the production and consumption of know-how must be more complex than is generally assumed.

This complexity is made all the greater by the fact that the production of skills is, by nature, a fairly unpredictable process. The more distant the horizon, the more difficult it is to anticipate future needs. Beyond a certain horizon, then, the demand for skills is intrinsically unforeseeable. Moreover, if we assume that an individual's various skill levels are constantly changing, that these changes are wrought by the education system and/or the production system and/or simply by social interaction, it becomes necessary to consider the production of skills as a system of cooperation between the educational and the productive spheres. This cooperation is entirely intuitive and interactive. Each of the two systems establishes its strategy in response to the action of the other. Each acts on different information, but the information is subject to that same intrinsic unpredictability as soon as any attempt is made to adopt a long-term perspective.

1. Introduction: contextual elements and proposed line of approach

This report deals with the regulation of the supply of and the demand for skills in the labour market in developed countries, especially those of the European Union. Economic and social changes in those countries help to determine the ways in which their labour markets operate and develop. In particular, they are locked into a process of globalisation and technological change, especially in the domain of new information technology. This global transformation process is liable to vary in its impact on individual countries, regions, economic sectors, etc.

1.1 The demand structure: globalisation, information technology (IT) and unemployment

Various authors (Castells, 1996; Petit, 1998; Vinokur, 1999, etc.) share the view that the socioeconomic changes experienced by our societies and labour markets are ascribable to 'globalisation' (some speak of 'information capitalism' or of the 'economy of the knowledge-based society', etc.).

This phenomenon has its roots in the 1980s and is characterised by a number of major changes:

- quicker and cheaper exchanges of goods and information;
- free (or largely unrestricted) movement of goods, services and capital;
- concentration of the world’s capital into fewer hands;
- widespread monopolistic competition, even in traditionally ‘non-commercial’ spheres such as education and training;
- internationalisation of development funding;
- government support designed to increase the productivity and competitiveness of national economies, perhaps at the expense of social protection; and,
- globalisation of production facilities and sales outlets as international borders become more open.

In the view of Castells (1996), these changes are linked to an expansion and ‘rejuvenation’ of capitalism, which are opening a new chapter in its history, a chapter that he calls ‘information capitalism’. As Carnoy emphasises (1999, p.147), the essence of globalisation does not lie purely in trade figures and investment volumes or in the extent to which a national economy is truly national but in a new way of perceiving socio-economic time and space.

In this framework, it is recognised that the changes prompted by the spread of new information technology have three characteristic features:

- acceleration;
- turbulence; and
- universality.

These three characteristics require the sort of precise analysis that transcends the scope of this report. Acceleration should be understood as the frequency of changes within a given length of time, turbulence relates to the diversity of places within the production system where changes are liable to occur, and universality denotes the speed with which these changes permeate the entire economy.

Changes in demand have also been reflected in more restricted access to jobs and hence to serious mass unemployment, affecting all groups in the labour market, but particularly young people and the least qualified. The effect of these changes has therefore been to increase uncertainty about the future nature and level of demand in the medium and long term.

1.2 Changes on the supply side: an ageing population, rising educational attainment levels and more training opportunities.

Turning now to changes in the supply of labour, we might ask how the active population has been developing in relation to the changes in the production system. If we examine the development of the supply of labour in the countries of the European Union, some broad trends are discernible in almost every Member State:
a general increase in the number of university and college graduates in the labour market, each generation emerging from the education system more highly qualified than the one before;

an increase in economic activity rates which is directly linked to educational attainment levels, especially among women (Cedefop, 1998a, pp. 40-46);

major demographic changes (Cedefop, 1998a, pp. 36-40), including the ageing of populations, which is transforming the web of relationships between initial education, further training and occupational experience;

an increase in the number of places on training courses and of opportunities for training outside schools and colleges and hence in the prospects of acquiring skills which diplomas cannot even begin to measure (Cedefop, 1997a, and Planas, 1990);

changes in production processes and work organisation which have tended to create more opportunities for on-the-job training (Cedefop, 1995 and 1998b);

the development of education and training into a process of lifelong learning;

polarisation of the lifelong-learning process on the basis of differences in initial education levels (Cedefop, 1997a, and Planas, 1996), effectively closing the door to lifelong learning on those who enter the labour market with low skill levels (Steedman, 1999, and Cedefop, 1999); and finally,

the gradual transformation of training into a commercial product, which has had a significant impact on the supply structure within the labour market.

If we examine how education systems have evolved in recent decades, it becomes apparent that the countries of Europe have largely opted to prolong the process of formal education at a time when youth unemployment has been high. Is this strategy that education systems have adopted – a strategy which often dovetails with government policy in those countries of the European Union where the education system is tightly controlled by the state – a rational response to the various developments in the labour market?

National statistics on youth unemployment and the results of random surveys show that, in all countries, young people with higher qualifications are more likely to find work. Qualified young people, however, compete in the labour market with older jobseekers who have fewer qualifications but more experience. Given the structure of labour markets, recruitment decisions do not always favour the best-qualified candidate (Bédouwé and Espinasse, 1996a), and in certain countries of the Union we see the emergence and growth of phenomena such as job downgrading or reluctance to employ job applicants who are perceived as overqualified.

How should the educational sphere (initial and further training, general and professional education, formal and informal education) respond to this situation? It cannot remain inactive in a society in which change is gathering momentum, in which new technology is being superseded ever more quickly and in which individuals spend increasingly long periods of time in pursuit of knowledge and skills – in short, in a society whose future shape is less predictable or, more precisely, is predictable within an ever shorter time frame.

How are young people (and others) to be prepared for a labour market in which the required skills are increasingly ephemeral and for a working world in which businesses, in the face of ever fiercer monopolistic competition, have to slash the time it takes to turn innovative ideas into products and to put those products on the market?

How does one resolve this problem, which is essentially about the divergence between the horizons of the production system (i.e. technological innovations and order books) and those of the education system, which operates in terms of an individual’s lifetime and the time it takes to implement educational re-
forms? Is an increase in training really compatible with the needs of the economy?

1.3 The proposed line of approach

A problem of this type can be addressed from many angles. Some think that price flexibility is an essential and sufficient means of solving this problem of disparate timescales (Friedman, 1997). From a more educational point of view, the problem might be approached through curricula and examination requirements. We could also investigate behaviour patterns and expectations, which are the driving forces of negotiation between the players in this field. Widely though their approaches may vary, all scholars are interested in the same fundamental problem, namely the development of skills and their integration into society and the business world. Some analysts, bewitched by the speed of technological progress in particular areas, have even concluded that the development of job descriptions is now totally unpredictable, and so they implicitly consider our type of research to be futile, because they have overestimated the speed and universality of technological change while underestimating the adaptability of our societies.

Let us examine the 'canonical' form which is used to describe relations between the worlds of business and education and which we shall refer to in this report as the customer-supplier model. An example of this model is provided in Cedefop's first research (Cedefop, 1998a, p.35).

Such a model is extremely potent. It describes the main interactions in terms of economic logic. It serves to reduce the bulk of the empirical and theoretical research in this domain to order and enables statisticians to structure the available data. It serves to identify the main underlying trends that govern the awarding of qualifications and brings into focus the various interpretations of the body of theoretical knowledge.

At a certain level of macroeconomic abstraction, it touches on reality. The education system provides at least part of the training that producers receive. The labour market uses qualified people and thus provides one of the means by which the performance of the education system can be evaluated.

This model certainly corresponds to some extent with the way in which politicians - and the public at large, for that matter - see the problem: businesses and their employees need qualifications, and the purpose of education and training systems is to satisfy that need.

This equation, however, raises a host of old familiar problems (Blaug, 1970).

The customer-supplier model is based on the simplistic assumption that every course of training leads to employment in one of a restricted and clearly defined range of jobs. Conversely, each job presupposes the successful completion of one of a restricted and clearly defined range of training courses. This perception has at least two drawbacks: from a technical point of view it clearly depends directly on the breadth of the designated occupational and qualification categories, while from a factual point of view it is clearly erroneous; one need only study a table of occupations and formal qualifications to see that, however wide or narrow the designated categories, there is little evidence to suggest that this type of correspondence between jobs and training courses exists outside the trades and professions for which specific qualifications are required by law.

According to the perception described above, the product exchanged in the marketplace is aptitude, certified by a degree, diploma or other formal qualification or at least by evidence of a completed learning process within the education system. This highly restrictive hypothesis, however, has attracted strong criticism (Carnoy and Levin, 1985; Tanguy, 1985). The strict interdependence of training and employment which underlies such a hypothesis implies a perfect level of information about what every job entails and about the way in which job descriptions will develop. The 'suppliers' will not be able to satisfy the 'customers' unless the latter can clearly describe their present and future needs. This is subject to two conditions, which are only very partially fulfilled.
a) Jobs must be defined in terms of 'prescribed' job descriptions, i.e. the tasks they entail must be entirely specifiable.

b) The medium- and long-term development of jobs must be predictable, i.e. we must know how technology and markets are going to develop.

It is incontestable (and, it must be said, universally accepted) that these conditions cannot realistically be fulfilled. Be that as it may, this model remains very largely the basic frame of reference.

If one thing emerges clearly from the debate between the two sides of industry, it is that education and training have long been presented (and still are, to a degree) as a panacea for all the ills of society, especially those inflicted by unemployment.

Among labour-market analysts, the customer-supplier model still has many adherents. Some of them apply it directly in order to make forecasts about training requirements and to fashion instruments with which the education system can be guided. This is the case in the developing countries, but it also happens in developed countries. These researchers, in other words, believe that the advantages to be gained from such an approach in terms of deducing the production level of education systems from variations in economic production and in global macroeconomic performance justify the statistical risk inherent in the acceptance of technically unsound hypotheses. Recent developments in the realm of endogenous growth have confirmed them in this belief.

The relationship between the creation of human productive capacity and its use in production and development is not a straightforward one. It does seem to us, however, that it is possible, and indeed desirable, to see that relationship in less mechanical terms and to regard it as more dependent on the interactivity of the market and more in tune with the changes in our societies. To put it another way, we are suggesting an approach that fits more neatly into the contextual framework we have just presented, characterised as it is by momentous changes that have affected both the supply of labour and the demand for labour.

If, for the sake of realism, we abandon the purely functionalist rationale and its implicit hypotheses of a perfect supply of information and ideal education systems, we must propose a new rationale based on the concept of skills and on a dynamic view of their creation. This implies that we should put forward an almost completely revised analysis of the mechanisms by which people are placed in employment and by which their skills are brought into line with their tasks. It also means that we shall have to redefine the very concept of mismatches.

This new perspective will lead us, in the course of the present report, to reply to three types of question.

1. How is human capital to be defined and measured when we no longer regard certificates as the sole proof of qualification? How do we then recognise and certify the assets that are actually exchanged in the labour market?

2. What role do demand for labour and, more particularly, technological and organisational change play in the development of skill requirements?

3. How is a balanced skills market to be defined and achieved? And what constraints and adjustment mechanisms does this entail?

2. How can human productive capacity be defined and measured?

In this chapter, we shall address the various problems associated with any attempt to define and measure human productive capacity in the context of the economic and social changes that our societies are currently undergoing. Our examination will be conducted in three stages.

a) We shall try to circumscribe the concepts of qualification and skill.
b) We shall then relate the concept of skill to the problem of measuring human productive capacity.

c) Finally, we shall examine the diverse solutions that have been adopted to address the problem of recognising skills.

2.1 Qualification and skill: a matching pair or two different perceptions of the labour market?

Human productive capacity, people’s capacity to perform tasks or achieve objectives — what we shall call skill for the sake of simplicity and as the closest approximation covers a host of terminological concepts. Moreover, the definition of each term often varies within the scientific world, either from one discipline to another or from one school of thought to another, as well as within the working world (for example the debate in France between management and the unions on the concept of skills).

In fact, the terminology used in this domain is largely derived in two different ways from the language of industrial relations.

1. Some of it is the vocabulary (and the semantics) used in the market to match supply with demand. In a market characterised by extremely imperfect information, such matching is a crucial factor. At the institutional level, the debate on certificates, on their recognition and on the extent to which they feature in collective agreements and pay scales, demonstrates the importance of words. At the political level, the current debate on the recognition of skills acquired on the job by means of ‘pseudo-diplomas’ illustrates what an extension of this vocabulary can imply. At the theoretical level, the theory of signals and its concomitant, the theory of information, also show us that words, the concepts they represent and the strategic use that is made of them are themselves a balancing mechanism.

2. The terminology and the underlying conceptual debate pose a fundamental question: what exactly is exchanged in the labour market? The question may appear incongruous and the answer self-evident. However, as soon as we move away from the standard neoclassical paradigm, the answer becomes less obvious. Irrespective of the duality of the labour market/job market, there is evidently little to be gained by suggesting that work/labour is exchanged in the market if work or labour cannot be regarded as a homogeneous good or as an entity with fully defined characteristics. Attempting to understand the labour market, in other words to discover how people are allocated to economically useful tasks, entails a careful definition of the characteristics of labour and an evaluation of the heterogeneity of productive capacities, not only between workers but also the range of ability levels within any given individual as examined by cognitive scientists and ergonomists. This is clearly all the more essential if our aim in conducting such an analysis is to learn lessons about the education system and its regulation.

To simplify the debate, we shall formulate our proposition around the concepts of qualification and skill.

It is plainly not a simple question of terminology. As Lichtenberger wrote (1999, p.93), scarcely anyone still disputes today that the emergence of the concept of competence in the domain of industrial relations and in the management of human resources is no mere cyclical effect associated with a particular style of management or with the erosion of previously acquired guarantees but is actually a sign of profound change.

Accordingly, no consideration of the relationship between the production system and the education can ignore this debate.

Summing up such a debate, however, is no easy task. Three elements seem to be essential if we are to define what this debate is all about.

a) On the one hand, there are clearly observable changes in the way in which labour is mobilised and used in the market.

b) On the other hand, behind the terminology there lies an issue that is crucial to the development of social and industrial rela-
tions. Governments, employers and labour are establishing their positions in a debate which is gradually taking centre stage within the collective-bargaining process and may well come to be at the heart of the future development of labour law.

c) Finally, acceptance of the concept of competence as part of the currency of collective bargaining necessarily implies that competence, i.e. skills, must be made measurable and negotiable. This brings us back to the problem of formal recognition.

2.1.1 From qualification to skill – quantitative and qualitative changes

If we identify qualification (productive capacity) with the certification provided by the system of education and (chiefly initial) training, the problem is a simple one.

A certificate is required for a job, except in the case of unskilled work performed by non-certificated employees. One is a necessary and sufficient condition of the other, provided there is no shortage of work for holders of a particular certificate.

Imbalances can take two forms. There may be too many qualified people for a given type of employment, or there may be too few qualified people for the available jobs. In either case, it would be necessary and sufficient to produce exactly the right number of people with the certificate in question in order to redress the balance.

Expressed in this intentionally rather provocative way, these are the first principles of educational planning based on anticipated market requirements in terms of qualifications (the 'manpower approach'), as examined by Blaug some 30 years ago. This approach often completely assimilates initial education to the skill level of a labour force, taking no account of training in the workplace. But, as Blaug (1970) emphasised, one of the main problems of the educational economy concerns the way in which training, and especially initial education, contributes to the qualification of the labour force. At the individual level, this qualification is a complex function of basic intelligence, psychomotor capacity, occupational experience, formal or informal training in the workplace and educational attainment. More recently, using approaches that often vary widely from one discipline to another, researchers have been trying to introduce the concept of skills, which seems to be gradually superseding that of qualifications. Going beyond the purely semantic debate, let us examine more closely the scope and purpose of this concept in the definition and measurement of productive capacity.

The concept of skill – sometimes referred to as competence – has been developed as a better means of describing the complex diversity of ways in which the productive capacities of individuals are amassed. There are, of course, 'explicit' initial and further education and training, but there is also on-the-job training, which may be entirely informal or partly formal and may or may not lead to the award of a certificate, and there is also the social learning process. This complexity is accompanied by an array of acquisition mechanisms which is made all the more extensive by the fact that most skills can be acquired by different complementary and/or alternative means.

This concept, then, is presented as a key to better understanding and measurement of individual human capital in a context of an expanding education system and diversification of training scenarios. The purpose of this concept of skills is to arrive at a definition of individual human capital which more accurately reflects the way that capital is used in the workplace by taking due account of the extracurricular acquisition of knowledge and skills. Its aim is to embody the complexity,

---

1 Ahamad and Blaug (1973, p.13) put it this way: This means that educational plans which are drawn up on that basis may over-estimate the change in investment necessary for different types of education, since part of the forecast shortages and surpluses will tend to be eliminated by on-the-job training and by employers' retraining schemes.

2 The concept of skill that we shall use in the rest of this report is defined in subsection 2.1.2 below.
the individuality and the efficiency of human labour. Skill is at least partially at odds with the concept of qualifications, which is based on the principles of standardisation, transparency and formal recognition. The concept of skill is intended to go beyond the idea of prescribed work that is basic to the Taylorist system of industrial management, but it also calls into question both the advantages and drawbacks of the occupational recognition that derived from Taylorist work organisation. To cite Lichtenberger (1999, p.94), we should not become involved in a similar process today in the confrontations about the primacy of skill, which is both decried as symbolising the dismantling of hard-won gains and lauded as recognition of a neglected asset, namely the identification of employees with their work or, as one trade unionist put it, the human side of work.

The skill of an individual seems to be more closely related to his or her ability to solve problems; such problems are generally new and cannot always be resolved by recourse to existing systems (Legrand-Lafoy and Roussillon, 1995). If this is the nature of skill, we might wonder whether it can be exclusively acquired in the scholastic environment. Indeed, it seems more likely to be an intrinsic function of a person’s job and to be definable by the extent to which it matches the requirements of that job. Skill appears to be dissociable from the concept of occupational experience, even if formal training is the essential source of basic skills and the bedrock on which experience can be built up.

This accumulation of experience is quite different to the ‘learning by doing’ to which Arrow refers. It is not merely a matter of simple productivity gains achieved through training in competitive tasks performed in a Taylorist context. On the contrary, it is about gathering experience of a non-routine nature, resulting from the active involvement of the individual. This idea of the dynamic development of skills is reflected in the managerial approach. The literature in which that approach is propounded defines it as a process, as a chain of operations set off by a particular event (the intention of resolving a problem) which transforms inputs (resources) into output (performance) (Devallae, 1998, p.13). It is also an ability to mobilise a specific combination of knowledge and of know-how in order to achieve a given performance standard.

Conventional training alone will not develop skill. It is necessary, says Delavallae (1998, pp.13-14), to put trainees into learning situations that will enable them to use the knowledge they have acquired in training and thus to enrich the know-how they will require for the solution of new problems and to monitor their progress closely. Training, be it initial or further training, is presented here as one input among several in the creation of skill. In most cases, it is a necessary condition. Only in exceptional cases is it the sole condition.

In this model, enterprises need to recognise the skills of individuals, but certificates or academic records alone do not provide them with the necessary information. The information that can be obtained from certificates and CVs is imprecise and inadequate, as is demonstrated in Mincer’s literature on the functions of education and experience as well as in the report by Espinasse and Vincens (1998) on the development of the relationship between certificates, occupations and pay levels in the five largest countries of the European Union, which is even more relevant to our present analysis.

2.1.2 Towards a definition of skill

Let us now consider the purpose of thinking in terms of skills. If we accept that skill is really the good that is traded in the labour market, how does this alter the analysis of matches and mismatches between qualifications and job requirements?

If we may come back to the problems involved in the definition of skill, our aim is neither to propose a precise and exhaustive definition of skill nor to resort to one of the many definitions that exist in academic literature or in the field of industrial relations. Defining skill is more than a mere academic exercise; it is a vital social issue for all interested parties in every country (Merle, 1997), an issue on which consensus is seldom achieved.
Instead of an outright definition, we shall try to plant a few markers in order to stake out more clearly our understanding of skill. This understanding is based on three characteristics on which we believe there is consensus.

a) Skill is a vector

The skill of an individual is the conjunction of a number of elementary capacities (knowledge, know-how, life skills, etc.). Each individual is equipped with a vector which is specific to him or her and which would probably turn out to be unique if it were defined in sufficient detail. Reducing this vector to a set of formal qualifications is often a rather unrealistic simplification, for if skill were synonymous with qualification, how could individuals with the same diploma have different job and career prospects, for example? Each component in this vector is acquired by different means. Some are acquired through explicit formal training, others are obtained in less formal contexts, such as training on the job and learning by doing, while others are acquired in social life outside the workplace or are simply inborn (or picked up in infancy or early childhood). Lastly, some skills may also be acquired by some combination of these means.

The purpose of applying Lancaster's producer/consumer model (1966 - see Box1 below) is to provide a dynamic and individualised explanation of the production of skills on the basis of knowledge, seen here as a production input. The same skill level may be attained by various combinations of inputs. This level will depend on the individual's ability at the start of the process, on the knowledge he or she has acquired through implicit and explicit training and the time invested by the individual in the absorption of knowledge. The two main production methods are explicit training, especially initial education, and implicit training, through occupational experience, but we cannot exclude other less formal means of skill production. Initial education and the acquisition of experience in or away from the workplace enable individuals to amass specific knowledge but also to develop other qualities which are often of a more general nature, such as the ability to learn and personal initiative. Skill cannot be regarded as a stock of fixed knowledge that is acquired once and for all time at the start of a person's active life. On the contrary, skills are developed throughout one's working life or at least during the first years of an individual's career. After a certain period, the marginal utility of the time spent in various forms of training diminishes as its marginal cost increases, eventually reaching a point at which individuals have no more to gain by developing their skills.

b) The economic value of a skill is specific to each job (i.e. work situation) and to each company

As a general rule, workers will not use all the skills they possess in the performance of their tasks. Different situations in the workplace will demand the use of different skills. There is no intrinsic or absolute skill. Useful or productive skill depends on the conditions in which an occupation is pursued. Some authors even doubt the very existence of individual skill or at least that it can materialise fully outside the collective context.

In the behaviourist and evolutionary approaches, skill is seen as an accumulation of knowledge resulting from a collective learning process within an organisation. One of the problems lies in assessing the extent to which individual skill contributes to the collective competence of a company, organisation or team of employees. For example, the collective competence of individuals $i$ and $j$ will be greater than the sum of their individual skills if they form an organisation, thus:

$$C_{ij} > C_i + C_j$$

Within a company, the concept of skill is not only a matter of know-how when it comes to solving problems affecting the relationship between the company and its environment but also of know-how in dealing with relationships within the company (Marengo, 1995). Skill is therefore understood as the result of efforts made by the company to create capital in the form of human resources and information (Devry, Debuissson and Torre, 1998, p.126). Unlike individual skill, this collective competence is an intrinsic part...
Box 1: A model of skill acquisition

Let us return to Lancaster's consumer/producer model. Skills are produced by the individual on the basis of the acquisition of a body of knowledge. The fundamental hypothesis is that skill may be regarded as an output which depends on a temporal production process in which various inputs are used. In Lancaster’s theory, each skill is associated with the satisfaction of a need, and the individual seeks to satisfy the most useful combination of needs.

If skill is defined in Lancaster's terms as a collection of characteristics produced from consumed goods, i.e. knowledge (Lancaster, 1966), it may be notated as a vector of characteristics at date t. This vector is represented as Zti. At any given moment, the production of an individual's skill Zi at date t may be expressed in the following formula:

\[ Z_i = f(x_i, t_{ET}, t_{ITW}, t_{ITOW}, E_i) \]

The individual will be able to produce his or her characteristic skill on the basis of the types of knowledge (x,) he or she wishes to acquire (scientific knowledge, technical knowledge, relational knowledge, etc.),3 of the time he or she devotes to the three means of acquiring knowledge (ET represents explicit training, ITW stands for implicit training in the workplace, and ITOW is implicit training outside the workplace) and of the individual's own initial capacity to produce these skills (Ei).

The utility of an individual's set of satisfied needs, which will depend on the skills the individual has produced, may be expressed in the following formula:

\[ U = U(Z_1, \ldots, Z_i, \ldots Z_m) \]

Each skill (Zi) has a production cost:

\[ p_i = w(T_{ET} + T_{ITW} + T_{ITOW}) \]

The individual is restricted by his or her monetary income, which may be derived from an economic activity for which he or she is remunerated with wage w or from other sources of funding (student grant, parental assistance, etc.), which we shall notate as v. We shall assume here that w will not be dependent on Z during the skill-production phase.4

\[ p_i x_i = wt + v \]

A further constraint on the individual is the time (t) that he or she is able to devote either to paid employment or to a course of training (h).

\[ T = \tau + t_w = T_{FE} + T_{FHE} + T_{w} \]

The individual's potential income (R) is therefore equal to the cost of the inputs involved in the acquisition of knowledge (book purchases, course fees, etc.) and to the opportunity cost involved in sacrificing a regular wage for the period of the various training courses.

\[ p_i x_i + w \tau \]

The maximisation formula may be presented algebraically like this:

\[ \max U(Z_1, \ldots, Z_i, \ldots Z_m) \]

subject to the following constraints:

\[ p_i x_i = wt + v \]

\[ T = \tau + t_w \]

---

3 The number of areas of knowledge will not necessarily correspond to the number of skills.

4 The question of the economic value of these skills is not explored in the model; it is merely assumed that acquired skills will enhance the utility of the individual. The assumption that pay does not depend on acquired skills is only tenable in the short term and that w will increasingly become a function of Z.
of the organisation and is created by a collective learning process based on interaction (Lundvall, 1997) or on organisational knowledge creation. In the view of Nonaka (1993), interactions between different skills are developed by the production of tacit and codified knowledge in a crystallisation process. When this happens, the tacit and codified knowledge that has been created and acquired becomes part of a company’s capital assets. This process of modifying and recreating skills constitutes a system of organisational knowledge creation in the sense that the organisation retains and reveals the traces of those players who, collectively and through individual interaction, have created knowledge. The knowledge creation itself results from a process of incessant updating of the forms of knowledge in the framework of a specific activity (Devry, Debuisson and Torre, 1998, pp.123-124).

It is, however, obvious that this collective competence poses problems of measurability, recognition and, above all, of transferability to the individuals who make up the organisation.

c) It is not easily measurable in advance (other than in terms of probability)

The vectorial dimension of skill, the range of variations in the relative importance of individual skills and the vast array of working situations in which these skills come into play make it impossible to determine in advance how a particular set of skills will translate into productivity. In any recruitment process, the employer initially seeks indicators of applicants’ productivity potential. This information is partly provided by paper qualifications (Arrow, 1973), which are an imperfect measure of the individual’s propensity to work productively. An examination, on the other hand, in which the various skills of applicants were put to the test would be a considerably more reliable ‘signal’ (as defined in Spence, 1974) of the productivity levels that individuals might be expected to achieve in a given job. Recruiters are faced with a twofold problem. On the one hand, they have to identify the skills that the individual possesses; on the other hand, they have to translate those skills into a potential level of productivity for each job vacancy.

The fact that a jobseeker possesses a degree or diploma gives prospective employers a rough guide to the sort of performance they might expect from such a candidate, more or less irrespective of the job in question. Selection on the basis of skill levels, however, is liable to result in the recruitment of candidates with widely disparate productivity potentials if skill is not clearly measured, which is why it is essential to measure skills accurately or to assess and recognise them.

2.2 Skill: from concept to measurement

According to Wolf (1994), while skills are of major importance in national and European policies, there is still a need to reach agreement on what skill actually means. The issues of definition and measurement, says Wolf, are crucial. The skills of individuals in the labour market pose problems in terms of measurement and, in a more general sense, in terms of management of the information required for dealings in the labour market.

There is a need to try to conceptualise the measurement of skills and to standardise the instruments of evaluation.

In fact, it is just as essential to know the value of human resources as it is to know the value of the other factors of production. It is simply more complex to measure the former than the latter. The problems involved in such an evaluation may be categorised under two headings:

a) the ‘macroeconomic’ problem of evaluating the available human capital;

b) the ‘microeconomic’ problem of information and human-resource management for employees and employers.
2.2.1 What statistical concept can be used for the macroeconomic analysis of skill?

During the eighties, the 'global' measurement of human capital became a particularly ticklish problem, as Castells emphasises (1997, p.58): For the first time in history, the human mind has become a direct productive asset, rather than just a decisive production factor; its significance and productive value is also changed by its cultivation, through training in the broadest sense.

Those years were marked by a significant change in the nature of investments. The balance between physical and intangible investments varied widely. An OECD report (1996) shows that, in 1987, expenditure on intangibles was the major form of investment in Germany, Sweden and the United Kingdom. The report also highlights the complementary nature of these two types of investment as well as the high level of technology that these investments had generated.

The volume of intangible investment has a direct bearing on production methods and, moreover, on the development of production models. The statistical measurement of skill is therefore a challenge to those who are responsible for macroeconomic management. Growth models and analyses too often estimate the impact of the human factor indirectly by means of an external indicator (Denison, 1962), which is more or less well adapted for use in the model or analysis. No direct account is taken of certificates, although they are admittedly very imperfect indicators of skill, and analysts are content to include two types of labour (skilled and unskilled) among the factors of production.

The challenge is to endow macroeconomic analyses with a more precise conceptualisation of the stock of human resources and to create the statistical tools with which such analyses can be conducted (IFAC, 1998).

To convince ourselves of this, we need only call to mind some problems that are examined with the aid of a proper macroeconomic analysis of human resources. For example:

- the structural disruption of the active population caused by mass training systems, including higher education;
- the accelerated transformation of employment structures and job descriptions;
- the obsolescence of skills in the labour market;
- the restriction of the internal markets within labour markets and its impact on careers and on informal mechanisms for the production and recognition of skills.

We are familiar with the limitations of any attempt to codify knowledge (Lundvall and Borrás, 1997). The main limitation is undoubtedly the distinction between codified and tacit knowledge. It is a key element in identifying and understanding the nature of the cognitive changes in which the very concept of skills is rooted.

It is clear that the intrinsic complexity of the concept of knowledge, combined with the constraints of collecting and codifying the necessary statistics, make it impossible to effect a direct macroeconomic measurement of skills and that economists will therefore have to make do with indirect measurements.

The simplest way of measuring skills indirectly is to assess the quality of the labour force on the basis of its stock of formal qualifications. This has two strategic advantages.

- The information is available and can be quite reliably codified.
- This makes it possible to design models on the basis of a heterogeneous labour force, the various components of which are competing for access to jobs.

This solution also presents a number of disadvantages, because it ignores such factors as occupational experience, seniority in the labour market and the acquisition of knowledge outside the education and production systems.

One means of introducing the concept of skill into macroeconomic analysis was suggested in
the framework of the Cedefop Diplomas and the Labour Market project (Béduwé and Espinasse, 1995b). It consists in considering a simplified concept of skill based on a vector with two components: the educational qualification (possibly measured by the length of the course of study required for its attainment) and the employee’s total seniority (for which age might serve as a suitable approximation).

This method would enable analysts to take account of empirical evidence which is available in all countries of the European Union. Apart from the regulated trades and professions, access to which depends on possession of a legally prescribed diploma or degree, all trades and professions have members with a variety of qualification levels and seniority. Statistical analysis very clearly demonstrates, in each country and in every period, a substitution effect between the acquisition of these two components of skill.

*The curve on the graph in Figure 1 gives an example of this sort of equivalence in the domain of access to employment. By way of example, let us consider the minimum level of educational attainment and professional experience of survey respondents in executive posts in company administration in France for the years 1982 and 1990 (Figure 1). These posts are open to first-time job applicants, provided the time they have spent in secondary education and at university and/or college comes to a combined total of 12 years! In other words, only the highest level of educational achievement can compensate for a lack of professional experience. Conversely, such posts are also open to non-graduates who have more than 20 years’ professional experience. Employees whose levels of edu-

---

6 These two curves were drawn on the basis of a method proposed by J.M. Espinasse (1997) to define the minimum skill requirements. They represent minimum combinations of educational attainment (established on the basis of the respondents’ declared qualification level) and seniority in the labour market (calculated on the basis of age and estimated date of completion of formal education).

7 Measured on the basis of seniority in the labour market.
cational attainment and/or professional experience exceed these thresholds automatically possess the minimum skill requirements for executive posts. In practice, recruitment decisions are plainly not based on the criteria of formal qualifications and professional experience alone. Not all of those who are eligible\(^8\) for a particular type of post will be appointed. Candidates will be expected to possess other skills too. This way of quantifying the concept of skill is obviously very restrictive. It does, however, provide the basis for a macroeconomic approach to the measurement of skill.

2.2.2 The measurement of skills and its microeconomic foundations

The word 'skill' (French compétence)\(^9\), in the sense in which we use it here, has only begun to find its way into the vocabulary of economics and has hardly ever been tested. The concept itself, however, is not really new. Human capital, as originally defined, comprises all the productive capacities of each individual, including his or her operational aptitude in the widest sense (general knowledge, specialised knowledge, know-how, experience, etc.). The two main instruments for the creation of human capital are in-service training (experience and continuing vocational training) and initial training within the education system. In the view of Becker (1993, p.19),\(^10\) schooling is at the heart of this creation of human capital: Human capital analysis assumes that schooling raises earning and productivity mainly by providing knowledge, skills, and a way of analysing problems. However, he modifies this statement a few paragraphs further on (p.20): Of course, learning and training also occur outside of schools, especially on jobs. Even college graduates are not well prepared for the labor market when they leave school, and they are fitted into their jobs through formal and informal training programs. The amount of on-the-job training ranges from an hour or so at simple jobs like dishwashing to several years at complicated tasks like engineering in an auto plant.

Becker, then, does not dismiss the other means of creating human capital, such as the informal training that individuals receive within the family, through their social contacts and even during their national service. He says that other activities which are not directly linked to the training process contribute to the creation of human capital and increase individual productivity. In particular, the various activities in which jobseekers engage during their jobsearch enable them to increase their knowledge of the labour market and so to invest in their own productive potential.

Expressed in such general terms, the definition of human capital is hard to criticise, but the reduction of this general definition to the oversimplified equation

\[
\text{qualification} = \text{length of study}
\]

which is found in many applications of empirical findings is no doubt rooted in the need for measurements which is inherent in statistical and econometric approaches. In measuring human capital, a lack of data often makes it impossible to take account of the diversity of forms that human capital can take and the various ways in which it can be created, while the polarisation of educational economists on the subject of formal qualifications is also a stumbling block. Nevertheless, even when the theory of human capital was still in its infancy, Rosen (1972, p.326) emphasised that experience, which is a proxy for implicit training, appears in many cases as a more important skill factor than initial education: Yet, much evidence suggests that a large fraction of directly marketable skills possessed by individuals are not acquired from formal schooling, but rather from work experience.

More recently, the introduction of the concept of the job into neoclassical analysis of the labour market (Lazear, 1995a and 1995b) paves the way for a new conception of qualification which is closer to the concept of skill and less

---

\(^8\) In terms of experience and qualifications.

\(^9\) See section 2.3.1.

\(^10\) Third edition of Human Capital.
closely related to initial education. Lazear states (1995b, p.263), in connection with the limited significance of the correlation between education and pay levels within a specific occupational category or company, that For example, rates of return to education estimated by using within-firm data might be very low because a firm's decision to hire a worker trades off unobservables against observed variations in education. All workers hired into a given job might have the same amount of human capital irrespective of differences in their level of schooling. However, the relationships between skill and pay levels and, more generally, between skill and jobs, while commonly acknowledged, remain largely unexplored, although some empirical studies have stressed the important role of particular skills in relation to educational attainment. (Lee, 1986; Black and Lynch, 1996)

Acknowledging that skills are heterogeneous necessarily entails addressing the problem of their transferability, for skill is all the more marketable if it can be transferred. Is the transferability of skill linked to the way in which it is acquired? Is skill – or, to be more precise, a skill – more easily transferable if it is acquired through initial education (to put it in more general terms, through an explicit form of training) or if it is acquired on the job?

To Perkins and Salomon (1989), work experience often appears to be a more effective means of producing transferable skills than initial education. Taking the opposite view, Nordhaug and Gronhaug (1994, p.91)11 emphasise that competence acquired through education generally proves to be transferable to a larger number of companies than the competence that is born of experience. The apparent contradiction between these two propositions probably derives from the difference in the level of generality or specificity of the skills on which the respective authors based their analyses. In other words, it derives from a lack of consistency in the measurement of skill or competence.

Opting for the view that skill should be considered as a vector is one way of circumventing this lack of consistency. Rather than being considered in its immeasurable globality, skill is broken down into a number of distinct elements which are easier to calibrate and are open to more precise analysis.

2.3 Recognition of skills, industrial relations and regulation of the labour market: towards a new dynamism?

The debate about qualification versus skill is no mere academic exercise. Not only is it high on the political and social agendas, particularly in the context of pay negotiations; it is also at the heart of the issue of mobility within the labour market.

2.3.1 Skill at the centre of industrial relations

A consensus on the concept of qualification, though achieved at the end of a long, hard struggle, is now one of the cornerstones of industrial relations as we know them. Its impact on collective bargaining, on the nature of employment contracts and on pay scales is crucial and has been the subject of an enormous wealth of literature.

As Barbier et al. (1996) stress, the concept of qualification is attached to the social model of the glorious thirties, which was characterised by the development of large industrial corporations, the Taylorist system of scientific work organisation, the centralisation of managerial functions, centralised pay negotiations, workforces structured on the basis of seniority, strong trade unionism, and so forth.

The concept of qualification, in the form in which it is recognised by management and labour in at least some countries of the EU,12

---

11 Individual competence may be gained through education and experience in the work place. Competence obtained through education is general in the sense that is applicable in more than one firm and often in a variety of jobs. Competence gained through experience is more or less specialised by being linked to the idiosyncracy of the firm in which it has been acquired.

12 Especially in France and Spain.
is associated with the idea of a stock of knowledge which is necessary and sufficient for the pursuit of a given occupation and on the basis of which hierarchical ranking and pay structures can be determined. This knowledge and its validity are held to be certified by the formal education system (schools and, in some cases, institutions of further and higher education) – so much so that, in some languages, qualifications and certificates are synonymous terms.

In order to arrive at a better understanding of the nature and dimension of the changes that are taking place, we must examine the role played by the traditional concept of qualification in the labour market and its association with the idea of certification.

In different ways in different countries, but throughout the European Union, qualification and the manner in which it is certified remain important elements of industrial relations.

They largely define the structure of the hierarchy, the allocation of responsibilities and employees' pay levels. In the recent past, formal qualifications were plainly a fundamental element in the regulation of the labour market. They continue to play a key role to a great extent, even though this role is gradually changing as technology transforms organisational structures and as new generations appear in the labour market with ever more degrees and diplomas.

The concept of skill is quite a different matter. It relates to a person's capacity to assume a specific and measurable set of responsibilities in the context of a given occupation. It therefore constitutes a revalorisation du travail concret – a revaluation of actual work (Lichtenberger, 1999, p.93). The manner in which this capacity is acquired is of little importance, and its link with the certificates awarded by the education system is loosening.

The accelerating pace of change to which we referred before has also made itself felt in several aspects of individuals' careers. The changing skill requirements, whether in terms of basic or specialised skills, that individuals have to fulfil in the course of their working lives call into question the validity of the concept of a trade or profession as a relatively stable body of predefined knowledge and abilities that can be encompassed in a similarly stable curriculum of initial education which qualifies individuals for employment in particular occupations.

Today, that body of knowledge and know-how which is defined as a trade or profession is less and less stable, and its role in industrial relations, though not disappearing, is tending to change. The symbol of this change is a shift in terminological usage which reflects the desire to move from the measurement of productive potential by membership of a trade or profession or by educational qualifications towards a less organic type of on-the-job measurement. Behind this change lie two incontrovertible facts: on the one hand, there are the objective changes in the content and character of trades and professions, and on the other hand there is the pressure for a certain degree of deregulation, or for a new form of regulation, of industrial relations in which membership of a trade or profession and external certification have traditionally been a key element in the collective definition and association of employees and in the establishment of their vested rights. These changes pose new challenges. They are a source of new conflicts and require new compromises, which, according to Y. Lichtenberger (1999, p.104), can only take shape in the context of a redefinition of work itself, of its purpose, of the value of the diverse forms of investment, of development prospects, etc., and thus of the concept of skill.

Such a transformation also entails a profound change in the very nature of the employment contract. Alain Suppiot (1994) enumerated the principal developments in this direction, while conceding that none of them had yet been fully absorbed. Subordination, he said, has been constantly diluted, organisations are delegating increasing powers of initiative and responsibility, the link between work and pay is loosening in favour of greater
continuity of income, given the vagaries of working life,\(^\text{13}\) etc.

One effect of the erosion of the traditional importance of trades and professions is the development of 'transverse' skills, in other words skills which can be used (and re-used) in a wide range of real working situations and which may apply to operations carried out by members of quite distinct trades and professions and may therefore cut across boundaries drawn in collective agreements and pay scales. These skills assume a strategic value in the careers of individuals. They also play a strategic role in the new forms of work organisation and risk management.

Our education and training systems, as we shall see below, are still far from establishing transparent, i.e. clear and legitimised, systems for the recognition of skills that have been validated either by the training systems themselves or by the labour market. This deficit has a fundamental bearing on the development of a system of further training and industrial relations which can meet the challenges that already confront us.

Following a period during which companies tried to foster loyalty among their staff by developing internal labour markets and concluding collective agreements in which training and promotion prospects were guaranteed, the business world is now retreating, at least partially, from this policy, which was designed not only to prevent industrial conflict but also to ensure a constant supply of quality labour. This retreat began in the early eighties, when companies began to reserve the benefits of secure employment for the members of their staff who were indispensable to the production process. Today, without actually reneging on collective agreements, firms are trying to lessen their impact. In particular, career patterns and individual training programmes, which, in accordance with the idea of an internal labour market, had long been institutionalised in career plans and sometimes even in collective agreements, are now more likely to be left to the initiative of the individual employee.

A reduction in the average length of service within companies is observable in most countries of the European Union, albeit to a varying extent from one country to another and more especially from one generation to another of the active population. While the phenomenon is most conspicuous in the countries of Southern Europe, such as Spain, average seniority has fallen in all countries of the EU and among all age groups represented in the labour market.\(^\text{14}\)

Finally, if we seek to move from a training-based approach to employment to a skills-based approach, we must bear in mind that, over and above all the concepts and socioeconomic analysis, we are also dealing with a subject at the heart of industrial relations and collective bargaining. It is quite likely that this debate will soon affect the very definition of the employment contract and of the relationship between employers and employees.

### 2.3.2 Recognition of skills and mobility within the labour market

The transformation of occupational structures, the pace of technological innovation and certain institutional changes have been conducive to the accelerated growth of mobility

\(^\text{13}\) Lichtenberger (1999, p.104), for example, takes up the hypotheses advanced by Suppiot (1994) and says that, even if people in stable occupations escape this dualisation of the labour market, the change in the nature of employment contracts poses them no fewer problems. The new reference value of a specific job of work, perceived as a service and not as a good, possessing social utility and value for other people besides an employer, the value of accountability, which is not about the apportionment of blame but about a stake in the struggle to overcome the risks and vicissitudes of business activity – these values are only beginning to emerge as portents of social confrontations to come.

\(^\text{14}\) European statistics (Eurostat Labour Force Survey) for the period 1992-97 reveal that the percentage of employees with less than one year's service has generally been rising in all age categories throughout Europe and especially in the youngest age groups. The European average rose from 49% to 52% for employees under the age of 20, from 33% to 39% for the 20-24 age bracket and from 21% to 23% for those aged 25-29. It remained fairly stable in the case of employees over the age of 30, rising from 10.09% to only 10.12%.
in the labour market, although voluntary mobility will undoubtedly wane during periods of high unemployment.

At the same time, the labour market in many countries of the European Union, especially in the South, has been marked by companies’ more frequent recourse to the external labour market at the expense of their own pool of labour. This tendency reflects one of the solutions adopted by businesses, along with insecure terms of employment, subcontracting, outsourcing and so on, to resolve a central problem arising from the effects of globalisation on developed economies, namely the need to reduce the wage bill for the sake of competitiveness without (excessively) reducing nominal wages for fear of provoking social unrest. One of the methods used to achieve this aim has been the reduction of the number of tiers in company hierarchies. This reduction automatically limits the promotion prospects of company employees. Moreover, the in-house labour market, which primarily serves to prevent the loss of skilled labour, entails a number of costs, which become unnecessary at a time when labour is no longer in short supply. Finally, this internal market is a long-term managerial instrument which operates on the assumption that company labour needs are constant and foreseeable. The accelerating life cycle of skills tends to diminish the expedience of such a policy.

Labour mobility in Europe is reaching levels that are comparable with those in economies which have traditionally been more open, particularly the US economy, even though the bulk of this movement between companies is occurring within the borders of individual countries (Tassinopoulos and Werner, 1998). Human resource management is increasingly characterised by recourse to the external labour market. This implies a greater need for information about skills, both for firms and for jobseekers. The informal mechanisms for recognising skills acquired after initial education, which have historically been very closely linked to the existence of internal labour markets (Doeringer and Piore, 1971), are dwindling in importance as the balance swings in favour of the external market and as skill requirements change ever more rapidly.

In addition, major changes have been observable in the forms of employment contracts, changes designed to bring greater flexibility to employment relationships. These changes relate to key elements of the ‘standard’ employment contract from which most national labour rights derive. One such element is the ‘permanence’ of contracts. Many factors (outsourcing, subcontracting, direct labour, etc.), if not destroying these principles, contribute at the very least to restricting their impact as well as effecting profound changes in the very nature of contractual relations between enterprises and workers (Dupuy and Larré, 1998). Lastly, telework will no doubt further complicate the traditional relationship between employers and employees.

The identification and validation of skills used to take place for the most part within companies. The company’s prolonged first-hand knowledge of its employees was, in a sense, the basis of their career development and the key to the company’s efficient deployment of its human resources. The gradual demise of these forms of skill recognition, which derive their legitimacy from the internal labour market, creates a more pressing need for tangible evidence of skill at a time when the abundance of certificates held by the active population is tending to obscure the evidential value of each certificate.

Such a situation complicates the recognition of skills and the management of human resources. In fact, monitoring career development is not only a matter for companies but also concerns the organisations in their vicinity. Human resources are developed to some extent by a host of agents outside the education system – professional bodies, civic associations, etc. – some of which have no transparent and legitimised mechanisms for recognising the acquisition of skills.

At the present time there are still very few recognition systems15 which can accommodate

15 There are exceptions, for example the individualised monitoring of members of certain professions or the informal mechanisms which have traditionally operated or have been developed within particular economic sectors or geographical areas.
this huge wave of more numerous, more diversified and longer training processes. For the moment, it remains difficult to imagine how the transparency required for the transferability of skills acquired from a variety of sources can be achieved.

The challenge for each individual throughout his or her career is to turn to account the knowledge and skills that have been acquired informally. It must be possible to draw up an inventory of this knowledge and these skills in a form that third parties can recognise, so that such a portfolio of informal qualifications has a guaranteed market value. It is an essential record of the individual’s achievement and sometimes the only record. It is also an insurance policy against the risks of downgrading and the disadvantages of a career interruption.

Having one’s skill recognised and being able to market it are crucially important. Failure to do so can lead to exclusion from a market which successive new generations are flooding with a welter of paper qualifications, imperfect though they may be as skill indicators. Just as the absence of certificates is a handicap for young first-timer jobseekers, others are handicapped by the absence of explicit recognition of the skills they have acquired in the course of their working lives.

In the view of Jacques Delcourt, expressed at the AGORAI seminar, the non-validation or non-certification of training or achievement is something that particularly affects lower-skilled workers and those who have failed at school. These workers are liable to find their access to vocational training blocked because of the low level of general education they have received or, worse still, because they have no formal qualifications certifying any level of education at all. This applies especially to the older generations, who have generally received less schooling. It applies even more to young people who have come out of the education system empty-handed. There are some programmes that enable individuals to have the knowledge and skills they have obtained outside educational institutions validated with certificates that are recognised by the education system as equivalent to certain college and university entrance qualifications. These programmes, however, are generally run on a small scale and meet with stiff resistance from the educational establishment.

A more common phenomenon are the systems whereby credits awarded for work experience help to qualify applicants for access to courses of continuing vocational training and for setting up in business. This recognition of informal learning processes could rectify the paradoxical situation that exists in all European countries in which those who already have the highest qualifications benefit most from further training.

Finally, recognition of skills acquired outside the formal education system can also be an effective instrument against exclusion from the labour market and/or from further training. We are thinking here in particular of those employees who, because of their age and their occupational history, do not possess formal qualifications but are nevertheless well endowed with practical know-how.

As Marsden (1994, p.20) points out, if the qualifications associated with a job and specific to a company lose some of their appeal because employment in the internal labour markets is becoming less secure than in the past, an effective system for the recognition of acquired skills could serve as an acceptable compromise. The author proposes on the one hand that the creation of qualification systems based on skills should be supported (the success of which would depend on the establishment of an appropriate regulatory system) and on the other hand that care should be taken to ensure that appropriate incentives existed for employees to undergo training and for companies to provide training opportunities (Marsden, 1994, pp.20 and 21).

2.4 From recognition to validation of skills

The preceding paragraphs have shown that the problem posed by the conceptualisation of skills cannot be reduced to a problem of measurement. Measurement, however, is still a very real problem, for identification and knowledge depend on measurement in some
form or another. Many efforts are made, partial and imperfect though they may be, to measure skills. These efforts are one of the keys to the transparency that is required of the various subsystems of skill production as well as the labour markets.

The technical structure of the measuring instruments and the associated vocabulary may indirectly influence the perceptions of skill that are establishing themselves and the information systems that derive from these perceptions. Definitions and measurements, then, have a potential impact on the information structure of the market, on training policies and on industrial relations.

The attempts to make the market transparent by recognising individual skills involve the development of various forms of 'standardisation' and/or 'matching', which inevitably favour certain specific skills at the expense of others. They also highlight the differences between the various philosophies of education, training and work and, in more general terms, of society.

In that respect, the semantic (and statistical) debate is the tip of an iceberg comprising all the domains of education and production or, more broadly speaking, an element in a wider economic and social debate that is very much dominated by the single philosophy of neoliberalism (Alaluf, 1992).

If this debate remains technocratic in nature, it is liable to exclude skill, the traded asset, from the definition of the rules governing wage differentials. However, as A. d'Iriarte (1996, tr. from p.30) points out, if the proclaimed intention to reconcile, through lifelong learning, the prospects for economic competitiveness, personal development and social cohesion is to have any chance of success, the actors with leading roles in the dismantlement and reconstruction processes must agree to play supporting roles.

At the present time, considerable efforts are being made in Europe to evaluate and recognise qualifications as such, whether formal or informal, irrespective of where and how they were acquired.

These efforts are being pursued in several directions (Bjørnåvold 1997b).

- At an individual level, skills acquired through the 'formal' systems are evaluated by a 'diploma' (in the generic sense, i.e. any paper qualification). They are only one element of the human capital, or skills profile, of an individual and, cumulatively, of a country. Several countries are therefore in the process of introducing systems for the evaluation of qualifications and skills acquired informally with a view to measuring the available national resources of human capital, making the labour market more transparent and arriving at a more precise definition of the potential (or 'value') of that section of the labour force whose skills have mainly been acquired outside the formal systems. This is particularly important in the case of those with the fewest formal qualifications and the older age groups.

- At the company level, there is a gradual movement towards evaluation and stock-taking in the realm of intangible assets, including human resources. Since methods for the evaluation of intangibles are still relatively new, there is a tendency to underestimate them (OECD, 1996) in both budgetary procedures and general resource management.

- At government level, it is noticeable that governments have been trying to introduce new methods of quantifying public expenditure of human capital. These efforts do not seem to be having much impact on the rationale or operational structures of the education system.

The aim for governments is to initiate the creation of efficient systems to define and inventory specific skills, thereby guaranteeing the transparency of labour markets. To that end, their strategy will no doubt consist in establishing collective definition parameters with a view to laying down ground rules for skill evaluation and certification methods. This role is similar to the one played by governments in the commodity and service markets.
Recognition of skills implies the creation of a common, comprehensible and universally recognised language. That requires technical instruments for the validation of acquired skills as well as legitimisation processes.

Bjørnåvold (1997a and b) and Cedefop, 1998a, pp.189-198) enumerates the developments that are taking place and the real benefits of constructing a mechanism to measure skills acquired by informal means.

Whatever the means of acquisition and whatever the type of skill, there are two qualities that the certification system must possess: validity and legitimacy.

If the methodology of skill recognition is to be devised in a wide variety of situations and institutional contexts, it requires the establishment of common objectives and codes of practice. The pivotal priority for any methodology of this kind is to ensure that skills can be made transparent and transferable.

The methodological approaches that have been tried out are diverse and are rooted in the context of each country. A detailed analysis of the various proposals would constitute a research study in its own right (see the material produced in this domain by the Cedefop team headed by Bjørnåvold). Despite the diversity of methods, we shall identify a few common elements which can contribute to a general consideration of the issue.

In the view of Bjørnåvold (1997b), we should distinguish between two quite different methodological approaches: those based on dialogue and guidance (these include the French Bilan de compétence16, the British APL-NVQ17 system and the Netherlands system) and those based on specialised computer systems (such as the European skill-accreditation system (European Commission, 1996).

2.4.1 Dialogue and guidance

From a comparison of the French Bilan de compétence, the British APL-NVQ system and the Netherlands system, Bjørnåvold concludes that each of them uses the following four instruments in combination.

a) interviews with the person who is being assessed,

b) evaluation and diagnostics,

c) self-assessment, and

d) more or less 'conventional' examinations.

The ways in which these instruments are used in practice do not differ radically from one country to another. The analysis shows that evaluation is based on a combination of a candidate's own contribution and the formalised technical instruments. Assessors always take account of the applicant's reflections on his or her own practical experience and of the applicant's self-assessment. They neither restrict their appraisal to 'objective' performance indicators nor base their decision on subjective data or self-assessment alone.

This sort of two-track approach is a characteristic of the process of evaluating and recognising skills. The methods in use are designed to combine the individual and contextual dimensions of skill assessment. These skills are specific to the candidate, but they must be legitimate in the eyes of third parties, i.e. other employees, companies and training institutions.

As for the formal qualification (the 'certificate'), the main distinction between the different systems is that some, like the French system, certify acquired skills in a record of achievement ("porte feuille de compétences"), while others, like the British system, accord formal recognition by means of a certificate or diploma awarded under the system of national vocational qualifications (NVQs). In the latter case, such certificates can not only be used in the labour market but can also serve as a 'bridge' between the formal and informal training systems.

16 A form of skills analysis.

17 Accreditation of Prior Learning – National Vocational Qualifications
2.4.2 Specialised systems

For some years now, new computerised instruments for the evaluation of informally acquired skills have been in use. The justification for this type of approach is that such instruments reduce costs, can be extended to all types of skill and are objective. In some countries, these methods coexist with the conventional methodology described above.

Let us take the case of Ireland, for example, which is pursuing the following aims:

- to develop a specialised system enabling individuals to access information about the occupations that interest them;
- to provide individuals with easier access to assessment standards to make them aware of the demands associated with the acquisition of particular qualifications;
- to define a standardised method of compiling a record of achievement;
- to help individuals to identify more clearly the additional training they require.

At the present time, the most ambitious initiatives in this field have come from the European Union, the prime example being the European skill-accreditation system. One of the fundamental aims of this system is to offer all individuals the opportunity to have their skills assessed; the results of this assessment would then be recorded in a personal record book. The technological basis of this project comprises electronic tools which are universally accessible through the Internet.

The main difficulties of the latter type of approach lie in the obvious limitations of a procedure which is totally automated, in their European and hence multicultural dimension and, at a more fundamental level, in the difficulty of translating elements of knowledge into signals that can be evaluated.

2.4.3 Skill and legitimacy

The impact of these methods is closely connected with their legal basis and their legitimacy (OECD, 1996). The distinction between legal basis and legitimacy is pertinent, because they are not so much alternative terms as complementary factors in the efficiency of the system. The legislature cannot prescribe mechanisms for recognising and harmonising skills without having previously brokered a compromise between diverse and often divergent interests.

The introduction of totally automated solutions can only partly satisfy the need for transparency on which the recognition of knowledge and skills is based. To be suitable, according to Bjørnåvold (1997b), solutions must take account of the social dimension of the methods they involve and must focus explicitly on the issues of acceptability and legitimacy. One strategy is to devote very close attention to the legitimacy of the institutions responsible for validation.

To be legitimate, institutions must satisfy at least three conditions (Bjørnåvold, 1997b, p. 77).

a) All the players involved must be consulted and must make their positions clear.

b) Relevant and useful information must always be common knowledge.

c) A consensus must be reached, and sanctions must be available to deal with abuses.

The policy of skill validation that is being defined will inevitably have far-reaching effects on the development of the education and training systems. It will also have an impact on all the systems of industrial relations. It must therefore be examined and evaluated from both of these perspectives.

2.5 Conclusions

As we have seen, the shift from qualifications to skills is emerging as an undercurrent, caused on the one hand by changes in production deriving from the development processes which we highlighted in the introduction (Chapter 1) and with which we shall deal in greater detail in the next chapter (Chapter 3) and on the other hand by changes in the processes whereby human capital is created within individuals.
From this, we conclude that the skill of the individual, in other words the sum total of the specific characteristics which determine his or her productive capacity in a given context, is becoming the tradeable asset in the labour market.

The vectorial quality of skills means that the process by which they are produced necessarily involves co-production by a variety of agents, a process governed by the interchangeability of their components and not by any rigidly prescribed procedure.

This change, however, is not solely a change in the technical aspects of the production process. It is occurring in a wider framework of equally profound changes in industrial relations, in the very substance of employment contracts and in the role and place of education and training systems in the production of human capital.

The changes that are taking place also require more refined information systems which are able, on the one hand, to appreciate the specific nature of individual skills, irrespective of the conditions in which they were acquired, yet equally capable, on the other hand, of constructing an information system that is sufficiently standardised and transparent to manage human resources; such management must be based on increasing mobility of labour as well as on individual career development and the principle of lifelong learning.

These information systems on human skills are already being created in various countries in an uncoordinated manner, each system taking account of specific national circumstances. They naturally tend to be more refined than systems based on formal qualifications. Be that as it may, they remain imperfect, as Marsden comments when he writes of these new 'skill-based qualification systems', which coexist with the older systems. To aim for complete transparency of individual skill levels in the labour market would, as Eymard-Duvernay and Marchal (1997) point out, be illusory. The measurement and validation of skills is developing with a wide margin of tolerance, determined by the coordinates that society has plotted in any given context.

The definition of the concept of skills itself, the instruments for measuring them, the certification mechanisms and the processes by which these systems are legitimised necessarily imply a change in the ground rules, since the various participating players defend interests which are often conflicting. Thus the definition of the operational concept of skills will not be the result of scientific analyses but rather of a 'collective interpretation', which will take account of the more or less informal balance of power that exists between business, labour and government and of the social context in which they operate.

3. Skill levels, individual skills and demand for labour

The traditional model of the relationship between formal training and employment to which we have referred in the foregoing chapters assigns a leading role to the demand for labour in the development of skill levels within an economy.

For the proponents of the manpower approach, the mere observation of a fluctuation in global output translates into a shift in the level of demand for skilled labour. They infer directly from this that education systems should adjust their output levels.

The theoreticians of endogenous growth have noted that the production system increases its productivity when it employs more highly skilled labour. They therefore ascribe these gains to higher public investment in explicit training.

Both of these groups believe that analysis of the demand for labour in relation to the production of goods and services and economic growth has – or should have – direct repercussions on the output of education systems and, moreover, on the quantitative and qualitative equilibrium of the labour market.

The present chapter, which is devoted to a study of the influence of technological and organisational innovations on the demand for and the use of manpower, is written from a
different perspective to that of the traditional model.

We have adopted a non-determinist position with regard to technology and the innovation process. In other words, we do not regard technology as an independent variable that is solely responsible per se for its effects on the various elements of the production process and on the management of human resources. On the contrary, without denying the importance of technological innovation, we postulate that its influence is conditioned by factors inside and outside the enterprise itself, prominent among which are management strategies and objectives.

Be that as it may, we shall analyse the influence of technological progress and organisational change on the demand for qualifications (Section 3.1) and skills (Section 3.2), but we shall also try to identify the contextual elements that do most to strengthen these influences.

We shall organise the body of literature analysed in this chapter into two categories based on two fairly distinct schools of thought.

The first school essentially reasons in terms of labour along the lines of classical macroeconomics. It does not differentiate much between types of manpower, generally confining itself to a distinction between skilled and unskilled labour. Within this framework, the influence of technological progress, organisational changes and institutional constraints is analysed.

The second school of thought comprises those authors who are more explicit in addressing the heterogeneous nature of the manpower factor and adopt an approach based more or less directly on the concept of skill. Their aim is to understand how the market absorbs variations in the demand for specific skills, variations caused not only by growth or fluctuating production levels but also by technological progress and organisational change, without necessarily resorting to adaptation of the system of basic formal education or even of continuing vocational training.

3.1 From techno-economic development to a skilled labour force

The eighties were marked by a widening of the gap between skilled and unskilled workers in most developed countries. This was primarily reflected in a comparative loss of status for low-skilled workers, whose relative pay levels and/or employment prospects deteriorated.

The impact of technological and organisational innovation on employment is the subject of widespread polemics, in which two broad sets of questions have been raised: one of these relates to the volume of employment and the other to its characteristics. The analysis of the development of demand for skilled labour serves as a framework in which these two types of question can be addressed.

Many empirical studies discuss the various factors that can contribute to a fall in demand for unskilled labour. It is a matter of unbalanced technological progress (Berman et al., 1994; Entorf and Kramarz, 1994) but also of fiercer competition with countries where pay levels are low (Wood, 1994; Sachs and Shatz, 1994; Bonnaz et al., 1994) or of changes in the structure of trade in goods (Krugman and Lawrence, 1993) and of the changing sectoral balance of employment (Berman, Bound and Griliches, 1994). The findings of these studies generally indicate that the fall in the percentage of low-skilled workers is not simply linked to the decline of those sectors of the economy which chiefly employ that type of labour. This reinforces the hypothesis that technological progress pays a leading and direct role in the significant loss of low-skilled jobs. Most of the studies conducted in the English-speaking world only hold international trade responsible for 15 to 50% of the fall in demand for unskilled labour, while emphasising the role of technological progress (Bound and Johnson, 1992; Borjas, Freeman

18 These conclusions, however, are not unanimously accepted, particularly because they do not take account of the relative development of pay levels in the various sectors of the economy and the role of wage flexibility as a strategy used by businesses to adapt to international competition.

In most cases they stress the role of the disequilibrium of technological progress (Cotis, Germain and Quinet, 1997). Whereas technological progress used to be regarded as a source of deskilling, the advent of the new forms of information technology have altered this assessment. It has become the ally of skilled labour, usurping the role of unskilled labour.

3.1.1 Technological progress and demand for skilled labour

If we take a more detailed look at the literature on the technological progress of recent decades, the relationship between such progress and the demand for skilled labour frequently emerges as an extremely complex one and depends on the level of observation adopted by the researcher (Spenner, 1985). In general terms, there are two opposing ideas:

1. The use of technology creates new occupations (Nelson and Phelps, 1966), which sometimes necessitate higher skill levels within the workforce as the production process becomes more complex. This only
The skills market: dynamics and regulation

applies, however, when the technology in question mobilises other forms of technical capital to supplement education. Welch (1970) was one of the first to demonstrate a complementary relationship between the value of education and investment in technology.

2. As new technologies emerge, the degree of automation is sometimes so high that it becomes possible to entrust production tasks to less skilled employees. Technology may be the basis of an investment that serves as a substitute for education: human skills are replaced by the capacities that machinery and software can provide.

These two ideas proceed from different assessments of the complementary relationship between skill levels and physical capital. Most of the empirical studies (Griliches, 1969; Hamermesh, 1993; Dormont, 1995) tend to suggest that capital and skilled labour are p-complementary, whereas unskilled labour is a p-substitute for both capital and skilled labour. These studies keep emphasising that the most highly educated employees have a comparative advantage when it comes to learning about and applying new technology. General education fosters an ability to cope with the unknown and strengthens the adaptability of an enterprise, which justifies the payment of salary premiums to university and college graduates (Murphy and Welch, 1989). Bartel and Lichtenberger (1987), on the other hand, defend the idea that the degree of complementarity between skilled labour and capital depends on the average age of the capital. Recently acquired machinery calls for the provision of a specific course of explicit training. But as time passes, this gives way to a less formal learning process based on the use of labour with lower levels of initial education.

Technology therefore demands different types of labour at different times.

In fact, the use of new technology by the least-skilled category of labour is often very difficult to analyse. Technology can hasten general downgrading of the workforce by simplifying their tasks or, conversely, it can significantly upgrade the workforce by presenting additional training opportunities.

According to one interpretation, the ‘technological experience’ is a factor which standardises jobs through the mechanisation or automation of tasks. This probably happens whenever a given physical investment is widely made within an industry, requiring the same skill profile and therefore generating a supply of labour with the appropriate skills. In this case, the jobs concerned are unlikely to involve a variety of tasks, and so they become standardised. This ultimately reduces the development and career prospects of the lowest-skilled workers.

The second interpretation, by contrast, sees technology as a means of access to jobs and training for low-skilled and unskilled labour. It is in fact possible to use the least educated employees in the new roles resulting from technological innovation. This idea seems to be confirmed by the findings of Bartel and Sicherman (1995), who based their research on the data from the National Longitudinal Survey of Youth relating to the industrial sector for the years 1987 to 1992. They observed that the higher an individual's education level, the better were his or her chances of obtaining training within a company, but they particularly noted that technological progress lessened this impact of education on training. This finding also seems to be consistent with the logic of those companies which use further training to give their least-qualified employees the opportunity to work with new technology. As Bartel and Sicherman (1995, p.13) put it, thus it appears that technological change has acted to reduce the gap in the stocks of human capital accumulated by different education groups through formal company training. Lastly, Levin and Rumberger (1989), referring to numerous studies conducted in the United States over the previ-

---

19 Capital and skilled labour are said to be p-complementary if, at a constant production level, a rise in the relative price of capital results in a fall in the relative use of skilled labour.

Unskilled labour is said to be a p-substitute for capital (or skilled labour) if, at a constant production level, a rise in the relative price of capital (or of skilled labour) results in an increase in the relative use of unskilled labour.
ous decade, concluded that some factors (particularly the shift in the balance of employment towards the service sector) would increase global demand for skilled labour, while others, such as the introduction of new state-of-the-art technology, could contribute to deskilling of some jobs at the very least.

In France, Goux and Maurin (1995a) show that the introduction of robots or digitally controlled machinery seems to reduce the need for managerial staff to a greater extent than it reduces demand for white- and blue-collar workers, who are still required to look after the new machinery. In terms of the whole French population, they observe a capital-for-labour substitution effect resulting from technological progress, but this effect does not generate any impetus in favour of educationally qualified labour.20 The more recent findings of Greenan et al. (1999), based on company data, suggest the opposite, indicating a significant degree of correlation between computerisation and higher skill levels; these results compare with those obtained on the basis of American statistics by Bernt et al. (1992) and byAutor et al. (1997). All of these research findings show that the percentage of blue-collar workers in industrial and service companies, as well as of white-collar workers in non-managerial posts in service enterprises, decreases as the companies’ degree of computerisation and their input in terms of research and studies increase (Greenan et al., 1999, p.427).

The possibility of an initial selection bias, whereby companies select from the certificated applicants for each job category those considered most likely to maximise the benefits of the relevant new equipment, has been studied, but such a bias would not alter these findings. Nevertheless, a French study based on data from individuals tends to validate this selection hypothesis. Entorf and Kramatz (1994) concluded that the selective effect of new technology is probably accompanied by the exclusion of part of the workforce. Gollac and Kramatz (1997), however, demonstrate21 that the workers who operate the new technology are protected from the risk of unemployment in the short term.

Even though the generally accepted rule concerning the role of capital as a complement to skilled labour and a substitute for unskilled labour seems to be fairly sound, it is observable that the links between technological progress and types of labour are still the subject of a broad empirical debate. This debate still seems to have a long way to run, because it is very plain in the case in point that the empirical results are difficult to reduce to a common denominator and that they are affected by research methods (Castaño Collado, 1994).

### 3.1.2 Organisation change and demand for skilled labour

Has the transition from a Fordist system of work organisation to a more flexible system altered the nature of companies’ demand for skilled labour? In general terms, technological innovations and the increase in physical and human capital have played a key role in the transformation of the Taylorist system (Milgrom and Robert, 1990; Boyer, 1994). The organisational structure of companies is changing and is being reorganised around teams that are more directly linked to central management.

This transition encourages versatility and decision-making by the workforce, even in the absence of technological innovations (Lindbeck and Snower, 1996). Alongside the appearance of new types of technology, the diversification of demand has also undermined the principles of Taylorism and Fordism (Stankiewicz, 1988).

20 What they say is this: If we except the traditional (but tenuous) links between the accumulation of capital and the number of specialised and managerial posts, the net effect of the new technologies on the development of employment structures seems at the end of the day to have played a less important role in France than the increase in the supply of workers with educational qualifications and the decrease in their relative pay levels (tr. from Goux and Martin, 1995a, p.31).

21 Their research is based on the 1993 survey of working methods and organisation among blue-collar employees.
According to one radical view, the establishment of new production facilities is accompanied by a redefinition, and possibly even demolition, of the boundaries between the constituent tasks of standardised jobs. The new equipment takes care of some of the tasks for which employees with specific know-how have hitherto been required (Freyssinet, 1977). The simplification of jobs is reflected in the downgrading of those who perform them (skilled workers, ledger clerks, etc.) and reduces the opportunities for on-the-job training by eliminating the need to learn.

The Taylorist model is based on the standardisation of jobs. It boils down to a rationalisation of labour, characterised by minimal product diversity, sharp horizontal division of labour (and hence a vertical flow of information) and little flexibility of capital (as well as copious stocks). Tasks are split up, and each individual operation is optimised, which leaves little scope for general or specialised training. In the first half of the twentieth century (especially in the United States), the spread of this type of work organisation enabled companies to bring in workers who had little education or training but who were quickly able to achieve a prescribed level of productivity in the performance of 'scientifically organised' tasks.

Alternative organisational models take account of the contribution that training makes to human behaviour in a more satisfying working environment. Investments in training are again being seen as a more abstract form of rationalisation, relating less directly to productive acts, which in turn are less precisely defined, than to a set of practices and behaviour patterns that are required in order to create and maintain a flexible process and cohesive operational teams.

In some industries (the car, machine-tool and chemical industries) where state-of-the-art technology is in use, neither the market nor the product warrant rationalisation along Taylorist lines. Kern and Schumann (1989) note that the introduction of new technology in German industry has been accompanied by a diversification of job descriptions and the broad use of the skills of a limited number of workers (line operators in the car industry, installation operators in the chemical industry and system managers in the machine-tool industry). Decision-making is devolved to the shop floor in response to a situation in which customised manufacture is becoming essential. Versatility as a principle of work organisation, however, is liable to create a new type of segmentation of the labour market, both within and between companies (Caroli, Greenan and Guellec, 1997).

Some empirical studies in France have identified links between the development of demand for skilled labour and organisational change in companies, although they do emphasise the complexity of the correlation. Greenan and Guellec (1994), in a study based on French industrial firms, highlight the existence of a significant link between work organisation, technology and the skill level of the workforce. Companies in which communication is most intensive are also those with the highest-skilled workforces and those which use the most up-to-date automated equipment. On the basis of data from British and French companies, Caroli and Van Reenen (1998) reach a similar conclusion, identifying a positive correlation between the probability of organisational change within an enterprise and the proportion of certificated employees in that enterprise. A study by Greenan (1996a), however, shows that the effect of change on the demand for skilled labour varies in accordance with the nature of the innovation in question. If it is an organisational innovation, it influences the employment structure by shifting the balance between skilled and unskilled labour, which sometimes results in a reduction in the overall payroll. Companies

---

22 Two surveys were used for this study: the working methods and organisation survey of 1500 manual workers conducted by INSEE (Institut national de la statistique et des Etudes Economiques - National institute for statistics and economic studies) in 1987, and the innovation survey, involving 7,000 enterprises, which INSEE conducted in 1991.

23 We refer here to the survey on organisational change conducted from 1988 to 1993 by the SESSI (Services des statistiques industrielles - Service for Studies on Industrial Strategies and Statistics) with a sample of 822 businesses.
that have opted to move towards a ‘flexible’ form of organisation\(^{24}\) will increase their proportion of skilled labour without increasing the size of their workforce. For blue-collar workers, the organisational change means a wider range of tasks within a single job. Technological innovation, on the other hand, leads to fewer job cuts and is less drastic in its impact on employment than organisational change. Technological innovation does not affect the company’s skill structure. However, such innovation is made by companies with a specific skill structure.

So according to the various studies, significant links do exist between organisational change and the skill level of a company’s workforce, although these links are generally quite difficult to analyse. Like technological progress, organisational change seems to lead to an upgrading of the workforce, but there again empirical findings often depend on the level of observation adopted by the researcher. Moreover, many factors associated to a greater or lesser extent with technological progress or organisational change influence relative demand for unskilled labour. For example, a relative abundance of formally qualified labour combined with rigid real wages will be conducive to the substitution of qualified labour for unqualified labour, even if such a substitution is neither technically nor organisationally essential. This hypothesis has more adherents in Western Europe than in the United States, where human capital has become more expensive as well as being in greater demand than hitherto (Levy and Murname, 1992). It rekindles the question of a possible trade-off between pay inequalities and the risk of unemployment (Cahuc and Zylberberg, 1996; Cahuc et al., 1999) and triggers debates on the influence of the minimum wage and of compulsory employers’ welfare contributions on the cost of unskilled labour.\(^{25}\)

\(^{24}\) In the sense of Aoki’s ‘Model J’.

\(^{25}\) From this perspective, the hypotheses that technological progress destroys unskilled labour and that the relative cost of unskilled labour is too high have influenced the debate on the minimum wage (Dolado et al., 1996; Abowd et al., 1997; CSERC [Conseilsupérieure de l’emploi, des revenus et des coûts - National council for employment, income and costs], 1999) and on the role of compulsory non-wage labour charges (Dreze and Malinvaud, 1994; Sneessens and Shadma-Mehta, 1995). The institutional constraints that affect the cost of labour in general and of unskilled labour in particular have accelerated the substitution of capital for labour and, by transitivity, the substitution of skilled labour for unskilled.

3.2 From labour to skill: what about the role of demand?

In the previous subsection, we showed that demand had an impact on skill levels, which were implicitly assimilated in most of the studies to formal qualifications (or, worse still, with the duration of a person’s formal education). Let us now consider what impact demand could have if the system operated on the basis of practical skills. Have the gradual erosion of Fordist organisation and the influence of new technology on the production process actually changed the nature of the skills that companies demand? If they have, to what extent has the development of the nature of these skills altered the relationship between the education system and the production system?

Understanding the problem of technological progress in terms of skills as defined in Chapter 2 not only enables us to return to a more refined view of labour as a heterogeneous production factor than is presented in the simple dichotomy of skilled and unskilled labour but also lets us take account of the demand for labour without automatically assimilating skill with possession of the ability to perform one specific job or with a person’s level of educational attainment. This change of position to embrace the idea of skill as a vector enables us to appreciate more clearly the impact on the labour market of technological progress, as Bouadballah et al. emphasise: The problem of heterogeneity of labour is not only rooted in educational investment or in the origins of individuals but also within the enterprise itself, where it is a function of the division of labour adopted by the company... Ideally, the definition of the skill level required by an enterprise or an industry could be based on a harmonisation model reflecting the numerous dimensions of the tasks that employ-
es are performing at any given time (Bouabdallah et al., 1999, p.197).

3.2.1 Skills and technological progress

Abandoning the ‘match/mismatch’ approach, let us consider the skills that workers require in order to adapt to technological and organisational changes. Several types of skill can help a worker to adapt to an environment which is developing as a result of significant and relatively frequent technological progress.

Let us consider first of all how a company can be induced to develop these skills in an environment that has been destabilised by factors such as technological progress. In this type of unstable environment, it is in the company’s interests to define a genuine manpower-management strategy that will minimise the cost of adaptation. On the basis of the analytical framework proposed by Léné (1998), two types of strategy are conceivable.

a) The firm may seek to reduce the risk of failure to adapt by trying to anticipate future developments and by broadening the skills of its employees ‘before the event’.

b) The company may develop its employees’ adaptability in situ by working on their response to developments as they happen in order to reduce the amount of time and money required for the adaptation process.

This can be done at four different levels (Léné, 1998):

a) increasing the learning capacity of an employee, for example by reducing in regular stages the discrepancy between the skills required for a post and the skill of the incumbent;

b) providing a series of learning experiences; this succession of experiences increases the productivity of the training process by purposes in the period to come. The firm only has to pay training costs but does not incur any adaptation or opportunity costs, because it entirely foresees the changes. This textbook case, however, does not translate into practice. In this matter, more than in any other, the idea of perfect information is an illusion.

In Scenario 2, the firm is now unable to foresee the exact nature of the required skills and takes precautions to ensure that it is not overtaken by events. The diversification of the employees’ initial skills is one way of reducing the cost of adaptation. As is done with an investment portfolio, the company diversifies its assets to guard against the risk of failure to adapt to changes.

In Scenarios 3, 4, 5 and 6, the nature of the company’s work is such that it cannot anticipate its skill requirements because of unexpected extraneous events, such as the appearance of a new form of technology. Its only possible strategy is to develop the adaptability of the workforce. The quest for flexibility involves the achievement of greater versatility, the ability to respond more rapidly to the promptings of the market or to technological developments.

Which of these two strategies is chosen will depend on the nature of the future change and the extent to which it is foreseeable.

In Scenario 1, the company need only teach its employees the skills that will serve its

</table>

On the basis of a study of the relationship between skill requirements and technology in the United States, Levin and Rumberger (1989) put forward a list of 13 skills that determined an employee's adaptability to new forms of technology and work organisation:

1. initiative and dynamism
2. cooperation
3. teamwork
4. ability and willingness to teach and learn from colleagues
5. evaluation
6. communication (good use of communication channels)
7. reasoning
8. identification and resolution of problems
9. decision-making
10. acquisition and use of information
11. planning and establishment of aims and priorities
12. knowing how to learn (cognitive and emotional qualities)
13. openness to multiculturalism

means of gateway effects ('learning by learning' – Stiglitz [1987]);

c) increasing the transferability of learning outcomes; interdisciplinary skills are the foundation stones of a diversified economy, and complementary learning processes are reflected in shared production savings;

d) encouraging the 'learning company' (Ama-dieu and Cadin, 1996) and the development of cognitive skills, which require diversified activities, cooperation and functions which are not rigidly compartmentalised.

Adaptability is called for here in changing conditions of production and is identifiable, for example, in some of the phenomena we have described, such as functional mobility. It may require more knowledge, and hence more training, in cases where tasks are quite highly differentiated and possess a certain degree of complexity. Nevertheless, in general terms, adaptability tends to imply a more behavioural set of skills, which can be acquired in the course of socialisation processes (Castillo, 1988). It is a matter, in other words, of demonstrating adaptability when the work process itself demands only a very low level of training. The term 'adaptability' therefore relates to the temporary – or generally insecure – nature of employment and describes the non-voluntary performance of a variety of tasks and duties.

It is clear from this context that enlisting the help of the education system in the quest for adaptability is not necessarily the most rational or the commonest strategy for companies to pursue, especially when we consider the time it takes to produce skills.

At a more macroeconomic level, the analysis undertaken by Bishop (1998) on the basis of American data also indicates that the rise in the level of education in general and of initial education in particular does not necessarily meet the needs of a production system in the throes of a radical transformation. Moreover, Levin and Rumberger (1989) state that the level of qualification (i.e. formal qualifications) demanded by the labour market will not alter appreciably in the near future. What is more likely to alter, on the other hand, are

26 On this point, see chapter 4 of the present report.

27 In the view of Levin and Rumberger, these skills should not replace the traditional knowledge and techniques that workers are expected to possess and practise but must supplement them.
the types of qualification that will be needed as new technology and new forms of work organisation demand different types of aptitude (communication and reasoning skills, for instance). In the case of young people's education, the main aim, say Levin and Rumberger, is to provide not so much the level of instruction as the type of education that workers will need. The school system must prepare the future labour force to adapt to change rather than simply teaching them what they would need to work in a postulated stable environment (see Box 2).

In even more general terms, Howel and Wolff (1992) conclude that the emphasis is gradually shifting from motor skills (manual dexterity and physical strength) to cognitive skills (ability to interact with others and management skills).

3.2.2 Skills and organisational changes

The emergence of new models of work organisation is leading to the transformation of people's skill profiles. Numerous studies seem to show that the old definition of needs, based on a uniform body of knowledge, remains necessary but is no longer sufficient. Veltz and Zarifian, for example, consider that the skill profiles of people and organisations, of course, are still defined by reference to specialised knowledge, but they increasingly include the ability to apply that knowledge to specific situations and chains of events. Maintaining equipment, for example, implies the ability to react to breakdowns but also the ability to foresee them... (Veltz and Zarifian, 1993, p.19). The skill profile associated with a particular job is based on an exhaustive description of an employee's duties and hence of the knowledge he or she must be able to apply; this is a legacy of the Fordist model of the division of labour. Educational qualifications were never enough to equip employees for their job, even if that job only comprised standardised tasks, but they did go at least part of the way28 to matching an accumulated body of knowledge with a set of relatively foreseeable and standardised job requirements. Individual skill, on the other hand, depends more on versatility and the ability to respond to new situations.

Let us examine, for example, the organisation of work in the Japanese firm 'Model J' presented by Aoki (1990) and based on versatility and decentralisation of information, which seems to correspond to the 'holistic firm' described by Lindbeck and Snower (1996). The useful skills in companies of this type are the ability to process information, to solve problems and to adapt to the physical, and particularly the human, environment through understanding and cooperation between colleagues. However, although there is a wealth of human capital in Japan, the acquisition of the individual and collective skills on which the success of 'Model J' depends is based on the internal market (Inohara, 1991) and not only on the performance of the education systems.

Technological progress and organisational change, moreover, are very closely bound up in the development of these individual skills. In Europe and the United States, the 1980s saw the emergence of research into the qualities that were required following the introduction of new technology (Adler, 1987) and into changes in systems of work organisation. In this context, skill (Table 3) seems to be a vector, the points in which are responsibility, expertise, interdependence and training. Office work, where computerisation has necessitated an upgrading of skills and job descriptions,29 is a prime example of this phenomenon.

Explicit training, however, is not the natural response to the development of this skill profile, whether in industry or the service sector. Jones and Wood (1984) cite the example of the introduction of new electronic

---

28 Other considerations were involved, particularly for unskilled labour, such as the unique code of conduct and morality on which the Ford Motor Company based its recruitment and wages policies.

29 This upgrading of skills includes attendance at formal educational courses in subjects such as banking systems to supplement on-the-job training, daily practice in teamwork, constant efforts to improve one's own aptitude and to familiarise oneself with new services, etc.
technology in a transmission-systems plant, necessitating the use of tacit specialised knowledge that the machine operators possessed. This knowledge, which they had acquired through experience, enabled the company to effect the transition to the new production methods without having to provide special training.

In France, in a study on manufacturing industry, Greenan (1996b) shows that the links between skills and work organisation will depend primarily on the type of company. The 'flexible' firm, for example, is characterised by development of the skills of all categories of labour, which goes hand in hand with an increase in employees' responsibilities, a reduction in the number of tiers within the hierarchy and the creation of operational teams. In other enterprises, organisational change affects only some of the firm's employees and has little impact on skill development.

For our part, we wish to emphasise the fundamental role of the players involved in a process of change in determining how that change is implemented. In practice, the strategies adopted by the management and by the staff and their representatives determine the pace and intensity of the technological innovation, the way in which it is implemented and its impact. According to Lope, Miguez et Ros (1992, p. 52), the will of the company is the main determinant of the characteristics of technological innovation.

At the end of the day, even within a single enterprise, various forms of skill management will establish themselves (Lope 1994). Company strategies mirror the segmentation of the labour market. For example, the various groups of employees benefit to varying extents from the training provided by companies (Cedefop, 1997b). In general, training programmes connected with technological or organisational innovations and with policies designed to promote worker participation are administered in a selective manner. Training is segmented on the basis of quantity and quality criteria and is targeted at strategic groups of employees within the enterprise while neglecting others. In this respect, it seems appropriate to distinguish between the core of a company and its periphery in the context of human-resources management and to postulate a tendency to polarise the two.

Other factors besides industrial relations influence decisions on technological and organisational innovation. Working conditions and

30 SESSI survey on organisational change from 1988 to 1993, based on a sample of 1496 businesses.
The skills market: dynamics and regulation

the characteristics of the market in which the company operates cannot be ignored.

3.3 Conclusions

Let us say in conclusion that our aim in this chapter has been to show the way in which the problems of general skill levels and individual skills have been related to the development of demand in the labour market. We have sought to discover whether changes in demand really have created a new need in terms of skill levels and, if so, what the nature of that new requirement is, given that a person's skill level, or qualification in the wider sense, is no longer considered as a homogeneous entity that can be assimilated to his or her level of educational attainment.

The findings of the various studies underline the complexity of the link between technological and organisational changes on the one hand and the demand for skills on the other. It is clear that companies will try to avail itself of manpower with the highest possible average level of competence and, above all, with the greatest capacity for rapid adaptation of its skills to a market dominated by increasingly short-term planning.

The most generally accepted conclusion on the impact of innovative processes is that their relationship with skilled labour is complementary; the transition from the perception of skill as qualification for a job to that of skill as general competence redefines the nature of the relationship between the process of innovation and productive capacity.

Skills are not homogeneous, and their usefulness depends on their being practised in real working situations. However, in a context of changing circumstances within the production system, adaptability emerges as a key skill.

On the one hand, adaptability (or the ability to deal effectively with unfamiliar and unexpected situations) is based on the transversality and transferability of skills. On the other hand, it constitutes the basis of their durability in the context of the current innovative processes and of the diversity of forms of human-resources management that these processes entail.

It is far from certain that companies, with the aim of ensuring that highly adaptable individuals are on their payroll, will choose a strategy based entirely — or even principally — on recourse to the formal systems of education and training.

4. The skills market and its regulation

We have briefly outlined the value of the concept of skills as an instrument for analysing the labour market. We have also provided a rapid review of the interaction between the main thrust of economic development and the redefinition of the demand for labour. We have explicitly advanced the hypothesis that the good which is traded in the market is neither labour as an amorphous entity nor a form of qualification that is synonymous with the product of purely explicit training. We have assumed that the traded item is the skill profile of the individual, in other words a set of characteristics which are specific to the individual and which govern his or her productive capacity in a given context.

We shall now try to use this view of things to analyse the procedures by which skills are traded in the marketplace. To that end we shall try to identify the structural reasons which lead to difficulties in matching available skills with required skills. We shall then consider how the market maintains a balance in spite of the discrepancy between the horizons of suppliers and demanders. That will lead us on to propose a new definition of mismatches and a way of analysing the methods used to resolve them. We shall examine more specifically the consequences of our analysis for education and training systems and for their regulation and their ambitions.

4.1 The discrepancy between temporal horizons

The question of qualification or skill requirements elicits different answers, depending on the temporal horizon within which it is asked.
The answer to the question is fundamentally diachronic, as are any mismatches between supply and demand for qualifications. The effect of the changes that are taking place in connection with the globalisation process is that decisions relating to the production, circulation and accumulation of capital are governed by short-term priorities, whereas decisions relating to human and social reproduction demand a long-term, or indeed ultra-long-term, perspective (Vinokur, 1999).

In the relationship between the supply of skills and demand for skills, time plays a wide variety of roles. Time features as the period required for the acquisition of skills and as their useful lifespan; it is used to define the horizons of forward planning and hence as a unit of economic measurement. If we are to define these roles more precisely, it would seem useful to distinguish between the two groups of players (individuals and enterprises) in order to highlight the incompatibility of the time frames in which their respective economic calculations are performed.

4.1.1 Formal education and the origin of skills: the temporal dimension of supply

So that we can more clearly understand the temporal dimension of supply and of the consumption of skills, we must first identify the various aspects of a skill in terms of the most probable time and place of acquisition, its place in the structure of all individual skills and its lifespan.

Skills are not isotropic, nor do they endure for the same length of time or become obsolete simultaneously. But categorising skills in isolation, outside the context of their application, is a difficult task and demands a formidably rigorous approach. At the same time, it is obvious that skills do not all possess the same quality or the same productive and social value, either for individuals who are developing their 'human capital' or for companies when they recruit new staff.

A number of skills are accorded the status of 'prerequisites' and are of an 'irreversible' character; this is the case, for example, with the skills that relate to communication or access to information; other skills, however, are more easily 'renewable', subject to certain conditions. We should emphasise the 'long life' of the first set of skills, which derives from the fact that they form a framework for subsequent learning processes and/or from their transferability (a prime asset in a rapidly changing world), as well as the broad range of contexts to which they are applicable.

In the context of numerous efforts to distinguish these skills from other skills of a cyclical nature, they have been given names such as 'key skills', 'core competences', 'transverse skills' and more besides.

So it is possible to distinguish, albeit rather schematically, 'framework' skills (which normally have a long lifespan), 'transverse' skills (which can be used in a wide range of situations) and 'specific/cyclical' skills. A further breakdown of these skills into personal, social and productive uses is difficult and probably serves no purpose.

Most training activities impart each type of skill, but the various forms of training and the institutions which provide them are of a specialised character and are essentially designed to create skills of a specific type; schools, for example, aim – or certainly should aim – to impart 'framework' and 'transverse' skills, whereas institutions which provide further training endeavour primarily to teach 'specific/cyclical' skills. In-house company training, for its part, imparts skills connected with teamwork, the use of specific technology and company organisation.

4.1.1.1 Skills and the individual's horizon

Time has two functions in relation to the skills of an individual: the first is the period spent learning a skill, which usually coincides with part of the initial education process or further training, be it implicit or explicit, in-service or outside the work context, and the second is the period spent using one's acquired skills.

The time spent acquiring skills comprises the period spent in general education and initial
vocational training and the time devoted to training during one's working life. Since individuals sometimes work during their initial education (cf. Béduwé et al., 1999; Planas 1999), a clearer definition of terms would be desirable, and perhaps a distinction ought also to be made between framework training courses, as in the initial education process, and adaptation courses, advanced training and occupational retraining, which build on the original framework.

The time taken to produce qualifications is tending to increase. First of all, initial education is becoming longer, either because the period of compulsory education is being extended by law or because continuation in education beyond the minimum school-leaving age is becoming increasingly important in practice. In addition, the time taken to produce the skills connected with framework training is also increasing as a consequence of the strategic choices made by individuals. Initial education, moreover, is irreversible for at least two reasons. On the one hand, such a long period of full-time education would be impossible to repeat in a person's lifetime. On the other hand, we are only young once, and the customary time for initial education is when individuals are at their most malleable, both mentally and physically, which reinforces the irreversibility of the initial education process.

This extension, be it compulsory or otherwise, of the initial education period helps to establish its irreversibility; this is not to say that it is less adjustable but rather that it is firmer and more adaptable and opens more doors to lifelong learning (Cedefop, 1997b; Planas, 1990 and 1996). When young people receive their initial education, they naturally have long-term strategies, since they are aware that investments in this education process form the basis of their future social and professional status (A. and P. D'Iribarne, 1993), and/or of their prospects of obtaining further training. The maximum time horizon to which these young people's educational decisions relate will necessarily coincide with the envisaged duration of their active lives.

The time frame within which young people expect - and the society in which they live expects them - to reap the benefits of their initial education and, in more general terms, of all their acquired skills should be the duration of their active lives, in other words the long term. This is a very different perspective to the short-term ad hoc nature of a demand for skills in response to a temporary shortage.

The contradiction between these two temporal perspectives emerges clearly from a comparison between individuals and enterprises. Individuals, possessing skills from which they wish to derive benefit over a long period of time, are subject to antithetical forces: on the one hand the long duration of their active lives increases the length of time they spend in formal education, while on the other hand the pace of economic change implies a shorter lifespan for the skills they acquire. Like any other product, it might be thought that a skill has a fixed life cycle - shorter for some skills, longer for others - which has to be respected. This confronts the individual with a problem regarding the obsolescence and transferability of his or her acquired skills. In their economic calculations, individuals cannot be certain how long their skills will serve them and must take that uncertainty into account if they are to recoup their investment.

Moreover, the individual calculation will depend on the various institutions which regulate the supply of skills in the labour market. The school system, but families, associations and companies too, play an important part in the configuration of young people's initial education. The experience provided by families and the social environment, as well as work performed as a student, just like the knowledge imparted by the education system, endow young people with a basic set of skills. Empirical studies in France and Spain, for example, show that young people who have had jobs during their time at school and/or university are at an advantage when they seek work after completing their education (Planas, 1990; Béduwé and Cahuzac, 1997; Béduwé et al., 1999). The skills acquired during these informal educational experiences often serve no direct occupational purpose nor
have they always been intentionally acquired, but they constitute an essential part of the key or transverse skills, the productive value of which is rising. The time taken to acquire these skills is often lengthy, and their profile is not always explicit, which makes them difficult for conventional information systems to pinpoint.

To put it schematically, three types of institution can influence the production of skills in the countries of the European Union:

a) educational institutions from all the systems of initial education and initial vocational training;
b) institutions governing explicit further training; and,
c) institutions influencing the acquisition of social and occupational skills outside the education system.

These three categories of player have reached very different levels of institutionalisation and recognition, differences which exceed even the disparities between them in terms of market value. In the various countries of the EU, the rationales behind these institutional categories are extremely diverse (Vaniscotte, 1996; Aventur and Môbus, 1996), and their practice differs widely, depending on the degree of involvement and coordination of government, employers and labour within such institutions (Soskice and Hancke, 1997). Moreover, the time frames within which the aforementioned skills are produced, if not totally variable, differ widely in accordance with the respective national philosophies underlying each of the institutions. The individual, when calculating, must therefore take account of these disparate time frames within which skills are produced.

31 This type of skill can be likened to the social skill postulated by Dutrenit (1997), which relates to the ability to perform the activities of everyday life in all spheres with a minimum of correction from others and with a certain sense of responsibility and initiative.

32 It is, however, possible to associate certain types of less commonplace careers with certain forms of recruitment on the part of employers (Stoeffler-Kern and Tchibozo, 1999)

4.1.1.2 The global supply of skills

The previous point showed the temporal horizons that govern the supply of skills at the individual level. We must now ask how long it would take to renew the global supply of skills.

Two major processes can influence this renewal.

1. The first is linked to the demographic renewal of the generation leaving the system of initial education. The cohort embarking on its first year in the education system will not necessarily receive the same training as the one entering its second year. It is this phenomenon which has prompted observers to describe the active population as a stack of cohorts that differ not only in terms of numbers (possibly) but also – and this is especially true of the past 30 to 40 years – in terms of the length, nature and content of the initial and basic training they receive (EDEX, 1999). These changes in the length and specialisation of training may be interpreted as responses to the demands of the market or as relatively autonomous processes which depend on the relationship between the demand of individual and families for training on the one hand and public education policy on the other. In the first of these processes, changes in the overall supply of skills are primarily linked to the pace of the changes that affect two consecutive cohorts as well as to the length of the training cycle and its degree of specialisation. For example, we might conclude that it is possible to alter the structure of the output of engineers, in other words to adjust the balance between the various specialisations, within two or three years, because a substantial core of the engineering curriculum is common to all specialisations. Conversely, in many countries medical students begin to specialise at quite an early stage, which makes response times very long; the output of physicians could not be altered within two or three years, even if it were possible to alter the distribution of matriculated

33 We refer here to the WP1 phase of the EDEX project (for the website see footnote 40).
students among the various medical specialisations within that time frame. About 3% of the total supply of labour is renewed every year, which limits the scope for adaptation. Furthermore, the average size of cohort coming out of the education system is diminishing from one generation to the next because of the falling birth rate.

Another question that arises is that of the self-regulation of this global supply of skills, irrespective of the capacity of the initial-training system. Do the various market operators, and particularly young people themselves, correctly anticipate the development of the demand for skills, particularly by taking due account of the time required for the production of skills? Working within this framework, several empirical researchers have suggested a number of ways to create a model that would indicate whether individuals' training choices depend on their present situation in the labour market or on anticipation of their future situation. In a 'cobweb' type of model, it is assumed that students deduce the future labour-market situation from the present situation, which creates cycles of endogenous fluctuations and sometimes totally chaotic developments. The main exponent of this hypothesis was Freeman (1976), who tested it on young American engineers. An alternative hypothesis, developed primarily by Zarkin (1983) and Siow (1984), assumes that individuals in the labour market have rational expectations on the basis of the available information. In other words, students are able to anticipate perfectly any changes in the way in which the demand for skills is developing. Borghans, De Grip and Heike (1996) tested these two hypotheses on data relating to Dutch students and seemed to conclude that the former was slightly superior to the latter; most of their findings would indicate that the cobweb model had performed marginally better. Finally, the hypothesis of rational expectations on the part of students seems to have been largely invalidated by the Dutch research - as indeed it had been in Belgium too (De Meulemeester, 1992 and 1995).

2. The second process whereby the global supply of skills can be adjusted is that of further training. In this case, the pace of change depends on the nature of the desired modification and on the way in which it fits into working practices. It is likely, for example, that changes to certain characteristics of word-processing software would be easily assimilated by users. But the bulk of the forces that determine how quickly skill profiles are adapted by means of further training depend on interaction between the relevant players - companies, individuals and public authorities. It is clear that a society in which companies' management of human resources is based on a long-term perspective and in which individuals are able to keep building upon the framework of initial education they have all received will be better able to alter the stock of skills held by the entire active population.

In our societies, the initial education of the population - and hence, in economic terms, that of the active population - is irreversible in the sense that an inadequate basic framework of initial education tends to exclude individuals from jobs as well as from subsequent training opportunities (Steedman, 1999), since initial education forms the basis of further training. Within the system of initial education system itself, although the practice of re-entering the education system as well as changes of course and of university have become a prominent feature of the development of higher education in many countries of the EU, the scope for acquiring knowledge, and hence skills, is not isotropic. It would be easier, for example, for a graduate in chemical engineering to supplement his or her qualifications by doing a year of economics or business management than the reverse.

When we speak of the time taken to produce qualifications and skills, we must also distin-
guish between the lengthy period required for basic framework-type training courses and for the experience that shapes a person's life history and human capital on the one hand and the short periods required for specialised training of a cyclical nature on the other. Thus the strategies used to produce qualifications and skills are necessarily the result of a combination of many instruments that are available in the various education and training systems.

In practice, one of the main aspects of the change that has taken place in the education and training systems of the industrialised countries is that of the concurrent use of time for basic and specialised training. Our education systems are divided into a minimum of four subsystems, which are institutionalised to a greater or lesser degree from one country to another: there are the school, college and university system, the system for the occupational integration or reintegration of young people or adults who are unemployed or at risk (transitional measures, youth schemes, sandwich courses, reintegration schemes for women, etc.), the system of lifelong learning and the system based on experience, which is tending to become institutionalised as mechanisms are established for the recognition of informally acquired skills. Current research shows that these systems are gradually becoming more complementary than mutually exclusive (Planas, 1996; Bjørnávold, 1997b; Steedman, 1999), which suggests that the development of skill is governed by the principle of the polarisation of training paths on the basis of the initial education process.

4.1.2 Enterprises and the need for skills: 'customer' requirements

In the customer-supplier model that was introduced in the introduction to this report, the enterprise is the main user of the qualification – in terms of essential knowledge and abilities – produced by the education system. It is one of the natural outlets for the products of the education system.

If we think in terms of skills, as we have been doing in this chapter, the analysis becomes more complex, because the enterprise is both a consumer and a producer of skills, and it is impossible to draw a rigid line between these two roles, since some specific skills can be acquired concurrently from the education and production systems.

We shall now examine the temporal dimension of the need for skills, beginning with the needs of the company then moving on to the wider context.

4.1.2.1 Skill provision at the company level

The time constraints on a company will be determined by two groups of variables.

First of all, they will depend on the company's strategic horizon (Galtier, 1996). If the company intends to continue its present activity over a very long period of time, its horizon is distant, and its main problem is the uncertainty that inevitably accompanies any project. If, on the other hand, the company is operating within a shorter time frame, it will intend to alter the use of its capital in the relatively near future. It is therefore highly probable that a change will also occur in its demand for labour, in other words in the set of skills it requires in order to adapt to the new use of its capital.

The time constraints will also depend on the 'staff dimension' that obtains within the enterprise. By staff dimension, we mean all the factors which make up the company's human-resources policy and which determine whether the company has an internal market, a training policy, etc., and, if so, how these are structured.

The combination of the two groups of variables determine company policy. It is obvious that a company working within a short time frame will try to obtain the skills it needs from the market without any soul-searching about the future use of those skills. A company that operates within a lengthy time frame, on the other hand, as well as securing the skills it needs for its short-term goals, may also try to create a bank of skills for its future needs. It will tend to develop a training policy and will have regard to the potential of individuals
when it recruits new staff. Nevertheless, even if a company has long-term goals, it may not have a long-term staffing policy and may be content to take what it needs from the market at any given time. The state of the labour market is plainly of great importance in this respect.

It is essential to bear in mind that the industrial-relations model which governed the economy until the eighties was characterised by a high degree of institutionalisation and state intervention and was based on a system of work organisation with a marked division of labour and standardisation of tasks and that it based the use of labour on the concept of skill levels (skilled/semi-skilled/unskilled). Since the eighties and particularly in the course of the nineties, competition between companies has become increasingly global in nature, and uncertainty has beset productive organisations; the labour force is becoming segmented and diversified, and the trade unions are being weakened. Nation states are losing a certain amount of their power to control the national economy. The authority of the traditional collective mechanisms to regulate working conditions and terms of employment is gradually being eroded (Miguelez and Prieto, 1999). Personnel administration, in short, is turning into 'human-resource management'.

The tradition of industrial relations has therefore been jeopardised by companies’ growing preoccupation with ‘management’. In the English-speaking world, at the cutting edge of business-management theory, concepts such as ‘human-resource management’ (Storey, 1995), with its inherent idea of a workforce committed to the goals of the company, are gradually replacing conventional theories of industrial relations and their view of a labour market governed by partisan interests and conflicts (Kölher, 1999). The tidal wave of human-resource management is engulfing the structure of industrial relations, breaking it down into a variety of individual negotiating mechanisms in the realms of training, career development and even pay.

For more than a decade, the structure of productive organisations and the system of work organisation have been undergoing profound transformations. In particular, the rigidity of the Taylorist model of scientific management has been challenged at the same time as flexible decentralised organisational structures are being developed (Martin, 1999). The instability and uncertainty of the markets and the fluctuations in demand call for new and more dynamic organisation and production methods and hence new and more flexible methods of manpower management.

But the new forms of industrial relations, and especially the aforementioned individualisation of companies’ relations with their staff, are very important developments. Companies are, of necessity, developing their systems of human-resource management to take account of the temporal dimension. However, the procedures they adopt for that purpose vary considerably, especially because of the need for greater flexibility in the use of labour, involving recourse to both the internal and the external labour markets. As the Cedefop report on current vocational education and training research in Europe shows (Cedefop, 1998a, Part Two, Chapter 2), the time frame within which companies operate, in conjunction with the timescales governing the supply and demand of labour, are closely linked to the flexibility of their human resources, which derives in turn from their manpower-management policy.

This way of managing human resources, however, may jeopardise the functioning of a company’s internal labour market, depending on the skills that the company requires. If the skill level is low and the desired skills are commonplace, according to Eliasson and Vikersjö (1997), a large firm will often do better to recruit the skills it seeks in the local labour market than to provide in-house training for its employees. Conversely, where the skill level is high and the skills are relatively rare, the company can and must establish an internal system to develop those skills.

---

36 See chapter 2 (sections 2.1 and 2.3) on this point.

37 See also Part Three of the present report.
In the domain of recruitment, and hence external flexibility, companies faced with new skill requirements have changed their recruitment procedures with the aid of new methods for the identification of skills\(^3\)(Alpin and Shackleton, 1997). As levels of educational attainment continue to rise, employers seem to be trying harder to find evidence of personal qualities that are difficult to evaluate, more or less irrespective of degrees, diplomas or any other formal certification the individual may possess. Alpin and Shackleton (1997), referring to research conducted by Bartram (1995), specify that these selection methods will depend primarily on the size of the company, with small and medium-sized businesses attaching greater importance to personal qualities such as integrity, honesty and interest in the work of the company. Eymard-Duvernay and Marchal (1997), incidentally, conclude their work on recruitment by stressing the need to use a combination of methods for selecting staff and identifying skills. This, they say, is the only way to inject dynamism into the workings of the labour market. Otherwise, the aim of complete transparency is illusory, and even if it could be achieved, it would be harmful (Eymard-Duvernay and Marchal, 1997, p.226).

4.1.2.2 The global demand for skills

The development of competition in the product market, due for example to the opening of international trade or to technological and organisational changes,\(^3\) has direct repercussions on demand for skills in the labour market. One of the problems for the production system is that it has to try to adapt this constantly changing demand for skills to the supply of labour that is available in the market. Obviously, these adjustment problems may be fairly minimal on a macroeconomic scale, even if particular companies or industries do experience temporary skill shortages. Any attempt to regulate this demand for skills would involve reducing the time taken for the specific demand to materialise and increasing the foreseeability of that demand.

The growth of global demand is often regarded as inevitable; it can serve to enhance the efficiency of the production system, provided that it can take place without delay. For that reason, workers have to adapt, and the identification of a mismatch, or the fear that a mismatch will emerge, will then result in action on the supply side. It would not be idle to explore this postulate, because the demand for skills is not rigidly dictated by technology; it is the product of numerous choices on the part of organisations and even institutions, and the dictates of technology are sometimes a secondary consideration when those choices are made.

4.1.3 To what extent does supply determine demand?

The problem of skill requirements cannot be presented in terms of mere adaptation to the needs of the moment but rather in terms of foresighted management of human resources. This being the case, we can then start to consider the supply situation as a challenge to companies, prompting them to respond by making more and better use of the available skills. As Bruno puts it when referring to mismatches between supply and demand, In most industrialised countries there is a perceptible sort of sequential order whereby cognitive advances made by the company executives lead to technological and organisational changes, which also require greater knowledge on the part of workers on the shop floor, while cultural development at grass-roots level within the company creates new opportunities which directors and middle management perceive and subsequently exploit. Consequently, the process is in permanent imbalance, which makes the occurrence of mismatches easy to explain, impossible to avoid and, we have to say, desirable... (Bruno, 1998, p.3). At the macroeconomic level, empirical evidence shows that the distribution of formal qualifications within the labour market tends to follow what has been termed the 'supply effect' (Mallet et al., 1997). The results of a macrostatistical analysis conducted in six countries of the EU

---

\(^{3}\) Such as the production within companies of 'skill profiles' and 'skill frameworks' (Alpin and Shackleton, 1997, p.13).

\(^{3}\) We referred to this point in chapter 3.
(France, Germany, Italy, the Netherlands, Spain and the UK) confirm that the availability of young people with a higher level of education and training, generation after generation, who enter the working population leads to changes in the structure of qualifications within occupational categories by means of a simple knock-on effect. Everything would seem to indicate that the various occupations take from the labour market what they find and not what they require in terms of their specific needs. According to these findings, the development of certification levels in each occupation can be explained by the general growth in the number of certificates rather than by particular recruitment patterns within each occupation. This development could have been expected on the basis of factors such as an increase in the numbers in an occupation or the speed with which the skill requirements for the various occupations are changing (Cedefop, 1997a).

The overall result of this analysis is somewhat troubling in relation to the general ideas on which education policies are founded. The widespread belief that the development of initial education responds to changes in company demand, or at least that each occupation harnesses this development in accordance with its own internal dynamics, is not really compatible with the homogeneity observed in the distribution of qualified individuals throughout all occupations.

In the light of these findings, it is plausible to consider that the rising level of qualification is based more on a social demand for exogenous training than on the requirements of companies. This is not to say that these extraneously generated dynamics have no effects on job content and on company behaviour, as Bruno indicated (see above).40

40 In the framework of the Targeted Socio-Economic Research (TSER) programme administered by Directorate-General Research of the European Commission, a research project on educational expansion and the labour market (EDEX) is currently being conducted with a view to examining these findings in greater detail (website: http://193.49.48.153/edex/)

4.2 From modular skills to modified requirements

In a context in which the demand for qualifications is undergoing radical change, mainly as a result of technological and organisational changes, the development of the nature and content of jobs compels the production system to alter its skill requirements at very short notice, often on a timescale far removed from the one that has traditionally governed the production of skills and the associated qualifications. At the same time, as Europeans spend an increasing number of years in formal education against a backdrop of high unemployment, the education system is producing an ever-growing number of qualifications and qualified people. As they 'multiply', however, diplomas seem to be less and less able to provide all the information that is required for the recruitment and promotion processes.

Accordingly, we must investigate the way in which adjustments are made in the skills market. Several questions arise. Are there mismatches between supply and demand, and, if so, what kind of mismatches are they? How are adjustments then made? What role can the education system play in these adjustments? Before answering these questions, let us begin by returning to the constraints that affect any attempt to adjust the balance between the supply of skills and the demand for skills.

4.2.1 Adjustment and associated constraints

Notwithstanding the problem of the temporal dimension, the mechanisms for adjusting the balance between supply and demand in respect of qualifications or, to be more precise, in respect of skills do not work instantaneously and are based on various different principles. In this subsection, we shall present the three main constraints to which these mechanisms are subject:

a) the non-economic functions of the education and training systems;

b) the amount of information available in the skills market; and,
c) the institutions that regulate the supply of and demand for skills.

4.2.1.1 The multifunctional nature of the education system

The first category of constraint is deeply ingrained in the multifunctional nature of the education system and, more generally, of all explicit education and training systems. The value of a diploma exceeds the productive value assigned to it by the market. We must avoid an over-simplistic view of the education system and its role, because the general demand for education and training is relatively independent of the skill requirements of the production system. The demand for formal education derives from the role of formal qualifications in social and professional life. The growth in the demand for education and training is not purely associated with job prospects, expected productivity gains and the material rewards that individuals hope to reap from their qualifications. Carnoy (1982) said that, even in an economy that proved incapable of absorbing an increase in the number of certificated people and required some of them to accept jobs hitherto occupied by employees with less training, the incentives that had prompted the rise in education levels would continue to operate. After almost 20 years, these words still ring true.

P. and A. D’Iribarne (1993 and 1999) underline the importance of the symbolic role of education in France. It is not possible, they say, to understand the relationship between the education system and the production system in France while neglecting the symbolic aspect of education. And that presupposes an understanding of the role played in modern France by the distinction between that which is more noble and that which is less so. [...] In contemporary French society, a person’s ‘scholastic nobility’, acquired by virtue of his path through the education system, will determine, and determine for the rest of his days, his degree of personal nobility. (P. and A. D’Iribarne, 1999, p.28). What is true of France is also true, albeit in different ways, of the countries of ‘Old Europe’. In order to comprehend the relationship between the systems of education and production, it is necessary to understand the mechanisms, which are probably different in every country, whereby each country uses its education system to confer various grades of ‘nobility’, which are based today on conception rather than execution and on independence and responsibility rather than service to others.

The question of the relationship between training and jobs, of the correspondence between training levels and job status, is a similar sort of problem. The education system produces skills but also produces a social hierarchy; as far as the elite groups within that hierarchy are concerned, the system confers its highest status on people in careers with a very broad professional function (A. and P. D’Iribarne, 1993). Nevertheless, the general rise in education levels poses the problem of reconciling a status conferred by the education system with a production system that remains more hierarchical than the education system. This, according to Carnoy and Levin (1985), is a manifestation of the conflict between the dynamics of capitalism and those of the democratic state.

4.2.1.2 The information value of skill

The rise in the education levels of the active population is inevitably transforming the role of training and certification as signals. In fact, the profusion of paper qualifications diminishes their market value, which is the main hypothesis of the credentialist theories, and affects their classification value. The hierarchy established by the education system tends to become ever less clearly reflected in the employment hierarchy. The grading process initiated by the educational institutions when they award diplomas only comes to fruition in the pursuit of an occupation, when the employee’s acquired skills assume their full significance. Differentiating mechanisms supplement or alter the hierarchical model drafted by the education system when it awarded its diplomas.

Although educational qualifications are part of the hierarchical structure that is erected within the production system, they are only the foundation stones. The proliferation of diplomas modifies the information they con-
The skills market: dynamics and regulation

The abundance of signals kills the signal and shrouds the array of qualifications in the marketplace and the skills they represent. If the number of years of study increases and if there is little differentiation in the training offered to young people, the information value of the diploma will diminish, except in the case of its absence, where the negative signal will be amplified. The education system is therefore proving less and less able to supply all the information that is required for the recruitment and promotion processes. Formally qualified recruits possess productivity potential which the productive organisations must turn to account. Responsibility for training lies with individuals, whereas the power to codify it in terms of skills often rests with employers. Recognition of new codifications of skills poses numerous problems, as we saw in Chapter 2, with regard to both the measurement of each skill and acceptance of the codifications by the various players in the labour market.

4.2.1.3 The institutions

Besides the bodies within the education system, various other institutions regulate the skills market on a more or less formal basis. From the family to careers-guidance officers, from social networks to the state, which often sets a minimum price for skills, from small businesses to entire industries, from the trade unions to the employers’ organisations, a host of institutions are involved to a greater or lesser extent in the production and use of skills.

The role of these institutions in the segmentation of the labour markets in Europe in recent decades has been of particular significance. The stability of the internal and occupational labour markets in each country has had a great impact on the regulation of the skills market, even though that stability sometimes appears to be under threat (Géhin and Méhaut, 1993; Moncel, 1996; Récio, 1999). The segmentation process has affected not only the funding of skill production but also the transferability of skills and therefore, ultimately, their consumption by institutionalising the rules governing their acquisition. The acquisition of skills in less and less regulated, less and less institutionalised markets, necessarily undermines the existing forms of regulation, especially in relation to new entrants to the labour market. This development has to be taken into account if we want to understand the adjustment mechanisms that will apply to the skills market of the future.

4.2.2 Towards a new definition of mismatches

In an analysis in terms of skills such as we have presented here, a mismatch at any given moment in time is not a problem per se. If we apply strictly commercial standards, the duration and cost of the adjustment process are the only significant factors. In other words, the mismatch problem that is inherent, for example, in an underskilled economy generates at least two types of cost: the direct cost of adapting to the new skill requirement (the cost of training, for instance) and the indirect costs associated with the length of the transitional period (opportunity costs resulting from a delayed response).

At the macroeconomic level, let us consider two types of imbalance between supply and demand with regard to skills and two time frames – the short term and the long term – corresponding to cyclical and structural imbalances respectively.

In his analysis of financial markets in the General Theory of Employment, Interest and Money, Keynes ranks expectations on the basis of the time frame within which the enterprise is able to judge whether they have been fulfilled. Keynes thus distinguishes between short-term expectations, corresponding to...
production and employment decisions that can quickly be reversed, and long-term expectations, involving investment decisions that are often irreversible, with regard to largely or entirely unforeseeable events with macroeconomic repercussions. Whereas short-term expectations are usually fulfilled, long-term expectations pose a number of problems. As Faveraux notes (1986, p.253), the Keynesian analysis may be adapted to the commodity and service markets, even though these markets have only treated short-term expectations as extraneous variables and are only concerned with companies' long-term expectations in so far as they affect the workings of the financial markets. One might also try to transpose this analysis to the skills market by distinguishing short-term cyclical imbalances from long-term structural disequilibrium. Short term imbalances will be due to exogenous shocks which affect the supply of skills or the demand for skills but have no irreversible macroeconomic impact. Long-term imbalances of a more structural nature will relate to more irreversible strategic decisions taken in a context of profound uncertainty,44 in which the various players' decisions could have chaotic results.

At the same time, these two imbalances, the structural and the cyclical, might be reflected in a jobs squeeze and a surfeit of skills or in a skill shortage. Quite clearly, these are not alternatives, and there could be an intermediary situation in which an oversupply of some skills coexisted with a shortage of others. For the sake of simplicity, however, we shall hypothesise that one type of imbalance would be strongly predominant at any given time.

The first situation will occur when the supply of skills is increased, as a result of education policies, for instance, while demand remains more or less constant or develops independently of supply variations. The second situation will tend to occur when demand for skills grows because of technical progress or organisational changes, while the supply of skills remains constant or increases by a far smaller amount than demand.

The four possible types of mismatch are presented in Table 4:

The first row of Table 4 indicates the type of skills shortage that some European reports have envisaged (European Commission, 1992). This scenario has posed challenges and elicited responses that have often been encountered over the past four or five decades in the various countries of the EU. This scenario originally provided the justification for the consensus which led to the rise in education levels in Europe in the course of these decades and for the development of both national and Community vocational-training policies supported by the European Social Fund.

The second row, on the other hand, relates to situations in which there is a glt of skills,
The skills market: dynamics and regulation

and particularly of formal qualifications, within the economy. This type of mismatch, which generally arises from an overabundance of skilled labour, has increasingly profound adverse effects on the labour market. On the one hand, educationally qualified people, especially those in the youngest age groups, find themselves downgraded in relation to the initial education they have received and/or consider themselves overqualified for the work they are expected to perform. At the same time, the glut of certificated manpower restricts or ruins the employment and training prospects of individuals with insufficient education. Nor does further training, be it formal or informal (i.e. on-the-job training), represent a second chance in most cases (Planas, 1996), because it is generally provided on a selective basis to those with a certain level of basic theoretical knowledge.

Let us now consider the characteristics of these imbalances and the options for adjusting training systems in the light of the constraints presented above. Needless to say, we shall only be able to examine some of the adjustment options here. Training systems are not the only solution to mismatch problems; it is perfectly possible to rectify a shortage or surplus of skills by acting on production technology. However, we shall consider such actions here as exogenous factors.

**Case A: cyclical imbalance and skill shortage**

This first case relates primarily to the active population within the labour market. The company chooses from the market the skills which it lacks and which will minimise its adjustment costs. It will select the range of skills that is closest to the vector it seeks. It may choose these skills from its internal labour market, redeploying its existing human capital or possibly by offering further training. It can also recruit from the external market, engaging young people with formal qualifications or more experienced workers who are unemployed or are enrolled with a temporary-employment agency. Lastly, it can lure employees away from other companies. On a macroeconomic scale, this is liable to increase the price of skill without resolving the shortage. Other options exist, such as reorganising the workforce or subcontracting, which would make a third party responsible for finding the necessary skill.

Any structural adjustments to the system of initial education, on the other hand, are liable to create irreversible situations at quite considerable expense without meeting the short-term needs. Adjustment times would be lengthy, and several cohorts would emerge from the education system to find that their course choices had been based on false assumptions and were now irreversible. The idea is fairly simple and universally recognised: to meet an immediate need for computer engineers (for the millennium bug, for example), it is not enough to create one or more new engineering courses. For one thing, it will take quite a long time to establish and run a new training course, and the chances that it will meet the short-term need of the production system may be reduced by intervening variations in the needs of the system, possibly stemming from technological or organisational changes. For another thing, the vast majority of the engineers coming out of the education system will be inexperienced and are therefore unlikely to be fully operational within a short period of time. Quite clearly there are other options besides this rather extreme example; further training, for instance, would serve to accelerate the adjustment process. Such measures, however, must be temporary, lest they create structural imbalances.

The speed of adjustment depends on flexibility of supply. Any constraint that limits this

---

45 With regard to these two perspectives, reference may be made in particular to the studies by Alba-Ramirez (1993) and by Garcia-Serrano and Malo-Ocaña (1995) in Spain or by Forgeot and Gautier (1997) in France.

46 This level of knowledge is necessary in order to transcend the narrow know-how connected with work that can often be learned on the job with the aid of informal instruction from an experienced worker. Without this theoretical knowledge, it is difficult to imagine how recognised skills can be any more than a set of memorised instructions for specific operations (Marsden, 1994)
flexibility will delay the adjustment process, even if we assume perfect information on the development of the skill requirement. That is why the system of initial education, because of its multifunctional nature, its long-term perspective and its reaction times, cannot easily deliver a precise short-term response to labour shortages. This does not in any way imply that that the education system is powerless or ineffective in the face of specific labour shortages. On the contrary, it affords the best protection against a skill bottleneck by offering a high level of general training which serves to reduce the time and expense involved in the production of essential skills. 47

But every nation has developed further-training institutions which, in certain conditions, have furnished proof of their ability to resolve this type of imbalance. They offer the advantage of responding more flexibly to a sudden demand for specific skills while shortening adjustment times. Further training, however, remains highly dependent on the level of initial education that employees have previously attained.

Case B: Structural imbalance and skill shortage

On the basis of the plausible but unverifiable hypothesis that the development of our societies and production systems will generate demand for higher skill levels in the long term, we can foresee two possible types of skill shortage.

The first is that a skill might generally be in short supply because of job growth within the economy. This is currently the case in France and Spain, for example, with regard to foreign-language and computer skills. It is conceivable that these two skills will become a structural necessity for a great number of jobs in the modern economy. In this situation the education system has to intervene by offering courses which will enable people to acquire at least some degree of proficiency in these skills.

The second possibility relates to a shortage of certain skills that have to be adapted to specific individual profiles. The solution for the education system in this case is to create initial or further training courses as a means of adjusting the training structure to take account of this need.

In both these situations, the education system can pursue either of two compatible strategies. The first is to opt for general training, thereby making the new skill easily transferable to people in all occupations. That will lay the foundations for more learning, enabling young people to adapt to the growing demand for skills. But it will not make them instantly competitive in the labour market. The second strategy is to make 'ready-to-use' manpower available in the labour market by providing instruction in the skills that trainees need in order to find jobs on completing their education. In the medium term, however, this option poses the problem of obsolescence and redeployability of the skills in question.

The response that turns out to be most effective in this case is a combination of specialised training (as brief and inexpensive as possible) built on a foundation of previously acquired skills – and hence based on knowledge of the individual skill profiles of the active population in the labour market, however their skills may have been acquired. This entails linking the various training systems and facilities (co-production).

Case C: Cyclical imbalance and a glut of skills

A cyclical imbalance corresponding to a sharp variation in supply may result from deficiencies in the market and in the various institutions which regulate the supply of and demand for skills.

This type of short-term imbalance does not necessarily create inefficiency within the production system, which is able to adapt to supply growth (Bruno, 1998). It may even stimulate technological and organisational changes within enterprises. However, if it persists, it is conceivable that the phenomena of frustrated ambitions among overqualified young

47 This argument reinforces the 'learning by learning' theory as expounded by Stiglitz (1987).
people and career bottlenecks for experienced employees will begin to outweigh the benefits of such an imbalance.

That, in fact, will depend on the precise characteristics of the imbalance. We shall explore two possibilities:

1. The new cohorts emerging from the education system may be overqualified — in other words overeducated — in relation to the specifications listed in the job advertisement. This implies that some of the skills acquired in the education system are liable to go unused and that the price of these surplus skills will fall, all other things being equal. This will translate, for example, into a reduction in the financial benefits of education for new entrants to the labour market or an increase in graduate unemployment, which could lead to a reduction in the initial investment in human capital by subsequent generations. The evidence suggests, however, that no such mechanism is at work (Carnoy, 1982). Besides the explanations in terms of opportunity costs, young people's current educational strategy can be justified by the fact that investment in general training enables them to preserve or improve their relative position within the labour market, even if their job prospects or salary expectations are diminishing in absolute terms.48

2. The new cohorts may not have the skills that companies require, as a result of growth in demand. Young people may resolve this mismatch by acquiring skills in the labour market during the first years of their active lives. Now that access to internal labour markets has been closed in certain countries of the European Union,49 young people find themselves compelled to acquire skills in a number of insecure jobs before gaining a sound foothold in the labour market. In this case, it is the job-seekers themselves who incur the adjustment costs.

For those cohorts that are already part of the active population, the problem is primarily about experience acquired on the job and further training. Work experience can play an ambivalent role. It may enhance an employee's adaptability by providing first-hand examples that are similar to the new situation faced by the workforce and by enabling the employee to become accustomed to mixing and matching all the skills that can be used in the new situation. But work experience can also have the opposite effect if it only provides the employee with practice in daily routines, deeply ingraining particular habits and making it more difficult for the employee to shake these off and adapt to new requirements. Further training is, by definition, a means of adaptation to new skill requirements. But these requirements must also be clearly identified, and the conditions for an efficient transition (prior training, motivation, etc.) must be guaranteed.

**Case D: Structural imbalance and a glut of skills**

The existence of a structural imbalance associated with sharp variations in the supply of skills poses the same problems as in the previous case, but this time the problems are considerably more serious, because the market and the institutions have repeatedly failed to regulate the supply of skills.

The multifunctional nature of the education system, the consensus established by individuals, business and government on the desirability of educational growth and the weak influence of prices as regulators of access to training are undoubtedly the main causes of this potential imbalance.

The fact that access to education costs next to nothing in most countries of the EU means that cost has virtually no role to play in regulating entry to the system. In certain conditions, it might be possible to correct this imbalance by ensuring that people know the truth about the financial benefits of education, about career opportunities and about the

---

48 The explanation of these strategies has been extensively developed in specialised literature, particularly by Boudon (1973) and Thurow (1975).

49 We refer especially to the studies by Recio (1999) for Spain and Moncel (1996) for France.
probability of academic success or failure. This type of approach, however, poses the problem of accurate short-term anticipation of behavioural changes on the part of those who determine the supply of skills and demand patterns. Another option would be to reintroduce some degree of competition (Glennester, 1991) into an education market which, according to the advocates of the liberal approach, is too dependent on the centralised decisions of the public authorities. This would serve to match the quality and quantity of the supply of formal qualifications, and more particularly of skills, with the demand emanating from the production system by virtue of direct regulation by the price mechanism. Competition between educational establishments and training systems (Rapple, 1992; Blair and Stoley, 1995) would serve to reduce the distortions in the skills market. Once again, however, this is an option that ignores the antithesis between the timescales governing the production and consumption of skills.50

Finally, it must be said that the arrival of masses of certificated young people in the European labour markets over the past 25 years has neither created any irreversible structural imbalances nor led to any profound changes in the methods by which holders of certificates are selected within the various occupations (Mallet et al., 1997; Béduvé and Giret, 1999). On the contrary, it is observable that the percentage of certificated employees is fairly constant from one occupation to another, even if we make allowance for technological progress (Giret and Masjuan, 1999).

4.2.3 Predicting long-term needs in situations of uncertainty: a case for qualitative adjustments?

We should examine the possibility of forecasting and anticipating long-term needs that ought to be addressed. The exercise we conducted over the last few pages necessitates further reflection, based on the characteristics of the ‘long term’ which were defined in the introduction, particularly the shortage of information and the uncertainty it breeds.

In a context of uncertainty, more than in any other situation, long-term adjustments depend on identification of the ‘durable’, which, if we think of skills, can only be defined in terms of those which allow access to other skills as yet unknown and thus implicitly defy long-term definition. In other words, it is a matter of defining the framework skills and of focusing on adjustment measures with a view to ultimate general acquisition of those skills.

This will surely ask questions of the institutions responsible for initial education but also of those involved in further training which perform, in a manner of speaking, the task of teaching adults to read and write all over again.

The initial-training institutions must examine the content and methods of compulsory education (Cedefop, 1999) and on the content and priorities of upper-secondary, further and higher education.

One aspect of these essential reflections on initial education which ought to have profound long-term effects is its ‘cultural’ reform.

Despite the constant repetition of the mantra that training is a matter of ‘lifelong learning’, our systems still tend to act as if initial education were the time for learning everything, once and for all. As a result, they are inclined to respond to the emergence of new knowledge and scholarship by adding to the structure, which is liable to make them less and less effective. Today, providing a good basic education means making crucial cultural choices about the strategic content of basic education.

The increase in the knowledge and ‘wisdom’ that is available in our societies (thanks to scientific development and its propagation by the new forms of information and communication technology) has not been integrated into our education and training systems in a thoughtful and selective manner but has

---

50 Unless we assume that all the competing training systems operate on the basis of perfect information.
rather been grafted onto the traditional models of cultural values and access to knowledge. In addition, the introduction of the 'skills culture' as opposed to the 'knowledge culture' is still proceeding very tentatively in our systems of initial education. Blaug (1999) highlights this point when he defends the idea of qualitative adjustments to education systems.51

This being the case, it is essential to define a 'minimum training platform' (Cedefop, 1999). In general terms, our school systems have responded to increases in knowledge by adding to the structure without any real effort to be selective and hence to establish priorities. In this way, our school systems have incorporated more knowledge, more foreign languages and specialised languages, have diversified their methodology and fostered interdisciplinary skills, etc., without establishing priorities or, to put it another way, without defining the essential core of our culture. The effect of this accumulation on school curricula has differed between countries but, in general, the key knowledge and skills have not been targeted. The purpose of defining the minimum training platform is therefore to guarantee the dissemination of key knowledge and skills and thus to lower people's expectations of initial education, which should not involve itself in every possible field of knowledge but serve as a reliable gateway to lifelong learning.

Changes in this direction are 'spontaneously' validated,52 but they are still too limited in their effects. There is a noticeable absence of any determined bid to put framework skills at the core of initial education, and why should they not be introduced as an element of the re-education process in further education?

4.2.4 Regulation of education and training institutions

Institutional regulation is also a complex matter. The education system, by dint of its diverse functions, cannot decide independently to restrict the annual flow of qualified pupils, students and trainees from its establishments. Although it is possible to achieve this effect by tightening entry requirements or by reducing pass rates, the whole issue remains a social and political minefield. On the one hand, a high cultural and social value attaches to education in most countries of the EU; it is the key to upward mobility for individuals, many of whom come from deprived social backgrounds. On the other hand, the internal inertia we alluded to above makes the education system a complex organisation (Hoenack, 1994), based on a somewhat contradictory incentive system (Carnoy and Levin, 1985; Franchi, 1992). A general rise in education levels, for example, poses the problem of the linkage between the grading effected by the educational establishments and a production system with a more pronounced and stabler hierarchical structure, which, according to Carnoy and Levin (1985), is a manifestation of the conflict between the dynamics of capitalism and those of democratic government. Nor should we ignore the sometimes antithetical interests of the various players involved in the operation of the education system. Even if they are in more or less tacit agreement on the internal regulation of the system, their aims will not automatically be compatible with staff cuts or with major changes in the methods used for the dissemination of knowledge or even in the nature of that knowledge.

A more general explanation of this deficiency in terms of the players’ strategies may be that

51 Blaug (1999, p. 6) states, for example, This is to deny that workers do need a minimum threshold of competencies in order to perform adequately on a job, and one comprehensive American study tried to specify these minimum computational, reading and communication skills. While these specifications are largely qualitative and not quantitative in nature, and hence cannot be mechanically applied to different types of school leavers, they suggest that at best so-called at-risk students, namely school leavers from immigrant minority and extremely poor families, might fail to meet the minimum standards, which brings us back to the question of how to help the potential school leavers without drawing undue attention to them.

52 Educational innovations and a shift in the curriculum towards more application-based courses in secondary and higher education are occurring in all Member States on the basis of a greater or lesser degree of judicious guidance.
of a 'consensus' in favour of raising education levels (Béduwé and Espinasse, 1995b) in the context of a job shortage. Keeping young people in the initial education system is an effective way for governments to deflate the active population and, more specifically, to reduce youth unemployment while responding to a recurrent aspiration of society to raise the general level of knowledge. Because of the shortage of work, young people perceive a fall in the opportunity cost of continuing their education and prefer to preserve the advantages of student life than to venture into the uncertainty of a deeply depressed labour market. Moreover, by simply perusing a breakdown of the unemployment figures by level of education, young people will see that graduates are more likely to find a job, even if the level of qualification required for such jobs corresponds to an ever diminishing extent with the education level of a young graduate. For that reason, most parents encourage their sons and daughters to continue their education at college or university. Lastly, employers, who do not have to finance this raising of education standards, can make use of this rise in the general skill levels of the labour force to drive down pay levels while enjoying the benefits of a workforce that is better educated and hence likely to adapt better to changing circumstances. An analysis of the arguments advanced in the eighties and nineties by governments, trade unions and employers in Spain on the subject of education and training highlights a desire to increase the general level of education of the labour force that is most often unconnected to the needs of the production system (Llorens et al., 1996).

A surplus of certificate holders raises the problem of relevant information in the labour market. It is very clear that, from a credentialist point of view, this situation is highly inefficient, because it does not enable prospective employers to identify clearly the productive capacity of job applicants. On the demand side, skill requirements themselves are becoming less standardised because, faced with the deficiency (caused by overabundance) of the institutionalised differentiation criterion (the certificate), employers have recourse to more individualised criteria, particularly behavioural attributes. Besides the new qualities that are now needed because of changes in work organisation, behavioural skills are eclipsing know-how, not because the latter has declined in importance, but because there is an abundance of know-how in the labour market, and possessing it is no longer an adequate distinction. In this context, numerous new forms of private recruitment mechanisms are emerging – new employability indicators, social networks, etc. (Vinokur, 1995) – to supplement or replace the institutional or market mechanisms for the reconciliation of supply and demand in the domain of jobs and labour.

Given this rise in the supply of qualified labour, the emergence of a new type of certification based on skill is regarded as a priority objective, especially as the demand for flexibility imposed on every sector of the economy has hardly spared the education system. Criticism of the present system has been steadily growing, as Vinokur (1995) emphasises, and apparently, certificates are even regarded by some as a standard 'imposed' by the education system. Unless it were the subject of negotiation among the various institutions, the gradual replacement of certificates by skill as the recognised qualification would undermine the social edifices associated with certificates (D'Iribarne, 1996) and, in the wider context, the systems of industrial relations that exist in most countries of the European Union. In those countries, however, there are no signs that any other type of credential is establishing itself as an alternative to the educational certificate for the time being. This, suggests Marsden, is due to the absence of prior agreement among the various players: The measures designed to reform the qualification sys-

53 This constraint, however, weighs far more heavily on new entrants to the labour market than on experienced workers. The past experience of the latter, recorded in a CV for example, does tell the prospective employer about the candidate's productive potential, even though this type of information is not generally presented in a very standardised manner.

54 Or negotiated, in cases where companies generate competition between training establishments. This perception of certificates seems to be increasingly significant in the United States.
tems on the basis of recognised skills, which could be regarded as components of wider qualifications, offer an opportunity to preserve transferability where it already exists and even to introduce it where it is still very limited at the present time. But [...] the reforms have little chance of success unless appropriate incentives can be established for the various players and a suitable framework for cooperation between employers and employees. Unless that happens, the capacity of European businesses to adapt to economic change will remain limited, and the human cost will rise sharply (Marsden, 1994, p.23).

In order to adapt, the education system must develop the information value of its certificates and encourage the various operators in the labour market to recognise the skills it imparts. Education systems are currently trying to send out a far greater volume of signals about the content and quality of the courses they teach. In the realm of initial education, this is done primarily by intensifying relations between the education and production systems, which promotes certain types of course, such as apprenticeships, or serves to involve all the economic players in the mechanisms by which certificates are created (Möbus and Verdier, 1997). In the realm of further training, the education system can play a part and can even organise a new type of certification by combining the validation of skills acquired on the job with more theoretical training modules.

Finally, we cannot rule out long-term self-regulation by the market. A persistent glut of certificated labour would result, for example, in lower returns from education for new entrants to the labour market, downskilling mechanisms and/or a shortage of job opportunities or, possibly, a freeze on social mobility. In such a situation, it might be in young people's interests to invest less in their education. That, however, will ultimately depend on the stability of the consensus and on whether and to what extent the various players have an incentive to break it.

55 On this point, the reader is referred to issue no. 15 of the European Journal Vocational Training, published by Cedefop in 1998.

4.3 Conclusions

The aims of this chapter were to foster a better understanding of the mismatches that currently exist in the skills market and to define the mechanisms with which these imbalances can be corrected. We shall conclude our reflections with a few remarks on these points.

It seemed to us that it was difficult to arrive at an objective and precise assessment of the mismatch problems in the skills market for several reasons:

First of all, to speak of mismatches in the skills market as opposed to the qualifications market is to refer to a situation which is far more difficult to grasp. As the average period of formal education has lengthened in most European countries, the role of initial training and formal qualifications has been changing. Although their function as a preliminary filter has been reinforced, final decisions on recruitment and promotion seem to be determined to an increasing extent by the skill factor. As we saw in chapter 2 above, the ways in which skills are produced and acquired are extremely diverse. In the skills market the divergences between the time frames within which the various players operate prohibit any instantaneous adjustment of the market; the production of skills is a long-term process, with a horizon that stretches at least as far as the active lives of the individuals in the labour market, whereas the consumption of skills is determined to a great extent by short-term fluctuations.

Moreover, the development and institutionalisation of new subsystems of vocational training, such as continuing training, youth-training schemes, recognition of informally acquired knowledge and skills, etc., tend to increase the complementarity of the various forms of skill acquisition, which can sometimes make them less substitutable. Paradoxically, this development does not seem to shorten the time frame within which skills are produced. On the contrary, it exacerbates the initial complexity of the 'multifunctional' training systems, in which the creation of skills for use in the productive system is but...
one of several objectives. The demand for skills is based on quite a different type of logic. Its development is always closely linked with the continuous process of change in the productive system, with the development of international trade and with technological change, and these factors tend to shorten the time frames in which it operates. The problem for the productive system will be to try to reduce, as quickly as possible, the discrepancy between this demand and the pool of skills that are available in the labour market so that it can remain competitive.

Thinking in terms of adjustments ultimately means harnessing the dynamics of social interaction which determine the motivation of the various economic players. There is no reason whatever why different players should be motivated in the same way or why they should all aspire to reduce the number of mismatches between skill levels and jobs.

If we consider four highly theoretical types of disequilibrium based on time frames and on a shortage or glut of skills in the market, it emerges clearly that the dynamics of adjustment differ widely, depending on the extent to which the future state of the market is foreseeable. In the short term, cyclical imbalances are often foreseeable and therefore less detrimental. A glut of skills might even present a business with an opportunity, encouraging it to make better use of its available skills and thereby serving as a source of innovation. It is the existence of unused and/or easily redeployable skills that gives an economy the freedom to make the best use of the pool of available skills from day to day, to make the labour market work and to integrate technical progress and growth. Skill shortages may be measured by the amount of time and adjustment expenditure that individuals and companies have to invest in order to acquire the missing skills. If these required skills are clearly identified and based on simple framework skills, the shortfall is generally made up by means of ad hoc decisions which can quickly be reversed. In this context, further training of a formal or informal nature serves as a rapid response to a specific skill shortage. Long-term structural imbalances, however, are more difficult to anticipate because they are not easily foreseeable. A structural skills deficit is damaging to both the individuals who are affected by it and to the companies who incur the necessary adjustment costs. At the other extreme, a structural glut of skills, like ‘overeducation’, may seem to be something of a challenge to our economies, since it confronts them with the need to make the best possible use of an increasingly abundant stock of human capital. Failure to use the potential of an individual will often result in frustrated ambitions, thereby creating a sense of social exclusion and alienation from the production process which will be reflected in company productivity figures. The overproduction and/or underutilisation of skills may seem like a waste of resources. At the same time, it is the key to the effective dynamic allocation of the labour force to the jobs that have to be done and is thus a guarantee for businesses, individuals and society at large. Avoiding any waste of resources and preventing the frustration of people’s expectations while maintaining the flexibility that will enable individuals to adjust their skill profiles in response to the continual redefinition of economic needs is one of the central problems facing all modern economies. It is a political problem in the most emphatic sense of the term, because the difficulties arising from imperfect information and from the incompatibility of the time frame within which skills are produced with the time frame within which new skills become necessary make it structurally impossible to devise a solution based on reliable economic or social calculations. The way in which the initial education process is administered can be likened to a short-sighted surgeon performing an irreversible operation; as it trains individuals, the system produces knowledge over a lengthy period of time without being able to foresee the future development of skill requirements, even though such development is liable to affect the entire careers of its trainees.

Any attempt to regulate this type of structural imbalance must involve an identification of that which is ‘sustainable’; in other words, the priority aims in the long term must be to identify framework skills and to ensure that they are acquired by everyone. This implies that adjustments to the system of ini-
tial education should focus on quality rather than diversity and should include, for example, the development of minimum skill platforms which will guarantee access to other forms of skill acquisition, such as systems of lifelong learning.

Finally, it should be said that the huge influx of young certificate holders into the European labour markets over the past 25 years has neither created irreversible structural imbalances nor effected profound changes in the ways in which the various trades and professions select qualified job applicants. On the contrary, statistical findings reveal a fairly steady production of qualified personnel across the entire range of occupations, irrespective of technological progress; individuals would appear to be recruited to the various trades and professions on the basis of what is to be found in the labour market rather than in response to specific needs.

5. General conclusions

In this report we have presented a selection of the literature that deals with the question of deploying labour in a way that will guarantee the development of the economy and of employees’ careers.

This selection derives from a simple idea that underlies the basic approach of the EDEX network, to which the authors of the present report belong; this approach has been directly validated by the network’s own empirical research findings (Mallet et al., 1997).

The idea may be summed up simply: in order to understand more clearly how individuals are assigned to jobs, we must distance ourselves from traditional ways of analysing the relationship between training and employment. All too often, these methods boil down to an analysis of educational certificates and employment. They induce researchers to present the problem in terms of a functional relationship between a customer (the productive system) and a supplier (the education system). For our part, we intend to study the relationship between skills and employment. This amounts to confirming the hypothesis that human productive capacity is divisible into a number of components that may be acquired in various places, at various times and by various means. If this hypothesis is true, the relationship between the production and consumption of know-how must be more complex than is generally assumed.

It is clear that our reflections have yet to reach their final destination. Their merit lies in the fact that they shift the issue towards new ground, namely that of skills, the macrosocial dimension of which has yet to receive much attention, and that they see the origin of skills in the framework of structural cooperation between the education system and the production system.

It seems appropriate to conclude this report by presenting some points for consideration that derive directly from our approach.

5.1 Is the state of the market ‘determinable’?

The skills that are available in the market are produced by complex mechanisms in which – even if we simplify the equation drastically by excluding the role of social life – at least two factors are involved: the education system (initial education and further training) and the production systems. These two systems are jointly and severally responsible for the availability of know-how.

To suggest that the education system, whatever its forms and methods, is the only place, or even the main place, where specific skills are created is to misunderstand completely the true nature of the labour market.

The production of skills is inherently chaotic in the sense that, at any given moment, the future state of the market, i.e. the nature and volume of skills being traded, is not yet (totally) determined. The longer the timescale, the greater the uncertainty. It therefore becomes structurally unforeseeable beyond a certain horizon.

This assertion goes beyond the classic problems of momentary imperfect information. This imperfection in the market results from
the difficulty of correctly determining the skills required for a job and of assessing the future performance of an individual in that job on the basis of the signals he or she sends out. In fact, the productive value of an individual with a given set of characteristics will depend on that individual's interaction with the job and the working environment. Ascribing skills to an individual, even at the present moment, remains an exercise in probability. However, a mistake can be easily corrected, because the individual 'mismatch' will quickly become apparent and can be rectified by terminating the employment contract or by honing the employee's skills (by means of explicit further training or in a less formal manner). Finally, the problem can be solved—at least in theory—by creating greater 'transparency', for example of information in the market.

The inherent imperfection of information in the skills market lies in the very nature of human work and economic development. Globalisation, technical progress and the development of monopolistic competition tend to reduce the time frame within which reliable information is available. Outside that time frame, rational expectations are all we have.

This chaotic dimension applies to the demand for skills. A number of techniques, tools and concepts that will be used in future years by the young people who are being educated today are not yet operational at the present time, and some will be based on fundamental discoveries that have yet to be made.

It also applies—and this is not such a widespread idea—to the supply of skills. Individuals, in the course of their working lives, draw on their experiences in and outside the workplace to adjust and supplement their repertoire of skills. These changes result from the interaction between their initial education (in school and in society) and the series of productive tasks they subsequently perform (possibly coupled with additional training they receive). These interactions are strictly individual and, as such, are strictly unforeseeable. They are even less foreseeable in the case of careers in which individuals eventually find themselves in a job involving the use of technology that was unknown at the time of their initial education.

Beyond a certain horizon, we do not know what the skill requirement will be, just as we do not know the nature and volume of the skills that will be available. It is a fact of life which we have to accept and which, in itself, gives no grounds for concern.

Let us imagine an education system that could produce people who were trained specifically for the jobs that would exist at a given time, in other words taught to perform the tasks pertaining to those jobs and to them alone. That would constitute a barrier to innovation and to economic development.

It is thanks to the existence of unused or easily redeployable skills that economies find the scope to optimise the use of their human capital from day to day, that the labour market can function and that technical progress and economic growth can be absorbed.

Overproducing and/or underusing skills may seem like a waste of resources. But it is also the prerequisite for efficient dynamic deployment of labour and therefore a guarantee for enterprises, employees and society at large. Avoiding wastage of resources and the frustrations associated with underused human capacity while maintaining the flexibility that is necessary to enable individual qualities to readjust to needs that are constantly being redefined: that is one of the central problems of modern economies. It is a political problem in the true sense of the term, because the problems of imperfect information and of the incompatibility between the timescales that govern the production of skills and their consumption make it structurally impossible to find a solution based on reliable economic or social calculations.

Satisfying people's aspirations, rewarding their efforts and achieving economic development by deploying the main source of the wealth of nations—their human capital—is a great art and will never be reducible to economic models or, worse still, to economic planning.
This clearly does not mean that information about the system or reflection on future developments are worthless. On the contrary, it is essential to guide the system by advancing rational hypotheses on the future of society and on the durability of human skills. What it simply means is that we must refrain from postulating the existence of fixed, rigid chains of causation between the information that is collected, the decisions that are taken and the effects that are produced.

5.2 Skill: two producers, one product?

If we assume that an individual's skill (and its various components) undergo constant change, that this change is effected by the education system and/or the production system and/or simply by social interaction, it becomes necessary to consider the production of skills as a system of cooperation between the educational and the productive spheres. This cooperation is entirely intuitive and interactive. Each of the two systems establishes its strategy in response to the action of the other. Each acts on different information, but the information is subject to that same intrinsic unpredictability as soon as any attempt is made to adopt a long-term perspective.

We are confronted with a game which, despite occasional conflicts of interest, is globally cooperative by virtue of the durability of human beings and their participation in productive activity.

Their actions are sequential. The young person goes through the education system before entering the production system. This remains true even if it is possible to have one foot in each camp (apprentices or students with jobs) or to come and go between the two systems.

The components of the skill on which both systems work may be the same. They are often distinct. The purpose of the system of initial education is to produce individual skills which are durable and adaptable and which can be converted fairly easily into know-how as information about actual requirements crystallises. The production system creates concrete skills that are compatible with the effective operation of organisations at a known stage of technological progress. Complementary by nature, the two systems act in the framework of a division of labour and must therefore coordinate their efforts.

The transition from school to work, what we call the insertion professionnelle [vocational integration] in France, is a very special moment in the cooperation between the two systems as it is then that their strategies come into contact and undergo fine tuning.

It is also the moment when the differences between the interests of the two systems come into play. The fact is that the transition, i.e. the acquisition of the specific skills that were not produced during the young person's initial education, has its price, which each of the players tries to avoid paying. If it is company policy to operate an internal labour market, this will induce such companies to bear the brunt of the cost. As these policies are restricted or reversed, an increasing share of these costs is transferred to young people, who are compelled to take the sort of insecure jobs that are characteristic of the first years of a person's working life, and to the public authorities, which have to pay for support schemes and unemployment benefits.

The transition from school to work is the moment when the production system stocks up with ‘semi-finished’ products. At that precise moment, the production system has a customer/supplier relationship with the education system, and its normal behaviour as a customer is to try to obtain the best products at the lowest prices. It is in the company's interests to transform immediately and more or less intensely the skills it acquires at that moment.

It is not part of the task of enterprises to produce skills for themselves. The contribution of the production system to the creation of skill is therefore forced upon it to an extent. It only makes this contribution because, at a given moment, certain specific skills can be more efficiently produced in the enterprise. It may simply be a by-product of the work process. It is often a voluntary measure and is organised in the framework of a company's human-resource management policy in the expectation of higher productivity.
This remains true even when companies invest heavily in the training of their employees (under young-specialist programmes, for example). The level of its training investment may prompt a company to create an explicit training structure, more or less parallel to the traditional school and college system and totally disconnected from the company's productive activity. It is still true when the enterprise, through the various forms of apprenticeship, agrees to become directly involved in the initial education of young people.

In all of these cases, skill is regarded by the company as an intermediate good which must subsequently be turned to account in order to provide a return on the company's investment. Otherwise, the company will suffer a net loss or, to put it another way, will be subsidising its competitors.

The education system and the production system therefore have clearly differing positions in relation to the production of skills.

The aim of the education system is to allow everyone to fulfil his or her potential as far as possible. Though operating in a context of extremely imperfect information, it is required to adopt a long-term perspective. One of its aims will be to develop the framework skills that seem likely to prove durable and to provide the best basis for subsequent further training, whether explicit or implicit.

The production system only concerns itself with the creation of skills within the scope of its productive activity and is subject to the constraints that are imposed by that activity. Its action is determined on the basis of relatively complete and contextualised information. It perceives training as an intermediate activity, albeit an indispensable one in virtually all cases, but also considers it essential to minimise the cost of training.

This diversity of aims is reflected in a particular type of division of labour. The specific skills that the two systems try to foster on a priority basis are not the same ones (in general). Some skill components cannot be taught by the education system (implementing companies' in-house procedures, for example). Others, such as basic general knowledge, are clearly the domain of the public authorities and hence of the systems they administer.

5.3 Initial education: managing the unforeseeable?

The role and function of initial education appear to be highly complex. Its produces for the ultra-long term (the lifetime of individuals). The knowledge it disseminates will be used - in whole or in part - in a society about which there is little reliable information, the details of its future application of technology being practically a closed book. Once young people leave the education system, they will draw on what they have learned in order to expand and adapt their skills. The tactics they will employ to make these adjustments will depend on the jobs they do, on the environment that confronts them and on the network of relations they establish. These tactics will also be determined by the education they have received at school, which constitutes a stock of capital that is both irreversible and irreplaceable. The fact is that no individual can ever devote so much time to self-development as is done during the initial education process or ever forget absolutely everything he or she has learned at school.

Educationalists are well aware of the extreme difficulty of this exercise. There seems to be less such awareness among some others, who persist in trying to guide education systems on the basis of forecasts derived from projected trends in the production of goods and services. This approach, while recognisably logical in economic terms, is unsustainable outside a certain time frame, for it is quite obviously incapable of taking into account the complexity and endogenous nature of the mechanisms by which skill is produced in the medium or long term.

The existence of a horizon beyond which the systems' strategic policy can no longer be based on knowledge and has to rely on rational expectations reveals a sharp division within the raft of policies for the development of skills.
Some of these policies result in decisions whose impact on skill requirements is foreseeable, while the effects of other decisions lie outside our present field of vision.

In the first case, the producers of skill possess more or less perfect information about the nature and volume of demand for skills. In the second case, such information does not exist, nor could it. None the less, the future availability of skills is always on the agenda for the systems of initial education, since their mission is to provide training that will last a lifetime.

Two strategies compete to determine the nature of initial-training policies:

a) According priority to the familiar, i.e. training young people on the basis of familiar technology and adapting them to the present state of the market. This has the advantage of making the trainee more immediately effective and facilitating his or her integration into employment. The disadvantage of this approach is that it involves heavy investment in 'perishable' technology and transfers a greater part of the long-term management of knowledge away from the education system.

b) Embracing the unfamiliar. Attention is focused on sustainability, on skills that stand a good chance of being usable for a very long time, irrespective of short-term productive considerations. There is a danger that this attempt to facilitate the trainee's long-term adaptation will make it more difficult for the trainee to find work and will retard his or her inevitable accumulation of skill outside the education system.

Presenting these two approaches as alternatives is actually a distortion of reality. In fact, the legitimate aim of the education system is to equip young people with directly usable skills while endowing them with the qualities they need to maintain a high level of know-how throughout their working lives. It is difficult, however, to merge these two approaches, especially when the aim is to provide training that is applicable to everyone.

It is conceivable that in quite a few cases short-term adaptation and long-term development will prove to be incompatible to a certain extent. A number of cyclical adjustments to the definition of education policies in general and vocational-training policies in particular are due to the difficulty of choosing between two strategies: prioritising integration, thereby setting in motion the virtuous circle of skill creation through work experience, or providing long-term protection against skill obsolescence at the risk of retarding access to employment.

5.4 Lifelong learning: social measure or economic policy?

Lifelong learning, which was conceived as a dynamic means of adapting individual skill profiles to the needs of the production system, is not in itself a new idea. On the contrary, it represents a normal and stable means of ensuring that skills are produced and that the market operates smoothly. It is effectively the only way to reconcile changes in production levels, the integration of technological advances and organisational reform. The fact is that our societies have always managed to absorb technological and organisational changes just as they have managed to adapt to variations in production. What is relatively new and recent is the willingness of the public authorities to address the problem and to try and place explicit training (continuing vocational training in the present case) at the heart of the adaptation mechanism.

The concept of lifelong learning covers two distinctly different situations.

The first relates to marginal adjustments to clearly identified specific skills. Such fine-tuning, which is the key to the smooth and sustainable operation of the market, depends on the fulfilment of three conditions:

a) a clear training strategy, based on direct and thorough familiarity with the knowledge to be imparted or the behaviour patterns to be inculcated;

b) effective involvement of the trainee;
c) previously acquired skills, especially basic skills, that the trainee needs in order to follow his or her training programme; skills, of course, are not uniform in scope, and some skills are either impossible or too expensive for a company to modify.

If these conditions are met, companies may opt, on the basis of efficiency criteria, for either of two solutions: providing their staff with further training or letting them learn on the job at the expense of temporary reductions in productivity.

On the other hand, some members of the active population, young and not so young, are more or less totally excluded from social life and the pursuit of a career because of deficiencies in their basic skills. For that reason, efforts are being made in the domain of social welfare to make them more employable and to limit the impact of their exclusion, which entails a second type of adjustment. These measures are the subject of a government initiative. It is naturally very difficult for the public sector to plan measures that fulfil all three of the criteria we defined above.

Economic performance of education and training: costs and benefits

Alan Barrett

Abstract
One of the most fundamental principles in economics is that resources should be allocated to ensure the highest possible return. It is not sufficient that an investment yields a positive return; efficiency in the allocation of resources requires that the highest return is derived from a particular investment. While such thinking forms the cornerstone on which investments in financial assets are made, its application in the area of human capital investment is less well established.

Many papers have been written which seek to measure the benefits of education and training but very few have attempted to relate costs and benefits. This paper explores the issue of empirically estimating the return to education and training. Concerning the benefits of education and training, three types of research works are distinguished. The first group looks at how the earnings of individuals with greater amounts of training differ from those with less training. The second group looks at how firms that offer higher amounts of training differ from other forms in terms of productivity growth. The third set of papers is concerned with how growth rates across countries can be related to differences in investment in education. In addition, the concept of market failure can be employed to illuminate our concerns in this area.

1. Introduction

One of the most fundamental principles in economics is that resources should be allocated to ensure the highest possible return. It is not sufficient that an investment yields a positive return; efficiency in the allocation of resources requires that the highest return is derived from a particular investment. While such thinking forms the cornerstone on which investments in financial assets are made, its application in the area of human capital investment is less well established.

Given Becker's theoretical formulation of education and training in terms of an investment model, the relative underdevelopment of the empirical side of the investment approach to human capital is perhaps somewhat surprising. Many papers have been written which seek to measure the benefits of education and training but very few have attempted to relate costs and benefits. The term 'returns to education' is frequently used in papers that look at how extra years of schooling are rewarded in the labour market but the use of the term is misleading. By 'return', the authors usually mean the coefficient on years of schooling in a Mincer-type earnings equation. Such a measure says nothing about how the benefits of education are related to the costs so they leave us without a true measure of 'return', correctly defined.

In this paper, I will explore the issue of empirically estimating the return to education and training. I will look at a selection of papers that have attempted to measure the benefits of education and training but very few have attempted to relate costs and benefits. The term 'returns to education' is frequently used in papers that look at how extra years of schooling are rewarded in the labour market but the use of the term is misleading. By 'return', the authors usually mean the coefficient on years of schooling in a Mincer-type earnings equation. Such a measure says nothing about how the benefits of education are related to the costs so they leave us without a true measure of 'return', correctly defined.

Throughout the review of the papers, I will assess the difficulty of estimating reliable rates of return to education and training. An enumeration of the difficulties provides a clue as to why such estimation is rarely carried out in the form of estimating properly defined rates of return. I will make a proposal on how more robust rate of return estimates could be made but the issue remains of whether research effort can be most usefully devoted to refining our efforts in estimating returns or to approaching the issue from a different perspective. I will briefly suggest how the concept of market failure can be employed to illuminate our concerns in this area.

2. Individuals and wages

I mentioned in the introduction that many studies have measured the benefits of additional years of schooling by estimating Mincer-type wage equations and including a measure of schooling. The studies that I will discuss in this subsection apply a similar approach and use a measure of training received as an explanatory variable in the wage equation.

Before looking at the studies, it is worth thinking about what precisely is being estimated through the use of a wage equation and how the estimated effects relate to the notion of a rate of return. By including a measure of training in a wage equation, the wage difference associated with different levels of training is estimated. The precise interpretation of the estimate depends on the measure of training used. Often, some measure of time spent in training is used so the estimated coefficient on training can be interpreted as the effect of an extra unit of time spent in training on wages.

While this quantity is of interest, it is not a rate of return in the strict sense of the word. For a rate of return to be estimated it would be necessary to calculate the costs of the training and the benefits. While the wage equation provides an estimate of one benefit, there are numerous and comprehensive reviews are offered elsewhere.
are benefits to the employee from training other than a wage increase. Let us consider both the costs and benefits in turn.

If we are interested in the individual's return on training, then we must focus on the costs incurred by the individual. Where the employee pays out-of-pocket expenses, that element of the costs is readily identifiable and quantifiable. Beyond that, however, matters get complicated. We know from Becker's work that employees may incur training costs through reduced wages. The difficulty in trying to measure the cost that the worker incurs in this case arises because we do not know what the employee's wage would have been in the absence of the training. Similarly, if the worker undertakes training in his/her own time, we do not know how to place a value on that time which could be spent doing other things. Finally, if the employer incurs the full cost of training and the worker receives some benefit, it would appear that the rate of return from the perspective of the employee is infinite. In this situation, it would clearly be desirable to calculate some sort of combined return across the employee and the employer.

While the wage increase associated with training is clearly a benefit to the employee, it is unlikely to be the only benefit - if a comprehensive rate of return is to be calculated, other benefits should ideally be valued and included in the calculation. Clearly, this is far from simple. The provision of training reduces the likelihood that someone will suffer unemployment. This means that training increases lifetime earnings for a reason other than the increase in wages. Calculations that simply look at the wage increase at a point in time miss this element but it could be quantitatively important. Another benefit from training is the increased job satisfaction that we associate with being better able to perform a task or with the increased responsibility that training can lead to. While this is another important benefit of training, its quantification is difficult and so its inclusion in a rate of return estimate is problematic.

The valuation and calculation of the full costs to the individual and the full benefits would be required if a true estimate of the rate of return were to be calculated. No studies have done this so let us look at the studies that have at least looked at the wage effects of training. Such studies are at least a start on the road to rate of return estimates. I will explore their usefulness in contributing to rate of return calculations and will end the section by suggesting how they might be expanded.

Booth (1991) uses a large-scale British data set from 1987 in measuring the benefits of training. While she finds a positive effect of training on wages, especially for women, the measure of training used provides a first insight into the difficulty of reliably estimating a rate of return to training. The information on training is provided by the individuals recalling the amount of training they received in the past two years. While asking people to recall what qualifications they have received is unlikely to cause too much difficulty, a question would have to be asked about how reliable responses can be when recalling training. In the case of 'formal job-related training courses' the individuals were asked to recall how many days of training they received. In the case of informal training, the individuals were only asked to recall if they had received any such training across a range of categories in the last two years. The information on informal training is likely to be more reliable but because of its crudeness, it would be less useful in estimating a rate of return. Even in the case of the information on formal training, while the number of days of training may contain some information on training intensity it is far from perfect.

A paper similar in style to Booth (1991) is Lynch (1992). She uses a data set that was generated in the United States. A large group of young people was interviewed each year between 1979 and 1983; in each interview they were asked about the amount of training they had received that year, along with questions on wages and other aspects of their labour market experience. Given that the individuals are recalling their training in the current year and not over two years, as was the case in Booth (1991), it is likely that her measure of training is more reliable.
The value in Lynch's paper comes not from a better effort at estimating the rate of return to training. Instead, she uncovers some interesting results about the relative impact of training received with the current employer and with a previous employer. Off-the-job training with either the current or a previous employer is observed to lead to higher wages for the individuals involved. However, on-the-job training with a previous employer is not rewarded by current employers. The immediate question that this gives rise to is why one form of training is recognised and valued by current employers while the other is not. One possible explanation is that the nature of the off-the-job training provided by a previous employer may be more readily observable to a current employer. This would be true if the off-the-job training was provided in a structured way whereby a certificate was awarded.

A related issue concerns the implications of Lynch's findings for the investment decisions of individuals and firms. The finding that the training provided by one employer is rewarded by another implies that the original employer is not capturing all the return to the training investment. For this reason, while the original employer may have been prepared to provide the training, he/she will not have paid for it. The individual would have had an incentive to pay for the training, as they are reaping the benefit even though they have moved to a new employer. The opposite holds in respect of the on-the-job training. As there is no wage gain with a new employer, an employee who might consider moving has no incentive to invest in on-the-job training. Clearly, these are the types of issues that Becker brought to the fore in discussing general and specific training. As regards rate of return estimation, the issue implied is that a correct assessment of training benefits requires a knowledge of to whom the benefits accrue and an ability to measure benefits even when they are spread across employers.

Before leaving Lynch's paper, two additional points should be made. First, it must be emphasised that her paper has great value in pursuing its objective of uncovering the relative impacts of training provided by the current and previous employer. However, as part of our general interest in the rate of return to training, we can ask how far it gets us in that context. Recall that what has been estimated is how wages respond to training inputs. There is no information provided on the costs of the training so a rate of return calculation is not possible. Also, a wage increase represents only part of the payoff for training. If productivity has increased more rapidly than any wage increase, the employer has appropriated some of the benefit. For this reason, a focus on wage increases may underestimate the full impact of training.

The second point concerns the issue of mobility of employees between firms. As discussed, one of the important issues in the economics of training is the extent to which trained employees take their skills and move elsewhere. Two concerns arise. First, employers are less likely to provide training if they think workers will leave. Second, if workers build up skills that are specific to one firm, the value of these skills is then lost when they move elsewhere. In this way, the economics of training sees costs of mobility and so a limited reading of the literature might leave someone with the conclusion that mobility was undesirable.

A broader reading of labour economics points to the benefits of employee mobility between employers and so counteracts the view that might emerge from the training literature. As discussed in Filer et al. (1996), economic efficiency requires that employees sort themselves into jobs where they are most productive. Often, employees cannot know where they will be most productive so an element of 'job shopping' can occur whereby they try a number of positions by way of gathering information. Even if employees have found their most productive position at one point in time, demand shifts across occupations can result in different jobs becoming better matches so again, mobility is economically beneficial.

In addition to the theory in this area some empirical studies have shown the value to individuals of mobility across jobs. For example, Bjorklund and Holmlund (1989) have shown that wage gains from changing jobs in Sweden were 2% while research in Canada has shown increases of 9% (Abbott and Beach...
1994; Abbott et al. 1995). Assuming these wage gains result from employees finding themselves in positions where they are more productive, there is clearly an efficiency gain in them moving. Even if they have lost the use of some specific human capital, the loss is more than offset by the productivity gains. The concern remains, however, that the first employer loses whatever investments they have made in the employee and hence the employer may not make such investments.

The issue of the effects of training on wages and productivity is addressed in Bishop (1994). This paper again looks at the impact on the wages of individuals of training but because the data was generated at the level of firms, Bishop is able to go beyond the analysis of both Booth (1991) and Lynch (1992). He uses two data sets, both of which contain information provided by employers on two of their recent hires. By tracking the two individuals across a large number of firms and by assessing how the experiences of the two differ in terms of training received, wage growth and job performance, Bishop is able to measure the impact of training not just on wages but also on productivity.

One possible advantage of Bishop’s measure of training is that it is the employers’ estimates of the amount of training. In the cases of both Booth (1991) and Lynch (1992), it was the individuals who had provided the information. As employers are more likely to have kept records, it is likely that their information will be more accurate than that of the individuals who rely on memory. Bishop adds to the reliability of his training measure by going beyond the ‘days measure’ used by Booth and others. He creates a ‘training-time index’ by multiplying the amount of time spent in training by the value of the time. The value of the trainee’s time is taken to be their wage rate; the value of any time devoted by another employee to the training of the trainee is also factored in according to their wage rate. In this way, Bishop produces a measure of training input that goes much further towards being an ideal measure.

Bishop’s main finding is that training raises productivity more than it raises wages. This is enormously important because it shows that attempting to estimate the full return on training by observing wage increases will lead to an underestimate of the return to training. Similar to Lynch (1992), Bishop also finds an effect of training provided by a previous employer in the current workplace. While Lynch’s findings were restricted to wage effects, Bishop demonstrates that previously acquired training increases productivity with the current employer. As noted when discussing Lynch (1992), this implies that some employers benefit from the training investments of others; as those who paid for the training are not recouping the full benefit, there is a reduced incentive for investment in training.

Before leaving papers that have looked at the effects of training on the wages of individuals, I want to draw attention to an important point that is emphasised by Groot et al. (1994). In estimating the effect of training on individuals’ wages, it is usual to look at a sample of people and to look at how much more is earned by those with more training, controlling for other factors that influence wages. When looking at the results that emerge, it must be remembered that training is not distributed randomly across the population. Instead, those who are likely to benefit from training are likely to acquire more of it. This could be because they choose themselves to train more or because an employer sees their potential and provides them with more training relative to less able employees. Either way, any observed relationship between training and wages may partly reflect the greater propensity to train by those who will use it best. The random distribution of training would produce a smaller relationship between training and wages.

As regards the estimation of the rate of return to training, an analysis of training benefits that does not take account of this ‘self-selection’ issue could seriously overstate the rate of return to training that would apply to a random selection of people. Groot et al. (1994) find for their sample that there would be no benefit from training for those who did not participate, had they participated, so the issue is a real concern. Statistical techniques are available to overcome the difficulty so in some senses this particular problem is less of
a concern when it comes to the estimation of rates of return to training. Nevertheless, it is important that researchers are aware of the difficulty and are sufficiently competent with the techniques to overcome it.

I began this section by pointing out that the studies I was about to explore were limited as regards making rate of return calculations. The crucial omissions are the failure to relate costs and benefits and the failure to measure benefits in a broader manner. I return to this issue below when I consider how work in this area can be expanded.

3. Firms and productivity

I now want to consider the returns to training from the perspective of the firm. I will follow a similar approach to the one just adopted in the case of individuals. I will firstly ask what would I ideally like to see measured and will then look at what the studies have actually explored. As with the case of individuals, it will be seen that the existing work is some distance from what we would like.

It seems reasonable to say that individuals' interest in training may be multifaceted, in the sense that they may undertake training in the hope of getting a wage increase, reducing their chances of unemployment or improving their job satisfaction. However, in the case of firms the interest in training is likely to be more narrowly focused on increasing profitability. It may be true that some firms have a sense of social responsibility or, in the case of family-run firms, an interest in providing employment. In most cases, however, firms' primary concern is in making profits. As such, the rate of return calculation of greatest interest to firms should be the increased profitability that arises from spending on training.

The route through which training increases profitability can be multifaceted. The most direct link would be the increase in each worker's productivity that comes about through training. Another link between training and profitability would arise if training improved job satisfaction among employees. Productivity could increase because the increased satisfaction of the employees leads them to work harder or because of a reduced tendency to quit. In estimating the effect of training, these effects would be of interest but in estimating the underlying rate of return, these 'intermediate' effects can be captured by looking at profitability.

In this subsection, I will consider some of the studies which, in addition to Bishop (1994) mentioned above, have attempted to measure the effect of training on productivity by drawing on samples of firms. Although profitability would capture more directly the return to training for companies, little work has been done on that angle. As with the previous discussion of individuals and wages, it will be seen that while the studies are of value, they do not try to estimate the rate of return to training, thereby leaving a gap.

One of the earliest studies to look directly at the link between training provided by companies and subsequent productivity growth in those companies was Holzer et al. (1993). They generated a data set from a number of companies that applied for training grants under a programme run by the state government of Michigan. They found that training did lead to productivity growth but the methodological details are of greatest interest so I will consider some of these.

The first methodological issue is the point on self-selection, discussed already in the context of Groot et al. (1994). The first selection issue arises from the fact that all the firms in the sample had demonstrated an interest in training through applying for a grant (even though not all firms were actually awarded a grant). Holzer et al. maintain that this will produce a downward bias in their estimated effect of training on firm performance. As they are more interested in uncovering an effect of training, rather than in precisely measuring it, they are unconcerned about this bias. Clearly though, were a rate of return estimate to be made, this difficulty could not be ignored. The second selection issue arises because the firms who respond to the survey are not necessarily a random draw from the full sample. In particular, firms who had a positive experience of a programme are more likely to re-
spond to a survey about that programme. Although the authors explore this second selection issue to a degree, they do not employ any statistical techniques to overcome it, largely because some more casual observation leads them to believe that it is not a large problem.

The second methodological issue concerns the time period of analysis. If an analysis were conducted in which training provided in a particular year was related to productivity in the same year, the estimated relationship would almost certainly be biased. It could be that the most productive firms could afford to undertake more training, whereby the causation ran from productivity to training. This would produce an upward bias in the measured effect of training. It could also be that some firms had unobservable characteristics that lead them to be more productive and to provide more training. For example, if firms have good managers, it could be that they have positive impacts on productivity and training. A regression analysis will produce a positive estimate of the effect of training on productivity but clearly this may be a false conclusion. At least partly to overcome this difficulty, Holzer et al. estimate the effect of training on subsequent productivity growth. To do this, it is necessary to have information on the firms at two points in time. While this might seem like a simple requirement, in practice it can cause difficulties. There is the added expense of surveying companies at two points in time or the added complications that arise by surveying them once and asking for retrospective information.

An additional methodological issue that arises in the Holzer et al. paper concerns the measurement of productivity. Rather than using some measure of output per worker, the authors rely on what they describe as their most reliable measure of the quality of output, the scrappage rate. This is the proportion of items that must be scrapped because of faults. There is clearly of value in estimating whether training has the effect of reducing the scrappage rate but this is a long way from measuring productivity. The scrappage rate could be reduced if all employees worked more slowly; this in turn could actually reduce productivity. Finally, Holzer et al. use annual hours of training per employee as their measure of training. I have already discussed under Bishop (1994) that measures of training need to be cost-based if a rate of return calculation is to be undertaken. Simply looking at hours tells us little about cost as I do not know if expensive instructors were hired, if expensive equipment was used and what the value is of the foregone time of the trainees.

I noted above in the context of another paper that the deficiencies I am pointing out with regard to rate of return estimates are not necessarily criticisms of papers. Holzer et al. were not trying to estimate a rate of return so it would be unfair to criticise them on that basis. My interest in discussing their methodology is based on the notion that the estimation of the benefits of training, which must underpin a rate of return estimate, would be based on a methodology similar to the one they use.

A paper similar to that of Holzer et al. is Bartel (1994). Like Holzer et al., her approach is based on the idea of estimating in a regression context the relationship between training and productivity. Her paper is an interesting contrast with the earlier paper in terms of its data strengths and weaknesses. Bartel's measure of productivity is much more direct than the scrappage rate; it is based on sales per employee which is clearly much closer to the ideal concept of productivity or output per worker. However, her measure of training is much weaker than that used by Holzer et al. For each of the companies in her sample, the workforce is divided into seven categories. The data provide information on what proportion of these seven categories receive some sort of training in each of the companies and this is Bartel's measure of training intensity. This is much weaker than Holzer et al.'s measure. Bartel again finds a positive relationship between training and productivity growth but her work clearly leaves us a long way from a rate of return measure.

The data limitations that characterise the papers of Holzer et al. and Bartel have more recently been overcome to some degree in a series of papers by Sandra Black and Lisa Lynch (Lynch and Black 1995; Black and
Lynch 1996, 1997). As the authors describe, the data set that they use ‘was designed to overcome some of the limitations of previous studies and to collect more precise data on human-capital inputs and establishments’. One dimension along which the Black and Lynch data are superior is the number of observations. Whereas Holzer et al. and Bartel had data sets with around 250 observations, Black and Lynch have information on 1,621 manufacturing companies and 1,324 non-manufacturing companies. Clearly, such numbers give Black and Lynch much greater flexibility in the issues they can explore as cell sizes will remain sufficiently large as the data are cut in different categories.

The other dimension along which the Black and Lynch data are superior is the information on training. The usefulness of this information is seen in the results presented in the 1995 and 1996 papers. According to their results, simply looking at the numbers of employees trained does not lead to an observed positive relationship between training and productivity. However, by looking at types of training provided, positive relationships are observed. For example, in manufacturing, the higher the proportion of training that is off-the-job, the higher is the effect on productivity. In non-manufacturing, training in computer skills was seen to have a positive effect on productivity.

Although the data used by Barrett and O’Connell (1998) share with Holzer et al. and with Bartel the difficulty of a limited number of observations, their data also share with Black and Lynch a richness in terms of the dimensions of training included. The most original and useful element of these dimensions was the division of training into general and specific categories, where the distinction follows that of Becker. They find that while specific training does not have a statistically significant effect on productivity, general training does. As such, their results support those of Black and Lynch in that they show that the type of training matters.

I have now considered a range of studies that have sought to estimate the effect of training on productivity. While this is not the same as estimating a rate of return to training, it is a first step because the productivity gain that results from training would generally be agreed to be an important component of the total benefit. Mincer (1991) takes estimates from a range of studies of the type just presented and attempts to translate them into rate of return estimates. To do this it is necessary to introduce a variable that I have not yet considered, namely, the depreciation rate. The studies I have looked at have typically estimated the effect of training on productivity within a short time period. However, it seems reasonable to assume that the benefits of training would last beyond the immediate period. I am not aware of any work that has attempted to empirically establish how fast training depreciates. It may be possible to derive some proxy estimates from the shape of the experience-earnings profile but in general, we do not know what the depreciation rate of training is. Mincer assumes an annual depreciation rate of 4% and produces rate of return estimates that range from 8.7% to 26%. These estimates would be quite sensitive to the depreciation rate assumed so their reliability would have to be questioned.

Before leaving studies of the link between training and productivity, I will draw attention to two additional pieces that have focused on methodological issues in this area. The first piece is by Barron, Berger and Black (1997, Chapter 5). They study the issue of differences between workers and their employers in survey responses to questions about the amount of training received, plus other labour market matters such as hours worked and wage rates. By separately surveying employers and their workers, Barron et al. develop a very direct test of the differences. They find that firms generally report more training than workers and describe the correlation between responses as being ‘surprisingly low’. What is perhaps more surprising is that the differences in responses are of a similar order of magnitude for formal and informal training. A reasonable expectation would have been that greater agreement would exist about formal training. The implication of these findings for rate of return estimation is severe. If we are unsure about the reported information on training, even data sets like Black and
Lynch's become suspect in spite of their apparent richness.

A second paper that has addressed the methodological issues in this area is Huselid and Becker (1996). They consider two separate, yet related, problems. When discussing Holzer et al. above, I talked about the need to have information on firms at two points in time for meaningful estimates of the effects of training to be derived. To generate such information and avoid recall difficulties, it is useful to survey firms at two points in time. Huselid and Becker point out that survey response rates from firms are typically quite low and certainly lower than response rates from individuals. While this is a problem in a once-off cross-section, it is considerably more of a problem in a short panel. In the example of a survey the authors use, the response rate from the two surveys leaves usable information on only 10% of the original firms. Clearly such a low response rate raises questions about how representative a sample can be.

The second problem considered by Huselid and Becker again derives from the need to estimate how training leads to changes in productivity. In order to look at changes, it is necessary to difference the data. If the cross-sectional data suffer from measurement error, differencing compounds the associated difficulties. From the work of Barron et al. (1997), we know that measurement error is indeed a problem so the issue raised by Huselid and Becker is an important one.

3.1 Different forms of training

The discussion so far has generally looked at the impact of training, broadly defined, with less emphasis on work that explicitly aims to compare the effects of different types of training. In this section, I will briefly look at some such studies. Much of the discussion is taken from ILO (1998).

One issue that has been addressed is whether apprenticeships provide participants with better subsequent labour market outcomes relative to other forms of skill acquisition. According to Ryan (1998), the evidence for developed countries is that apprenticeship does yield better outcomes in terms of pay and employment relative to public training programmes. However, comparisons between apprenticeships and vocational schooling show more mixed results. Another area of comparison explored is that between general and vocational secondary schooling. Psacharopoulos (1994) discusses how rate-of-return analysis has shown technical and vocational education to be less beneficial than more general, academic education. The ILO (1998), however, is sceptical of the use of the rate of return methodology in establishing priorities between vocational and general secondary education. In particular the ILO argues that the external benefits of vocational training are not adequately factored into the analysis. They also argue that the more important policy issue is the exploitation of complementarities between different levels and types of education.

Yet another comparison in this area has been between different systems of human capital use. Two studies of the engineering industry have attempted to assess the reason for productivity differences between plants in the Netherlands, Britain and the United States. The first study focused on the first two countries (Mason and van Ark 1993) and found that the higher level of productivity in Dutch plants relative to those in Britain was partly related to a higher proportion of the Dutch employees having craft-level skills and technical qualifications. In the second study (Mason and Finegold 1995) the higher level of productivity in the US plant was found to be related to the presence of a greater number of graduate engineers.

These comparisons of different elements of human capital investment and raise the issue of whether it is more useful to assess the value of training generally relative to other possible investments or whether we should focus within training and assess relative values of different approaches. Even the answer to this question depends on the relative costs and benefits. The benefits here are the information that can be generated on rates of return while the costs are the expense of generating those rates. To the extent that work to date has looked at training broadly defined and generally found evidence suggesting a
healthy return to training expenditures, it could be argued that the 'within training' analysis would now be of greater value.

4. Economic growth and education

In this section, I want to consider the research that has been concerned with the impact of human capital investments on the level of national income and the growth rate of income per capita. Much of the work on this issue has been done within the general context of growth theory. Growth theory in turn has been dominated by the move from neoclassical models of growth to endogenous growth models. As such, any discussion relating to this area must incorporate elements of these competing views.

My approach will be as follows. In the appendix, I outline the Solow growth model (1956) which is the starting point for much of developments in this area. This appendix is intended for those with a particular interest in the theory; other readers can proceed directly onto the next section. In the section that follows, I give more recent theoretical work; this may again be of greater interest to some readers relative others but it is useful to consider the mechanisms through which human capital is thought to influence growth. Then I go on to consider the empirical work of recent years that, broadly speaking, estimates how variations in human capital investment across countries are related to variations in output per head and its growth. I will end the section with an assessment of the work.

4.1 Recent theory of economic growth

The Solow model (which is discussed in the appendix) is a highly abstract version of an enormously complex phenomenon. It analyses growth per capita in terms of simple savings and investment functions and population growth. In spite of its simplicity empirical explorations of the US economy showed the model in a good light as it predicted well much of the American growth experience of the twentieth century. However, in more recent years a number of issues have been raised which have prompted people to look beyond the Solow model.

Romer (1994) discusses the sources of these developments and makes the following points. One difficulty with the Solow model concerned its predictions on crosscountry growth experiences. Given its neo-classical underpinning, the model predicted that convergence in income levels across countries would be observed. Simple analyses of cross-country growth experiences do not reveal a pattern of poorer countries growing faster than richer ones.

A second difficulty with the Solow model according to Romer was the manner in which technological change was treated. There is something intellectually unsatisfying about treating technological change as being exogenous, especially as it is the engine of per capita output growth in the Solow model. Romer (1994) notes that technological advancement typically comes about through conscious economic decisions made by individuals and firms. Hence, an exogenous treatment seemed to avoid that fact. In addition, the Solow model assumed a world of perfect competition, one implication of which was that payments to capital and labour would exhaust output. In order for firms to recoup the benefits of research and development, it was necessary that scope exist for prices to be above marginal cost. For Romer, the need to move beyond perfect competition in modelling of this nature was the real motivator for what became known as endogenous growth theory.

Romer's (1986) model represents one of the early attempts at 'endogenising' growth. He included an assumption that broke away from the constant returns to scale assumption that characterised the Solow model. He did this by including in the production function a term that he calls 'knowledge'. Labelling the knowledge that each firm produces through its own research and development as k, the sum of knowledge across firms as K and some fixed factor of production as x, the production function can be written as:

\[ Y = f(k, K, x) \]

This says that the output of each firm is partly dependent on the knowledge generated by
other firms. As this knowledge cannot be kept secret or perfectly patented, there are 'spillovers' in knowledge whereby all firms benefit from the research and development of others. By assuming that the production function exhibits increasing returns in $K$, an internal dynamic is generated that makes growth endogenous to the system. Increases in output lead to more resources being available for research and development; this in turn leads to more knowledge being generated and hence more output. By extension, this model also predicted that convergence across countries might not arise.

Lucas (1988), like Romer (1986), tries to introduce an endogenous engine of growth into a growth model and uses human capital for this purpose. He proposes two variations. First, he takes human capital to be the general skill level that a worker possesses and denotes this $h$. Each worker can add to his human capital by devoting part of his non-leisure time to human capital accumulation. Assume that each worker devotes a fraction $u$ of his time to production and $1-u$ to human capital production. If there are $N(h)$ workers with skill level $h$, the effective workforce in production is

$$uNhdh$$

In addition to the effect of each individual's human capital on production, Lucas proposes an additional effect. He assumes that there is an external effect of human capital (not unlike Romer's external effect of knowledge) whereby the average amount of human capital in the economy also enters as an argument in the production function. As such, Lucas writes the production function as follows:

$$Y = A f(K, uhN).h_a$$

where $h_a$ is the average level of human capital in the economy.

For human capital to become the engine of growth in the model, Lucas needs to specify the manner in which human capital is accumulated. He does this by assuming that human capital accumulation is a linear function of the existing level of human capital:

$$\text{changes in } h = h(t) \delta[1-u(t)]$$

Lucas tests his model against the data for the US and finds that while his model performs well, it does not perform substantially better than the Solow model. In spite of this, he still maintains that an advance has been made because the model that includes human capital in this manner is at least consistent with cross-country differences in the growth experience.

Lucas' (1988) second approach to incorporating human capital hinges on the idea that human capital is generated during the production process, and not outside of it as his first model suggests. This distinction can be interpreted as that between formal education and learning on-the-job. He assumes there are two consumption goods, $c_1$ and $c_2$. The production of good $i$ is summarised as:

$$C_i = h_i u_i N$$

where $h_i$ is the human capital specialised to the production of good $i$ and $u_i$ is the fraction of the workforce devoted to the production of good $i$. To operationalise the idea that human capital accumulation is the outcome of the production process, Lucas assumes that the growth in $h_i$ is related to the effort devoted to the production of good $i$, $u_i$:

$$\text{changes in } h_i = h_i \delta_i u_i$$

While this equation for human capital growth may look very similar to the version above, the interpretation is quite different. In the equation above, the value $u$ refers to time away from the production of consumption goods; in this equation, it refers to time spent in the production of consumer goods. Either way, human capital contributes to economic growth and is the engine for continued growth.

Romer (1990) introduces human capital into his growth model in another novel way. He specifies three types of skills:

$L$, physical skills like eye-hand co-ordination and strength;

$E$, educational skills acquired in primary and secondary school; and
Economic performance of education and training: costs and benefits

S, scientific talent acquired in post-secondary education.

In addition to the educational variables, Romer also specifies an experience variable Z that denotes total man-hours of time spent on-the-job.

Consumption goods are produced using L, E, Z and intermediate producer durables Xc = (Xc1, Xc2, ...). Note that scientific education S is not a direct input into the production of consumer goods. Instead, S enters the model through its effect on Xc. The list of X includes as yet undiscovered inputs. Research is devoted to developing new inputs that make the production of consumer goods cheaper. The research process is improved by S and this is the mechanism through which S impacts upon economic growth. One of the values of Romer's (1990) approach is its explicit treatment of different forms of human capital which can be exploited in an empirical framework.

Mankiw, Romer and Weil (1992) also explicitly include human capital in their theoretical model but unlike Lucas and Romer, they base their model in the neo-classical spirit of Solow. The specify their production function to be:

$$ Y = K^\alpha H^\beta (AL)^{1-\alpha-\beta} $$

where H is the stock of human capital. They do not assume increasing returns or the existence of externalities. They go on to test their model and their results will be outlined below. For now, it is sufficient to note that this is a theory emphasising the importance of human capital in explaining economic growth but which does not rely on the type of assumptions which characterise the endogenous growth models.

4.2 The empirics of economic growth

Much of the early empirical work on economic growth was concerned with what became known as growth accounting. By this it was meant that annual growth rates for an economy (typically the United States) were broken down into the sources of that growth, following Solow's model. These sources were increases in the amount of capital and labour and a residual; the residual was thought to capture improvements in capital and labour, or alternatively put, technological improvements and human capital improvements. Griliches (1996) discusses this work and writes about his efforts and those of others to develop measures of human capital that could be used in these growth accounting exercises. One approach was to weight different types of labour (such as educational groups) by their market wage. The basic finding was that educational improvements could explain about a third of the residual that could not be explained by the growth in capital or labour.

With the development of cross-country datasets, the focus on a single economy shifted to international comparisons of the growth experience. Romer (1990) contains an empirical exploration of the growth process across countries and how human capital affects the pattern of growth across countries. The data used by Romer partly come from those assembled by Summers and Heston (1988); the measures of human capital are taken from the annual statistical yearbooks published by Unesco. The main human capital variable used is literacy. One reason for this relates to a general problem when undertaking cross-country analysis, namely, the difficulty of finding variables that are consistently defined and measured across countries and over time. Romer chooses to focus on literacy partly for this reason. His results therefore relate primarily to the connection between basic literacy and the rate of growth in output per head and the rate of investment.

The variables used by Romer are as follows (it is worth listing them as Barro (1991), discussed below, uses a similar set):

C: a constant;

Y60: real per capita income in 1960;

GROWTH: the annual average rate of growth of Y60 over the years 1960 to 1985;

GOV: the share of GDP devoted to government spending on items other than investment goods;
INV: the share of GDP devoted to investment;
LT60: the percentage of the population that is literate in a survey year that is close to 1960;
LT-DIFF: changes in the literacy rate between 1960 and 1980;
NP60: the consumption of newsprint in 1960;
RD60: the number of radios per 1000 inhabitants in 1960.

The sample included all the market economies included in the Summers and Heston data, except for Kuwait and Saudi Arabia; this left 112 countries. Regressions were run in which the dependent variable was GROWTH. The basic results show that the initial level of education (as measured by literacy levels) had a positive partial correlation with growth but subsequent analysis throws a question mark over this result. Romer is concerned about measurement error in both the income and literacy variables and so reestimates the basic equations using instrumental variables.

The reestimations give rise to a number of issues. Once instrumental variables are used to correct for measurement error in the income and literacy variables, neither is found to be significantly related to the rate of output growth. Part of the explanation for this arises because of the correlation between literacy and income. As such, Romer runs separate regressions in which he excludes literacy and then income. While income on its own is found to have a significant effect on growth, no such significant effect is found for literacy.

This finding of no significant effect of human capital is counter-intuitive but further analysis by Romer uncovers the reason for the result. The initial level of literacy and its rate of change are found to be positively correlated with investment. Once investment is excluded from the regressions both the level of literacy and the rate of change are found to have a significant effect on the growth rate. However, as Romer points out it is important to be careful in interpreting the partial correlations. It could be that investment, the growth in output and the growth in literacy are simultaneously determined; the directions of causation are less clear.

Barro (1991) begins with the observation that one implication of the neo-classical growth models, such as Solow's (1956), is that a country's per capita income growth should be inversely related to its initial level of per capita income. Alternatively put, there should be convergence between countries in terms of per capita income. Barro then notes that these hypotheses appear to conflict with the evidence and that there is little evidence of convergence. His empirical work attempts to work out this contradiction. Whereas many studies had previously focused on the variables that Solow emphasised, namely the savings rate and population growth, Barro, like Romer (1990), incorporates human capital into his empirical modelling.

Again like Romer (1990), Barro draws on the data of Summers and Heston (1988) and examines 98 countries for the years 1960 to 1985; his data are supplemented with data from the United Nations, the World Bank plus some other sources. While Romer used literacy as his measure of human capital across countries, Barro uses school enrollment rates. In particular, his human capital variables are the 1960 rates of primary school and secondary school enrollment. By including these variables in cross-country regressions with the growth rate as the dependent variable, Barro can assess what impact their inclusion has on the relationship between initial levels of income and growth.

The human capital variables are found to have a positive and significant relationship with per capita growth. In addition, and this is the point stressed by Barro, once the human capital variables are included, the initial level of income is found to have a negative and significant coefficient. This leads him to note that 'for a given starting value of per capita GDP, a country's subsequent growth rate is positively related to [these] measures of initial human capital'. He goes on to note that 'given the human capital variables, subsequent growth is substantially negatively
related to the initial level of per capita GDP'. The implication of this latter statement is that while convergence may occur, it is conditional on there being an initial level of human capital. In this way, the importance of human capital from a macroeconomic perspective is seen.

I noted in the theory section that Mankiw, Romer and Weil (1992) construct a Solow-type model in which they explicitly include human capital. Their core empirical concern is then the following. The standard Solow model, which does not explicitly include human capital, assumes that all output is paid to capital and labour according to their marginal products; this is a consequence of the constant returns assumption. The shares of output that are observed to be paid to capital and labour can then be taken as measures of their marginal products. This in turn allows us to calculate the elasticities of output with respect to capital and labour growth. One empirical difficulty for the Solow model is that regression estimates of the effect of investment on output tended to be greater than that predicted by the model. This result was one of the motivators of the thinking behind endogenous growth theory, discussed above.

Mankiw, Romer and Weil (1992) use the percentage of the working age population that is in secondary school as their measure of human capital. They find that by adding human capital to the type of cross-country regressions which are run by Barro and Romer, the estimated elasticity of output with respect to investment becomes more in line with the predictions of the Solow model. This is because investment leads to higher income levels that in turn leads to higher levels of human capital.

They also find that human capital, as they measure it, is positively and significantly related to the level of national income for the sample of countries that they examine. Their confidence in their augmented-Solow model is reinforced by the finding that 80% of the variation in income levels across 98 countries can be explained by three variables: investment, human capital and the sum of population growth, technological change and depreciation.

Benhabib and Speigel (1994) have made a particularly useful contribution which seeks to discover the mechanism through which human capital affects growth and income levels. In the theoretical section above, human capital was modelled as affecting output in two broad ways. First, in a model like Mankiw, Romer and Weil (1992) human capital affects output directly by being another input in the production function. But in a model like Romer (1990), we see human capital entering the picture in a second manner. Here human capital affects output indirectly by increasing total factor productivity. In Romer's case, the mechanism was that greater scientific skills increase the rate at which new and improved intermediate outputs were developed. The introduction of the new intermediate products into the production function acts as an impetus to growth. Benhabib and Speigel (1994) refer to Romer's mechanism as a possible source of human capital's affect on output but they also mention the mechanism of Nelson and Phelps (1966). They suggest that the importance of human capital arises in the adapting of new technologies from abroad. Some countries will be technological leaders; others will need to acquire and use technologies being developed by the technological leader. Human capital facilitates this.

Benhabib and Speigels' (1994) empirical work tries to establish which of the two broad patterns of influence of human capital is true. They find no support for the Mankiw, Romer and Weil (1992) view. This is surprising given the positive results that Mankiw et al. produced. Benhabib and Speigel address the discrepancy; one explanation lies in the different measures of human capital used. Support is found for the Romer/Nelson and Phelps view. But in addition to the roles suggested by these authors, Benhabib and Speigel also discuss how their results point to the importance of human capital for countries trying to attract physical capital, or foreign direct investment.

In giving a general review of the work in this area, Griliches (1996) describes as robust the finding that the initial average level of schooling makes a positive contribution to growth. However, he also makes reference to 'the re-
peated finding' that 'changes in the estimated level of schooling or human capital do not contribute to growth, at least as measured over the 1965-85 period'. He offers one possible explanation of this apparent contradiction; in many countries increased numbers of educated people were absorbed in the public sector. To the degree that public sector employees make smaller contributions to economic growth, the increase in human capital will not have translated into economic growth.

Whether this argument by Griliches is true or not, it does draw attention to the possibility of a break in the link between human capital accumulation and growth.

5. Discussion

I have now reviewed the research that has been done on the impact of training on the wages of individuals, the impact of training on productivity and the impact of education on growth rates and income levels across countries. I now want to discuss what has emerged from two perspectives. First, I will discuss the implications for research; I will then go on to discuss the implications for policy.

5.1 Implications for research

In terms of calculating rates of return to education and training, the cross-country work provides the least scope for producing anything that might resemble a reliable rate of return.

The work that has been done across countries appears to show that an initial level of human capital is a necessary condition for development. However, as discussed by Benhabib and Speigels (1994), the precise mechanism through which education affects growth is unclear. Romer's (1990) finding of a positive correlation between investment in physical capital and an initial level of human capital suggests that human capital is a necessary condition for development. However, the evidence is much weaker when we ask if human capital provides a sufficient condition for development. It could be that without physical capital accumulation, additions to the human capital stock do not add to growth.

Apart from the difficulties of demonstrating a link between human capital and growth, any effort at estimating a 'macro' return to education or training would have great difficulty in accounting for other benefits of training. For example, higher levels of human capital are often associated with reduced levels of crime. However, to capture this effect across countries with any degree of reliability would be enormously difficult. For this reason, both empirical and theoretical work at this level can best be directed towards uncovering the mechanism through which education and training influence growth.

The work at the level of individuals and firms provides much more scope for estimating reliable rates of return but as was made clear in the discussion above, there are many difficulties when it comes to such returns. In the case of individuals, these difficulties are not entirely insurmountable so let me propose an approach that would at least go some way to improving our estimates in this area. As I noted when discussing the benefits to individuals of training, in order to make a valid rate of return calculation it is necessary to have a full valuation of all costs and benefits. To the extent that individuals pay out of pocket expenses, this element of cost is transparent. If the individual partly pays for the training through reduced wages, it is clearly more difficult to estimate costs but it is not impossible. Through the estimation of wage equations, it is possible to estimate what the wage of an individual would be given a range of characteristics. By comparing a hypothetical individual with a similar person who is being trained, it is possible to derive an estimate of the wage disadvantage suffered while training.

But can we get a full valuation of the benefits to the individual of training? The wage gain has clearly been studied at length so we certainly have information on that point. The reduced incidence of unemployment could be estimated using a panel of individuals and associating differences in unemployment incidence and duration across individuals with
differences in training acquired. By applying the estimates over the life-cycle it would be possible to estimate how life-time earnings would be affected by training, through the reduced unemployment effect.

Valuing the intangible effects of training would be the most difficult element of this exercise but again it is possible to get some estimate. Take the case of increased job satisfaction. As no market exists in which people can buy job satisfaction, we do not know what people are willing to pay for increased job satisfaction or how they value it. But this issue has arisen in other areas of economics, in particular environmental economics, and innovative approaches have been developed to put values on “goods” that are not valued in the marketplace.

One such approach is called ‘contingent valuation’. Any standard textbook on environmental economics will contain a discussion of this technique; one such example is Pearce and Turner (1991). To illustrate how this operates I will use as an example an area of scenic beauty. If a proposal exists to construct a motorway that will destroy the scenic attributes of the area the issue arises of what value people place on the scenic area. Without such a valuation it is not possible to determine whether the value of the motorway is sufficient to warrant the destruction of the area. Contingent valuation generates an estimate of the value by surveying people and asking how much they would be prepared to pay to keep the scenic area. Alternatively they can be asked how much they would be willing to accept to forego the scenic area. Either way, it is possible to generate an estimate of the value using carefully designed survey techniques to overcome some obvious difficulties with the method.

This approach to estimating value for ‘goods’ that are not traded in the marketplace could in principle be extended to provide an estimate of the value of the intangible effects of training. Referring again to the benefit of increased job satisfaction, it would be possible to get an estimate of the value of this benefit by surveying workers and asking them to place a value on the increased job satisfac-
Let me develop this with a concrete example. Ever since Becker's work on general and specific training, we have been aware that under conditions of perfect competition in the labour market employers will not pay for training that can be used by the employee elsewhere, i.e. general training. This is because employees can take the general training and use it elsewhere, thereby denying the first employer a chance to recoup the investment. However, employees might pay for the training through lower wages during the training period. If there is some constraint on employees' ability to take lower wages (such as a minimum wage) then they may not receive general training and so the level of training provision will be below the optimum. In this situation, the rate of return to training will be high relative to other investments. Hence, we could get an insight in to the underprovision of training by estimating the rate of return or by identifying a reason for its underprovision.

This line of thinking will be familiar to labour economists. However, more recent work that has been written about by Acemoglu and Pischke (1999a and b) has begun to cast some doubt on the rigid implications of the Becker theory. They provide examples of where employers do provide and pay for general training and present scenarios which show rational economic behaviour on the part of the firms. For example, Bishop and Kang (1996) discuss a situation of asymmetric information. When an employee is not able to signal perfectly the generality of the training that they have received with one employer to another, skills that are technically general become de facto specific. In this situation, the employer has an incentive to contribute to the provision of general training. Acemoglu and Pischke (1999b) show how wage compression can produce the same effect of turning general skills into de facto specific skills. If workers who receive training cannot go elsewhere and earn a wage equal to their marginal product because wages have been compressed, for example by unions, then the mobility argument which is crucial to Becker’s result breaks down.

The Acemoglu and Pischke line would suggest that concerns about underinvestment in human capital may be unfounded. If this is so, then rate of return estimates may not be of great importance. However, the endogenous growth theory developments discussed above have introduced a new set of concerns over market failure in human capital. If the externalities of the sort suggested by Romer and Lucas are large and prevalent, then underinvestment in human capital from the aggregate perspective will arise. I have noted already that estimating returns at this macrolevel will be unproductive. For this reason, it appears that efforts to deepen our understanding of the link between education, training and growth and the possible existence of externalities and hence market failure may represent the most fruitful research avenue.

5.2 Implications for policy

The central question I want to address in this final section is whether governments should contribute to the funding of employer-provided training in the light of the research results discussed above. I will not consider the issue of education as the case for government funding in that area is well understood and accepted. As always, the principles upon which this question should be answered can be taken from elementary public economics. We know that government intervention should occur where there is market failure such as the existence of externalities or public goods, or where the government wishes to alter the distribution of resources. Hence, we must ask what market failure arises in the case of employer-provided training.

There are two standard arguments given in respect of employer-provided training. A market failure can arise in the case of employer provision of training because an employee may quit, thereby preventing the employer from gaining a return on the training. A second market failure can arise in that either firms or individuals with liquidity constraints may not be able to borrow money to finance training.

In the light of the studies presented above, I would argue that there is evidence to suggest that market failures may not be as prevalent.
as is sometimes thought. The papers by Acemoglu and Pischke address the issue of market failure quite directly and cast doubt on its prevalence. Many of the studies that looked at the effect of training on company productivity are also indicative. As they generally found a positive effect of training on productivity, this would suggest that trained employees are not necessarily leaving but rather stay and allow the training they received to translate into productivity increases. We have also seen evidence that training increases profitability so it would generally appear that companies have an incentive to undertake training.

Even if companies have an incentive to undertake training, they may not undertake if they, or the employees, face liquidity constraints. In the case of large firms, it seems unlikely that this is a real constraint. As such, if governments were to fund training in these large companies it is likely that all that is being achieved is the subsidisation of an activity that would have occurred anyway. As the training would be of value to the firm and they are in a position to finance it, the training would probably be undertaken in the absence of any government funding. In this way the government’s money is not only wasted — as the money is transferred to a company that is already profitable, it is being transferred in a way that is counter to standard distributional considerations.

For firms which face genuine liquidity constraints, and these will typically be smaller sized enterprises, there remains an argument in favour of government funding. In this case, government funding will lead to training being provided that would not otherwise have been. What is more, by not offering finance to larger firms who are less likely to face liquidity constraints, extra resources are available for smaller firms, or for other programmes.
Appendix

The Solow model

Any discussion of growth theory must begin with an outline of the Solow growth model (Solow 1956). This model has been enormously influential in terms of generating empirical work on growth and additional theoretical work which has departed from the Solow view.

The model begins with the aggregate production function, which shows how output (Y) is a function of the amount of capital (K) and labour (L) employed, and the state of technology (A):

\[ Y = A f(K, L) \]

Output increases with additional amounts of K and L, but at a decreasing rate if more L or K is added to a fixed amount of the other factor (i.e. diminishing marginal returns). If both K and L are increased by the same proportion, output also increases by that proportion (i.e. constant returns to scale). Should the amount of K and L remain the same but technology improves (i.e. an increase in A) then the amount of output produced also increases.

The focus of the model is on how output per capita grows over time so a restatement of the production function allows for a focus on this point. Given the assumption of constant returns to scale, it is possible to re-write the production function in per capita terms:

\[ Y/L = A f(K/L, 1) \]

Denoting per capita values by lower case letters, we can write this as:

\[ Y = A f(k) \]

i.e. output per head is a function of capital per head and the state of technology.

Moving on to issues of growth, Solow noted that changes in capital per head would be the result of investment per head and population growth (assuming that all the population are in the labour force, which is a useful simplifying assumption). Investment per capita is assumed to be equal to savings per capita, which in turn is equal to output per capita multiplied by the marginal propensity to save, s. In terms of our notation:

\[ \text{Investment per capita} = sf(k). \]

Population growth is assumed to be at an exogenous rate of n. If capital per head is to be kept constant, investment per head would have to be at a rate of nk.

Combining these assumptions, we can say the following:

changes in capital per head \( (k) = sf(k) - nk. \)

Given the assumptions employed by Solow, the model generated an additional crucial implication. In the 'steady state', growth in output per capital will be zero; investment per head will be sufficient to maintain capital per head but this in turn will be enough only to maintain output per head. This result is derived from the assumption of diminishing marginal productivity. To understand why, assume initially that

\[ sf(k) > nk. \]

Here, investment per capita is greater than the required replacement rate. As such, capital per head will rise and so \( sf(k) \) and \( nk \) will rise also. But by the assumption of diminishing returns \( sf(k) \) will eventually rise more slowly than \( nk \) and so will eventually will equal \( nk \). A similar logic applies if \( sf(k) < nk. \)

Now capital per head will be falling, until \( sf(k) = nk. \)

Given that output growth per person will be zero in the steady state, the model predicts that output per head will only increase if A increases, i.e. there is a technological improvement. This in turn took the focus away from human capital as being the engine of growth. Exercises that looked at the sources of economic growth typically measured increases in L and K and labelled the additional growth that could not be accounted for by changes in K and L as the Solow residual. While it was conceded that the residual may be picking up improvements in human capital, the focus of the exercise follows the explicit factors which Solow had modelled and hence relegated all besides capital and labour into the residual.

Unemployment and skills from a dynamic perspective

Joost Bollens

Abstract
It has been suggested that during the last decades the relative labour market position of the low-skilled has declined markedly, due to a variety of factors. Some authors attribute a substantial part of the explanation of recent European unemployment history to this relative demand shift against the low-skilled. A general increase in skill mismatch is, in their view, one of the main causes of the peculiar persistence that has characterised European unemployment in the past 20 years. This view, however, has not gone unchallenged. Others have argued that the observed persistence is caused by other factors, the incidence of long-term unemployment and everything this brings about, being one of the most important. In this contribution, the two rival views, their microeconomic underpinning and the available empirical evidence as well as the corresponding policy implications are compared.

1. Introduction

There is undeniably a relationship between skills and unemployment. Compared to better educated workers, the unemployment rates for workers with low educational attainment, are, almost without exception, consistently higher throughout the EU. As such, this is not a new phenomenon. However, it has been suggested that during the last decades the relative labour market position of the low-skilled has declined markedly, due to a variety of factors. Some authors attribute a substantial part of the explanation of recent European unemployment history to this relative demand shift against the low-skilled. A general increase in skill mismatch is, in their view, one of the main causes of the peculiar persistence that has characterised European unemployment in the last twenty years.

This view, however, has not gone unchallenged. Others have argued that the observed persistence is caused by other factors, the incidence of long-term unemployment and everything what this brings about, being one of the most important.

From a policy point of view, it is important to know which view is most in line with reality. Depending on the chosen theory, policy prescriptions differ. More particularly, there are some implications for organisation of a VET policy to alleviate unemployment problems.

In this contribution, a comparison is made of the two rival views. Although both theories originally stem from a macroeconomic perspective, i.e. a highly stylised and aggregated world, and essentially deal with macro phenomena, most attention will be devoted to their microeconomic underpinning and the available empirical evidence at this level.

2. Basic facts

2.1 Unemployment

A good overview of the recent unemployment history of European countries can be obtained from looking at Figure 1. Two particular evolutions attract attention. A first remarkable observation is that, while US unemployment rates were invariably above European rates during the first part of the observed time span (and for that matter, also during the 1960s and the beginning of the 1970s), from 1983 onwards US unemployment rates are consistently below European. If a straight trend line was drawn through US and EU unemployment evolution, the US line would decrease, starting at 10% in 1975 and arriving at 5% to 6% in 1997. The European trend line, on the contrary, would definitely increase.

</table>

Another striking observation relates to the cyclical behaviour of both series. The US series displays a nice cyclical pattern, with alternating valleys and peaks. In the European series, on the other hand, in the observed time span there was actually only one substantial decline. Still, there seems to be some relationship between the behaviour of both series. Whenever US unemployment starts to rise, European unemployment will follow suit, suggesting a common underlying cause. However, once peaked, US unemployment starts to decrease quite instantaneously, while European unemployment seems to need much more time.

### 2.2 Unemployment duration and educational attainment

Someone who is in unemployment for at least one year, is called long-term unemployed. As can be seen from Table 1, long-term unemployment is quite significant in most European countries, contrary to the US, where long-term unemployment as a percentage of total unemployment is almost negligible (6% in 1990 for North America).

Another important feature of unemployment relates to the fact that unemployment rates differ between educational attainment groups, typically the lower skilled experiencing a much higher probability of being unemployed than the higher skilled, although there are a few exceptional countries with a reverse relationship. Tables 4 and 6 to 8 document the relation between educational attainment and unemployment rates. While this inverse relationship is not particularly European, nor limited to the past 30 years, there are some indications that the position of the lower skilled has markedly deteriorated in recent history.

A last remarkable fact regards the relation between skills and unemployment duration. As Table 2 indicates, long-term unemployment is disproportionately hitting lower-skilled workers.

### 2.3 Summary: some stylised facts

Under the proviso that not all countries in the EU have experienced an identical development, still some stylised facts can nevertheless be drawn from the preceding figures:

- over time, unemployment rates have grown, sometimes dramatically;

Source: Eurostat, labour force survey and own calculations.

Legend: Educational attainment: H = Third level education; M = Upper secondary Level; L = Less than upper secondary level

(1) If U is the number of unemployed, and UH is the number of unemployed with third level education, etc., then 0.06 is equal to UH/U, i.e. the share of group H in unemployment.

(2) Analogously, if UH_LTU is the number of long-term unemployed (12 months or more), and UH_LTU is the number of long-term unemployed with third level education, then 0.03 is equal to UH_LTU/ULTU, i.e. the share of group H in long-term unemployment.

(3) If WH is the number of employed with third level education, then LFH = (WH + UH) is the number of persons with third level education in the labour force, and then 2.7 is equal to (UH/LFH)X100, i.e. the unemployment rate for group H.

(4) Here the same denominator is used to scale the number of long-term unemployed from group H, etc., i.e. 0.5 is equal to (UH_LTU/LFH)X100.
unemployment appears to have a persistent nature, i.e. once the unemployment rate has gone up, e.g. in a period of a cyclical downturn, it has a tendency to remain on this higher level, i.e. it does not return to its initial equilibrium level, even when the business cycle becomes more favourable;

typically, the unemployment rates are higher for lower skilled than for higher skilled workers, even though the share of the lower skilled in the labour force is decreasing over time;

the incidence of long-term unemployment (more than one year) is on a historically unprecedented high level. Moreover, it is typically the lower skilled workers who are worst hit by long-term unemployment;

here it is noteworthy that over time, inflow rates into unemployment in EC countries changed little. What did change over time are the outflow rates, which dropped substantially. In other words, increase in unemployment rates can not be attributed to an increased probability of losing a job. It is the decreased probability of finding one, once unemployed, that is the driving force for EU unemployment growth (Bean 1994; Layard et al. 1991). This evolution is particular for EU countries. In North America, both inflow and outflow rates are high, and consequently, the duration of a typical unemployment spell is low, while in Nordic countries and Japan, at least until the end of the 1980s, inflow rates were low, and outflow rates were high, which also gave rise to a low duration (ibid.);

high unemployment rates sometimes go hand in hand with high vacancy rates.

This latter relationship can be illustrated by the so-called Beveridge curve (OECD 1993; Calmfors 1994; Van Der Linden 1997). The Beveridge curve depicts the relationship between the number of job seekers (unemployment rate) with the number of vacant jobs (vacancy rate). This relationship is assumed to be inverse, i.e. an increase in the number of vacancies will ceteris paribus reduce the number of unemployed, and vice versa. This curve can be seen as a measure for the effectiveness of the matching process between vacancies and unemployed (Calmfors 1994). The observed evolutions (higher unemployment rates, persistence, simultaneously high unem-
Unemployment and high vacancy rates) imply that over time the Beveridge curve has shifted outwards, as depicted in Figure 2. A point like A is typical for the beginning of the 1970s, whereas a point like B corresponds to the actual situation, i.e. the unemployment rate compatible with a given vacancy rate is much higher than it used to be.

Apparently, the matching process has become less efficient over time. How can this be explained? In the next section, we introduce two competing theoretical frameworks that both fit the above-mentioned observations. One is an approach of equilibrium unemployment, enriched with a hysteresis component. The other emphasises the importance of skill mismatch. The remainder of this survey will be devoted to an elaboration of the different claims put forward by these theories to establish which theory is most in line with reality. This is important, because, as will be duly shown, policy prescriptions differ, depending on the chosen theory.

3. Explaining the facts

3.1 Equilibrium unemployment, persistence, hysteresis and state dependence

3.1.1 Equilibrium unemployment and hysteresis

To grasp the main gist of the first approach we labelled 'equilibrium unemployment, enriched with hysteresis', we start with a short intellectual history of the main ideas.

During the 1960s, economic policy-making was to a large extent founded on the so-called Phillips curve, which posits an inverse relationship between inflation and unemployment. According to the then prevailing consensus, one could achieve and maintain a permanently low level of unemployment merely by tolerating a permanently high level of inflation (Mankiw 1990). However, in 1968 Milton Friedman and Edmund Phelps, independently, concluded that the trade-off between inflation and unemployment as described by the Phillips curve, could not be generally true.

Subsequent developments proved Friedman and Phelps correct. With the 1970s came an era of stagflation, where rising inflation rates went together with high unemployment. Both authors had, in their refutation of the Phillips curve, put forward the notion 'natural rate of unemployment'. This natural rate is a kind of long-term equilibrium rate of unemployment. Actual unemployment rates can differ, but in the end they will drift towards this underlying equilibrium value. The natural rate depends on the 'actual structural characteristics of the labour and commodity markets' (Friedman 1968, as quoted by Cross 1995). The natural rate does not depend on nominal variables, such as the level of aggregate demand. A demand shock, e.g. a traditional stimulation of demand by fiscal policy, will affect the actual unemployment rates, but not the equilibrium rate. Thus unemployment will drift towards its equilibrium value.

As already said, macroeconomic developments in the 1970s coincided with the predictions of the natural rate hypothesis. A series of supply shocks (e.g. rise in commodity prices, such as oil) led to a sharp increase in the actual unemployment and inflation rates in the OECD. With the 1980s, however, came some rather puzzling new developments, especially in Europe. As a reaction to the high levels of inflation, at the beginning of the 1980s disinflationary policies were pursued, with a tight monetary policy, and a major and prolonged fiscal contraction (Blanchard and Summers 1986a, 1986b). This large, adverse demand shock resulted in a further rise of (European) unemployment.

After inflation had been stabilised at a lower level by 1985, and after a beneficial oil shock in 1985-86, the original factors that had propelled unemployment growth, had largely disappeared. One expected now a substantial decrease of unemployment. This, however, did not occur (Cross 1995; Bean 1994; Layard et al. 1991). Or, put differently, as the equilibrium unemployment rate is the rate at which inflation is constant, the then prevailing actual unemployment rate appeared to be the equilibrium rate, suggesting that not only the actual, but also the equilibrium unemployment rate had risen sharply.
'While this could as a matter of logic be due to shocks increasing both the equilibrium and the actual rates, empirical attempts to identify such shocks have failed. Lower productivity growth and higher oil prices may help explain the 1970s, but there are very few identifiable adverse shocks which can explain a doubling of equilibrium unemployment in the 1980s' (Blanchard and Summers 1986a, page 1, our italics).

At this point, the issue of hysteresis was brought forward. The persistence of European unemployment rates, which could not be reconciled with prevailing theory, switched attention away from the original source of increase in unemployment toward the question of how the effects of shocks are propagated over time, leading to an equilibrium rate of unemployment that depends not only on the current values of the relevant forcing variables, but also on the history of unemployment' (Bean, 1994, p. 603).

By introducing hysteresis, one incorporates the empirical observation of the 1980s that, once unemployment has risen, it has a tendency to remain at this higher level, so that today's equilibrium unemployment level depends partly on past unemployment. Several possible explanations for the emergence of persistent unemployment have been given: insider-outsider models (and hiring and firing costs) (e.g. Blanchard and Summers 1986a, 1986b; Lindbeck and Snower 1986, 1987), outsider characteristics (e.g. Budd et al. 1987; Franz 1987; Price 1988; Tötsch 1988; Layard et al. 1991), and capital shortage (Modigliani et al. 1987; Burda 1988; Bean 1989).1

We will principally discuss the 'outsider characteristics' explanation. In their influential 1991 textbook, R. Layard, S. Nickell and R. Jackman (or LNJ for short), use the acronym NAIRU, which stands for 'non accelerating-inflation rate of unemployment'. The long-run NAIRU happens to be equal to the natural rate of unemployment. However, there is some 'short-run NAIRU', consistent with stable inflation, which, violating the natural rate hypothesis, can partly be determined by nominal variables, such as aggregate demand, which affect actual unemployment. Therefore, 'there is short-term "hysteresis", in the sense that past events affect the current short-run NAIRU. But there is no long-term "hysteresis": there is a unique long-term NAIRU. In the end, the unemployment rate always reverts.' (LNJ 1991, p. 10).

The underlying mechanism is as follows. An increase in actual unemployment rates leads to an increase of long-term unemployment. For reasons which will be elaborated later (see 3.1.2), long-term unemployment leads to a distance between the long-term unemployed and the labour market, in fact rendering them unemployable. Therefore, they no longer exert a downward pressure on wages, which is in a sense a change in the structural characteristics of the labour market. The effectiveness of a given level of unemployment i.e. the exertion of a downward pressure on the wage is lower, the higher the share of the long-term unemployed. The equilibrium rate of unemployment determined by wage-setting and price-setting, will therefore at any given level of unemployment be higher, the higher the share of the long-term unemployed.

For the sake of completeness, it should be mentioned that LNJ also consider insider power as a potential source for hysteresis. The argument runs essentially as follows: 'if last year's workforce was small relative to this year's expected employment, then [requesting] a higher wage this year will involve little extra risk, since most existing workers are already safe.' (LNJ 1991, p. 28). However, on the basis of empirical evidence, they conclude that the outsider is more important than this insider variant.

The capital shortage version of hysteresis states that depressed demand has negative effects on investment and capital accumulation, induced by the reduction of capacity utilisation (Heylen 1993).

The measurement of persistence has been a hot topic in applied econometrics, but has now...
Unemployment and skills from a dynamic perspective

Hysteresis

Hysteresis is derived from the ancient Greek ὑστερέω, meaning to come later, and was first used in physics by James Ewing in 1881 (Cross 1995). Amable et al. 1995, as well as Cross 1995, argue that the hysteresis concept as used in economics, does not square with the usage of the term in physical sciences. Although this is largely a discussion of semantics, the arguments are convincing:

Hysteresis in essentially a non-linear phenomenon, as opposed to the linear version used in economics. 'The equilibrium unemployment rate no longer returns to the status quo ante once a temporary shock is reversed, but instead displays remanence. This means that the new equilibrium will not be the same as the old, but will remain displaced' (which can not be reconciled with the natural rate hypothesis). Moreover, 'the equilibrium rate of unemployment retains a selective memory of past shocks: It neither forgets all past shocks, as in the natural rate hypothesis; nor does it, like the elephant, remember all past shocks'. 'Only the non-dominated extremum values of shocks affect the equilibrium path', implying that 'shocks arising from changes in nominal variables, can, by way of the selective memory process, shape the equilibrium path for unemployment'. Which, again, contradicts the natural rate hypothesis.

What is generally called 'hysteresis' in economic usage, therefore, is not hysteresis at all, but rather 'a form of persistence of deviations from the natural equilibrium path'. From now on, we will avoid usage of the term 'hysteresis', and will speak about 'persistence' instead.

been pushed somewhat into the background. Models that attempt to model the dynamic behaviour of unemployment are to some extent rather empty or data driven, and, at best, say something about persistence, but seldom are able to discriminate between the possible causes or mechanisms of this persistence, and are thus not particularly helpful from a policy point of view. Moreover, the statistical tests used in these exercises are often questioned (since they have very low 'power' against alternatives).

A recent collection of papers (Henry and Snower 1996) from the IMF (International: Monetary Fund) is interesting because, using a comparable methodology for different European countries, it concludes that there is quite a lot of variation in the degree of persistence between individual European countries. The authors use structural VAR\(^2\) models, simultaneously modelling the dynamic behaviour of (un)-employment, labour force and wage formation. Table 3 gives model simulations of a temporary labour demand shock (see p. 26). (The authors also investigate the dynamics of permanent shocks).

Though these results should be handled with care, they suggest that most major European economies exhibit a substantial degree of unemployment persistence (Spain is also included in the study, albeit not in the table). Moreover, they suggest that the degree to which each country is characterised by this persistence, differs significantly. 'In France, persistence seems relatively low, but the minimum wage and social security policy have probably led to high trend rates in unemployment. Over the 1980s, unemployment has risen in Spain, but persistence has declined. In Germany [...] the

responsiveness of the general labour market to shocks appears low [...]. Italy and the United Kingdom exemplify policy initiatives that can improve the resilience of the economy to shocks. The evidence that this is happening is not clear, however, even in the United Kingdom, where reform has been in train for over a decade.' (see p. 31-32). Persistence in Spain is confirmed by Dolado and Jimeno 1997. Some other recent studies are Song and Wu 1997, 1998; both using panel data and panel-based tests, and Roed 1996. The only robust result seems to be that the hysteresis hypothesis is rejected for the US. For other countries, results remain rather inconclusive.

3.1.2 The duration of unemployment

The persistence in the LNJ view of the world is, to a large extent, due to the existence of long-term unemployment. In this section we review how long-term unemployment could lead to persistence. We start with a short description of exit rates.

3.1.2.1 Exit rates

Consider an age group (cohort) of persons who become unemployed at a given moment t. As time goes by, some will leave unemployment (because they find a job, or because they leave the labour force), while others will remain in unemployment. This can be graphically illustrated with a so-called survivor curve (Figure 3).

At point 0 on the horizontal axis, the cohort flows into unemployment. Therefore all, i.e. 100%, are still in unemployment. Twelve months later, in this example, 50% of the original group remain in unemployment ('survive'), indicating that in this first year 50% have left unemployment. The exit rate in this first year, i.e. the probability of leaving, is thus 50%. In the same fashion, we can compute the exit rate in the second year as the ratio of the number of persons who will have left unemployment by the end of the second year to the number of persons who were still unemployed at the beginning of the second year.

Exit rates are taken over time periods of one year. It is of course possible to extend the idea to shorter periods of time, e.g. months, or weeks. By the same logic, one can make the time period infinitesimally small. In this case, the exit rate is called a hazard rate. The hazard rate is an instantaneous exit rate, or, in other words, the probability of leaving a particular state (e.g. unemployment) at point t (say, after 12 months), given that one has remained in that state until t (say, during 12
months). Over time, hazard rates can be either constant, increasing or decreasing. A constant hazard implies that the probability of leaving unemployment does not change over time, i.e. the duration of the unemployment spell does not influence the exit probability ("someone who is long-term unemployed has, ceteris paribus, essentially the same probability of leaving unemployment today as someone who is only in unemployment since six months").

When the hazard is not constant, one speaks of duration dependence. When the hazard is decreasing over time, also called negative duration dependence, the probability of leaving unemployment becomes smaller, the longer one remains unemployed. The reverse holds in case of positive duration dependence, i.e. when the hazard rate increases.

3.1.2.2 State dependence

People do differ. Characteristics such as age, gender, educational attainment, work experience, ethnicity, etc. do have an important impact on the probability of leaving (and in the first place, on the probability of entering) unemployment. When one states that there is negative duration dependence in the hazard rates out of unemployment, one actually claims that the length of the stay in unemployment, i.e. the duration itself has, in some sense an autonomous impact on the exit probability, over and above the impact of the aforementioned individual characteristics. Negative duration dependence implies that something happens or changes during the stay in unemployment, either because the unemployed themselves change, or because they are perceived to have changed.

In fact, there is a huge and thusfar unresolved debate on these matters. A lot of research points to negative duration dependence and thus state dependence, but there is also a lot of evidence that points to the absence of duration dependence. In this last case, observed differences in hazard rates are completely accounted for by heterogeneity, i.e. personal characteristics that were already present at the beginning of the unemployment spell (in Section 4.1 the evidence will be surveyed). Assuming that negative duration dependence is present, there have to be some processes or forces that act during the course of the unemployment spell. Some of these processes are readily identifiable.

- The fact of being unemployed, especially for persons that find it hard to find another job, can trigger off a process of discouragement and demotivation, which eventually can lead to habituation and resignation (see Section 4.2). This will probably lead to a reduction of the job search activity, and hence to a reduction of the exit probability.

- Being in unemployment, particularly long-term, can lead to a loss or an erosion of acquired skills (be it skills acquired by formal or informal learning, or more general skills (such as reading and writing) or more specific skills) (Phelps 1972a; Pissarides 1992; Acemoglu 1992). Moreover, even if there is no loss, previously acquired skills and knowledge can quickly become obsolete and outdated when no longer used and updated. Working is, in a sense, continuous training on the job (Section 4.3). If erosion and depreciation of skills take place over an unemployment spell, there is a direct effect on employability, and hence on the exit probability.

- Unemployment, and more particularly long-term unemployment, is said to affect work attitudes and work discipline (Phelps 1972a) such as keeping appointments (e.g. starting on time), accepting authority, being able to concentrate on one task for a longer period, social functioning and in general meeting the strict requirements which exist within most labour situations. This process does not necessarily affect the individual's employability in a direct way, since a loss of work attitudes is not always directly observable and often only becomes apparent after he/she has been hired. Indirectly, it can be of influence if potential employers come to associate long-term unemployment with loss of work attitudes.

- This last mechanism can be generalised as a loss of reputation argument. Given that a hiring process is a situation with asym-
metrical information, where the potential employer normally has only limited information about the productivity of a potential employee, employers may use the unemployment duration as a signal of productivity, and thus rank candidates by their unemployment duration (Blanchard 1991; Blanchard and Diamond 1994) (see Section 4.4). This can be seen as a form of statistical discrimination (Phelps 1972b; Arrow 1972). If this mechanism acts, the hazard rate obviously will decrease with duration. Note that this will be the case, even if the former explanations have no or only a marginal significance (Cockx 1998). This mechanism will possibly be reinforced if public employment services discriminate between unemployed with different unemployment durations (Winter-Ebmer 1991). The common practice of ranking unemployed by their employability in order to tailor activities, can easily become a self-fulfilling prophecy.

3.1.3 Relation with observed facts and policy conclusions

Two of the most singular stylised facts from Section 2.3, namely persistent unemployment and the apparently shifted Beveridge-curve, can be readily explained. A rise in unemployment, due to a succession of severe negative shocks, leads to long-term unemployment. The long-term unemployed become disenchanted from the labour market, which, through the mechanism(s) described above, leads to persistence. As the long-term unemployed become unemployable, the number of effective unemployed will be lower than the total number of unemployed, and therefore, a higher unemployment rate will be compatible with a given vacancy rate.

As to the huge differences between the unemployment rates of different skill levels, LNJ observe that the lower skilled are more likely to become unemployed than higher skill groups, but that, once unemployed, they do not remain unemployed longer. Therefore their higher unemployment rates are primarily due to higher inflow rates and not to a longer average duration (LNJ, 1991, p. 44-45, figures for Britain 1984 and the USA 1987). The authors acknowledge the importance of skill mismatch, but argue that skill (and other) mismatches are not a new phenomenon. Mismatch existed before the advent of the rise in European unemployment, and moreover, according to the authors, did not increase afterwards (except Sweden). Therefore, in their opinion, skill mismatch can not be held responsible for the observed changes in unemployment.

What has changed over the past decades, is the emergence and tremendous growth of long-term unemployment. The policy implications thus center on the prevention of long-term unemployment and the activation of the (long-term) unemployed. If long-term unemployment leads to discouragement and habituation, loss of skills and worker attitudes, it is important to act preventively by creating e.g. temporary work experience and recruitment subsidies programmes to prevent the disenfranchising processes. The long-term unemployed on the other hand, can be reactivated by training programmes that upgrade lost or outdated skills, and reestablish worker attitudes. Mandatory participation can be a solution for problems of habituation, while job-search programmes can be a remedy for discouragement (Cockx 1998).

These are the main ingredients of what has come to be known as active labour market policy (Calmfors 1994). These policies are strongly advocated by the OECD (1994), and are also recommended by the EU Luxembourg Summit of 1997.

3.2 Structural unemployment and skill mismatch

3.2.1 A shift in the demand for unskilled workers

In the persistence-framework elaborated in the previous sections, a rise in actual unemployment can have long-lasting consequences, but the underlying equilibrium unemployment rate is not necessarily affected. In the
end unemployment will tend to its long-run equilibrium. Active labour market policies will be necessary to enfranchise disenfranchised workers, but once this has been achieved, these policies are no longer needed.

A rival view states that during the course of past decades, not only actual, but also equilibrium unemployment rates have increased. This line of reasoning builds on the observation that over time, there has been a dramatic deterioration in the position of the low-skilled members of the labour force. In Europe, the shift in demand against the low skilled reveals itself in growing unemployment differentials between higher and lower-skilled workers. In the US labour market on the other hand, where wage rigidity is lower, the demand shift manifests itself through a substantial decline in the relative wages of the lower skilled, generating an increase in wage inequality.

Over time the qualification level of the population increases (Tessaring 1998). The shift in demand against the low-skilled, however, is not counterbalanced by this analogous shift in the skill composition of labour supply. Given the downward rigid wages, the low-skilled get struck in unemployment, and become long-term unemployed. Long-term unemployment persists because those unemployed do not possess the skills demanded by the labour market, and not, or not necessarily, because they become disenfranchised. In other words, this view does not demand negative duration dependence in the exit rates from unemployment, and can be compatible with pure heterogeneity (compare Section 3.1.2.2).

The demand shift against the low-skilled, together with the relative wage rigidity, is seen by several authors as an explanation for the persistence of high unemployment in Europe (Krugman 1994; Drèze and Sneessens 1997). It is in this context that the notion ‘skill mismatch’ is introduced. Loosely speaking, skill mismatch is a mismatch between the skill composition of labour demand and supply. However, before elaborating this concept, we will give some figures on the claimed demand shift against the low-skilled, and subsequently, a brief overview of possible causes.

For the time being, educational attainment is taken as a proxy for skill level (see Section 3.2.4). But even then, it is difficult to obtain figures that are really comparable over longer time periods (due to changing definitions of unemployment, changing categories of educational attainment, etc.).

Table 4 records the evolution of unemployment rates for low and high education groups for several countries. The table is taken from Nickell and Bell 1996, p. 303. It gives unemployment rates for low and high education groups over time, and only for males (the relationship between unemployment and skill level tends to be stronger for males, OECD 1994). It indicates that there has indeed been a deterioration for the low education groups over time, although a reverse process has taken place in some countries more recently. The North American countries and the UK are said to have a less rigid wage formation, which is thought to account for their particular evolution (Blau and Kahn 1996). Table 5 gives some indications about the evolution of relative wages, and it suggests that earnings inequality in the US has increased, while the same seems to be the case in the UK more recently.

Some more recent figures can be found in Tables 6 to 8 which confirm that the unemployment risk is unevenly distributed among the working population: typically unemployment rates decline with educational attainment, Italy, Portugal and Spain being remarkable exceptions.

3.2.2 Structural changes

There has undeniably been a shift in demand against the low-skilled, particularly during the 1980s. How can this be explained? The three following explanations are put forward (Drèze and Sneessens 1997):

a) skill-biased technological change: the introduction of new technologies leads to an increase in demand for more highly-skilled labour, at the expense of the low-skilled. The underlying mechanisms are related to the fact that more highly-skilled labour can adapt more easily to new technologies, many types of new technology are related
Table 4: Unemployment rates by level of educational attainment (males only)

Source: Nickell and Bell, 1996; See Nickell and Bell, 1995 for sources and construction.
to machines taking over the repetitive
tasks traditionally performed by low-
skilled labour and the observation that
computer technology leads to a greater in-
crease in productivity among more highly-
skilled workers than low-skilled workers;
b) 'deindustrialisation': the structural shift
from employment in industrial sectors to
the services sectors. Many jobs have been
lost in industry. Moreover, this loss of em-
ployment relates largely to low-skilled jobs,
as is clear from the fact that in the 1980s,
employment among white-collar, highly-
skilled employees in industry in countries
such as Germany, France and Italy actu-
al!

A quantitative assessment of these three ef-
fects and of their relative importance is diffi-
cult. There still remains a vigorous debate as
to the question whether these effects actually
do exist. This can hardly be surprising, given
that, referring once again to the quotation of
Blanchard and Summers in Section 3.1.1, the
'hysteresis'-assumption in the first place was
put forward because there were few identifi-
able shocks which could explain the unem-
ployment history in the 1980s.

As to the last effect, trade with low-wage coun-
tries has indeed risen over time: the propor-
tion of imports into EU countries from non-
OECD countries amounted to 5% in 1970 and
had risen to 12% by 1990 (OECD 1996). From
a traditional Heckscher-Ohlin model of trade,
one can deduce that, given certain conditions,
this kind of trade will eventually lead to an
equalisation of factor prices (wages) between
the trading countries. None the less, most
studies on this matter observe that this in-
crease only had a relatively small effect on
the division of wages and employment (OECD
1996). The main argument is that, although
trade with low-wage countries has increased,
overall this trade is relatively small within
European GNP. Moreover, this type of trade
relates chiefly to manufactured goods and
therefore primarily exerts an influence on the
secondary sector, a sector that is increasingly
losing importance.

'Teindustrialisation' on the other hand, can
hardly be denied. However, the destruction
of jobs in the secondary sector in many coun-
tries went together with a dramatic increase
in service sector employment. Moreover, in
addition to the many highly-skilled jobs, many
low-skilled white-collar jobs have been cre-
tated in the services sectors of the aforemen-
tioned countries.

Legend: x = no data available

This leaves the skill-biased technological change argument (or SBTC for short) as the main culprit, to some extent by default. A powerful counter argument against the role of SBTC is that, at least in the long run, there is no relationship between technological change (and SBTC for that matter) and unemployment: ‘output per head has roughly tripled since the middle of the nineteenth century, yet the average unemployment rate has remained virtually unchanged’ (Bean and Pissarides 1991, p. 330).

However, this does not necessarily preclude that there can be a short run relationship. In fact, in recent years there has been a renewed research interest in the issue of SBTC. The general proliferation of computer technology...
in the 1980s is regarded as an important explanation for the asymmetrical effects of technological change (Krueger 1993; Autor et al. 1998). Machin and Van Reenen (1998) find a strong relationship between technical change (measured both by R&D intensity and by computer usage) and the changing relative demand for skilled workers, not only for the US and Japan, but also for a number of European countries (Denmark, France, Germany, Sweden and the UK).

Berman et al. (1998) state that a comparable kind of SBTC occurred simultaneously in many countries (the research is limited to the manufacturing sector) in the 1980s and 1990s, and therefore can be regarded as pervasive. Draper and Manders (1997) conclude that in the Netherlands, over the period 1972-93, labour-saving technological change explains most of the displacement of low-skilled workers. Greenhalgh et al. (1997) conclude for the UK that, although trade and technological change both have a negative impact on the employment of the lower skilled, and changing domestic demand was more favourable for higher skilled workers, the technological change effects were by far the largest. This is confirmed by Machin (1996).

Summing up, one can conclude that most authors give the highest weight to the SBTC argument, while trade and deindustrialisation effects seem to have had a minor contribution. However, even the role of SBTC has not been unchallenged, and the empirical evidence remains fairly limited and circumstantial, as stressed by Drèze and Sneessens (1997). These authors, on the other hand, warn that some of the described mechanisms can become more important in the future. European trade with low wage countries having been relatively negligible to date, presumably will become more important. In particular, trade with eastern Europe is thought to be still far from having exerted its full effects.

### 3.2.3 Mismatch

When a jobseeker finds a job, a match has been realised between a worker and a vacancy. This matching process not only relates to what is conventionally described as the labour market, but also occurs within firms, i.e. on internal labour markets (Schettkat 1992). A mismatch situation then refers to a situation where some matches for one reason or another are difficult to achieve, resulting in either vacancies that remain unfilled, or in high unemployment in certain regions or among certain groups, and possibly the simultaneous existence of both difficult to fill vacancies and high unemployment.

This description of mismatch is rather loose, reflecting to some extent the state of the art of mismatch research. Quoting the editor of an influential book on the proceedings of a conference on mismatch:

"The major result of this volume, in my opinion, consists in highlighting the looseness of the "mismatch" concept [...] which explains why different mismatch definitions lead to such widely varying judgements on the same observable facts' (Padoa-Schioppa 1991, p. 2).

One element on which there seems to be growing consensus, is the fact that the use of the concept 'mismatch' is to be limited to structural, long-term imbalances. This implies that frictional unemployment, induced by turnover and job search, and resulting in a permanent coexistence of a certain level of unemployment and unfilled vacancies, is ruled out as a form of mismatch, since it is essentially a short-term phenomenon.

Different forms of mismatch can be distinguished:

- skill mismatch, which implies that there is a mismatch with respect to skills, i.e. that the skill requirements of jobs differ from the skill composition of labour supply;
- regional or geographic mismatch, which implies that there will be simultaneously regions which witness high unemployment, and regions where the labour market is tight. This is essentially a problem of low geographic mobility (either of workers or of jobs);
- industrial or sectoral mismatch, which, to a certain degree can be related to occupa-
tional and/or geographical mismatches, and therefore will not be completely independent.

3.2.4 Definitions and measurement problems

The measurement of mismatch is concerned with measuring the level and trends in mismatch. Several rival measures have been proposed. These measures are generally applicable for all kinds of mismatches. However, in what follows, we will focus on skill mismatch.

A first series of empirical measures use data on unemployment and vacancies. If $U_i$ is the number of unemployed in category $i$, and $U$ is total unemployment (over all categories), then the proportion of unemployed in category $i$ (e.g. skill category, region, sector, etc.) is $U_i/U$, or $u_i$, for short. Analogously, if $V_i$ is the number of vacancies in category $i$, and $V$ the total number of vacancies, the share of category $i$ is equal to $V_i/V$, denoted $v_i$. A first measure is as follows (Jackman and Roper 1987; Franz 1991):

$$M_1 = \frac{1}{2} \left| u_i - v_i \right|$$

If $u_i = v_i$ for all categories, $M_1$ will be 0, indicating that the coexistence of unemployed and vacant jobs is not associated with a dispersion between categories. If there are no categories where there is simultaneously unemployment and vacancies, $M_1$ will be equal to 1 (note that $u_i = u = 1$, and analogously, $v_i = v = 1$). A similar measure is as follows (Jackman and Roper 1987; Bean and Pissarides 1991):

$$M_2 = 1 - (u_i v_i)^{1/2}$$

$M_2$ will, like $M_1$, move between 0 and 1, under the same conditions.

Though intuitively appealing, the practical application of these measures has been limited because few countries have suitable vacancy data. Vacancies are difficult to measure (Muysken 1994). In the first place, the notion has some ambiguous features. Muysken illustrates this with the following example, which is quite relevant for mismatch measures:

'let a vacancy turn out to be hard to fill and therefore be filled by somebody who is not really qualified. Then does the vacancy cease to exist?' (Muysken 1994, p. 1).

Secondly, as opposed to unemployment figures, generally there does not exist one specific channel through which all, or most, vacancies are posted. A lot of countries collect vacancy figures based on the registration of vacancies by the public employment services (PES). A problem with this source is that, apart from its rather administrative nature, employers often have little incentive to notify their vacancies, especially when unemployment is high. For Flanders (Belgium) for example, it is known that the number of vacancies registered at the PES is only a fraction of the total number of vacancies, despite a legal obligation for all enterprises (with 20 or more employees) to notify. In addition, the vacancies reported tend to be those which are hardest to fill.

A third problem with these administrative data, is the fact that they are sensitive to institutional changes and do not seem to be comparable over time, making it hard to detect trends. For Germany, an analysis based on the official unemployment and vacancy figures shows little if any shift in the $U/V$ relationship since 1970. However, between 1970 and 1985 the share of vacancies mediated by the PES is thought to have fallen from 45% to under 25% (Abraham 1991). In the UK, an opposite trend has been witnessed; here the share of notified vacancies has increased over time (cited above).

Alternative sources of information about vacancies are the 'help-want' advertisement (e.g. in newspapers). Here is a danger of duplicate measurement, and it is also questionable whether advertisement behaviour has been constant over time, minimising the potential to detect real trends.

A last source of vacancy data, namely large vacancy surveys regularly conducted, happens to be the most reliable one. However, this approach is not very widespread because it is costly. In addition, countries that have conducted surveys have often only done so inci-
Unemployment and skills from a dynamic perspective

dentally, the Netherlands being an exception (Muysken 1994).

During the past few years in Belgium, an annual vacancy survey has been conducted (Simoens et al. 1997; Denolf and Denys 1996, 1998). These surveys suggest yet another potential problem for vacancy figures, which is more general, i.e. regardless of their source. It is shown that the required qualifications in vacancies are only one side of the picture: although for 1997, 42% of a representative sample of 1600 vacancies required only a lower secondary education degree, 67% of those low-skilled vacancies were eventually filled by candidates holding higher degrees. The same phenomenon of overeducation has been found for the other years.

Since disaggregated vacancy data are not available for many countries, or are not very reliable if they are, some mismatch measures have been proposed which only use information about unemployment. If \( N \) denotes the labour force (i.e. both workers and unemployed), and \( N_i \) is the corresponding number for category \( i \), one can construct the following measure (Jackman, Layard and Savouri 1991):

\[
M_3 = \frac{1}{2} \text{var} \left[ \frac{(U_i/N_i)}{(U/N)} \right]
\]

that is, measure 3 is based upon the dispersion (measured with the variance) of the relative unemployment rates for each category. Here one can discuss whether it is the dispersion of relative unemployment rates (as in \( M_3 \)) which is relevant or rather if the dispersion of absolute unemployment rates should be studied (\( \text{var} \left( U_i/N_i \right) \)). If aggregate unemployment \( U \) is not stable, e.g. is increasing, it is possible that the absolute and the relative measure will move in opposite directions.

As noted by Abraham (1991), if hiring behaviour differs between sectors (or between skill categories), a given categorical unemployment rate may imply quite different categorical vacancy rates. Then, an increase in the dispersion of categorical unemployment rates, holding mean unemployment constant, might either raise or lower the value of measures such as \( M_1 \) and \( M_2 \), which do take vacancy rates into account. In other words, if hiring behaviour differs between categories, neither the dispersion of absolute, nor relative unemployment rates is necessarily a good mismatch proxy.

On the other hand, if hiring behaviour is identical everywhere, it can be shown that both \( M_1 \) and \( M_2 \) depend on the dispersion of relative unemployment rates, which provides an argument for preferring the relative above the absolute variant.

However, this debate is far from concluded. Some authors derive on the basis of their theoretical model that relative unemployment rates are preferable to construct a mismatch indicator (Layard et al. 1991), while others, using another theoretical model, derive that the differences between unemployment rates are preferable (e.g. Sneessens and Shadman-Metha 1995, Sneessens et al. 1997).

Thus, Sneessens et al. 1997 argue that the variance of relative unemployment rates as a measure can be defended, provided one is willing to assume that for all categories the wages are equally sensitive to their own unemployment rates. This, according to these authors, need not be a very realistic assumption "when the focus is on the effect of downward wage rigidities at the low end of the wage spectrum (least-skilled workers)" (see p. 8). In the event that for some category the wage is less sensitive to its own unemployment rate, (typically when categories relate to skills, less or not at all if categories relate to regions or sectors), the contribution of structural disturbances to the change in the equilibrium unemployment rate should be measured by the change in the discrepancy between the unemployment rates of each category, rather than by the variance of relative unemployment rates.

Another forceful critique of the variance of relative unemployment rates as a measure for mismatch has been made by Entorf (Entorf 1998). He derives that if unemployment figures reveal additive upward shifts, this measure will be biased towards zero. Both with deterministic and stochastic shifts, these
measures of mismatch are likely to decline without any changes in the relative structure of sectors, skills or other grouping criteria’ (Entorf 1998, p. 43). In addition, it is shown that there is empirical evidence for sustaining the claim that actual unemployment figures in fact behave like a non-stationary time series. Therefore, the mismatch trends based on this indicator might be a simple statistical artifact.

A feature by which all the measures are plagued, is the fact that the obtained results often crucially depend on the classification used, that is, whether the categories used are more or less disaggregated. If the unemployment categories are too fine, implying that workers who compete for the same kind of jobs are assigned to different categories, the mismatch may be exaggerated. If the categories are too coarse, probably the more realistic case, mismatch may be understated. Moreover, one can argue that, as regards skills, the degree of heterogeneity within classifications has risen over time, which, again, jeopardises the potential for studying trends. For example, factory operatives might once have been largely interchangeable, but today there may be an important distinction between factory operatives who have education or training that prepares them to work with computerised technologies and those who do not’ (Abraham 1991, p. 466). Another disturbing feature, at least for occupational classifications, is that an occupation can easily change as is illustrated by the fact that a lot of job changers do report changes in occupation.

This may explain why skill measures in empirical applications often rely on educational categories, rather than on occupational or professional classifications. However, education as proxy for skills is not without its problems either. Skills can, broadly speaking, be acquired in three different ways: by formal education, by training and by experience (on-the-job training, work experience). When educational attainment is taken as proxy for the skill level, obviously two potentially important skill determinants are neglected.

As for the training component, which we define broadly to include all kinds of permanent and recurring adult education, it is well known that participation is not evenly distributed among the population. Typically, the higher educated tend to participate more in adult education and training (OECD 1997). Though the correlation between the acquired formal educational attainment and the probability of participating in adult education will be far from perfect, its existence suggests that neglect of the training aspect in an operationalisation of skills by educational attainment, is not necessarily a hindrance.

A similar relationship between the level of educational attainment and the probability of gaining work experience is less obvious (apart from the higher unemployment rates for the low skilled). However, one can argue that the ‘low skill, bad job trap’ (Snower 1996), where bad jobs are the ones associated with low wages, deficient training and low productivity, also relates to a rather limited potential to gain work experience valued by the labour market.

Educational attainment indices also have a few drawbacks. Educational categories used in different countries are notoriously difficult to compare, which hampers international comparisons. However, for the present purposes, it is primarily comparisons within countries which have to be made. Therefore the requirement is that the educational classification remains reasonably stable over time within a country, which in general seems to be a realistic assumption.

Another drawback relates to the fact that educational attainment is not necessary a good indicator of the quality of education (OECD 1994). Thus, in the US, where educational attainment at the level of secondary education is measured by time spent in formal education, wide variation can obviously be observed in pupil performance levels for a given level of educational attainment. This seems to be less of a problem for most European countries, which normally have a form of performance testing, at least at the end of secondary education.

Still, the more general critique regarding the effects of the level of aggregation in any clas-
sification on the 'observed' mismatch results, remains in full force for a classification based on educational attainment. For example, a tertiary level of educational attainment often comprises both academic and vocational degrees, and one can argue that it would be preferable to distinguish between those two fields.

Based on the preceding discussion, one can conclude that, while educational attainments cannot simply be equated to skill levels, they are the best proxy available for skills. However, a recent contribution of Manacorda and Manning (1997) puts this conclusion in an entirely different perspective.

They state that, when assessing whether there has been a shift in relative demand against the lower-skilled, it is of course necessary to take into account the changes in relative supply. That is, a shift in relative demand that is entirely offset by a comparable change in the skill composition of the labour force need not be problematic. This last situation can be called a neutral change, as opposed to an asymmetric, non-neutral or skill-biased change. Jackman et al. (1996, as quoted by Manacorda and Manning 1997) call a change neutral if the relative demand and supply changes mean that the unemployment rates for different skill groups are constant through time and the relative wages of different skill groups are constant as well.

Manacorda and Manning (1997) remark that, if the relative supply of better educated groups (education being taken as a measure of skills) increases over time, and if the unemployment rates of higher educated workers are lower, which seem to be two reasonable assumptions for most countries, this kind of 'neutral change' inevitably must lead to lower aggregate unemployment. They argue that the foregoing definition of neutral change therefore is not very sensible, and propose a rival definition, which leads to yet another measure of skill mismatch.

They 'define changes in demands and supplies for different skills (with other relevant factors constant) as neutral if the unemployment rate of the person at a given position in the skills distribution is constant and their wage relative to the average is also constant' (see p. 3-4). Now, someone’s position in skill distribution is determined by his or her educational attainment, but, as the supply of educated labour grows over time, the position of a person with a given educational attainment will be falling over time: assume that educational level X corresponds to the median position at a certain point in time, half of the labour force having a higher and half having a lower level.

As the labour force becomes more educated, 10 years later, level X will have moved to the left, say to the 40th percentile, with 60% of the labour force having a higher educational level. In this framework, a neutral change implies that unemployment rates are constant for a given position in the skill distribution, but the consequence is that unemployment rates for a given educational level will be increasing over time, at least if the labour force is becoming more educated. Another consequence is that the aggregate unemployment rate will remain constant. This is, according to the authors, a more sensible assumption, because over the past century there have been dramatic increases in educational attainments without a noticeable trend in the unemployment rate.

While conceptually appealing, this definition of neutral change is much harder to operationalise empirically than the conventional definition. Whereas someone’s level of education is directly observable, his/her position in the skill distribution is not directly observable, because the classification of educational levels typically consists of discrete categories. The authors assume that the level of human capital also varies within educational categories. Therefore, they have to impose some structure on the distribution of human capital within a given level of education.

A skill mismatch measure based on this framework will, in a comparison over time, compare changes in the position of skill groups, and therefore possibly lead to results which differ a lot from a more classical measure which compares changes in the position of educational groups. In Section 4.5 some
empirical results regarding the level and trends in skill mismatch are surveyed.

A last criticism which can be made of all the preceding measures of mismatch, is the fact that they conceive, or at least measure, mismatch as a one-dimensional phenomenon. Entorf (1998, p. 27) shows that, in a simple world with two regions and two skill categories and thus four possible combinations, one can easily construct examples in which a situation of perfect mismatch (all the unemployed in the first region being concentrated in the first skill category, and all vacancies in this region being in the second skill category, and the other way round for the other region) completely fades whenever one measures the mismatch along one dimension, either region or skill.

The necessity to measure mismatch as a multidimensional phenomenon is empirically confirmed by Sneessens et al. 1997, who obtain different results for the measured level of skill mismatch, depending on whether regional mismatch has been controlled or not.

Moreover, 'even with very detailed levels of disaggregation, mismatch measurement remains subject to potential misinterpretations. Structural problems might occur due to missing mobility also within well defined sectors. Recent evidence reveals that workers tend to move within sectors, rather than across sectors [...]'. Thus, the very important aspect of match and mismatch within sectors is not captured by the data, and the idea that mismatch could be reduced by moving labour across sectoral borders may be misleading.' (Entorf 1998, p. 28).

3.2.5 Relation with observed facts and policy conclusions

An increase in the level of mismatch (and skill mismatch) on the labour market will, other things being equal, lead to an outward shift of the Beveridge curve, such as the shift described in Section 2.3. Increased mismatch can thus be a sufficient condition for this shift, but is not a necessary condition: the observed shift as such does not prove that mismatch problems actually have increased.

For example, the framework developed in Section 3.1 offers a rival explanation. The hypothesis that (skill) mismatch increased, on the other hand, offers a more straightforward explanation for the apparent deterioration of the position of the lower skilled than the theory of disenfranchised unemployed. To some extent, the opposite holds for an explanation of the increased share and persistence of long-term unemployment. While this observation is perfectly compatible with increased mismatch, the disenfranchised-workers-approach is perhaps a more straightforward explanation. However, as in reality the lower skilled are typically over-represented in long-term unemployment, these two phenomena are difficult to distinguish.

As regards policy, a situation of increased skill mismatch probably will not be permanently alleviated, let alone solved, by the classical ingredients of an active labour market policy. Temporary work experience and recruitment subsidies programmes will be of little help. 'As soon as the subsidy is cancelled, the low-skilled worker will lose his job and unemployment will persist' (Sneessens 1995b, p. 19). Mandatory participation will be counterproductive, while job-search programmes will be discouraging for the lower skilled.

Several authors emphasise that only measures that aim at changing the relative cost of low-skilled workers (permanent subsidy, labour tax cut, lower social insurance contributions on the minimum and low wages, etc.) will prove effective to eliminate the skill mismatch problem (Drèze and Malinvaud 1994; Sneessens 1995b; Drèze and Sneessens 1997). This position can be defended, but it may be too pessimistic. As skill mismatch is primarily a problem of low skills which are no longer in demand (admittedly, no longer in demand at the going wage rate), obviously there has to be some scope to remedy the skills problem through training and education.

On the other hand, it is doubtful whether traditional programmes of labour market training, which either aim at upgrading lost or outdated skills and reestablishing worker attitudes, or have a rather narrow and specialised content and therefore are targeted on
workers who already possess a lot of qualifications, will prove sufficient. What these training programmes have in common, is their average short duration. The upgrading of the skill level of the lower-skilled, on the other hand, can only be brought about by programmes that are sufficiently long.

3.3 Job competition

The skill mismatch-hypothesis and the theory of unemployment persistence due to the disenfranchising effects of long-term unemployment can both explain the stylised facts outlined in Section 2.3. Which theory is more in line with reality, is largely an empirical matter. An empirical judgement however, will not prove easy, among other things because, even on a theoretical level, there is not really a consensus as to how mismatch should be defined, let alone measured. Yet, as already mentioned earlier, an examination of the behaviour of the exit rates from unemployment could possibly give an indication of which theory is dominant for a given country. That is to say, if for a particular country one observes that negative duration dependence is absent or negligible, this will be a strong indication for downplaying the role of the disenfranchised workers hypothesis. If, on the other hand, one observes negative duration dependence, both hypotheses become possible (or a mixture of them). The criterion of the duration dependence thus is at best a half-hearted judgement.

And even a situation of pure heterogeneity (where duration dependence is absent) will not prove that mismatch is to be the preferred explanation. As pointed out by Cockx (1998), a job competition hypothesis could equally well be responsible for high heterogeneity in exit rates. Job competition (ladder-effect, displacement-effect, bumping) occurs in a context of high unemployment. The higher skilled can always fill the vacancies which initially were intended for lower skilled. Therefore, a cyclical downturn with an increase in unemployment will hit the lower skilled much harder than the higher skilled, because the latter can always descend the skills-ladder, while the former soon reach the bottom. However, with an upswing of economic activity and a tightening of the labour market, the position of the lower skilled should improve again, at least, if job competition is the only mechanism in operation.

Job competition, in other words, can not explain unemployment persistence and therefore is, at best, a secondary explanation. This does not mean that job competition has to be excluded from the recent unemployment history of some countries. It is quite possible that it has substantially aggravated the position of the lower skilled, on top of the already devastating (joint) effect of skill mismatch and/or persistent long-term unemployment. It cannot be attributed a role of protagonist, either in explaining unemployment growth or in explaining unemployment persistence.

4. Corroborating evidence

4.1 State dependence versus heterogeneity

4.1.1 Introduction

In an empirical attempt to model the effect of unemployment duration on the exit probability, the basic variable is unemployment duration. Duration data are typically analysed with a specially adapted statistical tool, so-called hazard models (‘event history models’, ‘duration models’, ‘survival analysis’). In conventional statistical approaches, such as OLS regression, the omission of a relevant independent variable will bias the estimators of coefficients that are included only if the omitted variable correlates with the included variable (a typical example being the regression of income on years of schooling, omitting a measure of ability). In hazard models, this bias will be present even if omitted variables are not correlated with included variables. More disturbing yet, the omission of relevant variables will lead to the impression that the hazard rate out of unemployment is characterised by negative duration dependence, even if the hazard rate is constant. This is due to a sorting out process. The intuition behind this result can be shown with the following simple example. Suppose that there are two groups of people in unemployment, say the
low-skilled and the high-skilled. Suppose further that the high-skilled at each point in time have a high and constant probability of leaving unemployment, while the low-skilled also have a constant hazard rate, which however, as opposed to the high-skilled, is low. Figure 4 gives the hazard lines for both groups.

Now, if a student of this group of unemployed for one reason or another is not able to identify who belongs to the high-skill group and who belongs to the low-skill group, he will observe the dotted line, which suggests that hazard rates are decreasing. This can be explained as follows: at the beginning (inflow into unemployment), the population consists of both high-skilled and low-skilled unemployed. However, since the high-skilled have a high propensity to leave, as time goes by, i.e. if we move to the right, the share of high-skilled still left in unemployment will steadily decline. The share of low-skilled unemployed therefore will increase. The share of persons with high exit rates will decrease, and in the end only persons with low exit rates will be left. Without information with respect to skill, one will therefore, wrongfully, be inclined to infer that hazard rates are declining, i.e. that there is negative duration dependence. This is called spurious duration dependence, due to unobserved heterogeneity.

The crux of this argument is that in hazard models it is extremely important to model heterogeneity. Characteristics such as age, gender, educational attainment, work experience, ethnicity, etc., which have an important impact on the probability of leaving unemployment, will often be available and therefore can be included. However, other characteristics such as motivation, temperament, appearance, clothing, demeanour, or even certain aspects of acquired skills (command of language, literacy skills) will, more often than not, not be available for research and yet could exert a great influence on the exit rate from unemployment.

One has to admit that in more recent applications, attempts have been made to model unobserved heterogeneity (going from rather mechanical 'ad hoc' procedures to more advanced approaches which impose less 'difficult to justify' structure on data (Chamberlain 1985; Lancaster 1990)). Therefore, one should primarily be sceptical about first gen-
eration studies that demonstrate negative duration dependence.

4.1.2 Survey of some empirical results

The economic analysis of unemployment duration is based on job search theory (Devine and Kiefer 1991, 1993). A basic job search model predicts that hazard rates out of unemployment will be constant. After all, if an unemployed person finds out that obtaining a job is more difficult than expected, and the duration of the unemployment spell therefore longer than expected, he/she can always reduce his/her demands (be it by lowering the reservation wage, or by accepting job offers which he/she up to then did not consider). On the other hand, it can be argued that the prevailing systems of unemployment compensation interfere with this simple reasoning.

It is often asserted that unemployment benefit levels, replacement rates, the duration of entitlement to unemployment benefits and other aspects of unemployment compensation policies have an important impact on the probability of exit from unemployment. However, in a comprehensive survey of literature, Atkinson and Micklewright conclude that 'on the empirical side, we have found that, despite the large literature, there is relatively little evidence concerning several potentially important effects of unemployment compensation on labor market transitions' (Atkinson and Micklewright 1991, p. 1721).

More recent research confirms this conclusion to some extent. Several authors find no effects (Groot and Jehoel-Gijsbers 1992, Netherlands; Hernaes and Strom 1996, Norway; Wadsworth 1992, UK; Schmitt and Wadsworth 1993, UK; Gorter and Gorter 1993, Netherlands;), while others find small and sometimes more important effects (Stancanelli 1996, UK; Jensen and Verner 1996, Denmark; Lubyova and Van Ours 1997, Slovak Republic; Winter-Ebmer 1998, Austria; Ahn and Ugidos-Olazabal 1995, Spain; Lilja 1993, Finland). The overall picture therefore is quite blurry, although this reflects to a certain degree the huge differences between the unemployment compensation policies of different European countries.

As to the empirical standing of state dependence versus heterogeneity, Meager and Evans (1998) give a useful overview:

'Early US research with panel data, particularly on young people, suggested that an explanation rooted in heterogeneity had more explanatory power [Ellwood 1982, Chamberlain 1985, Lynch 1985]. European research yielded somewhat different results initially, however. Thus youth unemployment studies in the UK [Lynch 1989, Narendranathan and Elias 1993] indicated a role for both factors, [...]. Further UK studies, [Jackman and Layard 1991, Narendranathan and Stewart 1989, Layard et al. 1991] however, indicated evidence of state dependence, with the probability of a spell of unemployment ending being negatively related to the duration of that spell (after allowing for heterogeneity, both observed and unobserved). Recently, however, the balance of evidence has shifted again. Research in the UK quoted in Elias (1996), as well as that of Portugal and Addison (1995) and van den Berg and van Ours (1996) for the US, and van den Berg and van Ours (1994) for France, the Netherlands and the UK, suggest a limited role for state dependence, and that most variation in observed durations of unemployment can be explained by heterogeneity [...].' (Meager and Evans 1998, p.14.).

A few qualifications: van den Berg and van Ours (1994) find little support for state dependence, however, with one remarkable exception: for British male unemployed they find strong genuine negative duration dependence and little empirical evidence that heterogeneity counts for this group. Similarly, van den Berg and van Ours (1996) report for US white males negative duration dependence which dominates heterogeneity.

Korpi (1995) starts from the observation that earlier Swedish studies have repeatedly reported non-negative or constant duration dependence in the hazard. The author attributes this result to the (then actually) large scale of the labour market programmes, which typically focused on the unemployed with the worst employment prospects. Dejemeppe and Cockx (1998b) find for Wallonia (Belgium)
important heterogeneity effects, and a limited role for negative duration dependence.

The bottom line of this review seems to be that, given the present state of the art, the evidence points increasingly towards heterogeneity at the expense of duration dependence. The US and the UK, however, at least for males, are clearly exceptions to this general observation.

4.2 The impact of unemployment on psychological wellbeing

Longitudinal studies in several countries have shown that becoming unemployed often goes hand in hand with a significant deterioration of psychological health (De Witte 1993). Goldsmith and Darity (1992) cite a study that linked unemployment to significantly higher levels of anxiety, depression, somatisation, hostility and paranoia. Besides the impact on psychological health, physiological changes have also been reported (Baum et al. 1986 give some references).

Feather (1990) reviews a wide panoply of possible theoretical explanations for this observed reduction of psychological health. One approach, developed by Jahoda, starts from the functions of paid employment (Jahoda 1982). Apart from manifest functions, such as earning a wage, employment is thought to have several latent functions: imposition of a time structure, provision of social contacts, involvement in shared goals, assignment of status and identity, and enforcement of activity. The loss of a job will quite possibly involve a deprivation of both the manifest and the latent functions, which then is linked to psychological wellbeing.

Another, not necessarily conflicting explanation is that becoming unemployed is either initially perceived as uncontrollable, e.g. when due to a layoff, or over time becomes perceived as uncontrollable, e.g. due to a prolonged but fruitless search. This loss of control 'reduces an individual's perception of internal locus of control, presumably leading to a sense of helplessness' (Darity and Goldsmith, 1993, p. 60). 'Helplessness theory' can be summarised as follows: 'highly desired outcomes are believed improbable [...] and the individual expects that no response in his repertoire will change their likelihood' (Abramson et al. 1978, as quoted by Feather 1990, p. 71). However, not all authors agree that loss of control immediately leads to helplessness. Wortham and Brehm (1975) state that the first response of an individual to a loss of control is one of 'reactance', i.e. trying to reestablish control. As soon as it becomes apparent that this can not be successful, helplessness emerges.

Now, as stated by De Witte (1993), the deterioration of psychological health typically will stabilise after a certain period of time. The stabilisation of psychological wellbeing, albeit on a lower level, is explained by an adaptation process: the long-term unemployed adapt to their new role and withdraw from the labour market by lowering their employment commitment and their job search.

Thus, the line of reasoning is as follows: upon becoming unemployed, the unemployed persons experience a serious deterioration of
their psychological wellbeing, e.g. due to a deprivation of manifest and latent functions and/or due to a sense of helplessness. This results in a high level of stress, possibly cumulating, if it becomes clear that the probability of finding another job is small. These unemployed therefore will become discouraged and demotivated. However, high stress levels are not sustainable for long periods of time. Therefore, as the unemployment spells becomes longer, in an attempt to reduce cognitive dissonance, the unemployed will adapt to the new situation, by changing their preferences. The long-term unemployed thus will withdraw from the labour market and lower their employment commitment. Job search will be substantially reduced. Psychological health settles on a stable albeit lower level.

In the event that a long-term unemployed does find a job, according to De Witte (1993) this will lead to a substantial and instantaneous improvement in psychological wellbeing, possibly even to a restoration of the status quo ante. Darity and Goldsmith (1993) confirm that a myriad of studies find improved psychological wellbeing upon reemployment. However, they question whether this necessarily means that all adverse effects of unemployment are transitory and are readily offset by reemployment. They cite some studies that reported adverse psychological effects of unemployment that were not fully offset immediately by the emotional improvement due to reemployment. They conclude that 'it is evident that there is at least an extended interval where motivation and performance are likely to be reduced relative to the baseline even after reemployment' (see p. 61).

However, this last observation could be related to the fact that the long-term unemployed sometimes accept jobs that do not fully utilise their skills, which could account for some residual helplessness, since it is reported that 'satisfactory employment, relative to dissatisfied employment, increases self-esteem and decreases depressive effect to a greater extent' (see p. 61). De Witte (1993) also mentions that it has been reported repeatedly that long-term unemployed, when finding another job, often sacrifice on wage, status and work conditions in comparison with their previous job (which of course can be explained by the lowering of their reservation wage). Whether this sacrifice itself affects the restoration of psychological wellbeing or not, however, is not mentioned by the last author.

On balance, and acknowledging that this short and selective overview does no justice to what has become a discipline in its own right, one can conclude that the empirical evidence collected during the past 20 years by students on the psychological impact of unemployment, does sustain the hypothesis that long-term unemployment is characterised by negative duration dependence. The key observation is that long-term unemployed will tend to lower their employment commitment and will reduce their job search activity.

This last observation, however, is not entirely confirmed in non-social-psychology literature. Layard et al. (1991) review several job search surveys (US and UK), and conclude that, while unemployment duration does not seem to affect the time spent searching (hours per week), it does seem to affect the effectiveness of searching (less active methods, such as direct contacts with employers, as duration increases). However, they conclude that search activity only declines to a rather small extent with duration.

4.3 Loss and obsolescence of skills

The discrepancy between the number of authors who support the idea of loss and obsolescence of skills during protracted spells of unemployment and the number of studies that really give empirical evidence is enormous.

4 Although not directly related to this section, it is noteworthy that occupational skills training programmes for the unemployed are reported to have had a beneficial effect on the psychological distress of participants, by improvements in self-esteem, life satisfaction, and reductions in levels of depression (Creed et al. 1996, who also give some useful references). It is, however, not reported whether these beneficial effects were durable or not.
Basically, three mechanisms can be distinguished that relate unemployment to the retention and acquisition of skills:

a) unemployment may lead to a loss or erosion of acquired skills, primarily because they are no longer practiced due to being out of work;

b) unemployment may lead to an obsolescence of acquired skills;

c) unemployment may reduce (temporarily or permanently) the individual's potential to learn and acquire new skills;

Loss of skills

Some broad indications can be obtained from the International Adult Literacy Survey (IALS)-study (OECD 1997), which measured the literacy skills of adults in several OECD countries. A broad concept of literacy skills was used. Unsurprisingly, the literacy skills correlate with educational attainment. However, one consistently observed that literacy skills correlated with the labour force status of a respondent. Thus the unemployed score lower on literacy skills than working people. Obviously, to draw conclusions, one should check on educational attainment, but such exercises have not yet been reported. Moreover, since the IALS results are based on cross-sections of the population, one can never be sure about the direction of causality: do the responding unemployed in the sample score lower on literacy due to their being unemployed, or are they unemployed because they possess less literacy skills in the first place?

Obsolescence of skills

From the alleged great and increasing importance of on-the-job training and non-formal learning, coupled with the observation that employed persons participate more in training and education, one can infer that unemployment, while not necessarily bringing about an absolute decrease in acquired skills, will tend to widen the relative skill gap compared to those remaining in employment.

Acquisition of skills

Social psychology literature also gives some insights into the acquisition of new skills. Helplessness, so the theory goes, may reduce the motivation to acquire new skills, and possibly also diminish cognitive efficiency so that the unemployed may find it more difficult to learn new skills, even if they are motivated. Helpless people are for instance reported not to memory scan as rapidly as someone who is not helpless5 (Darity and Goldsmith 1993). Fleming et al. (1984) report that, in a laboratory setting, a control group of employed persons solved significantly more problems than the group of unemployed. Moreover, the stress levels of the unemployed rose during the task. Baum et al. (1986) compared persons who had recently entered unemployment with persons who were unemployed for between three to five months. They found that the longer-term unemployed persisted less on very difficult tasks requiring both persistence and concentration, and also solved less tasks. It is, however, not reported whether cognitive efficiency and motivation are restored upon reemployment. The results do suggest that training programmes for the unemployed could benefit from psychological support.

4.4 Employer behaviour

Employers may use unemployment duration as a signal for productivity, and thus rank candidates rather indiscriminately by their unemployment duration. In that case long-term unemployment leads to a loss of reputation and stigmatisation. Empirical evidence about such behaviour can be obtained from employer surveys. Meager and Evans (1998) give an overview of several studies which all confirm that a significant share of employers do take account, when recruiting, of unemployment duration: Atkinson et al. 1996, Colbjornsen et al. 1992, ESRI 1991, Gazier and Silvera 1993, Meager and Metcalf 1987, Ronayne and Creedon 1993. This list covers the UK, Norway, Ireland and France.

---

5 Memory scanning is searching the memory for appropriate information.
These results are confirmed for Flanders (Belgium) in Lamberts (1993), and for Austria by Winter-Ebmer (1991). It can be concluded that this kind of behaviour is quite consistently present in a lot of countries, which is an important indicator for supporting the presence of state dependence.

From a policy point of view, it is important whether discriminating behaviour is based on an objective evaluation by employers on the basis of previous experiences (e.g. because loss of skill, loss of worker attitudes, etc. really are prevalent), or on a more subjective, to some extent prejudiced, appraisal of the employability of 'the long-term unemployed' in general. If the latter case is more common, information campaigns and programmes to promote the employment of long-term unemployed to unmask received wisdom might remedy the problem. If the former is more common, a quite different approach is called for, e.g. policies to remedy loss of skills, work attitudes and the like.

4.5 Mismatch

An empirical evaluation of the importance of, and the trends in skill mismatch has been made by different authors, using different measures, based on sometimes substantially different theoretical underpinnings. Unsurprisingly, the resulting picture is most varied.

Layard, Nickell and Jackman (1991) (and subsequent work), using a measure based on relative unemployment rates, observe substantial mismatch in a variety of countries (occupational, sectoral, industrial and age mismatch), but do not detect a trend evolution. Mismatch therefore is important, they assess that the combined sources of mismatch can be held responsible for raising Britain's unemployment by some 40% above what it would have been otherwise, but the particular unemployment evolution of the past decades cannot be attributed to an increased mismatch. In their view, other forces were at work. Bean and Pissarides (1991), using a comparable measure, do not find compelling evidence for technology-induced skill mismatch in Britain.

Sneessens and Shadman-Metha (1995) and Sneessens (1995), using differences between unemployment rates, observe a significant increase in skill mismatch for France in recent decades. Sneessens et al. (1997) state that most of the increase in structural unemployment in France is related to skill mismatch, while increases in structural unemployment (skill and regional mismatches) are capable of explaining 75% of the increase in actual unemployment, at least until 1990.

For Spain, the picture is more complex. The increase in structural unemployment only represents 55 to 60% of actual unemployment changes, the remainder relating to a movement along the Beveridge curve (instead of a shift).

Franz (1991), working with both unemployment and vacancy figures for Germany, does detect some regional and skill mismatches, but states that it is less obvious whether these imbalances have increased.

Manacorda and Manning (1997), measuring skill mismatch based on their concept of the skill distribution, find evidence for an increased skill mismatch in the US and the UK, but find no increase for France, the Netherlands, Germany and Italy.

Entorf (1998) uses highly disaggregated data for Germany. Using panel-econometrics on a panel of 40 occupational groups for the period 1971 to 1992, he obtains that the matching efficiency is declining over time. However, matching efficiency seems to vary with the prevailing economic situation. Thus periods of easy match are typically times of high unemployment (1975/76 and 1983/84), and therefore he concludes that high unemployment is accompanied by lower mismatch. Moreover, the general level of mismatch is higher in the 1980s than in the 1970s.

After this overview, one may have the feeling that research results are rather inconsistent and therefore not very conclusive. However, although there is not a clear picture of the evolution of mismatch over time, most authors find, irrespective of the approach they use, that the level of mismatch is not negligible, and
sometimes even substantial. This observation warrants a policy interest in mismatch problems. Whether a policy oriented towards reducing mismatch problems will be enough, or whether it has to be supplemented by policies aimed at other malfunctionings of the labour market, depends on whether there has been an unfavourable trend in mismatch or not.

At present this last question cannot be answered unambiguously. Much more work is needed, both at theoretical level, to obtain a better theoretical underpinning of the mismatch concept (which possibly will lead to some convergence in the now widely different approaches), and at empirical level, to establish richer data with consistent time series and preferably, at a more disaggregated and multidimensional level.

As regards this last aspect, the last Holy Grail of labour economics, LEE (linked employer-employee data) (Hamermesh 1999), which consists of linking household data with establishment/firm data, looks promising.

4.6 Conclusion

On balance, the evidence is quite mixed. Some observations (e.g. the fact that genuine duration dependence appears to be negligible in a lot of countries; see Section 4.1.2 for France, the Netherlands, United Kingdom and Wallonia), are a strong argument against the theory of unemployment persistence due to the disenfranchising effects of long-term unemployment. Other elements, in particular the well documented observation regarding recruitment behaviour, as well as vast theoretical and empirical literature regarding the effects of (long-term) unemployment on wellbeing and job search behaviour, corroborate this theory. The demonstration of an increase in (skill) mismatch over time, on the other hand, has been notoriously difficult, due to measurement problems and the absence of suitable data, and also due to lack of consensus among its students. To decide that an increase in skill mismatch problems is not relevant because such an increase has not yet been demonstrated convincingly, is possibly too hasty.

Therefore, a conclusion could be that a mixture of both explanations has been, and still is, responsible for the particular unemployment problems encountered by European countries. This, however, does not preclude that different countries struggle with a different mix, some having predominantly a skill mismatch problem, while others are more obstructed by the burden of long-term unemployment.

In this contribution, is was asserted that the policy mix necessary to tackle and remedy a situation of skill mismatch is potentially quite different from active labour market policies that aim at the activation of the unemployed and prevention of long-term unemployment. While some countries or even particular regions within countries predominantly have a mismatch problem, other countries or regions seem to have less of a problem, so a differentiated policy approach is called for.

While this may sound logical, the actual policy approach recommended by the EU through its guidelines starts from the premise that European unemployment can be alleviated by a uniform and common set of policies for all countries. The two first guidelines are directed at the prevention of long-term unemployment. While the prevention of long-term unemployment may be a goal in its own right, e.g. for social and political reasons, the economic rationale for preventive policies, namely the claim that unemployment duration itself has a clear negative impact on employability, is questioned by a growing number of empirical results.

The massive deployment of labour market programmes that seek to intervene in the early stages of an individual's unemployment spell, e.g. training for the unemployed which has an important share, can thus be questioned on two grounds.

In the first place, dead-weight effects can be taken to be substantial, since early intervention will direct scarce resources towards the unemployed who would leave unemployment early anyway.

Second, for those unemployed really at risk of becoming long-term unemployed, early in-
tervention could be warranted provided it were possible to identify who is at risk and who is not (literature is rather pessimistic on the possibility of early identification). However, even if the unemployed at risk would benefit from current early interventionist programmes if they were targeted exclusively at the groups at risk — which is questionable since existing measures either lack enough depth to remedy their problems fundamentally (e.g. short training courses), or only have a temporary nature (e.g. temporary wage subsidies) — it stands to reason that the unemployed at risk will not benefit much when all the unemployed are targeted.

As regards the problems encountered when measuring mismatch phenomena, the absence of suitable and internationally comparable vacancy data has been one of the main obstacles. It could be argued that here remains a challenge for the EU statistical authorities.

5. Summary

5.1 Introduction

There is undeniably a relationship between skills and unemployment. In comparison with better-educated workers, the unemployment rates for workers with low educational attainment, are, almost without exception, consistently higher throughout the EU. This is not a new phenomenon. However, it has been suggested that during past decades the relative labour market position of the low-skilled has declined markedly, due to a variety of factors. Some authors attribute a substantial part of the explanation of recent European unemployment history to this relative demand shift against the low-skilled. A general increase in skill mismatch is, in their view, one of the main causes of the peculiar persistence that has characterised European unemployment in the past 20 years.

This view, however, has not gone unchallenged. Others have argued that this persistence is caused by other factors, such as long-term unemployment and everything this brings about.

From a policy point of view, it is important to know which view is most in line with reality. Depending on the chosen theory, policy prescriptions differ. More in particular, there are some implications for the organisation of a VET policy to alleviate unemployment problems.

In this contribution, a comparison is made of the two rival views. Although both theories originally stem from a macroeconomic perspective, i.e. a highly stylised and aggregated world, and essentially deal with macro phenomena, most attention will be devoted to their microeconomic underpinning and the available empirical evidence on this level.

5.2 Some stylised facts

- Over time, unemployment rates have grown, sometimes dramatically;
- unemployment appears to have a persistent nature, i.e. once the unemployment rate has gone up, e.g. in a period of a cyclical downturn, it has a tendency to remain on this higher level, i.e. it does not return to its initial equilibrium level, even when the business cycle becomes more favourable;
- typically, unemployment rates are higher for lower-skilled than for higher-skilled workers, even though the share of the lower skilled in the labour force is decreasing over time;
- the incidence of the long-term unemployment (more than one year) is on a historically unprecedented high level. Moreover, it is typically the lower-skilled workers who are hit most by long-term unemployment;
- high unemployment rates sometimes go hand in hand with high vacancy rates.

5.3 Theoretical background

5.3.1 A first theory: equilibrium unemployment, persistence, hysteresis and state dependence

By introducing hysteresis, one incorporates the empirical observation of the 1980s that, once
unemployment has risen, it has a tendency to remain on this higher level, so that today's equilibrium unemployment level depends partly on past unemployment. Several possible explanations for the emergence of persistent unemployment have been given. We have principally discussed the 'outsider characteristics' explanation. The underlying mechanism is as follows. An increase in actual unemployment rates leads to an increase in long-term unemployment. For reasons which have been elaborated in section 3.1.2, long-term unemployment is thought to lead to a distance between the long-term unemployed and the labour market, in fact rendering them unemployable. Therefore, they no longer exert downward pressure on wages.

How can long-term unemployment lead to persistence? The basic idea is that the length of stay in unemployment, i.e. the duration has an impact on the exit probability, over and above the impact of individual characteristics, such as age, gender, educational attainment, work experience, ethnicity etc. Negative duration dependence (which is present if the exit rates from unemployment decrease, the longer one is unemployed) implies that something happens or changes during the stay in unemployment, either because the unemployed themselves change, or because they are perceived to have changed. The following processes have been suggested:

- the fact of being unemployed, especially for persons that find it hard to find another job, can trigger off a process of discouragement and demotivation, which eventually can lead to habituation and resignation. This will probably lead to a reduction of the job search activity, and hence to a reduction of the exit probability;

- being in unemployment, particularly long-term unemployment, can lead to a loss or an erosion of acquired skills. Moreover, even if there is no loss, still the once acquired skills and knowledge can quickly become obsolete and outdated when no longer used and updated. If erosion and depreciation of skills take place over an unemployment spell, there is a direct effect on one's employability, and hence on the exit probability;

- unemployment, and more particularly long-term unemployment, is said to affect work attitudes and work discipline, which, indirectly, can be of influence if potential employers come to associate long-term unemployment with loss of work attitudes;

- this last mechanism can be generalised as a loss of reputation argument. Given that a hiring process is a situation with asymmetrical information, where the potential employer normally has only limited and incomplete information about the productivity of a potential employee, employers may use the unemployment duration as a signal of productivity, and thus rank candidates by their unemployment duration. If this mechanism acts, the exit rate obviously will decrease with duration.

Two of the most singular stylised facts from Section 2, namely persistent unemployment and the apparently shifted Beveridge curve (simultaneously more unemployment and more vacancies), can be readily explained with the former theory. A rise in unemployment due to a succession of severe negative shocks leads to long-term unemployment. The long-term unemployed become disenfranchised from the labour market, which, through the mechanism(s) described above, leads to persistence. As the long-term unemployed become unemployable, the number of effective unemployed will be lower than the total number of unemployed, and therefore, a higher unemployment rate will be compatible with a given vacancy rate.

In past decades, there was an emergence and tremendous growth of long-term unemployment. The policy implications thus centre on the prevention of long-term unemployment and activation of the (long-term) unemployed. If long-term unemployment leads to discouragement and habituation, loss of skills and worker attitudes, it is important to act preventively by creating e.g. temporary work experience and recruitment subsidies programmes to prevent the disenfranchising processes. The long-term unemployed can be reactivated by training programmes that upgrade lost or outdated skills and reestablish
worker attitudes. Mandatory participation can be a solution for problems of habituation, while job-search programmes can be a remedy for discouragement. These are the main ingredients of what has come to be known as active labour market policy.

5.3.2 A rival theory: structural unemployment and skill mismatch

This line of reasoning builds on the observation that over time, there has been a dramatic deterioration in the position of low-skilled members of the labour force. In Europe, the shift in demand against the low-skilled reveals itself in growing unemployment differentials between the higher and lower skilled workers. In the US labour market on the other hand, where wage rigidity is lower, the demand shift manifests itself through a substantial decline in the relative wages of the lower skilled, generating an increase in wage inequality. Over time the qualification level of the population increases. The shift in demand against the low-skilled, however, is not counterbalanced by this analogous shift in the skill composition of labour supply. Given the downward rigid wages, the low-skilled get struck in unemployment, and become long-term unemployed. Long-term unemployment persists because those unemployed do not possess the skills demanded by the labour market, and not, or not necessarily, because they become disenfranchised. In other words, this view does not demand negative duration dependence in exit rates from unemployment, and can be compatible with pure heterogeneity.

The demand shift against the low-skilled, together with the relative wage rigidity, has been designated by several authors as an explanation for the persistence of high unemployment in Europe. It is in this context that the notion 'skill mismatch' is introduced. Loosely speaking, skill mismatch is a mismatch between the skill composition of labour demand and supply.

To explain the shift in demand against the low-skilled, the three following explanations are put forward:

a) skill-biased technological change: the introduction of new technologies leads to an increase in the demand for more highly-skilled labour, at the expense of the low-skilled;

b) 'deindustrialisation': the structural shift from employment in industrial sectors to the services sectors;

c) increased competition from low-wage countries abundant in low-skilled, low-paid labour. This can be interpreted as an increased implicit supply of less educated workers.

Most authors give the highest weight to the skill biased technological change argument, while the trade and the deindustrialisation effects seem to have had a minor contribution. However, even the role of SBTC has not been unchallenged, and the empirical evidence remains fairly limited and circumstantial.

The measurement of mismatch is concerned with measuring the level and trends in mismatch. Several rival measures have been proposed. A first series of empirical measures use data on unemployment and vacancies. Though intuitively appealing, the practical application of these measures has been limited because few countries have suitable vacancy data. Therefore, some mismatch measures have been proposed which only use information about unemployment (measurement problems and rival measures are discussed in the report).

How does this framework fit the stylised facts? An increase in the level of mismatch (and skill mismatch) on the labour market will, other things being equal, lead to an outward shift of the Beveridge curve. Increased mismatch can be a sufficient condition for this shift, but is not a necessary condition. For example, the framework developed in Section 3.1 offers a rival explanation. The hypothesis that (skill) mismatch increased, offers a more straightforward explanation for the apparent deterioration of the position of the lower skilled than the theory of disenfranchised unemployed.

As regards policy, a situation of increased
skill mismatch will probably not be permanently alleviated, let alone solved, by the classical ingredients of an active labour market policy. Temporary work experience programmes and recruitment subsidies programmes will be of little help. As soon as the subsidy is cancelled, the low-skilled worker will lose his/her job and unemployment will persist. Mandatory participation will be counterproductive, while job-search programmes will be discouraging for the lower skilled. Several authors emphasise that only measures aimed at changing the relative cost of low-skilled workers (permanent subsidy, labour tax cut, lower social insurance contributions on the minimum and low wages, etc.) will prove effective. This position can be defended, but it may be too pessimistic. As skill mismatch is primarily a problem of low skills no longer required (admittedly, no longer required at the going wage rate), obviously there has to be some scope to remedy the skills problem through training and education. On the other hand, it is doubtful whether traditional programmes of labour market training, which either aim at upgrading lost or outdated skills and re-establishing worker attitudes, or have a rather narrow and specialised content and therefore are targeted at workers who already possess a lot of qualifications, will prove sufficient.

5.3.3 Job competition

The skill mismatch hypothesis and the theory of unemployment persistence due to disenfranchising effects of long-term unemployment can both explain the stylised facts from Section 2.3. Which theory is more in line with reality, is largely an empirical matter. An empirical judgement however, will not prove easy, among other things because, even at a theoretical level, there is not really a consensus as to how mismatch should be defined, let alone be measured. Yet, as already mentioned earlier, an examination of the behaviour of the exit rates from unemployment could possibly give an indication of which theory is dominant for a given country. That is to say, if for a particular country one observes that negative duration dependence is absent or negligible, this will be a strong indication for downplaying the role of the disenfranchised workers hypothesis. If on the other hand, one observes negative duration dependence, both hypotheses become possible (or a mixture of them). The criterion of duration dependence is thus at best a half-hearted judgement.

And even a situation of pure heterogeneity will not prove that mismatch is the preferred explanation. A job competition hypothesis, where higher skilled fill vacancies which initially were intended for lower skilled, could equally well be responsible for high heterogeneity in exit rates. However, with an upswing of economic activity, and a tightening of the labour market, the position of the lower skilled should improve again, at least, if job competition is the only mechanism operating. Job competition, in other words, can not explain unemployment persistence and therefore is, at best, a secondary explanation.

5.4 Corroborating evidence

State dependence versus heterogeneity

The bottom line of a review of recent research seems to be that, given the present state of the art, the evidence points increasingly towards heterogeneity at the expense of duration dependence. The US and the UK, however, at least for males, are clearly exceptions to this general observation.

Discouragement and habituation

On balance one can conclude that the empirical evidence collected during the past 20 years by students on the psychological impact of unemployment, does sustain the hypothesis that long-term unemployment is characterised by negative duration dependence.

Loss and obsolescence of skills

The discrepancy between the number of authors who support the idea of loss and obsolescence of skills during protracted spells of unemployment and the number of studies that really give empirical evidence is enormous. The few references found seem to support the claim.
**Employer behaviour**

From a survey of literature it can be concluded that a significant share of employers do take account, when recruiting, of unemployment duration. This kind of behaviour is quite consistently present in a lot of countries, which is an important indicator for supporting the presence of state dependence. From a policy point of view, it is important whether discriminating behaviour is based on an objective evaluation by employers on the basis of previous experiences (e.g. because loss of skill, loss of worker attitudes, etc. really are prevalent), or on a more subjective, to some extent prejudiced, appraisal of the employability of ‘the long-term unemployed’ in general. If the latter case is more common, information campaigns and programmes to promote the employment of long-term unemployed to unmask received wisdom might remedy the problem. If the former is more common, a quite different approach is called for.

**Mismatch**

An empirical evaluation of the importance of and the trends in skill mismatch has been made by different authors, using different measures, based on sometimes substantially different theoretical underpinnings.

Unsurprisingly, the resulting picture is most varied. The overview (in the report), may give the feeling that research results are rather inconsistent and therefore not very conclusive. However, although there is not a clear picture of the evolution of mismatch over time, most authors find, irrespective of the approach they use, that the level of mismatch is not negligible, and sometimes even substantial.

This observation warrants a policy interest in mismatch problems. Whether a policy oriented towards reducing mismatch problems will be enough, or whether it has to be supplemented by policies aimed at other malfunctionings of the labour market, depends on whether there has been an unfavourable trend in mismatch or not.

At present this last question cannot be answered unambiguously. Much more work is needed, both at theoretical level, to obtain a better theoretical underpinning of the mismatch concept (which possibly will lead to some convergence in the now widely different approaches), and at empirical level, to establish richer data with consistent time series and preferably, at a more disaggregated level.

**5.5 Conclusion**

On balance, the evidence is quite mixed. Some observations (e.g. the fact that genuine duration dependence appears to be negligible in a lot of countries), are a strong argument against the theory of unemployment persistence due to the disenfranchising effects of long-term unemployment. Other elements, in particular the well documented observation regarding recruitment behaviour, as well as vast theoretical and empirical literature regarding the effects of (long-term) unemployment on wellbeing and job search behaviour, corroborate this theory.

The demonstration of an increase in (skill) mismatch over time has been notoriously difficult, due to measurement problems and the absence of suitable data, and also due to lack of consensus among its students. To decide that an increase in skill mismatch problems is not relevant because such an increase has not yet been demonstrated convincingly, is possibly too hasty.

Therefore, a conclusion could be that a mixture of both explanations has been, and still is, responsible for the particular unemployment problems encountered by European countries. This, however, does not preclude that different countries struggle with a different mix, some having predominantly a skill mismatch problem, while others are more obstructed by the burden of long-term unemployment.

In this contribution, it was asserted that the policy mix necessary to tackle and remedy a situation of skill mismatch is potentially quite different from active labour market policies that aim at the activation of the unemployed and prevention of long-term unemployment.
While some countries, or even particular regions within countries predominantly have a mismatch problem, other countries or regions seem to have less of a problem, so a differentiated policy approach is called for.

While this may sound logical, the actual policy approach recommended by the EU through its guidelines starts from the premise that European unemployment can be alleviated by a uniform and common set of policies for all countries. The two first guidelines are directed at the prevention of long-term unemployment. While the prevention of long-term unemployment may be a goal in its own right, e.g. for social and political reasons, the economic rationale for preventive policies, namely the claim that unemployment duration itself has a clear negative impact on employability, is questioned by a growing number of empirical results.

The massive deployment of labour market programmes that seek to intervene in the early stages of an individual’s unemployment spell, e.g. training for the unemployed which has an important share, can thus be questioned on two grounds.

In the first place, dead-weight effects can be taken to be substantial, since early intervention will direct scarce resources towards the unemployed who would leave unemployment early anyway. Second, for those unemployed really at risk of becoming long-term unemployed, early intervention could be warranted provided it were possible to identify who is at risk and who is not (literature is rather pessimistic on the possibility of early identification).

However, even if the unemployed at risk would benefit from current early interventionist programmes if they were targeted exclusively at the groups at risk – which is questionable since existing measures either lack enough depth to remedy their problems fundamentally (e.g. short training courses), or only have a temporary nature (e.g. temporary wage subsidies) – it stands to reason that the unemployed at risk will not benefit much when all the unemployed are targeted.

Overqualification: reasons, measurement issues and typological affinity to unemployment

Felix Büchel

Abstract
This paper focuses primarily on two essential aspects of overqualification research: the reasons why people find themselves in underskilled jobs and the problems involved in establishing a valid means of identifying such a situation.

Starting with an extensive terminological discussion, the paper briefly introduces the various theories explaining the phenomenon of overqualification and discusses some influential factors that have rarely been examined in any work of literature, namely institutional and macroeconomic conditions and labour utility and productivity assessments on the supply and demand sides.

The next step is a systematic examination of the problems involved in identifying underskilled jobs. It begins with an explanation of the two main measurement strategies (the 'objective' and the 'subjective' approaches) and their diverse variants including unorthodox measurement processes. Thereafter, an extension of the subjective measurement strategy is introduced; in terms of validity, it is probably superior to the forms of categorisation that have been used hitherto.

The paper goes on to provide a comprehensive review of research literature, beginning with the origins of the debate in the educational expansion of the 1970s and 1980s. It retraces the academic discussion on the overqualification problem in the United States, then portrays the German situation as an example of the early development of overqualification research outside the United States. It goes on to introduce more recent work from the United States and Europe, including international comparative studies.

On the basis of longitudinal data from Germany, the theoretical analogy between unemployment and overqualification is empirically tested. The first part of this test focuses on four subjective indicators, which are tested for divergences between unemployed people, people in underskilled jobs and people whose jobs match their qualifications; the four indicators, which are already established in the field of static unemployment research, are problem-solving skills, morale, concerns about the future and participation in the political process. In the second part of the test, the set of instruments used in dynamic unemployment research is applied to analyse overqualification. The analysis is based on examples of movements from various types of employment status into underskilled work and from underskilled work into unemployment (downward career moves) as well as transitions from underskilled to adequately skilled jobs (upward career moves). Particular interest attaches to the question of the extent to which underskilled work and unemployment are alternative situations. Finally, the paper examines longer-term income effects of overqualification. Here, too, the main question is whether a period spent in an underskilled job creates income effects which – as should theoretically be the case – lie somewhere between the effects of a period spent in an adequately skilled job and those of a spell of unemployment.

The study ends with a catalogue of methodological conclusions, aimed at employment researchers, and substantive considerations, aimed at policymakers in the fields of education and employment.

Classification model of overqualification
Empirical results for Germany
‘There can never be too much education’ (Rumberger, 1981b, p. 7).
‘He is an overeducated s.o.b.’ (Harry S. Truman on J. William Fulbright)²

1. Introduction²

It has gradually come to be recognised and is now an unchallenged truism that the human capital a society has accumulated in the form of education, and especially vocational education, is a crucial location factor in the context of global economic competition. If the matter is considered in this light, however, the entire human capital created through the education system is not what counts but only that which is ‘productively’ invested in the economy. Because of the mass unemployment that prevails in most European countries, substantial volumes of human capital are lying dormant. The result of this is economic underachievement by the Member States of the European Union. The ‘superfluous’ skills and qualifications, in other words those for which there is no demand in the labour market, are not just temporarily sidelined but are also rapidly devalued as a result of disuse and the consequent absence of training opportunities. This hysteresis phenomenon, in which the unbalanced labour market is both an effect of past unemployment and a cause of future unemployment, causes the problems to escalate with the passage of time.

The losses to national economies and the social problems that are generated by unemployment are clearly recognised, not only in employment research but by the general public too. One of the main aims of this study is to draw attention to the fact that the actual surplus of vocational skills and qualifications produced by the education system considerably exceeds the surplus indicated by unemployment statistics, even if analyses of hidden labour reserves are taken into account.

Unused and therefore unproductive skills also come into the reckoning when individuals have jobs for which they are palpably overqualified. The analogy between such underskilled work, where the employee’s level of training exceeds the job requirements, and unemployment is unmistakable: the entire human capital of jobseekers lies idle, while only part of the human capital of overqualified employees lies idle. The latter phenomenon is also absolutely relevant to national economies; its significance can be measured if the number of overqualified employees³ is multiplied by the amount of skill wastage. The skill wastage may be empirically calculated, for example, as the difference between the remuneration of overqualified employees and the amount they would be earning if their job matched their skill and qualification level (see, for example, Duncan and Hoffmann, 1981; Daly et al. (forthcoming) and Büchel and Weißhuhn, 1997c and 1998). It is therefore no coincidence that the editors of the present report have combined the sections on unemployment and overqualification into a single section. A structural analogy between unemployed status and overqualification can also be derived from the terminological definition laid down by the OECD,⁴ which uses ‘unemployment and underemployment’ as a conceptual entity within its system. It divides the

² The author thanks Manfred Tessaring for most important observations and Johannes Giesecke for his valuable assistance in implementing an enhanced version of literature management software.

³ The overqualified percentage of the labour force varies widely, depending on the measurement process (on this central problem of overqualification research, see for example Smith (1986), Groot and Maassen van den Brink (forthcoming) and section 5 of the present study, which goes into some detail on the subject). The crucial point, however, is that this percentage is so high in all the Western industrialised countries that it cannot be ignored. For example, it exceeds the national unemployment rate in every country. Hartog (1997) and Borghans et al. (1998), as well as Groot and Maassen van den Brink (forthcoming) and Hartog (1999b) provide international comparisons of the frequency with which overqualification is observed.

⁴ Resolution I of the International Conference of Labour Statisticians (ICLS) on the ILO: see OECD, 1995a, pp. 44-45.
Overqualification: reasons, measurement issues

category ‘underemployment’, into two subcategories, namely ‘visible’ and ‘invisible’ underemployment. The first term relates to people who are employed but who have fewer working hours than they would wish (see for example Terry, 1981); the second term describes underskilled work (‘... refers to individuals who are working in jobs where their skills are not adequately utilised’).\(^5\)

At first sight, both of these subcategories appear almost too disparate to be two halves of the same whole. Visible underemployment is structurally closer to unemployed status, since the individual is working less than he or she would wish; in structural terms, it is akin to the German status of Kurzarbeit, applicable to employees on short time. On closer inspection, however, typological analogies are impossible to overlook. In neither of the situations can the full economic value of an individual’s vocational skill be realised; in the case of visible underemployment, this is because of an unwanted part-time working arrangement, which is ultimately due to restricted demand for the available skill profile; in the case of invisible underemployment, the reason is the low skill level required for the jobs that overqualified individuals take, presumably for want of something better.

The analogy between overqualification in general and unemployment lies in the fact that both are due to the aforementioned lack of demand for particular skills – with unemployment reflecting a total absence of demand and overqualification a shortfall in the volume of demand. The deficit in market demand for vocational skills and qualifications which is a consequence of chronic mass unemployment and which numerous studies have amply demonstrated is therefore systematically underestimated whenever overqualification is left out of the equation.

This typological analogy is presented in tabular form in some of the more recent publications of the U.S. Bureau of Labor Statistics. Hecker (1992, Table 1, p. 4), for example, presents annual figures under the following three headings: ‘All graduates in the labor force’, ‘Graduates in jobs that require a degree’, ‘Graduates in jobs that do not require a degree or who are unemployed’, the last column being divided into two subcolumns for graduates in non-graduate posts and unemployed graduates.

The structural analogy between unemployment and overqualification, however, has scarcely featured in employment research and its empirical surveying strategies. When researchers examine underskilled work and unemployment simultaneously or accord a similar level of priority to both, they are inclined to assume rather intuitively that both phenomena are serious problems for those who are affected by them and that their widespread occurrence on a macroeconomic scale may be regarded as a symptom of a profound disorder in the labour market.\(^6\) One exception is an earlier study of mine (Michel (1998b), which undertakes the first systematic examination with the instruments of dynamic unemployment research based on career cycles, assessing for example the probability of access to, continuation in and withdrawal from employment as well as the long-term effects of a period of overqualification.

The question arises as to why the causal link between dormant vocational skills and lower living standards has been clearly recognised and adequately researched in connection with unemployment, whereas considerably less attention has been devoted to the problem of insufficient coordination between the educa-

\(^5\) It should be noted that the term ‘underemployment’ is sometimes used in a different sense. Ruiz-Quintanilla and Claes (1996), for example, include part-time work, temporary work and unemployment in this category, ignoring the fact that the first two forms, especially part-time work, are often undertaken on a voluntary basis; this broad definition, however, is contrary to the intention underlying the OECD terminology. Another entirely unorthodox version is proposed by Lichter (1988), who uses a category labelled ‘underemployment by low income’.

\(^6\) See for example Bielinski et al. (1994 and 1995) in relation to eastern Germany, which seems to illustrate this phenomenon particularly well, or Cedefop (Tessaring, 1998) in the European context.
tion system and the labour market, a problem that manifests itself in the form of overqualification.\(^7\)

There are probably three main reasons. First of all, unemployment is a particularly flagrant waste of human capital, because the loss is absolute. Secondly, unemployment imposes a burden on national economies not only because the unemployed do not contribute to a country's productive output but also because part of the national product has to be diverted into a fund for the payment of unemployment benefits. And thirdly – an aspect that probably should not be underestimated – the precise volume of dormant human capital that results from unemployment has been statistically measured and recorded. Official statistics relating to overqualification, on the other hand, do not flag any problem, especially not in the highly aggregated form in which such statistics are characteristically produced and studied.\(^8\) Take the example of a man with a doctorate in philosophy who works as a taxi driver. He is not unemployed and therefore receives no state benefits – on the contrary, as far as the skill-related labour-market statistics are concerned, he even helps to furnish evidence that the economy employs philosophers and hence that there is a demand for philosophers. This signal is then transmitted to universities and their arts faculties and philosophy departments.

If dormant skills in the labour market are taken into consideration, it follows from the preceding observations that a new dividing line has to be drawn when we examine the labour market. The conventional boundary between jobseekers and employed persons must give way to a division between jobseekers plus people in underskilled jobs on the one hand and employed persons whose jobs match their skill and qualification levels on the other.\(^9\) It is evident that this type of approach must take account of the fact that a considerably higher volume of skill lies dormant when individuals are unemployed than when they are in overqualification, nor can it be denied that unemployment has a far greater impact on both the individual and society than the phenomenon of overqualification. Nevertheless, as far as the utility of acquired vocational knowledge and skill is concerned, there is still a typological analogy between unemployment and overqualification.

The present study pursues three principal objectives. Once the terminological concepts have been clarified, we shall present the first comprehensive investigation designed to establish which of the competing labour-market theories can help to explain the persistence of overqualification (section 3). A politically guided improvement of the interaction between the education system and the labour market, and hence an increase in the efficiency of the education system, cannot be achieved without knowledge of these causal

---

\(^7\) The contrast here between the public interest and the present state of research is particularly striking (cf. Büchel, 1996b).

\(^8\) Although it is theoretically possible to differentiate, i.e. to break official data down into narrower categories, it is often impossible in practice, because such differentiation presupposes access to the original figures from which the statistics were compiled, and access to these figures is frequently restricted by the authorities. For an example of this type of approach in connection with the subject of the present study, see Plicht et al., 1994.

\(^9\) On this point, compare the generally analogous but considerably more radical and empirically almost unworkable approach presented by Müller and Beck (1993): 'We are speaking [...] of underutilisation of the production factor labour when we refer to members of a country's active population who either do not have a job, even though they are prepared to work for the going rate of pay (unemployment type A) or do have a job but are not used efficiently in the production process (this is what we call hidden unemployment; unemployment type B)' (pp.54-55, including text in parentheses). The employees whom Müller and Beck define as 'not used efficiently' come from a wide variety of categories, such as employees who are surplus to requirements but cannot be dismissed, employees whose job dissatisfaction is reflected in reduced productivity and 'people who, in accordance with the accepted norms of administrative theory, remain in posts in which their services are effectively superfluous' [!] (p.54). For a critique of the conventional dichotomous division of the active population into employed and unemployed persons in a broader context, see also Sullivan, 1981, pp.335ff.
To supplement this investigation, we shall also review the current state of empirical research (section 4).

Our second objective is to discuss in detail the measurement problems associated with any attempt to define overqualification. It will emerge from this discussion that the volume of overqualification is less accurately measurable than unemployment. At the same time, it will become apparent that these measurement problems not only make international comparisons in the field of overqualification more difficult than those relating to unemployment; the diversity of measurement strategies, to which varying degrees of validity can be ascribed, also leads us to the unsatisfactory conclusion that there is scarcely a consensus on the volume of overqualification within the various national economies. This part of the study concludes with the presentation of our own model for the categorisation of overqualification.

The third objective of the study is to substantiate empirically the postulated analogy between jobseeker status and overqualified employee status. To this end, section 6 pursues an integrated approach, contrasting subjective indicators that are firmly established in employment research, such as satisfaction with life and concerns about the future, for unemployed people, people in underskilled jobs and those whose jobs match their qualification levels. The section also contains a longitudinal analysis of movements between these three types of employment status with a view to establishing whether significant exchange processes are observable, particularly between unemployment and overqualification, and whether the gap between these two situations is narrower than that between skill-matched employment on the one hand and unemployment or overqualification on the other. Section 7 draws conclusions from the preceding reflections and findings.

2. Subject of the study and definitions

The term 'overqualification' is generally used to describe a situation in which the knowledge and skills acquired through the education system are not exploited to the full. This definition is clearly very vague. For that reason, German researchers at any rate do not speak of overqualification unless the required skill level for the job is so far below the formal qualification of the employee that the work could obviously be performed by someone with a lower level of formal qualification.

This interpretation is not unconnected to the degree of formalisation of vocational training. The more institutionally standardised the qualification, the more plausible this approach appears. Applied to a rigidly segmented system such as the German one, which is divided into vocational training (non-academic) and higher vocational education (academic), this means that, on the one hand, people who have undergone vocational training - in the form of an apprenticeship, for instance - and are now in jobs for which no formal vocational qualification is required (e.g. a carpenter who works as a car-park attendant) and, on the other hand, graduates in jobs which could be done by people without higher educational qualifications (e.g. an engineering graduate working as a technician or even as a fast-food chef) are considered to be in overqualification.

As the definition shows, the important factor is the vertical dimension of occupational flexibility, not the horizontal dimension. Although the latter also results in the disuse of knowledge and skills acquired during the training process (if a qualified nurse, for example, works as a medical technician), the

10 Despite a comprehensive body of relevant American literature, this type of in-depth analysis has yet to be performed in the United States. As Hecker says, 'Currently, we do not know how many college graduates take noncollege-level jobs because of labor market supply-and-demand conditions, how many do so because their individual educational backgrounds limit their options, and how many do so through deliberate choice.' (Hecker, 1995b, p.41).

11 On this distinction, see also Plicht et al., 1994, p.178).
type of 'skill spillage' that occurs when the training curriculum is out of alignment with the job description is considered to be inherently unavoidable when jobs are allocated to jobseekers.

It may be assumed that this form of horizontal mismatch will become increasingly commonplace as the industrial division of labour grows in complexity. Accordingly, a high incidence of horizontal mismatches in a national economy can scarcely be cited as evidence of an inefficient education system. In Germany, for example, a very high percentage of the active population state that they are not working in the occupation for which they were trained. Not least among the reasons for this is the fact that the dual system of alternating practical and theoretical training is based on a highly refined catalogue of occupational disciplines; an employee can therefore claim not to be doing the job for which he was trained even though the content of his actual job is very similar to the one in which he is qualified. Such 'skill spills', i.e. elements in the training curriculum that are not needed at work, also tend to affect every person who starts a new job.

So the decisive question is whether an employee's post could also have been filled by someone with a lower level of formal qualification, which would mean that the employee's vocational training represents a wasted personal investment, at least in part. In the case of the qualified nurse who was mentioned above, however, this situation is unlikely to obtain, since it may be assumed that she would not have obtained her post as a medical technician if she had not been trained to an equivalent standard in an associated discipline; her fellow technicians may therefore be expected to possess a similar level of qualification.

In the literature from the English-speaking world in which the terminology of employment research is coined, the terms 'over-education' and, to a lesser extent, 'overqualification' have won acceptance as labels for the phenomenon described in this study. It should be noted, however, that in the initial phase of this discussion (see point 5.2.1 below) and even thereafter, in a few cases (see for example Dooley (1986) or Lambropoulos and Psacharopoulos (1992), who implicitly said the same thing, albeit in another context and without using the term 'over-education') these concepts were used not only to refer to an individual in an underskilled job but also to refer in macroeconomic terms to a surfeit, or alleged surfeit, of paper qualifications in the labour market, which manifests itself, for instance, in diminishing returns from higher qualifications (cf. Rumberger, 1981c, p.294). However, other terms in frequent use, namely 'skill underutilization' (see for example Kalleberg and Sørensen, 1973, p.217, as well as Staines and Quinn, 1979, p. 8) and 'surplus schooling' (see for example B.Tsang et al., 1991), relate explicitly to the individual. The term 'mismatch' occurs occasionally; from each of the contexts in which it is used, it is clear that the mismatch is between the formal qualification level and the skill level of the job (see for example Clogg and Sullivan, 1983, p.121); now and then the term 'occupational mismatch' is also encountered (Clogg, 1979, and Sullivan, 1978). This concept, however, seems to pose semantic problems, because in the strictly literal sense it includes overskilled jobs, 12 which are irrelevant in the context of our study and which, in a different framework, would have to be regarded as overqualification. 13

Other designations have not stood the test of time, such as 'overtraining' (Kalleberg and Sørensen, 1973) or the term 'nominal over-education', which Halaby used (1984, p.48) and ascribed to Clogg and Shockey (1984), although

12 Such a situation would arise, for example, if the holder of a master craftsman's certificate were the only non-graduate member of the management team of a sizeable construction company.

13 The difference between the theoretical approaches to the phenomena of underskilled and overskilled work is reflected, for example, in the fact that the proponents of the theory of career mobility (Sicherman and Galor, 1990) explicitly state that they can only explain the persistence of overqualification, not the occurrence of underqualified activity (cf. Sicherman, 1991, pp.109-110).
this reference could not be traced. The same fate awaited the terms *Grauzonentätigkeit* ('grey-area activity'), which Schlegelmilch used in 1982, and ‘inappropriateness of skills’ (Tessaring, 1998). Nor could Mincer win acceptance for his proposed alternatives to ‘over-education’. He criticised the tendency to confuse ‘education’ with ‘schooling’, which was only part of an individual's education, and suggested the terms ‘overschooling’ and ‘mis-schooling’ (Mincer, 1984, p.208).

Finally, there is surely a touch of irony in the fact that the expression ‘invisible underemployment’ which was quoted from the OECD terminology in the introduction to this study is conspicuous by its virtual absence from the body of literature on the subject of overqualification – *nomen est omen*!

3. Theoretical reflections on the causes of overqualification

3.1 Overqualification from the neoclassical perspective

From a neoclassical point of view, the phenomenon of overqualification, like that of unemployment, is a ‘non-event’. Where overqualification occurs, the neoclassical view is that it can only be the symptom of a temporary imbalance. This opinion is expressed by the authors of earlier conventional macro-economic studies on overqualification (see for example Freeman, 1976b).

In the longer-term adjustment process, for which, these authors believed, political support would be needed, the stiffer competition for adequately skilled jobs would lead to pay reductions at the top end of the labour market. This in turn would induce companies to adapt their production structures, the general effect of which would be an increase in demand for higher qualifications. On the supply side – always assuming perfect information – the diminishing return on higher levels of skill and qualifications would make advanced training a less attractive proposition. The demand-side adjustment would thus be reinforced by a reduction in the supply of skilled labour.

As always happens in neoclassical models, a stable balance would be restored; any remaining imbalances between the supply of skilled labour and the demand for skilled labour, which would manifest themselves in unemployment and underskilled labour, would then be no more than frictional loss.

Criticism of this view begins at the same points as the familiar criticism that has been levelled at the neoclassical understanding of unemployment. Market operators seem even less likely to conform to neoclassical theory in their responses to overqualification than they do in responding to unemployment. The information gaps are even wider, which means that longer reaction times may be expected on both sides of the market. Trusting solely in the healing powers of market forces to overcome overqualification ‘in the long term’ therefore seems just as inadvisable as it is in the case of unemployment; Keynes’ criticism of the neoclassical insistence on patience is very apt here too. As he said, ‘In the long run we are all dead’.

3.2 Decision-making in the event of an individual mismatch between a person’s skill profile and the job description

In the general empirical literature on the subject of overqualification, the labour-market theories referred to in point 3.3.1 below are generally cited as possible ways of explaining the phenomenon. These various approaches are then evaluated in the light of research findings to establish their empirical legitimacy. The observable degree of concurrence among all the relevant empirical studies is remarkably high.

None of the studies presented in section 4 focuses on the precept that the interests of both employers and employees must always be reconciled in any job-matching process, a precept which is very important if we are to grasp the overall picture (Franz, 1991, chapter 6). Most of the attempts to explain the persistence of overqualification that are enumerated in point 3.3.1 below are only able to explain the calculation underlying the decision taken by one side; apart from the theory of career
mobility – and even in that theory the interests of the employers' side are only implicitly assumed – there is not a single theory that can explain why the same decision is taken simultaneously by different players.

Equally scant attention is devoted in the body of empirical literature to investigation of the decision-making options of both sides in the labour market. In fact, the nature of the decision-making problem differs quite markedly between the supply and the demand side.

**The employee's decision**

For the employees' side, the implicit alternative to underskilled work is normally unemployment or withdrawal into the hidden reserve (for empirical evidence see Schlegelmilch, 1982 and 1983b). According to this premise, the main difference between overqualified employees and the unemployed is the former's unconditional desire for a job, what Schlegelmilch refers to as an 'I'd have done almost anything' attitude (Schlegelmilch, 1982, p.414).

It must clearly be assumed – implicitly, once again – that a person's acceptance of an underskilled job will have been preceded by a fruitless search for more suitable employment. This perspective, however, systematically obscures two other possible scenarios. Firstly, a spontaneous switch from another form of economic inactivity (that of the non-jobseeker) to overqualification is conceivable if an acceptable underskilled job offer were to materialise – an unexpected opportunity, obviously – and if that job seemed likely to benefit the individual more than continued inactivity.

It is also conceivable that underskilled work could be a genuine alternative to adequately skilled employment. This implies a 'voluntary' choice of lower job status. Teichler (1994, p.30), in a résumé of the findings of a study by Teichler et al. (1992), surprisingly reports that the majority of the academic respondents who were in underskilled posts had voluntarily chosen that employment status; Hecker (1995b, p.41) also discusses the same option in the U.S. context, though without empirically testing a hypothesis.

Such a decision could be taken, for example, if advantageous non-monetary working conditions, such as a lighter workload, a shorter journey from home to work, a job with high regional status, shorter working hours (if preferred), etc., outweighed the monetary disadvantages of an underskilled job in relation to adequately skilled employment and if income maximisation were not the basis of the jobseeker's decision (see point 3.4.3 below, where this factor is addressed in greater detail). Moreover, it might also happen, albeit more rarely, that a higher net income can be earned – at least in the short term – from overqualification than could be obtained from a well-matched job (cf. Lucas, 1977).

Although all the indicators suggest that this favourable pay differential will not be sustainable in the long run (see for example Büchel, 1994b), if the jobseeker does not possess this information or only wants to do the job for a limited time, it is entirely logical for him or her to accept an underskilled job as an alternative to more appropriate employment. There is empirical evidence of both the aforementioned types of decision in the present report.

**The employer's decision**

The motives behind the employer's decision almost never feature as a subject of empirical literature either. Nevertheless, this decision is quite different to that of the employee. The main alternative in empirical terms to appointing an overqualified candidate is most probably the selection of an applicant whose skills and qualifications are commensurate with the job description. This, however, presupposes the absence of restrictions on the supply side.

It is entirely conceivable, for example, that the local labour market might be unable to deliver a 'suitable' person for a particular job, i.e. one whose skills and qualifications match the job profile, perhaps because of the specific nature of the job in question. At the same time, the job might not be important enough to warrant the additional cost of casting the recruitment net beyond the local area. In this situation it would be futile to investigate the employer's motives for choosing an overqualified applicant.
This turns the spotlight onto another option that is open to employers: if there is not even an overqualified candidate for a post, or if overqualification is automatically regarded as a reason for rejection of an application, the employer may simply decide not to fill the post at all.14

When the empirical effectiveness of the competing attempts to explain the persistence of overqualification is assessed, due consideration must be given to the difference between the parameters governing the employer's and the employee's decisions. This means that, even if an explanatory method (based on one party's decision) proves to be especially effective, it is still only a partial analysis, and the persistence of the phenomenon will not be fully explained unless plausible explanations are found for the behaviour of the other party.

3.3 Explanatory methods based on partial analysis

3.3.1 Established methods

The explanatory methods we call 'established' here are those that have featured in empirical studies in the field of overqualification research. This, however, does not automatically imply anything about the popularity of a given method or its empirical substantiation.

The human capital theory

The human capital of employees comprises not only the certified knowledge they have acquired at schools or technical colleges but also contains other components, which are created as the employees gather work experience or which reflect their length of service with a company, for example. If these diverse components are interchangeable, it is conceivable that various people whose components are mixed in different proportions might possess an equal stock of human capital. In such a case, measuring the extent of a mismatch on the sole basis of formal qualifications would not furnish proof of inefficient skill deployment in the labour market.

This more methodological aspect of overqualification, however, only comes into play if a DOT/GED approach is adopted to measure the degree of overqualification; such an approach is not based on employees' subjective self-reported estimates but on a standard set of measures of required schooling for various occupational categories (see subsection 4.1 below). Accordingly, the human capital approach (Becker, 1964) is never used to explain the persistence of overqualification, except by Sichermann (1991), who makes a study of this aspect of the overqualification problem (p.114). Since the human capital theory may be deduced from neoclassical premises (see subsection 3.1 above), Rumberger’s comment, 'overeducation does not really exist in this conception' (Rumberger, 1981b, p.24) applies to the theory of human capital too.

Nevertheless, the great versatility of the human-capital theory surfaces once again in partial analyses in the field of overqualification research when, for example, it is demonstrated in western Germany that, in the course of a career in which a person's jobs generally match his or her qualifications, transitional periods spent in overqualification result in less erosion of human capital and hence of subsequent earning power than equivalent periods of unemployment (see subsection 6.6 below).

The assignment theory

The assignment theory, which was established by Tinbergen (1956), following preparatory work by Roy (1951), and was further developed by Sattinger (1975), Rosen (1978), Hartog (1980, 1981a and 1981b) and Mac-
Donald (1982) proceeds from the assumption that people with different skill levels are assigned to jobs with different requirement levels. Given the complexity of this allocation process, mistakes are inevitable. In other words, the phenomenon of underskilled (and overskilled) employment is inherent in an intricately structured market economy. The income effect of such mismatches is examined in assignment literature, which is able to demonstrate that the income differential arising from the discrepancy between individuals' formal qualifications and their job descriptions is exclusively incurred by neither the employer, as the job-competition model might lead us to expect, nor by the employee, as the human-capital theory would suggest, but is actually divided between both parties (Hartog, 1986). Hartog shows this explicitly for a case of directly measured overqualification (Hartog, 1985a). The ratio in which this income effect is split between the two parties can also be established for Germany and other countries. When the income losses incurred by each party from a mismatch are reduced, this eases the pressure on either side to avoid overqualification and makes the phenomenon all the more persistent.

Filtering, signalling and screening approaches

Filtering, signalling and screening approaches all proceed in similar ways from the assumption that human capital created in formal education does not directly determine employees' pay levels. The exact future productivity of job applicants is not recognizable to a prospective employer, who faces the problem of 'hiring as investment under uncertainty' (Spence, 1973, p.356). The quality of the applicants' training certificates serves as a manifest indicator of the latent variable 'future productivity'. This resolves the crucial problem of uncertainty or imperfect information, since candidates with a higher or more relevant educational qualification are expected to be more productive than others. The certificate only acts as a signal, a screening mechanism and a filter in the recruitment situation. Once the new recruit has started work, he or she can be extensively tested, as can the efficiency of the basis on which the recruitment decision was made, in other words the approaches we are discussing here; the effect of the certificate diminishes rapidly: 'To the extent that the employer does filter and does so accurately, the value of the college filter is reduced' (Arrow, 1973, p.215). Even if some certificates and/or their holders prove unproductive when put to the test, this will scarcely change employers' decision-making criteria, since employees with higher educational qualifications are more productive on average than their less-educated colleagues: what counts is the level of expectation. So it is not the actual human capital that yields an investment dividend but the certificate. To put it another way, the certificate, being a manifest quantity, is a tangible indicator of the holder's human capital, which, being a latent quantity, is not directly measurable – at least not in the recruitment situation; presumably these two quantities are not perfectly equal. On the basis of these premises too, the return on individual certificates may be expected to fall when the market experiences a glut of labour; nevertheless, the fact that a certificate attesting to a higher level of education is not only directly rewarded but also indirectly, because it serves as a key to skilled employment, tends to increase demand for higher qualifications within the education system, irrespective of market demand for labour.

This growing demand is further stimulated by factors extraneous to the labour market, namely the non-monetary returns to higher education, such as the accretion of social status and prestige; here too, the educational certificate serves as a signalling device. If the demand for labour with the skills and

15 See Rumberger, 1987 (United States), Daly et al., forthcoming (United States and Germany), Alba-Ramirez, 1993 (Spain) and Kiker et al., 1997 (Portugal).

17 On this aspect of formal qualifications, see Smith, 1986, p.98.
Overqualification: reasons, measurement issues

qualifications in question cannot keep pace with this expansion, the result – once all the matched posts have been filled – will be a rise in the unemployment rate for people with higher qualifications and/or an increase in overqualification.18

The distinctive feature of the aforementioned approaches is that they are almost impossible to test empirically within a microeconomic framework. Although nearly all the relevant empirical studies on the subject of overqualification resort to these approaches when they advance their explanatory hypotheses, they offer no explicit test. They circumvent the measurement problem by relying on the fact that the empirical legitimacy of these approaches is generally held to be irrefutable.

This probably applies even more to European countries with sophisticated systems of vocational education than, for example, to the United States. In Germany, for instance, virtually every job offer – at least above a modest skill level – stipulates that applicants should possess a specific formal qualification. The function of the required certificate as a signal and a screening device is not altered by the fact that, in recent times, especially at the highly skilled end of the jobs market, mere evidence of vocational training is no longer enough to secure a job. Additional tests, such as those conducted in the assessment centres of large companies, seem to be a response to the appreciable weakening of the signal emitted by university degrees, for example. The implication – which may not be entirely unfounded – is that we are seeing a decline in universities' ability to measure their students' skills and to translate the results of their measurements into a valid form of certification when students complete their degree courses. The signal function of a certificate, however, is unquestionably preserved by virtue of the fact that, while it may not be a sufficient qualification in itself, in the vast majority of cases it is probably at least a sine qua non for the jobs for which certificate holders apply.19

Job-competition model

The job-competition theory is based on the premise that an individual's place in the job queue is largely determined by the nature of the underlying variable 'education'. A higher level of education – whether or not the job actually requires it – implies lower training costs for employers. It will likewise take less time and effort to familiarise individuals with a job for which they are overqualified than for one that matches their formal qualifications.

Still greater importance attaches to the training costs involved in upgrading employees' skills and qualifications. The preference is to invest in employees who, on account of their educational background, are likely to be the cheapest to train. Accordingly, it is the overqualified candidates who raise the highest expectations in terms of returns on further educational investments and who therefore stand the greatest chance of being sent on training courses; these corporate expectations and the strategy of externalising training costs to which they relate (in the case of overqualified employees, the education system has already footed a good part of the bill) put overqualified people in pole position in the labour queue, ahead of those whose qualifications match the job description; in short, overqualified people have a head start in the recruitment stakes (Thurow, 1975, pp.75ff., pp.86 et seq. and pp. 91 ff.).

This model is therefore able to explain an employer's motivation for preferring overqualified candidates and, by the same token, the persistence of overqualification.

An important point is that the candidates' formal qualifications only determine their position in the job queue. They do not, however, affect the income they can expect to earn; that is determined by the job description

---

18 For detailed treatment of this phenomenon, see Rumberger, 1981b, pp. 25ff., as well as Tsang and Levin, 1985, p.95.

19 See also Rippe, 1984, pp.76 ff., on this point and, for a more general analysis, Weißhuhn, 1978.
alone. So all that Thurow’s job-competition model directly explains is the motivation of employers to put cost and productivity considerations first and opt for the candidate with the best formal qualifications.

This does not directly explain the incentive for the candidate to accept an underskilled job, because he or she cannot expect an education premium. Indirectly, though, the desire to acquire the highest possible level of educational certificate in order to secure the best possible position in the job queue helps to perpetuate overqualification from the supply side. If overqualification is always an option, this strategy seems rational, irrespective of the structure of demand for labour. The demand for education in this case is not based on absolute expectations but is governed by the desire to secure the best possible relative position in the labour market, even at the risk of subsequent devaluation of qualifications.

The upshot of this is that people with higher qualifications are squeezing the less qualified out of the jobs they have traditionally occupied. This applies at least to jobs with more than minimal skill requirements (cf. van Ours and Ridder, 1995). In this respect, the job-competition model is therefore compatible with the approaches described on the preceding pages.

Rumberger writes, ‘[...] the model does offer an intuitively appealing interpretation of the phenomenon of overeducation’ (Rumberger, 1981b, p.29); this may be the reason why this is the most frequently cited approach in the empirical literature on overqualification.

There is, however, one serious problem in relation to empirical testing, although it has surprisingly gone unmentioned in the literature that has been produced to date. This concerns the question of the type of training in which overqualified employees are expected to enjoy comparative advantages over their colleagues with well-matched jobs and less schooling. Is it initial training, when they are new to their jobs, in other words the training of recruits for their posts? Or do these advantages relate to future training courses to upgrade their skills and qualifications, particularly in connection with career development within the company? Thurow is not at all specific on this point.

The classic test of the job-competition model in relation to overqualification involves a comparison between the training activities undertaken by employees in underskilled jobs and those undertaken by employees in appropriate jobs (see for example Groot, 1993a and Hersch, 1995). If the validity of the initial premise is to be proved, it must be demonstrable that overqualified employees undergo less training than those whose jobs match their qualification levels, since people with better formal qualifications need shorter familiarisation periods and less training. In order to substantiate the second premise, however, we should need to arrive at the opposite result, since the greater learning capacity of the more highly educated employees will reduce training costs and therefore increase the return on investments in further training; at constant required skill levels, employees in underskilled jobs are therefore more likely to be sent for training than their less-educated colleagues whose jobs and qualifications are well matched.

There are several reasons why the second interpretation appears more credible. In very undemanding jobs, which would be underskilled for any employee, familiarisation normally takes the form of learning by doing. At least in European surveys, however, most of the training reported by overqualified respondents is formal in nature. If this line of argument is pursued, the training activities reported in surveys must relate primarily to further training designed to upgrade skills and qualifications. Such an interpretation also draws an analogy with the theory of ca-
reer mobility (see below). This not only concerns the employer's motivation but also that of the employee: the prospect of being at the front of the queue for further training and thus of achieving at least limited promotion is likely to increase a jobseeker's willingness to accept overqualification.

The job-matching theory

The theory of job-matching, which was developed in the 1970s, may be loosely divided into two types of model. In the first category, jobs are understood as 'pure search goods'. Information about an alternative job, in which an employee's qualifications and the job description are likely to be more closely matched, is obtainable at all times. If such an alternative is available elsewhere, the employee will switch companies (Burdett, 1978; Jovanovic, 1979a; Mortensen, 1988). In the second category of model, jobs are interpreted as 'experience goods': 'That is, the only way to determine the quality of a particular match is to form the match and "experience it" (Jovanovic, 1979b, p.973, quoting from Nelson, 1970; for studies on this type of model, see Johnson, 1978; Jovanovic, 1979b; Topel and Ward, 1992).

Length of service with one company is traditionally regarded as a suitable indicator of the quality of a match: 'Job tenure is my (match) quality indicator under the assumption that "good matches endure"' (Bowlus, 1995, p.336; for analogous rationalisation, see for example Schasse, 1991, and Topel and Ward, 1992). The assumption is that a mismatch will be identified relatively quickly by one of the parties, and the employment contract will be terminated. A good match, on the other hand, benefits both sides, and the contract will therefore last longer.

In the context of the present study, it seems logical to measure the quality of the match directly by reference to the correlation between qualifications and job descriptions. Employment in a job that is commensurate with one's level of training is obviously more likely to prove a better match than overqualification. Accordingly, the 'experience-goods' variant of the job-matching theory is able to explain the persistence of overqualification on the basis that, on the one hand, employees need a certain amount of time in the initial phase of their careers to find a 'good' match. Employers, on the other hand, do not respond quickly enough - if at all - to mismatches, sometimes because of a risk-avoidance strategy based on the precept that 'a bird in the hand is worth two in the bush', and therefore miss the opportunity to test whether the employee's skills are better matched to the requirements of a different job and hence the chance of improving their company's overall efficiency.

In the empirical studies on overqualification, the job-matching theory is only used on the odd occasion as a means of explaining the phenomenon. Sicherman (1991) uses it implicitly in testing his career mobility model: 'Overeducation might be an indication for a bad match in the sense that the worker's education might qualify him for a better-paying job. In such a case, it is likely that eventually the worker will change his job, that is, his occupation, firm, or both' (p.105). Sicherman tests it explicitly when he compares the job tenure of employees whose job descriptions are commensurate with their qualifications and those who are overqualified for their jobs. His finding that mismatched employees have shorter job tenures (p.106) is hardly surprising. To the extent, however, that a short stay with a company is a traditional indicator of a mismatch, as was mentioned above, this test is tautological in a sense; the best it can do is to verify the validity of the mismatch indicator selected by the job-matching theorists, namely job tenure.

Alba-Ramirez (1993) chooses a more effective test. He not only uses the duration of jobs, which can be observed longitudinally, but also has recourse to the employee's earlier career history. He examines the connection between the average duration of all previous jobs and the current job match. The analysis is extended to include two further partial indicators: whether the employee has ever changed firms and whether the employee has more than five years of seniority in his or her current job. On this basis, Alba-Ramirez likewise finds empirical evidence to validate the theory.
There are, however, two weak spots in this train of thought. The first is that Alba-Ramirez is only able to use prior work experience, a 'potential' measure; this is likely to cause serious reliability problems, especially in the case of older working women. The second is that he includes in the calculation the employee's seniority in his or her present job, which is a piece of right-censored data at the time of observation. Where employees have only had their present jobs for a short time, moreover, it will not yet be possible to establish a valid correlation between job duration and match quality.23

In the present study, we intend to test the empirical evidence for the 'experience-goods' version of the job-matching approach even more explicitly.

The expectation raised by the theory is clearly that the match between the demands of the job and the worker's skills and qualifications will be all the more perfect the older and more experienced an employee is (Franz, 1991, p.203).

Although the argument that 'older and more experienced' employees stand a better chance of being in a well-matched job by virtue of the progressive improvement in their ability to assess their own career prospects is certainly plausible, it does raise the question of the validity of the personal attributes cited by Franz. Merely growing older is obviously not enough in itself. The second attribute, increasing experience, certainly seems to be more serviceable. If experience is not intended to be synonymous with age, it is plainly not experience of life but occupational experience that is meant here. The theory does not suggest that occupational experience, which in this context means the knowledge accumulated by the employee about his or her productive capacity and the uses to which it can be put in the labour market, is likely to increase through continuous employment in one and the same job but only through a process of trial and error in various jobs with several different employers.

For this reason, it seems advisable to regard the frequency of job moves as a direct measure of occupational experience in empirical tests.24 This would be used to check whether an increase in the number of career moves actually reduces the probability of a subsequent mismatch between formal qualification and job requirements. A specific test (Büchel, 1998b, p.139) demonstrates that – contrary to theoretical expectations – overqualified employees have a record of considerably greater career mobility than those in jobs that match their level of training. This finding does more to prove the plausibility of the segmentation approach (see below), which predicts weak company attachment among employees in undemanding jobs.

**Career mobility theory**

The theory of career mobility, developed by Sicherman and Galor (1990) on the basis of Rosen's groundwork (1972), postulates that the return on investments in higher levels of education not only manifests itself in higher starting pay but also in better prospects of promotion within a company or of an upward move to another company. In other words, it focuses on income development over a period of time and may be regarded as a refinement of the human-capital theory. If tests control for required skill levels, promotion prospects will increase with rising education levels.

One proposition ('Corollary 2') is as follows: 'Individuals may choose an entry level in which the direct returns to schooling are lower than those in other feasible entry levels if the effect of schooling on the probability of pro-

---

23 Alba-Ramírez, like Sicherman (1991), establishes a strong positive correlation between job tenure and match quality (pp.272-273).

24 Even within the work of individual authors, this configuration is presented in different ways and hence inconsistently. Hersch (1991), for example, rightly speaks of employees who 'move into better matching jobs' (p.144), which they clearly cannot do unless they make a change (such as obtaining promotion within a company or moving to another company), whereas Hersch (1995) refers generally to 'previous work experience' (p.620), which is measured in total years of employment.
motion is higher in this entry level’ (Sicher-
man and Galor, 1990, p.177).

Sicherman (1991) operationalises this sort of
promotion as both a ‘move to higher-level oc-
cupation’ and the attainment of a ‘higher wage
level’ (p.109). A motive for accepting an
underskilled job can be deduced from the
above hypothesis: ‘[...] it will be rational for
some individuals to spend a portion of their
working careers in occupations that require
a lower level of schooling than they have ac-
quired. This observation can serve as a par-
tial explanation for the phenomenon of
‘overeducation’ (Sicherman and Galor, 1990,
pp.177-178; cf. Sicherman, 1987). The higher
the probability of promotion, however, the
greater is the possibility that the employee
will quit if promotion is not approved; this is
the other proposition (‘Corollary 1’) of the ca-
reer mobility theory (see Sicherman and

The appeal of the career mobility theory does
not derive solely from its high degree of plau-
sibility but also from the fact that – unusu-
ally – it can explain both parties’ motivation
for accepting an individual job/education mis-
match by means of the same approach.

Employees forego part of what they could be
earning now in exchange for a favoured posi-
tion in the promotion queue, thereby invest-
ing in increased future earning power. If, af-
ter some time in the job, they feel that their
employer has reneged on the deal, their only
option is to move to another company.

For employers this arrangement is enticing
in the sense that it gives them an opportu-
nity to ‘test’ new recruits, whose high level of
qualification predestines them for managerial
functions, at a reduced rate of pay over a cer-
tain period of time. There is something of an
analogy between this and the training proc-
есс under the German Duales System of al-
ternating classroom and workplace training,
in which the company with which a trainee
has been working decides at the end of the
training course whether to offer the trainee
an employment contract, in other words to
‘promote’ him or her to the status of a skilled
worker. A comparable configuration is becom-
ing increasingly commonplace in the academic
world, whereby individuals are not appointed
to traditional academic posts until they have
completed a traineeship in the institution in
question.25 The ‘course fee’ that the trainee is
implicitly expected to pay for his or her on-
the-job training thus assumes the nature of an
investment.

In a subsequent study, Sicherman (1991) went
back to the test of the theory developed in
Sicherman and Galor (1990) and tailored it
explicitly to the phenomenon of overquali-
ification. He found clear evidence, which is
hardly surprising, of the validity of the ca-
reer mobility theory he helped to construct.
Employees in underskilled jobs, he estab-
lished, are younger than those in well-
matched jobs, have a higher rate of internal
promotion and switch companies more often.

Alba-Ramírez (1993) arrives at similar re-
sults. The problem with the approach adopted
in both studies, however, is that, in compar-
ing employees in underskilled and well-
matched jobs, they operate with a constant
level of formal qualification but different lev-
els of skill requirement. If the structures they
identify correlate highly with job levels, the
findings will inevitably be misinterpreted,
because a causal link will be imputed between
the various identified effects and the job/edu-
cation mismatch, although it is possible that
the differences between the two groups are
to be entirely due to the fact that the members of
one group have more demanding jobs than
those of the other group.

In a test the author conducted on this theory
(Büchel, 1998b, pp.140 ff.), allowance was
made for this possibility by ensuring that,
once the conventional qualification-based test
had been completed, the effect of overquali-
fication was only investigated for certain jobs
which were as homogeneous as possible in
terms of required skill levels. The test shows
first of all that there is no significant differ-

25 ‘Evidently, in many companies, an employee’s
precise job is not determined until he or she has
successfully completed the traineeship programme’
iwd, 1994b, p.5).
ence between the promotion prospects of overqualified employees and those of adequately educated employees. Secondly, on the basis of the same investigative strategy, the test actually did indicate a negative correlation between the internal promotion of an overqualified employee and the probability of that employee leaving the company, just as the theory predicts, but it also demonstrated the same phenomenon for adequately educated employees. These findings clearly do not deliver a resounding endorsement of the career mobility theory.

In a more extensive test by Büchel and Mertens (2000, and forthcoming), the Sicherman (1991) findings are replicated with German data (full-time male employees in western Germany) – with the required skill level again being held constant. This test actually demonstrates a higher probability of promotion into an occupational group with a greater mass of human capital for overqualified employees than for those with adequate education. This also applies if we pursue the approach adopted by Robst (1995a), who analyses changes in occupational status rather than transfers from one occupational group to another. It has been demonstrated, however, that these findings largely derive from blurred distinctions between categories of occupational status. If changes in income are examined instead, and if the test controls for the base effect (income in the base year), it emerges that overqualified employees experience less wage growth than their adequately educated colleagues. This finding is consistent with that of the sociological studies which have established a link between better job/education matches and brighter career prospects (see for example Sorensen, 1977, and Spilerman and Lunde, 1991, p.716). This is another finding which undermines the attempt made in Sicherman (1991) to apply the theory of career mobility to the phenomenon of overqualification.

The theory of differential overqualification

A remarkable theoretical approach to the explanation of a greater risk of mismatch between formal qualification and job requirements for married women in restricted markets was developed by Frank (1978b; see also Frank, 1978a). He criticised the fact that the difference in the incidence of mismatches between male and female employees had always been ascribed to the personal characteristics of men and women (see for example Gwartney, 1970, Cohen, 1971, and Fuchs, 1971) and that the residual variance had been rather feebly explained away as ‘discrimination’ (see for example Oaxaca, 1973).

A theory of differential overqualification may be outlined as follows. The starting point is an income-maximising jobseeker. The expected rate of pay is governed by the skill level of the job alone, like the expectations in the job-competition model and the production theory (Frank, 1978b, p.362).

If ‘qualification’ is defined very broadly, jobseekers are, to a certain extent, overqualified for every job for which they are eligible to apply, since they will always possess certain knowledge that is never used in the performance of their duties. This overqualification gives rise to a wage deduction from the ‘optimum’ (purely education-dependent) income which would be obtained if a perfect match were to be made (p.362). The economically rational strategy for a single individual is therefore simple: the individual identifies that vacancy in the market system for which he or she is least overqualified. The sampling distribution of the degree of qualification depends on the total number of vacancies in all markets combined; this follows from the fact that the mobility of an individual within his or her own region is not restricted. The expected degree of overqualification (and hence loss of pay) for the single searcher approaches zero as the total number of vacancies in all markets approaches infinity.

In the case of married couples, the search problem is considerably more complex. Assuming an inclination towards paid employ-

---

26 On the concept of local labour markets, see for example Topel, 1986.

27 Frank chooses not to include transaction costs in the calculation underlying a migration decision.
ment on the part of both spouses, their aim would be to maximise the joint income. Because of the formal basis of the spouses' respective rates of pay, it is not possible simply to find the lowest possible degree of combined overqualification; consideration must also be given to the spouses' education levels, which may differ (pp.363-364). The optimisation process is further complicated by the assumed condition that both spouses will have to find work in the same local job market. Four general properties of the expectations with regard to a married couple are identified (pp.364-365):

i) The expected amount of the added overqualification degrees of a searching couple will exceed the expected degree of overqualification for a single searcher.

ii) The expected degree of overqualification of a husband will be lower than that of his wife, if his qualification is higher than her's (and vice versa).

iii) The expected degrees of overqualification for both partners will approach zero as the total number of vacancies in the market system approaches infinity.

iv) The expected degrees of overqualification for couples are not, as in the single-worker case, independent of the distribution of vacancies across local labour markets. The expected degrees of overqualification increase as vacancies are more evenly distributed across local labour markets — always assuming that migration is a possibility for the couple.

In this dilemma, the sheer complexity of which will overwhelm any couples trying to maximise their household income, Frank (1978b) says that the husband takes the initiative and acts in accordance with a 'male chauvinist family location decision rule' (p.364). He begins by seeking the best possible job for himself once he has performed the simple task of identifying the vacancy for which he is least overqualified (see above); in so doing, he also determines the local labour market in which both spouses will work. Once this decision has been taken, the wife conducts her own individual search to find the best possible job for herself within that market.

Assuming that the couple are entirely free to migrate, the crucial point is that the husband is clearly able to conduct his search across the whole range of local markets, in other words to apply for any suitable job vacancy in any market. The wife's subsequent search, however, is restricted to the local job market selected by the man. Since the number of job vacancies in the local market is smaller — very much smaller — than in the global market, the wife may logically be expected to find a poorer match. This disadvantage will surely be all the greater if the husband finds his optimum job in a small local market.

The disadvantaged position of married women may be reflected in either of two ways. If the woman is unable to take up a more attractive job offer at another location because her husband has already found his optimum job locally and is not prepared to move, she is a 'tied stayer' (Mincer, 1978). If, on the other hand, the man has decided to accept a lucrative job offer far away from the couple's present home, his wife is compelled to move with him, irrespective of the quality of her current job or her employment prospects at the new place of residence; she is a 'tied mover'. So whereas marriage tends to enhance a man's status in the labour market, the opposite may be expected to apply to women.

A high degree of empirical plausibility makes this another persuasive theoretical approach. It does not even rely on the assumption that the man will adopt an irrational 'macho' stance to establish the family location against the interests of his partner. Since, in terms of the whole population, the average level of formal qualification for husbands is always observably higher than that of wives, and since married women work fewer hours on average than married men, the use of the 'male chauvinist family location decision rule' should generally be rational too, given the aim of

\[28\] For a summary of the various reasons for this, see Cornwall and Rupert, 1997.
maximising the total household income – especially as it seems impossible to fully reconcile both sides' interests, not only because of the mathematical complexity of the decision-making operation but also because of crucial information gaps.

When Frank tested the theory (Frank, 1978b), the test was not explicitly tailored to overqualification but took the form of an income analysis. Studies have traditionally focused on the 'tied stayer' variant, presumably because of data limitations.

An income-based analysis, however, raises significant methodological problems. If an unequivocal causal link is to be established between the phenomenon of differential overqualification and income differentials, it will be necessary to control for those income-level variations between larger and smaller local labour markets (the usual distinction is between municipal and regional markets) which are not productivity-dependent. Such variations include, for example, local weighting allowances designed to compensate for higher housing costs. In addition, there would be a need to control for differences between municipal and regional occupational structures, for instance by including several hundred occupational dummies in the income estimates. None of the studies that have appeared to date have come up with a satisfactory solution to this problem.

A less complex approach can be adopted if the examination of relative incomes (which are only used, after all, as indicators of the job/education mismatch that this theory studies) is replaced by direct examination of the mismatch, which might be done by measuring the degree of under- or overqualification. The only example of this line of enquiry is found in McGoldrick and Robst (1996), who concluded that there was no empirical evidence to sup-

port the theory of differential overqualification, since the dummy variables they incorporated to denote different sizes of region did not have a significant effect in the model used to establish whether the probability of a married women being overqualified for her job was greater in smaller than in larger markets (p.282).

This test was reproduced in Büchel, 1998b, p.143 ff. The author's study was also the first to include tied movers in such a test. It also took heed of the criticism made by McGoldrick and Robst (1996) that the number of job vacancies was an inadequate indicator of the shortage of jobs since it did not take account of the number of people seeking those jobs; a more suitable measure of the 'tightness' of the labour market, they said, would be the regional unemployment rate. At the same time, for the sake of greater validity, this test included not only married couples but cohabiting couples too; married people not living together, on the other hand, were treated as single.

Like its predecessors, this study had to adopt an implicitly assumed correlational trend between the number of job vacancies, the total number of jobs and the population of the place of residence when it tested the theory, although it also controlled for the regional unemployment rate (see above). The problem of equating the place of residence with the job location can, however, be overcome by at least a proxy construction which controls for the distance from home to work.

The study demonstrated that married women in rural areas actually do register a significantly above-average overqualification rate if – and only if – an estimated distance from home to work is taken into consideration. This high-risk group can therefore avoid the overqualification syndrome if they commute into larger urban areas. However, where married women living in sparsely populated areas are unable or unwilling to commute, the probability that they will not find a well-

30 Teichler (1994), who focuses on Germany, identifies academics who have 'voluntarily' chosen underemployment in preference to a more appropriate post because they wanted to be close to their partner (p.30).

31 See also Büchel, 1999d, and Büchel (forthcoming).
matched job in the vicinity of their home is atypically high. This finding accords with the expectations of the theory.

The job-search theory

The basic assumption of the job-search theory (Stigler, 1961)\(^{32}\) is that jobseekers adopt a search strategy which will maximise their potential lifetime earnings. In the basic model of the theory, which has subsequently been extended in many different ways, it is assumed that, from a density function of wage offers, postulated as a known quantity, the jobseeker chooses the number of offers that will optimise the job search process. Once this chosen number of job offers has been reached, the jobseeker will select the highest wage on offer. The longer the jobseeker waits, the greater his or her chance of receiving an even higher wage offer. However, the longer the duration of the job search, which equates to a period of unemployment, the higher the cost to the jobseeker, not only in terms of higher direct expenditure arising from job applications but also in terms of opportunity costs, in other words the income the jobseeker has foregone in order to wait for a better offer, minus any unemployment benefit he or she might have received in the interim period. There is also a danger that acquired skills will become increasingly obsolete during that period.

As the job search goes on, the jobseeker's target wage may be expected to decrease, since the time limit on a person's working life will compel the jobseeker to operate within a restricted time frame. The longer the search for work lasts, the less will remain of the jobseeker's working life. After the wage level, this is the second decisive parameter governing the maximisation of lifetime earnings. The job search is maximised if the marginal cost of seeking a job is matched by the marginal increase in future earnings.

The expected decrease in the target wage as the off-the-job search continues may mean that the job-search theory can help to explain why people accept underskilled jobs, because a lower wage is likely to equate with a lower required skill level, for which the jobseeker will often be overqualified. The findings contained in Büchel (1992), for example, show that a high percentage of skilled workers in West Germany can only escape from a lengthy spell of unemployment by accepting jobs in which their specialised skills are not required.

It may therefore come as a surprise to discover that, in the existing body of literature on overqualification, the job-search theory is hardly ever cited as a means of explaining the phenomenon. One implicit exception is Patrinos (1995), who explains the acceptance of overqualification as a response to abnormally heavy pressure to find work but generally focuses on the economic resources at the disposal of jobseekers.

With regard to the serviceability of the job-search theory in the context of overqualification, however, it should be noted that the theory can only explain the temporary, short-term occurrence of overqualification, since it explicitly relates to off-the-job searches only. The theory is therefore unable to explain why overqualified people, having taken undemanding jobs, are then unsuccessful in their on-the-job search for a better job, which in this context would mean a job that is commensurate with their qualifications (on this expectation, see Rosenfeld, 1992). Hence, since the theory can only explain mismatches caused by frictional loss, it is not capable of explaining the persistence of a high percentage of overqualified employees in the labour force.

3.3.2 Unorthodox approaches

Rumberger (1981, pp.29ff.) speaks of two unorthodox approaches to the explanation of persistent overqualification. One of these is the segmentation approach, and the other is a 'radical' approach; in American terminology in this field, 'radical' stands for 'Marxist'.

Segmentation approach

The segmentation approach rejects the homogeneous neoclassical model of the labour mar-
Felix Büchel

ket as unrealistic and postulates the existence of labour-market segments in which widely disparate working conditions obtain. The assignment of labour to these market segments is decided by employers on the basis of a 'discriminatory' weighting of individual screening indicators, such as formal qualification; it is asserted that opportunities to move from one segment to another are extremely limited.

In the original model presented by Doeringer and Piore (1971), the basic assumption was that the U.S. labour market is essentially a dual market. The primary market is chiefly reserved for the traditional core workforces, and jobs in that market are characterised by high wages, employment stability and good career prospects. In a secondary or peripheral labour market with unskilled, poorly remunerated and insecure jobs, employers recruit their fringe workforces in times of prosperity; when cyclical downturns come along these fringe workers can be fairly easily offloaded with minimal transaction costs, because they are loosely attached to the company, which has accordingly invested little in the development of their human capital.

This simple methodological concept has proved to be highly resilient. Individual refinements, such as attempts to take account of regional characteristics, have seldom gained general currency. In the West German labour market, for example, Lutz and Sengenberger (1974) claimed to have identified a separate segment of the 'specialised labour market' which was characterised by insecure conditions of employment for skilled workers with good formal qualifications. This regional distinction was intended to take account of the fact that the Federal Republic of Germany, unlike the United States, had an established system of alternating on-the-job and theoretical training.

This distinction, however, is open to criticism on the grounds that every job requires a certain degree of skill, however minimal. Why successful completion of an apprenticeship, of all things, should be used as the decisive skill-categorisation criterion largely defies logic. The skill level required for a job is traditionally operationalised on the basis of the wage paid for that job, a variable that is hardly likely to be governed by 'natural' thresholds such as the difference between the wage of an unskilled or semi-skilled worker and that of a skilled worker. The infinite array of criteria that could be selected to distinguish between segments of the labour market and the resulting diversity of typological segmentation, which could hardly stand up to a validity test, have already come in for criticism from several sources, and rightly so (cf. Blien, 1986, p.147).

The segmentation approach does help to explain the persistence of overqualification in conjunction with the screening approach and the job-competition model. If all suitable jobs in the primary segment of the labour market are initially occupied, jobseekers who are less well equipped to withstand the screening devices (applicants with lower pass grades where formal qualification is the screening device, for example) have to settle for jobs in the peripheral segment. Since the boundary between the segments tends to be impervious, the result is a state-dependence effect, whereby the fact that a person works in the peripheral segment becomes a further negative screening device (see also Rumberger, 1981b, p.32).

Neubäumer, 1993 (see also Neubäumer, 1997, and forthcoming), adds a noteworthy dimension to conventional consideration of market segmentation in the present context by posulating the segmentation not only of the labour market but also the market in course places within the system of vocational training. In those occupations and industries where training and working conditions are poor (e.g. for hairdressers), training is provided in excess of requirements not only because the cost-benefit ratio of training is especially favourable to employers in these areas of activity but also – and this is the nub of Neubäumer's argument – as a means of coping with the loss of the best trainees, who move upmarket when they have served their apprenticeship. Because even the training
market is segmented, the less gifted applicants for training places, even though they are aware of the aforementioned situation, are compelled to accept training places in the peripheral segment of the training market. In so doing, they are also running the risk, once they have completed their course, of neither finding an appropriate job in the occupation for which they have trained nor of moving into a better segment of the market (assuming they are prepared to switch to another occupation). In such circumstances, their only alternative is often to settle for a relatively menial job.

Because its underlying hypothesis possesses a certain plausibility, the popularity of the segmentation approach remains undiminished. In very specific areas of the labour market, it is certainly possible to observe structures that are consistent with the propositions of the segmentation approach (see for example Büchel, 1994a). Economics-based analyses of overqualification, however, rarely have recourse to the segmentation approach. One reason may be that the approach cannot be built on theoretically self-contained foundations. The propositions of the segmentation approach can be easily constructed in a partially analytical manner on the basis of hypotheses deriving from various microeconomic theories, such as the screening approach or the job-competition model34 — but this also means that supposedly 'segmented' structures in the labour market can be explained in economic terms without recourse to the segmentation approach.

The Marxist dialectical approach

From a Marxist perspective, the incidence of overqualification on a large scale serves the interests of capital. The phenomenon therefore performs a similar structural function to mass unemployment, in that overqualified employees are regarded as a reserve army whose members could easily be reactivated (i.e. drafted into more demanding jobs) if the need arose. As this reserve of skills grows in size, the labour force comes under increasing pressure to 'toe the line', while wages are subject to downward pressure (for more precise details, see Rumberger, 1981b, pp.32 ff.; for a brief outline, see Levin, 1995, pp. 14-15). The systematic overproduction of qualifications in the education system (which can be manipulated by the capitalists in a capitalist state monopoly) therefore serves the purpose of systematically weakening the working class in the never-ending class conflict (cf. Bowles and Gintis, 1976, quoted in Rumberger, 1981b, p.35).

This view, however, is invalidated by the fact that the systematic expansion of education provision and the associated desire for an end to elitist educational privilege for the upper classes were being consistently advocated in the sixties by supporters of the far Left too.

Even as recently as the mid-eighties, voices in West Germany were calling for the problem of the overqualification of highly qualified labour and the question of the whereabouts and professional situation of university and college graduates to be 'addressed in terms of class theory' (Krais, 1983, p.36).

Although there are unmistakable signs in some European countries that employers may indeed be deriving certain benefits from the current mass unemployment, such as the resultant erosion of trade-union power, this alone is scarcely able to explain satisfactorily why the phenomena of unemployment and overqualification are so persistent. A disinclination on the part of employers to take effective action to eliminate such inefficient deployment of human capital, even if such an assessment could be substantiated, would be easily explicable within the framework of an empirical analytical theory, because it is no more than economically rational behaviour. A connection between overqualification and class conflict seems to be even more spurious.

The Marxist dialectic approach to economics has, of course, lost much of its appeal over the last few years. The sole purpose of describing it here is to ensure that all the relevant theories are chronicled in this literature survey for the sake of completeness.

34 See for example Hartog, 1985a, p.281.
3.4 Extraneous conditions

3.4.1 Institutional regulation

The methods based on partial analysis which are used to explain the persistence of overqualification and which were outlined in point 3.3.1 above are abstracted from the conditions imposed by the institutional framework. In addition to the indirect effect of these conditions, it is likely that their practical application will have a direct impact too. In the countries of Europe with their highly developed welfare systems and their traditionally high degree of corporatism, such conditions will probably have a far greater effect than, for example, in the United States, where most of the aforementioned approaches were developed. Remarkably, scarcely any of the relevant empirical works examine this aspect of overqualification.35

One important factor in people's willingness to accept overqualification is likely to be the differential between the rate of unemployment benefit or, alternatively, social security and the rate of pay for underskilled (normally simple) work. This brings two regulatory arrangements into play — minimum wages secured by the trade unions and the rate of unemployment benefit and social security payments set by the government. In recent times, as the 'jobs miracle' has unfolded in the United States, more and more voices in a number of European countries have been criticising the excessively narrow gap between the minimum wage and welfare benefits. As the gap narrows, the volume of overqualification may be expected to fall, because — in the eyes of many jobseekers — the reward for economic activity is not the pay itself but only the amount by which the wage exceeds the rate of welfare benefit. It does not 'pay', in other words, to take a cheap job.

The employment authorities are trying to counteract these calculations by enforcing the statutory criteria by which a reasonable job offer is defined. As these criteria become increasingly rigid, sometimes even compelling an unemployed individual to chose between underskilled work and loss of benefits, we may expect the percentage of overqualified employees to rise.

In Germany, for instance, these criteria have recently been considerably tightened in response to the sustained rise in unemployment. Staff directive 30/90 of the Federal Employment Services (Bundesanstalt für Arbeit), dated 19 March 1990, rescinded one of the provisions of staff directive 100/82 of 13 April 1982, which laid down that placement in employment at a lower skill level should only be effected if, despite adequate and appropriate efforts to fill the post in question over a period normally lasting three weeks, no jobseeker with the required lower skill level could be recruited.

On 1 April 1997, the new section 103b of the Promotion of Employment Act (Arbeitsförderungsgesetz) entered into force, drastically curtailing once more the right of unemployed people to reject job offers. In the first three months of unemployment, offers of jobs paying up to 20% less than the jobseeker's previous employment are classed as reasonable offers, and in the following three months this figure rises to 30%; from the start of the seventh month, a job offer is considered reasonable if the net wage (minus necessary employment-related expenditure) is at least equal to the rate of unemployment benefit (paragraph 3); in the case of full-time work, commuting times of up to three hours per day are considered reasonable (paragraph 4), as are temporary separation of spouses and 'Occupations [...] for which the employee is or is not trained or which he or she has or has not previously pursued' (paragraph 5 (my italics); see Federal Law Gazette (Bundesgesetzblatt) 1997/I, No 20 of 27 March 1997, p.700). Although these rules seem highly restrictive at first sight, the German welfare system is still relatively generous by international standards; in the United States, for example, entitlement to unemployment benefit is subject to the strict proviso that any available job offer — normally at the minimum wage — must be accepted.

35 Tsang and Levin (1985, p.101) and Rumberger (1981b, pp.124-125) are exceptions, although their propositions are couched in very general terms.
It is evident that curtailing the right to reject job offers will not of itself influence the percentage of jobs that are occupied by overqualified people. The impact of such a measure will very much depend on the way in which jobcentres apply the relevant legislation. In Germany, for example, there are some grounds for assuming that, even before the latest amendment of the Employment of Promotion Act, the criteria for the definition of reasonable work, which were already rigorously formulated, were not applied very consistently.

Some evidence for this allegation may be derived from the fact that labour offices rarely order the suspension of benefits for rejection of a job offer under section 119(1)(2) to (1)(4) of the Promotion of Employment Act (see for example the official bulletin (ANBA) of the Federal Employment Services, issue No 7/1997, Übersichten II, 7/8, pp.1042-3). This finding may indicate that very few offers of underskilled work have been rejected in practice, which would point to the efficiency of the strict criteria for the definition of reasonable job offers. But if this is the case, at a time when it is difficult to place jobseekers, the rising level of unemployment should be accompanied by a parallel rise in the percentage of jobs occupied by overqualified employees; this, however, is not borne out by the available empirical data (see Büchel and Weißhuhn, 1997a and 1998).

The formulation of statutory provisions governing protection against dismissal may be cited as another institutionally imposed condition that influences the volume of overqualification. In this domain too, there are great differences between many European countries and the United States, for example. It is conceivable, for instance, that an overqualified employee whose company wishes to offload him for productivity reasons has no prospect of finding a job commensurate with his level of training and that he therefore invokes his right to protection against dismissal. In the United States, he could expect dismissal and a place in the dole queue, but in countries with sophisticated systems of statutory protection against dismissal, such systems tend to increase the overqualified percentage of the active labour force.

Another institutional condition which probably has a considerable impact on the percentage of jobs occupied by overqualified employees is the funding structure of the various component parts of the education system. Higher education in Germany, for example, is largely state-funded, which is not the case in other countries. The external effects of this funding structure grossly distort the situation in the education market and are likely to produce a steady flow of overqualified graduates. While the acquisition of educational qualifications at prices 'below the market rate' amounts to rational behaviour in the eyes of the individual, since, given the current imbalance between supply and demand, highly qualified jobseekers are still in pole position in the labour market, in terms of the national economy it generates an excess demand for education.

Besides the conditions enumerated above, there are a host of other governmental or semi-governmental regulatory mechanisms which can directly affect the qualification structure of the labour force and hence, ceteris paribus, the percentage of overqualified employees. These mechanisms include the setting of quality standards in the education system, the formulation of rules governing scholarships and student grants and so forth. A detailed discussion of every conceivable contributing factor would be an unnecessary digression in the present context; the sole purpose of this part of the study has been to draw attention to the potential impact of the basic conditions in which the employment structure operates.

36 See section 1, and more especially section 2(3) of the administrative order issued by the Federal Employment Services (Bundesanstalt für Arbeit) in Nuremberg on 16 March 1982 concerning assessment of the reasonableness of a job offer (Zumutbarkeits-Anordnung – documented in the special issue of ANBA, dated 15 April 1982). The author wishes to thank Mr Reichel of the Federal Employment Services for putting together the relevant documentation.

3.4.2 The production structure and conditions in the labour market

The changes that the production structure undergoes in the course of time – as a result of technological progress, for example – can have a direct effect on the overqualified percentage of the labour force. For example, the incidence of underskilled jobs may be expected to rise if qualifications which were once in demand in the labour market (and were therefore produced by the education system) have been devalued over a period of time as the conditions of production have changed. A classic example of this would be the training of blacksmiths. In addition, job descriptions and skill profiles for particular occupations may change so dramatically with the passage of time that even those employees whose qualifications originally matched their job requirements will eventually come to realise that they are no longer qualified to do their job by present-day standards. Such a development is observable in journalism, for example. While it is conceivable that further training could update employees' skill and qualification levels, horizontal effects, which are not the subject of the present study, are likely to prove more significant than vertical effects. Irrespective of their empirical significance, however, such structural effects are possible and should therefore be investigated as a means of explaining the occurrence of overqualification.

The findings contained in Büchel (1998b, Table 5.16, p.216), however, show that this is not the most common route to overqualification. These findings, which were controlled for a number of variables – several socio-economic characteristics of the employee sample and general economic conditions – reveal that overqualification is immediately preceded by unemployment, by full-time training and by voluntary economic inactivity far more frequently than by adequately skilled employment.38

Besides the aforementioned structural changes that take place over a lengthy period, more rapid changes in conditions within the labour market might also conceivably influence the overall balance between the skill profiles of jobs and those of their incumbents. It may be expected, for example, that contractions and expansions of the labour market which result from cyclical or seasonal fluctuations will directly affect the probability of individuals being compelled to accept overqualification, not least on the basis of the hypothesis that overqualification is a direct alternative to unemployment in many cases. Büchel and Weißhuhn (1998) cite actual evidence of dependence – and inverse dependence – of the aggregate growth of unemployment on the level of overqualification.

3.4.3 Employees' utility preferences

The theoretical approaches discussed in point 3.3.1 above all assume behaviour patterns based on income maximisation. If this assumption is set aside and utility maximisation takes the place of income maximisation, new factors come to light – factors which are relevant in the context of overqualification.

In the typical dichotomy between unemployment and overqualification, leisure time39 plays a key role as a preference in a conventional assessment of the utility of a job offer. A change in the importance attached to leisure time, for example as part of a general shift in social values or as a regionally (as opposed to nationally, for example) conditioned reassessment of leisure time in Europe will therefore directly affect the percentage of jobs occupied by overqualified employees. The linkage is likely to be even less elastic with unemployment as the alternative than with the conventional alternative of a form of economic inactivity other than unemployment, since the 'distorting' base effect of unemployment benefit has to be taken into account.

38 The most common access route is from unemployment, followed by full-time training, with voluntary inactivity in third place.

39 It may seem euphemistic to refer to a period of unemployment as 'leisure time' but is nevertheless based on specialised usage.
As for the alternative status of employment commensurate with qualification level, which has been largely neglected in the discussion of the phenomenon of overqualification (see subsection 3.2 above), the connections between utility preferences and the decision to be taken are presumably even more intricate. Individuals who are not out to maximise their income have to assess a complex set of job characteristics.\(^{40}\) When people take more demanding jobs, they can expect heavier workloads, longer journeys to and from work, greater pressure to work overtime, less scope for negotiating reduced working hours and more besides. The ‘purpose’ of a job is also a factor. The need for a sense of purpose is surely universal, but it may take different forms from one social milieu to another. Schlegelmilch (1987), who reports findings from an analysis of job content among university graduates who have opted for an alternative lifestyle, records the following comments from a graduate working as a masseuse in a sauna: ‘When I think of all that intellectual work, all that studying … it makes me sick. You sit there at your desk, and maybe you write the odd article, and somebody says it’s quite good; that happens maybe once or twice in a year.’ (Schlegelmilch, 1987, pp.179-180). In an earlier work, Schlegelmilch also lists a number of irrational grounds (from an income-maximising point of view) for preferring underskilled to adequately skilled employment, irrespective of the demand situation in the market for adequately skilled jobs. These grounds include problems with a professional role, such as that of a teacher, anticipated problems with superiors (encountered in people of an anti-authoritarian disposition), the disillusionment of individuals with what they could achieve in their occupation in the prevailing conditions and so forth (Schlegelmilch, 1982, pp.418-419).

Individuals who rate the utility of non-monetary job characteristics higher than that of income are more likely to accept overqualification. A change in people’s priorities as part of a general shift in social values also has a direct effect on the percentage of the total labour force in underskilled jobs.

Many of the empirical findings in Büchel (1998b) show that people who subscribe to the statement ‘A successful career is not so important to me’ are more likely to be in overqualified for their present jobs. This correlation is particularly high in the case of West German women in the middle tier of the qualification hierarchy, i.e. holders of vocational diplomas (Büchel and Weiβhuhn, 1997a, Table 4-WA, pp.68-69); as was mentioned above, however, this pattern was also demonstrated by Schlegelmilch’s studies of disaffected graduates.

### 3.4.4 Employers’ productivity considerations

The most common decision facing employers in the context of overqualification (see subsection 3.2 above) is whether to select an overqualified job applicant in preference to one whose formal qualifications are commensurate with the job requirements. Their decisions will be governed by productivity-based considerations. This aspect has already been taken into account in the discussion of certain approaches in point 3.3.1 above; the intention in the following paragraphs is to subject it to more thorough scrutiny.

While the production theory-related effects of overqualification in the literature of the English-speaking world have already been fairly widely discussed,\(^{41}\) scarcely any findings on this subject are available for the European continent (the few exceptions are referred to below).

On this point, the author of the standard textbook for German employment researchers, 40 See for example Lucas, 1977, Sattinger, 1977, and Sattinger, 1980; the latter deals with this issue in detail on pp.72ff.

Wolfgang Franz, writes, 'If a job has a fixed rate of pay [...], the company's aim will be to identify the most productive applicant for that job', adding in a footnote, 'This is not necessarily the candidate with the highest (formal) qualification. Companies are rightly hesitant to engage “overqualified” candidates, for example because any dissatisfaction on the part of such an employee may have an adverse effect on his or her productivity [...] and because the probability that he or she will not stay long with the company is liable to be high' (Franz, 1991, pp. 211-212). The very wording of these assertions sounds a distinct note of caution, which lends Franz's statement the character of a supposition rather than a validated scientific finding. This means that it cannot be cited as evidence of such behaviour.

The main dimensions of productivity losses that result from overqualification respectively overeducation are given in the relevant literature in the English language as a lesser degree of job satisfaction (Khan and Morrow, 1991, Johnson and Roy, 1995, and de Witte and Steijn, 1998), poorer health (Amick and Lavis, 1998, pp.26 ff.), a higher incidence of shirking and absenteeism, narcotics (alcohol) consumption at work and 'sabotage' (for a general discussion of this point, see Tsang and Levin, 1985; also Haugrund, 1990, p.233).

Other factors with relevance to business management are an assumed propensity among overqualified employees to change firms more frequently, which would result in a loss of human capital developed specifically for the needs of the company as well as creating direct transaction costs and restricting participation in further training, thereby impeding the development of know-how within the company (Beneito et al., forthcoming).

If employers are aware of these risks to productivity that are inherent in overqualification, that knowledge may influence the wage rates they set. Unlike the United States, however, many European countries have special legislation granting an extensive right of protection against dismissal. If shirking by an individual worker is only discovered - assuming that it is discovered - after the end of the initial probationary period, those employers who have overqualified staff on their pay-roll can only cover themselves financially by converting part of the basic wage into a productivity bonus - not just for the individual in question but by way of a 'collective insurance premium'.

Such a strategy, however, depends not only on possession of all the relevant information but also on the absence of trade-union 'obstruction' of the wage-fixing process. Both of these aspects create an incentive for the employer to deal with the equation of gross pay and productivity on a one-to-one basis, i.e. in relation to an individual employee.

An examination of these quite considerable productivity risks to an employer who recruits overqualified personnel (which are confirmed in most of the literature from English-speaking countries) raises the question whether employers have any interest at all in employing people in jobs for which they are overqualified. Haugrund (1990) sees one such incentive (in the technical sector) in the expectation of above-average performance from these employees, along with their 'natural' function as a 'centre of competence' within their respective teams (p.233).

The key to this question, however, is the fact that an employer's basis of assessment can be influenced by extraneous factors. A change in the information base, for example, may be such a factor. It is already patently difficult for employers to measure their employees' productivity at the best of times (see Bodenhöfer, 1984, pp.13ff., and Rippe, 1984, pp.76ff.). The productivity effects of overqualification, such as an increased incidence of shirking, must be even harder to measure. It is conceivable that administrative and technical progress might serve to enhance the supervisory mechanisms available to employers (cf. Tsang and Levin, 1985). Where overqualification is assumed to be having adverse effects on productivity which cannot be nullified by pay cuts, the consequence should be a reduction in the volume of overqualification.

The general difficulties involved in obtaining information (with which Rippe, 1994, deals in detail) might also induce employ-
ers, however, to base their decisions on subjective experience gathered over a lengthy period. If the information situation is extremely bad, they have to rely on 'prejudices'. It is conceivable that, with a general change in social values (in society's evaluation of the productive utility of job-sharing or part-time work, for example), the assessment basis on which employers take their decisions will alter.

Such a change may even be caused by a major shift in the market situation: 'The higher the percentage of new recruits who are university graduates, the more widely an increasing percentage of graduates in middle management will be accepted as the norm' (Teichler, quoted in Der Spiegel, 1985, p.47).

In the context of the sea change that the labour market is clearly undergoing, this acceptance of higher education as the norm is likely to take root not only among job applicants but also in the minds of employers. A similar effect has been observed in the inverse relationship between the strength of the stigma attached to unemployment and the length of the dole queue (cf. Omori, 1997). This type of shift in values could therefore result in a sharp rise in overqualification in the future.

The opposite effect could be achieved by the exertion of direct political influence on the production system. Tsang and Levin (1985, p.101) listed some of the levers that could be used for this purpose, such as tax breaks to encourage the employment of appropriately qualified staff, but these levers seem almost unworkable. Indeed, Rumberger (1981b, pp.124-125) had already delivered a pessimistic verdict on the power of governments to reduce the degree of overqualification in the private sector.

Be that as it may, government measures certainly can be an efficient means of reducing the level of overqualification in the labour market as a whole in the sense that the state, as a major employer, is able to define its own staff-selection criteria. The findings set out in Büchel and Weißhuhn, 1997a and 1998, show that the state actually does this very successfully; the percentage of overqualified staff in the civil service is minimal, at least in western Germany. The only snag is that this strategy goes beyond the scope of the present part of our study, since the public sector is not subject to direct productivity criteria.

In the European context, apart from the classic income analyses performed by Duncan and Hoffmann (1981), productivity effects have only ever been analysed for Germany. Haugrund (1990) devoted a monograph to the subject. Despite its ambitious and highly detailed examination method, scarcely any general extrapolations can be made from the findings of the monograph, because it takes the form of a company study and focuses on a few technical trades. The author has also conducted three studies (Büchel, 1999b, which goes into greater detail, 1999c and 1999a). It emerges from these that productivity analyses only serve a useful purpose if the job-rerequirement level is kept constant. That is the only configuration which equates to the choice facing personnel managers who have to fill a vacant post.

The studies conducted in western Germany show that in unskilled jobs (in which the overwhelming majority of overqualified employees work) overqualified workers tend to keep better health, to change firms less frequently and to engage in more further-training activities than their less educated colleagues in similar jobs; there are no significant differences between the two groups in terms of the productivity indicators absenteeism and job satisfaction.

---

42 Tsang et al. (1991), for example, demonstrate that the adverse effect of overqualification on job satisfaction has been diminished over the years.

43 For a similar hypothesis relating to the academic world, see Büchel, 1996a.

---

44 See Büchel and Weißhuhn, 1997a and 1998, Tables 3-W-84, -91, -93 and -95; see also Keller and Klein, 1994.
This result is consistent with Thurow's job-competition theory, which predicts that people with more education will be at the front of the labour queue. On the other hand, it contradicts the traditional expectation that overqualified personnel will feel frustrated and therefore prove less productive than their adequately educated colleagues.

If overqualified workers are less productive than their adequately qualified counterparts, as is generally reported in the relevant literature, it is solely because these findings are obtained with enquiry methods in which the formal level of qualification is held constant rather than the skill level required for the job. It is obvious that such a strategy can bear little fruit, for it is hardly surprising that a taxi driver with a law degree is less productive than a law graduate working as a solicitor. The only relevant question in this context is whether the taxi driver with the legal qualification is less productive than his fellow cabbies whose only formal vocational qualification is their taxi driver's licence.

In general terms, the findings of the author's aforementioned studies can serve to break down prejudices about the productivity of overqualified employees and go at least some way to explaining the persistence of overqualification in the labour market by demonstrating that it makes economic sense for employers to hire overqualified staff, because they can be expected to be more productive in a given job than other, less qualified candidates.

4. Strategies for measuring the educational adequacy of a job

4.1 Existing measurement strategies

On the problems involved in measuring overqualification, the OECD notes in its Employment Outlook that 'invisible underemployment [the term used by the OECD to denote overqualification] refers to individuals who are working in jobs where their skills are not adequately utilised, and by its very nature is difficult to measure. For this reason, it is not discussed.' (OECD, 1995a, p.45, author's italics). What the OECD is expressing here is that there is no consensus among employment researchers on a measurement strategy, which is why no internationally standardised tables of comparative national statistics can be compiled for overqualification as they are for other phenomena, such as unemployment. The following paragraphs provide information about the various measurement issues. The box presents a typology of different measurement approaches.

4.1.1 The 'objective' approach

In the early days of empirical analysis of overqualification in the United States, the so-called 'objective' DOT/GED approach was regarded as the standard process for measuring the discrepancy between an employee's level of educational attainment and the actual education level required for his or her job. The measurement process is considered to be 'objective', in so far as it does not rely on the employee's own subjective assessment of the required education level. The basic principle of the measurement strategy is that it measures the required education level for a job by reference to its occupational category; all important microeconomic details of this occupation are recorded. Each occupation listed in the Dictionary of Occupational Titles (DOT; see Fine, 1968) is allocated a level of 'general educational development' (GED) from a scale of GED values. In the second stage of the process, this educational development level is translated into an equivalent number of years of schooling (see Eckhaus, 1964).
Overqualification: reasons, measurement issues

Once the formal qualification level in the form of the highest reported educational certificate has also been converted into an equivalent in years of schooling (unless, as usually happens in the United States, the information has already been collected in the form of a number of completed years of schooling), the number of surplus or deficit years of education can easily be established by subtracting one amount from the other; thus, overeducation (in years) equals years of schooling completed minus GED levels (in years) (see for example Rumberger, 1981b, p.58).

The measurement scale for the variables that are calculated in this way is recognisably based on the requirements of the human-capital approach. Accordingly, income effects of surplus and deficit components of human capital can be analysed in the framework of the traditional evaluation procedures, and the returns to these components can be compared with the returns to the 'required' components of human capital (see for Duncan and Hoffmann, 1981; Kiker et al., 1997, and Daly et al. (forthcoming)).

Teresa Sullivan (1978), Clogg (1979), Clogg and Sullivan (1983) and Clogg and Shockey (1984) increased the reliability of this measurement by excluding from the definition of overqualified workers all persons with a surplus of zero years of schooling; in their place they proposed the insertion of a 'safety margin' comprising a standard deviation in excess of the mean duration of education used for a particular occupation ('analog for deficit years'); this approach was subsequently adopted by other researchers (see for example Verdugo and Turner Verdugo, 1989, and Groot, 1993a). At this point, one should add the methodological remark that Hartog (1997, p. 2) and Hartog and Jonker (1998, p. 102) classify this type of measurement as an own, third category apart of the so-called objective and subjective approach (see section 4.1.2 below). The present author, however, follows the argumentation of Groot (1996) who takes it as a variant of the DOT/GED approach.

An enquiry strategy derived from the DOT/GED approach can be found in Plicht et al., 1994, who analysed the structure of overqualification among academics in the western part of Germany on the basis of the national microcensus. Since a standardised GED scale is not available for Germany, the authors themselves had assessed each individual job type to establish whether it was adequately skilled for an incumbent with academic training. This strategy, however, produces an unavoidable 'grey area' (Hecker, 1992, p.4) of occupations to which it is impossible to assign an unequivocal education level. Plicht, Schober and Schreyer call this the 'mixed category' of occupations.

A variant combining the approaches described in the last two paragraphs is described in Groot (1996). Although the occupations of the employees he studies are listed in the British Household Panel Survey (BHPS), on the basis of which he conducts his examination, no GED rating is available for the various occupations, just as in the case of the German microcensus. Groot compensates by calculating the mean number of years' schooling of the employees in each occupational category; those whose schooling exceeds the average for their group by more than a standard deviation are classed as overqualified.

The validity of the DOT/GED methodology has been criticised on several occasions, and with good reason. The first problem lies in the wide diversity of skill levels required for different jobs within a single occupational category, which the GED system does not take into account: '...estimates of the mean years of required schooling in an occupation are constructed by aggregating jobs, thereby ignoring variation in the mean years of required schooling across jobs within an occupation' (Halaby, 1994, p.48).

Besides, the use of a one-digit code to evaluate the level of education required for a job clearly cannot reflect the complexity of training requirement profiles: 'The GED scores are simply not detailed enough to produce sensitive measures and have validity problems of their own' (Clogg and Shockey, 1984, p.254). Besides, the conversion of GED into required years of schooling is not standardised. Rumberger (1987) rightly expresses the following criticism: 'Another problem with the DOT
### Typology of overqualification measurement approaches

<table>
<thead>
<tr>
<th>Short description of approach</th>
<th>Developers of approach and early studies</th>
<th>Advantages of approach</th>
<th>Disadvantages of approach</th>
<th>Selected follow-up empirical studies based on approach</th>
</tr>
</thead>
</table>
| For each occupation listed in the Dictionary of occupational titles (DOT), information about the level of educational requirements is available in an ordered scale (General educational development, (GED)).  
The GED scale has to be made compatible to the scale on which individuals report their acquired schooling (e.g. transformation into requested years of schooling).  
The information about the requested schooling to perform a specific occupation (SR) is compared with the acquired schooling (SA) of job-holders.  
Overqualification of an individual is stated, if SA > SR. | Scoville (1966), Berg (1970), Kalleberg and Sorensen (1973) | | | |
| | | | New occupations, such as e.g. in the IT industry, cannot be considered (until a new DOT is realised). | |
| | | | Change in job requirements is neglected (until a new GED scale is realised). | |
| | | | Defining required skill levels (construction of GED scale) is methodologically problematic. | |
| | | | Making the GED scale compatible to the scale of acquired schooling is methodologically problematic. | |
| | | | Usually high numbers of missing values in occupational information (caused by coding problems). | |
### Short description of approach

**Ib:** Variant of 'objective' approach: 'realised match approach'

Within each occupation (disaggregated as low as possible, usually on a 3-digit-level), the mean, median, or mode (M) and the standard deviation (SD) of acquired schooling of job-holders is calculated.

Information about M and SD of a specific occupation is compared with the acquired schooling (SA) of job-holders.

Overqualification of an individual is stated, if $SA > (M + SD)$.

### Developers of approach and early studies

### Advantages of approach

- Higher validity when categorising overqualification.

### Disadvantages of approach

- Genuine problem of neglecting heterogeneity of jobs within an occupation remains.
- Methodological problems in measuring means medians, or modes, and especially measuring standard deviations, in occupations with few employed.
- Problems with causal relations: the higher the share of 'effectively' overqualified workers within a specific occupation, the lower the measured share 'detected' overqualified workers (and vice versa).

### Selected follow-up empirical studies based on approach

### Short description of approach

**Ilia: 'Subjective' approach**

Each worker is asked about the educational requirements of his specific job (e.g. 'What kind of education is usually required to perform (get) a job like your's?' (required education, RE)).

The scale of the RE variable has to be made compatible with the scale of the respondents information of acquired schooling (ideally already by the designers of the questionnaire, e.g. by asking for years of schooling required).

Overqualification of an individual is stated, if SA > RE.

Number of missing values in the produced overqualification variable is slightly higher than in the standard subjective two-variable approach, because three source variables are involved.
is that categories of training requirements must be translated into equivalent years of schooling. Although such translations have been done in the past, there is no consensus on the appropriate conversion' (p.30). Of the many different measurement methods, each of which has a perceptible direct influence on the empirical results, three are presented by Rumberger (1980, p.105), Kalleberg and Sørensen (1973, p.221) and Burris (1983c, p.457) respectively. Furthermore, the DOT/GED system takes no account of the situation within a particular occupational category:47 'The DOT measure of required schooling can classify someone as overeducated when the person has a very good job within an occupation' (McGoldrick and Robst, 1996, p.281).

The final criticism is that the GED system, which dates from the sixties, does not respond to changes in the requirements for specific occupations, such as those resulting from technological progress (cf. Clogg et al., 1986, p.382; for a complete summary of the validity and reliability problems of the DOT/GED approach, see Rumberger, 1981b, pp.59 et seq.).

Given the objections enumerated above, some of which have serious implications, it is not surprising that this approach is hardly ever adopted any more in new studies on overqualification, which are largely based on the so-called 'subjective' strategy described in the next point.

4.1.2 The 'subjective' approach

The reservations about the DOT/GED approach which were expressed in the previous point relate to both of the steps that need to be taken to establish the education requirement for the practice of a particular occupation, i.e. the assignment of GED scores to the occupations in the DOT list and the calculation of the GED equivalent in years of schooling. This criticism is not levelled, however, at the idea of equating the required number of years' schooling with the actual duration of an employee's schooling. It follows from this that any improvement, especially if it relates to the reliability of the mismatch indicator, should focus exclusively on the process of determining the education level required for the job.

One effective way of tackling the problem is to ask employees themselves for a subjective assessment of the qualification level required for their respective jobs. Respondents may be asked to choose from a scale of requirement categories or to assess the qualification level in terms of a number of years of training. The questions are sometimes varied. Respondents may be asked for the qualification that is normally required for the work they perform (this is the case in the German Socio-Economic Panel (GSOEP) study and in other surveys such as the employment survey conducted by the Federal Institute for Vocational Training (BIBB) and the Institute for Employment Research (IAB) in 1991-92). Another common question asks for the qualification required to obtain the relevant job; this is the approach adopted in the Panel Study of Income Dynamics (PSID), although McGoldrick and Robst (1996, p.281) rate the PSID question inferior to that of the GSOEP. The nature of the question does not alter the process of equating the required qualification with the employee's actual qualification level in order to obtain the mismatch indicator.

The first such survey of job-requirement levels was conducted in the PSID of 1976, and others took place in 1978 and 1985. The same approach was adopted by the GSOEP.

Although there are no reports in the relevant literature of reliability problems stemming from incomprehension (cf. Hersch, 1991, p.141), the subjective nature of the question undoubtedly poses its own reliability problem.
It is conceivable, for instance, that reported requirement levels will tend to relate to conditions of recruitment at a particular time rather than present job descriptions; moreover, it is not impossible that cognitive dissonance might cause overqualified employees to imagine a higher requirement level than that which actually obtains (Hartog and Oosterbeek, 1988, p.186-187; on this aspect of data collection, see also Kalleberg and Sørensen, 1973, p.236).

Nevertheless, it may be expected that differences in required skill levels for people with equivalent qualifications will be sufficiently identifiable: 'Although this measure may contain much noise, due to differences in standards the individuals employ, it will certainly bring out differences among equally educated individuals in the demands that their jobs put on them (Hartog, 1985a, p.282; for a similar line of argument, see Witte and Kalleberg, 1995, p.301). For all its recognised flaws, the subjective approach is generally held to be more effective than the DOT/GED system: 'This [i.e. the subjective approach] has the advantage of obtaining information from the source closest to the actual job situation, taking account of all specific circumstances' (Hartog and Oosterbeek, 1988, p.186). A general reliability check on this strategy, involving a comparison of employees’ and employers’ responses, for example, has yet to be developed.

4.1.3 Unorthodox measurement strategies

Studies devoted to the examination of mismatches between job and qualification are characterised by an almost unbounded diversity of measurement strategies. The purpose of the following paragraphs is to show just how diverse these strategies can be by means of some examples from German literature.

Apart from the studies by Rippe (1988), Schwarze (1993), Plicht et al. (1994), Brinkmann and Wiedemann (1995) and the author, German employment research gives the impression of having been insensitive until quite recently to the methodological debate outlined above, which was conducted with great gusto in the pages of the U.S. journals. The diversity of methods not only raises questions about the reliability and validity of the measurement strategies but also complicates the quest for comparability of empirical data.

One classic measurement strategy in the field of German qualification research seeks to identify the extent to which knowledge and skills acquired in vocational training are usable in an individual’s current job; similar approaches are also to be found in earlier literature from the English-speaking world (e.g. Staines and Quinn, 1979, p.9). The problem with this strategy is that there are basically no jobs in which employees can draw upon all the knowledge and skills they had to assimilate in the course of their vocational training (cf. Suda, 1979, p.153). The assessment of the degree of applicability is likely to be very highly subjective. A validity test by Halaby (1994) on this type of measure produced disappointing results; Rippe (1988, pp.179-180) could only pour scorn on this measurement strategy.

Kaiser et al. (1980) used a system of seven job indicators designed to assess the job/qualification match – indicators such as the degree of variety in the job, cooperation with superiors, etc. The validity problems of this approach seem obvious (p.102).

Krämer (1982) establishes the degree of job/qualification match for executives of small companies by comparing their formal qualifications with a job grading that he assigns on the basis of their decision-making powers. On the basis of Krämer’s findings, it is doubtful whether his measurement strategy can be considered a success. For example, he reports that ‘It can actually be seen from the tables that all university graduates [in executive posts] are overqualified for the work assigned to them’ [!] (p.105).

Another approach tries to find a means of identifying overqualification on the sole basis of occupational status and formal qualification (see for example Henninges, 1991; Minks, 1992; Tessaring, 1994a; iwd, 1994a; Minks, 1996, and Velling and Pfeiffer, 1997). This strategy is clearly too basic to obtain valid results. The range of job requirements within various status groups is too wide to allow unequivocal categorisation. This is illustrated, for example, by the question whether or not a desk-officer post in an administrative body should be categorised as appropriate employment for a graduate of a higher technical college.\footnote{See for example Minks and Filaretow (1993, p.43), Gleiser (1996) and even Plicht et al. (1994); on the discussion of this question, see also Velling and Pfeiffer (1997, p.14, footnote 17); on the differentiation between graduates of technical colleges and universities, see Gleiser (1996, pp.36-37).}

As an alternative to occupational status, use is also made of the employee's position within a company, a category that is available from surveys such as the German microcensus (see for example Tessaring, 1994a, and Velling and Pfeiffer, 1997). A combination of the two status categories is used by Handl (1996), who uses information on both occupational status and company position to establish the level of an individual's employment. This, however, is unlikely to solve the aforementioned validity problems.

Earlier works sometimes had recourse to the employee's pay level as a suitable criterion of adequate employment (see for example Tessaring, 1984). The findings produced by Rumberger (1980), however, testify to the problems arising from income analyses in connection with the acquisition of data on overqualification: during the period covered by his study, the income position of college graduates in relation to high-school graduates had not deteriorated, but the relative inadequacy of their education had. Schlegelmilch (1982) applied a more refined strategy, combining reported data on occupational status and income level, on the basis of which she classified as underskilled any job done by a graduate for which no university degree was required and for which the incumbent received less than the minimum rate of pay for graduates in the German public service, i.e. point IIa on the statutory salary scale for federal employees (see p.407, footnote 31).

An original approach is used by Szydlik, at least in his studies in German (Szydlik, 1996a, 1996b and 1997a). He extends the subjective approach by combining the obtained variables relating to the job/qualification match with the question whether the employees work in the occupation for which they have been trained. The question is what additional information this disaggregation yields. In a vertical sense (and this refers not only to the basic principle underlying the strategy for measuring overeducation but also the line of argument used by Szydlik in the interpretation of his findings), the information that a person is not working in the occupation for which he or she has been trained cannot be regarded\emph{per se} as proof of a mismatch; in some cases, job descriptions in different occupations are far too similar to permit such an assertion (cf. section 2 of the present study).

A highly unconventional categorisation of mismatches can be found in Wonneberger (1994, pp.144-145), where a mismatch is deemed to exist if a person is trained for an occupation (for which an academic degree is not required) in which career prospects are poor.

The diversity of measurement strategies illustrated in the foregoing paragraphs underlines the soundness of Rumberger's postulation of the need for standardised measurement of overqualification (Rumberger, 1994, p.281). Teichler (1994, p.28) reports that various studies have put the percentage of graduates in overqualification at levels ranging from 40% to under 5%, depending on the criteria applied. Elsewhere, Teichler (1998, p.98) tells of an approach that involved assigning the 'overqualified' label to all university graduates who admitted to knowing non-graduates with similar professional duties to their own (!). In such a case, the size of each respondent's circle of acquaintances would
have a direct bearing on the findings of the study. It is patently obvious that such measurement strategies can yield little useful information.

**4.2 An innovative approach**

As a refinement of the familiar measurement strategies presented in subsection 4.1 above, the empirical part of this study (section 6) will introduce a new process for identifying overqualification. It is based on the conventional subjective approach. The innovative element is the inclusion of a third indicator to validate the overqualification variables which were initially obtained from the information on employees' formal qualifications and job-requirement levels. It has to be said that the disadvantages of this strategy are a slightly higher rate of missing values and a category entitled 'implausible combination of the three basic variables'. In addition, there is also an optional 'mixed' category to cover cases in which the information conveyed by the three basic variables does not permit a clear distinction to be drawn between a job/training mismatch and a case of overqualification. The crucial advantage of this triple-variable strategy is that it draws a far sharper line between adequate work and overqualification than the conventional double-variable approach (for details see point 6.1.2 below).

**5. Overqualification: a literature survey**

The educational policymakers' fear of producing surplus qualifications for which there is no demand in the marketplace is presumably as old as institutionalised education itself.

Tessaring (1980, pp.374-375) corroborates this, quoting from almost 300 years of German educational history. For example, in 1890 Bismarck pronounced these words of warning: 'One of the principal ills of our higher school system lies in the surfeit of academic schools and in the artful seduction to attend the same which our establishments practise, so that we breed learned young men far beyond our needs and beyond any possibility of their procuring suitable positions. Our higher schools are attended by too many young persons who are destined neither by talent nor by parental provenance for a learned profession [...]. The consequence is the excessive study of all academic disciplines and the education of a proletariat of scholars constituting a danger to the state.' [author's italics].

Similar quotations from other countries have also been recorded. The debate on the career prospects of qualified individuals leaving the education system was given a new lease of life in the sixties and seventies, when a rapid expansion of higher education took place almost simultaneously in the United States and some European countries, driven by demographic developments and political decisions. Education and employment researchers in the United States were the first to undertake systematic study of the consequences of a glut of higher qualifications and thereby set their seal on the scientific examination of the phenomenon of overeducation.

**5.1 Origins of the discussion**

**5.1.1 The U.S. discussion from the sixties to the eighties**

Treatment of the overqualification problem by American employment researchers may be considered to have begun with Berg's monograph of 1970. Under the catchy title *The Great Training Robbery*, Berg tried to demonstrate that the labour market was no longer able to absorb the output of university and college graduates comfortably following the sharp rise in their numbers in the wake of the baby boom and changes in educational preferences.\(^{50}\) The repercussions would be keenly felt in the form of unemployment and overqualification, accompanied by falling returns to education. As the Bureau of Labor Statistics later established, the number of university and college graduates in under-skilled jobs multiplied from about a million to 3.6 million in the short period from 1969 to 1980 (Hecker, 1992, p.5).

\(^{50}\) See also his subsequent works on this subject, such as Berg (1989).
Methodological innovation made a very early appearance in the study by Kalleberg and Sørensen (1973), which presented a simple measurement strategy for the collection of empirical data on overqualification. This approach was based on the DOT/GED system (for details see subsection 4.1 above) and followed on from the work of Eckaus (1964) and Scoville (1966), who took the measurements provided by the authorities for assessing the required skill level for jobs in the various occupational categories and adapted them for use by employment researchers. These multivariate data analyses did not yet control, however, for significant factors such as age.

In 1975, following thematically related preliminary studies (Freeman, 1971, and Freeman and Breneman, 1974) one of the two main protagonists in the U.S. overeducation debate, Richard Freeman, entered the scene. His question Overinvestment in college training? (Freeman, 1975b) is intended to be rhetorical. Freeman was firmly convinced that the college system in the United States had been producing a large surplus of qualifications since the sixties, which was not entirely due to the demographic effect of the baby boom. He tried to underpin this assertion in subsequent works, including a monograph devoted to the issue (Freeman, 1976b) and a contribution to the Review of Economics and Statistics (Freeman, 1977); this period also saw the appearance of his special studies devoted to specific occupational groups (Freeman, 1975a, 1975c and 1976a).

The ‘discovery’ of the growing imbalance between the supply of and the demand for higher qualifications in the U.S. labour market had already been made at that point (see for example Carnegie Commission on Higher Education, 1973), but it had not yet been sufficiently ‘marketed’. The pithy titles of his studies on the subject of overqualification, suggesting that the hypothesis underlying his research is an incontrovertible truth, and his sometimes drastic speculations on the consequences of the growing qualification surplus (e.g. ‘destabilizing political consequences’ – Freeman, 1976b, p.189) achieved their aim and made Freeman the most-quoted author in American literature on the subject of overqualification, even though numerous papers in a similar vein appeared at that time (see for example Jenkins, 1974; Rawlins and Ulman, 1974; Dore, 1976; Jaffe and Froomkin, 1978; Brinkmann, 1978; Suda, 1979; Denison, 1979, and a later work relating to Canada, namely Dooley, 1986).

Freeman’s presentation, which is quite one-sided at times, could not fail to provoke criticism (see for example Smith and Welch, 1978). Several replies were published in issue No1 of the Journal of Human Resources for 1980. Witmer (1980) and Schwartz and Thornton (1980) criticised Freeman’s methodological approach.

Russell Rumberger, who was to emerge as the second main protagonist in this discussion alongside Freeman, did not find any empirical evidence to suggest that the relative position of university and college graduates in the labour market was deteriorating, but did identify a rise in overeducation (Rumberger, 1980). Freeman, however, was unmoved by this welter of criticism, describing the claims of Schwartz and Thornton, for example, as ‘pure nonsense’ (Freeman, 1980, p.141). In a concluding review of the debate in the Journal of Human Resources, however, Kaufman (1984) advances arguments in support of Schwartz and Thornton. After the publication of another two shorter papers (Freeman, 1981a and b), Richard Freeman withdrew from this field of research.

Staines and Quinn (1979) adopted an innovative approach, analysing individual data on job characteristics in a partial time series. Survey data for the years 1969, 1973 and 1977 are examined. One category in the collected data is the respondents’ subjective assessment of their job/education match (p.9). Staines and Quinn also arrive at the conclusion that the overall degree of mismatch has tended to increase.

In subsequent studies, Rumberger (1981a, 1981c and 1984) concentrated on presenting...
evidence in support of his thesis that the development of the job structure in the United States is marked by a slower rise in skill requirements than would be necessary to ensure that enough appropriately skilled jobs were available for the masses of new university and college graduates entering the labour market. He even asks the question whether technical progress, contrary to common belief (see for example Cappelli, 1993, who examines the production system), actually leads to a reduction in the skill level required for the average job (Rumberger, 1981a, p.588; see also Rumberger, 1981b, p.67).

Rumberger’s studies are innovative in relation to Freeman’s in that Rumberger shifts the concept of overeducation from the macroeconomic level to that of the individual; all of his measurements are based on the DOT-GED approach. His monograph on overeducation in the U.S. labour market (Rumberger, 1981b) – the most important on the subject of overqualification along with Freeman’s The Overeducated American and perhaps also T.A. Sullivan’s Marginal Workers, Marginal Jobs (Sullivan, 1978) – goes far beyond any previous literature in its comprehensive and thematically broad portrayal of the researched aspects of overeducation.

Another major innovation in the study of overeducation is to be found in Duncan and Hoffmann, 1981 (see also the Duncan and Hoffmann study of 1978, which was the forerunner of this work). These two authors examined at an individual level the financial returns to necessary, surplus and deficit components of education, thereby establishing a direct link to the human-capital approach. In place of the DOT/GED system, they used subjective data obtained directly from employees about the skill level required for their respective jobs; this information had originally been collected from the 1976 survey batch of the Panel Study of Income Dynamics (PSID). A similar approach underlies studies by Rumberger (1987) and Shockey (1989).

New dimensions were added by Burris (1983a), whose study was the first to explore the sociological and political aspects of overqualification. Until then, studies had only analysed individual sociological or political aspects, such as the effects of overqualification on health (see for example Kasl, 1974; House, 1974; Coburn, 1975, and Caplan et al., 1980).

The studies by Jaffe and Froomkin (1978), Clogg (1979), Clogg and Sullivan (1983), Clogg and Shockey (1984 and 1985), Clogg et al. (1986) and Lichter (1988) – although Lichter’s definition of overqualification poses some problems – proved that the rise in overeducation in the United States was caused to a great extent by changes in the demographic structure of the potential labour force. The study by Burris (1983b) can be considered as part of this cluster, too.

The 1985 study by Tsang and Levin seeks to present the first integral economic theory to explain the persistence of overqualification; the study focuses primarily on productivity issues (for a critical appraisal, see deGrip, 1989; for a reply to this criticism, see Tsang and Levin, 1989.

By 1986, the postulate that overeducation was gradually developing into a critical problem within the U.S. labour market had come to be regarded as an established fact, but it was subjected to critical examination for the first time by Smith (1986); however, this methodologically based study, which was sharply critical of the measurement strategies used in support of the said postulate, had a limited impact.

5.1.2 The early discussion outside the United States: the case of Germany

Outside the United States too, the sometimes dramatic expansion of educational provision was the subject of controversy in various countries (for a general review, see Teichler, 1996,
It must be said, however, that the academic quality of the debates lagged far behind those in which the U.S. researchers were engaged, at least until the late seventies. The case of Germany may be cited as an example.

The study *Akademisches Proletariat?* (Schlaffke, 1972) caused quite a stir among German educational researchers. The study (in fact, the term ‘essay’ is more apt) strikes a perceptibly and no doubt deliberately polemical tone. The line of argument is inherently negative and fuels conservative prejudices; moreover, the author generally fails to provide his readers with sources in which they might find empirical figures to substantiate his hypotheses. The following quote exemplifies this approach: “How can a political scientist whose special papers at university were in the theory of the class struggle and strategies for overthrowing the system possibly explain the workings of our economic system to his pupils in a modern-studies class?” (p.47). If strict academic standards of empiricism and analysis are applied, this key contribution to the early German literature on overqualification is clearly not in any respect in the same league as its American contemporaries.

The only field of research which seemed to interest German empiricists was that of educational forecasting. As in the early discussion in the United States, it was not a matter of studying aggregated individual discrepancies between job requirements and formal qualifications but rather of alleged or expected imbalances between the aggregate supply of labour with particular qualifications and the aggregate demand for such labour. Besides the interest in quantitative forecasting, the main methodological bone of contention was whether the demand-centred manpower requirement approach or the supply-centred social demand approach should be adopted (for a detailed review of the host of conflicting predictions, see Tessaring, 1980, pp. 376).

The huge discrepancies between the findings of such studies, however, presumably sowed more confusion than reassurance in the minds of educational planners (cf. Schlaffke, 1972, pp.10 et seq.). Not until the end of the seventies did empirical research in Germany diversify into several different subject areas. Tessaring (1978) tried to trace the careers of graduates but had to rely on highly aggregated statistical material (see also Tessaring, 1981 and 1984, for similar approaches). A breakthrough was undoubtedly made in the empirical study of graduate employment when the micro-economic Infratest surveys were conducted in the autumn of 1978 and the spring of 1979 (see Stooss, 1979). Similarly designed analyses by the Institute for Employment Research (IAB) around that time laid the foundations for a new research tradition (see for example Kaiser et al., 1980).

The competition that emerged in the late seventies and early eighties between micro-economic empirical research, which strove to establish certain methodological standards, and the ‘essayist’ approach to the overqualification problem is exemplified by the papers published in an anthology of contributions to the Conference on University Expansion and the Labour Market – Problems and Research Perspectives (*Tagung «Hochschulexpansion und Arbeitsmarkt – Problemstellungen und Forschungsperspektiven»*), held in Berlin in November 1981. While some sound empirical papers were presented (Tessaring, 1983, and Schlegelmilch, 1983a, for example) there was certainly no shortage of representatives of the ‘old school’. Busch and Hommerich (1983), for instance, saw the cause of the escalating employment problem in changing ‘power constellations’ (p.71), while Krais (1983) proposed that the issue of graduate employment and career prospects be examined ‘in the light of class theory’ (p.36), and Nuthmann (1983) expressed the following view on the graduate overqualification: ‘Some of these activities, work forms and lifestyles may be directly connected with labour-market problems of the people concerned. In other cases, they are probably a reaction to growing economism and industrialisation, bureaucratisation and the increase in the statutory regulation and control of all aspects of life’ (p.11). In the years that followed, however, such approaches were almost entirely supplanted by empirical analytical research (see point 5.2.2 below).
It only remains to describe how the German Federal Government assessed the threat of an increase in sub-standard forms of employment for graduates as a result of the reform and expansion of higher education. The Federal Ministry of Education and Science seemed to be rather wary of vastly overoptimistic predictions of labour demand. The purpose of a course of study, namely to qualify the student for professional activity of a suitable standard, certainly remained intact (Aim of the course of study: The purpose of instruction and study shall be to prepare the student for a field of professional activity [... so] that he or she is capable of performing academic [...] work – section 7 of the Higher Education Framework Act (Hochschulrahmen- gesetz), quoted in Neusel, 1983, p.236). Expectations regarding the ability of the labour market to play its part in the achievement of this aim, however, were muted. As part of the process of developing 'points of reference' for the Permanent Commission on Higher Education Reform, the Federal Ministry of Education and Science called on employers to 'create jobs [for graduates] below the top level', and expressed confidence that even "underskilled" occupations could 'be a means of job satisfaction' (quoted in Neusel, 1983, p.240).

5.2 Present state of research

5.2.1 Recent studies relating to the United States and Canada

Recent studies from the United States on the subject of overeducation/overqualification have been characterised by the fact that, unlike the studies referred to in subsection 5.1 above, they rarely focus on the consequences of a glut of university and college graduates in the labour market. By the end of the eighties, the concept of 'overeducation' – relating to individuals – had become established as a separate category in the field of employment research, and subsequent studies became more widely diversified.

For the first time, the implications of overqualification for business management came under scrutiny. The question was whether overqualified employees were less productive in the same level of job than their adequately educated colleagues (Tsang, 1987, and Tsang et al., 1991). The relevant studies was based on in-house data of the U.S. Bell Companies. More recent studies examine the correlation between overqualification and health (Amick and Lavis, 1998) and between overqualification and job satisfaction (Hersch, 1991, Johnson and Johnson, 1992, 1996 and 1997, and Johnson and Roy, 1994 and 1995).

A latecomer to the debate described in subsection 5.1 above was the article by Verdugo and Turner Verdugo (1989), which followed on from a shorter study (Verdugo and Turner Verdugo, 1988). Adopting a similar approach to Duncan and Hoffmann (1981), but without explicitly referring to that approach, the authors believed they could disprove the Duncan and Hoffmann findings, because they calculated negative returns to components of schooling that employees did not require in the performance of their jobs. Their study aroused vehement opposition (Cohn, 1992, Gill and Solberg, 1992, then Cohn and Khan, 1995); the reply by Verdugo and Turner Verdugo (1992) to the criticism of their line of enquiry and of the way they interpreted their findings was rather unconvincing.

Sicherman (1991) studied overqualification in the framework of the career mobility theory (Sicherman and Galor, 1990). He used the phenomenon of overqualification as a practical example of the empirical relevance of the theory he had helped to develop. He dismissed the possibility that other theories could do much, if anything at all, to explain the phenomenon. An extensive review (and endorsement) of the career-mobility approach is contained in Hersch (1995).

The observation that the imbalance in the labour market for graduates which had begun to appear in the sixties had continued throughout the eighties (and that no improvement was in sight – cf. Shelley, 1992 and 1994) was the subject of another series of 'conventional' articles (Hecker, 1992, Tyler et al., 1995a, b and c) who criticised Hecker, and the latter's reply to this criticism (Hecker, 1995a); see also Amirault, 1992, Cappelli, 1993, Hecker, 1995b, and Zemsky, 1998.
An article by Halaby (1994) levelled methodological criticism at the DOT/GED approach and at questions on the occupational utility of knowledge acquired through formal education, to which the article ascribes little validity.

The study by Bishop (1995) gives a short introduction to the topic of overeducation and the respective state of research in form of a contribution to an encyclopedia of economics of education. In the same volume, the article by Levin (1995) presents a broader overlook to the environmental setting, in which this special field of research is done.

The connection between the quality of a university or college education and the probability of overqualification is examined by Robst (1995b). As expected, Robst establishes a negative correlation between the quality of the university or college a person attends and the probability of subsequent overqualification.

Lastly, an original study is presented by McGoldrick and Robst (1996), who test the theory of 'differential overqualification' developed by Frank (1978b); the originality of their approach lies in the fact that, instead of basing their test on income factors (see for example Ofek and Merrill, 1997), they use an employee-centred measure of overqualification. They reject the hypothesis that married women run a higher risk of overqualification in smaller local labour markets.

Madamba and De Jong (1997) reopen the discussion on the influence of demographic changes on the degree of overqualification. They find that, in the United States, male immigrants from India, China and Korea are more frequently overqualified, those from Vietnam are more rarely unemployed, while immigrants from the Philippines and Japan do not differ significantly in this respect from the longer-established Anglo-Saxon population. Zhou (1993), on the other hand, reported higher mismatch rates for Japanese (and Cuban) workers. To what extent the qualifications of those immigrants who were educated in their native countries can be made comparable is an exceedingly moot question, given the extreme variations in the quality of the school systems in their countries of origin and is a fundamental problem in studies designed to examine overqualification among immigrants.

On the basis of Canadian data, Vahey (forthcoming) certainly confirms in principle, at least as far as men are concerned, the findings of Duncan and Hoffmann (1981) and their epigones, according to which positive and negative returns to human capital may be expected for surplus and deficit years of schooling respectively; he demonstrates, however, that the returns vary in accordance with the skill level required for each job. For women, on the other hand, he finds insignificant effects at all job levels.

5.2.2 Recent studies relating to the countries of the European Union

The main distinct traditions of research into overqualification outside the United States exist in the Netherlands and Germany. In the United Kingdom the subject was not 'discovered' until the mid-nineties, although the subsequent volume of research on overqualification in the UK has been considerable. There are only isolated analyses for other countries.

The Netherlands

There are several analyses of job/qualification matches in the Netherlands. If we focus exclusively on the studies devoted to overqualification, it emerges that Dutch employment researchers, compared with their colleagues in other EU countries, have been the most prolific contributors on this subject in English, at least in the widely accessible English-language publications.

The first studies were undertaken by Hartog (1985a and 1986). His approach is very similar to that of Duncan and Hoffmann (1981), although he does not cite the latter work. Like Duncan and Hoffmann, he rejects unilateral determination of pay rates for the Dutch context too, either by the supply side through formal qualification (the human-capital theory) or by the demand side through job
requirements (the job-competition model). In the good old Tinbergenian tradition, he provides evidence of the explanatory capacity of the assignment theory. Extending this approach, Hartog and Oosterbeek (1988) identify a gradual rise in overqualification in the Netherlands over a period of time. Groot (1993a) refines the approach presented in Duncan and Hoffmann (1981), devoting special attention to the link between training activities and mismatches. Overqualification, Groot says, not only has an adverse effect on total income from employment but also has the same sort of impact on returns to in-service training.

In more recent papers on the subject, Hartog (1997 and 1999b) passes critical judgement on the body of research into overqualification. As far as future research perspectives are concerned, the author puts the case for longitudinal analyses, more theoretical input, more ambitious evaluation procedures and – in the old-established tradition of Dutch research in this field, which bears the unmistakable imprint of Tinbergen – for analytical approaches in which supply and demand effects are considered in combination. In the study by Hartog and Jonker (1998), the authors have access to the Brabant-survey which includes IQ measures. Having the opportunity to control for individual ability opens the door to new aspects. The authors, however, find that the impact of this variable on the risk to work overeducated is relatively low. In other studies (Hartog, 1999c, d and a), Hartog once again warns against investing overqualification with unduly pejorative connotations, referring to the positive, albeit limited, returns to surplus years of education which were previously identified by Duncan and Hoffmann (1981).

Borghans and Smits (1997) show that an increasing percentage of overqualified labour can also impair the earning potential of adequately educated employees. DeWitte and Steijn (1998) examine the effects of increasing automation on the incidence of overqualification. They discover a direct link as well as frustration effects in overqualified employees. Batenburg and Witte (1998) identify a rise in the mismatch rate within the Dutch labour market over the period from 1977 to 1995. Groot and Maassen van den Brink (1999) demonstrate the sensitivity of the measurement strategies used to identify jobs which are incommensurate with their incumbents' qualifications. Groot and Maassen van den Brink (forthcoming) present a survey of empirical findings from various countries. Among other things, this survey reveals a positive correlation between growth rates and overqualification rates. Van Eijs and Heijke (forthcoming) demonstrate that the current allocation of qualifications to job requirements is inefficient; this finding contrasts with Hartog's latest estimates. The study by Borghans and de Grip (1999) examines determinants of overqualification, categorising them by whether or not they are compatible with the allocation theory. A clear result, however, does not emerge. Van der Velden and van Smoorenburg (1999) compare results gained from the so-called objective and subjective measurement approach. Their major finding is that overqualification measured with an objective approach is clearly overestimated. On the other hand, they do not find hints for an underestimation of overqualification when applying the subjective approach.

Two Dutch authors are about to present a new anthology on overqualification (Borghans and de Grip, forthcoming(b)). In their editorial article (forthcoming(a)), Borghans and de Grip discuss the current issues in this field. The paper by Muysken and terWeel (forthcoming) seeks to integrate human-capital theory, job-search theory, the job-competition model and screening into a discrete theoretical approach. Borghans et al. (forthcoming) examine the connection between aggregated and individual overqualification on the one hand and low pay on the other and conclude that the impact of overqualification is greater than that of low pay. Finally, the study by Gautier (forthcoming) examines cyclical effects on the level of demand for various qualifications. One of his findings is that, during recessions, employees in unskilled jobs are paid off without regard to their qualification levels.

Besides the aforementioned works, there are several relevant essays in Dutch, such as Hartog, 1985b, Oosterbeek, 1986, Groot, 1993b, Groot and Maassen van den Brink,
Felix Michel 1996, Oosterbeek and Webbink, 1996, and Groeneveld, 1997, which testify, as in the case of Germany, to a wealth of research on the subject of overqualification that the international scientific community is unable to appreciate. The author's lack of knowledge of the Dutch language prohibits an evaluation of the content of these papers at the present juncture.

Germany

The only comprehensive monograph on overqualification in Germany is a study by the present author (Büchel, 1998b). One of the main innovative methodological elements of this study is that it is the first to adapt the existing instruments of dynamic unemployment research systematically for use in the analysis of overqualification. In this way, on the basis of panel data, it is possible to analyse the probability of individuals being recruited and of their staying with or leaving their firm, to determine longer-term income effects and more besides. Important preliminary work, especially with regard to the categorisation of overqualification, was performed in the studies by Büchel and Weiβhuhn (1997a and 1998). Schlegelmilch (1987) presented a monograph analysing data on overqualified graduates; another monograph, in the form of a company study, on the effects of overqualification among technicians and engineers (Haugrund, 1990) was designed more as a business-management resource.

Two individual papers dealing with the subject under examination were produced by Szydlik (1996a and 1997a). To generate the mismatch variables, Szydlik includes a question about the occupation for which the employee has trained (for a critique of this approach, see section 2 above) but does not use occupational status to validate the mismatch (Szydlik, 1996b, p.300, footnote 10) as Büchel and Weiβhuhn do (see also subsection 6.1 below). This produces distinctly higher percentages of overqualification than would result from an operationalisation based on the Büchel/Weiβhuhn approach. Velling and Pfeiffer (1997) also examine overqualification (as part of a wider-ranging study) for all qualification levels, though for western Germany only. Despite the use of a different database and a sharply divergent means of assessing the degree of job/qualification match, the study arrives at very similar findings to those of Büchel and Weiβhuhn (1997a and 1998). Lastly, Zwick (2000 and forthcoming) adopts an ambitious theoretical approach to examine the links between overqualification, wage levels and attitudes to education.

In continuation of the research tradition outlined in point 5.1.2 above, the main focus of German overqualification research has remained on university graduates, right down to the present day.

Straddling the border between 'old' and 'new' research is the work of Rippe (1988), who was the first researcher in Germany to conduct a broad investigation of the methodological side of job-match assessment and thus to reflect at least some signs of affinity with the body of U.S. research on that subject; until that point, Germans had been virtually oblivious to the discussion of these issues in the United States. Proceeding from the DOT/GED approach and the criticism levelled at it and at its application to the microcensus by IAB researchers, Rippe identified 'a lack of validated methods for assessing job matches by comparing existing and required qualifications'.

Plicht et al. (1994) presented the first broad-based study of the suitability of jobs held by university graduates in Germany. Their approach may not correspond exactly to the DOT/GED strategy, but it is related to the latter in so far as it does not have recourse to subjective assessment of job-requirement levels by the respondents themselves. Although it is designed as a cohort study without longitudinal examination of individuals, the authors postulate that the high percentage of young graduates in jobs for which they are overqualified is primarily due to the fact that overqualification is a natural phenomenon at this stage in a graduate's career. This interpretation was put into perspective in Büchel (1996a): although the risk of involuntary overqualification is higher at the start of a career than after a period of occupational experience, it has been proved that structural and cohort effects have played a dominant role.
Overqualification: reasons, measurement issues during the nineties. In other words, the percentage of graduates who tend to run a higher risk of overqualification on account of their membership of particular status groups (e.g. women and graduates of technical colleges) is rising steadily, and membership of these groups is largely unalterable in the course of a career.

The situation of academically trained career starters is examined by Büchel and Matiaske (1996) on the basis of longitudinal data from the German Socio-Economic Panel (GSOEP). It emerges from this study that a high risk of overqualification at the start of a career attaches to certain ‘soft’ academic disciplines which are mainly chosen by female students. An interaction analysis shows that the gender effect is governed by the student’s choice of subject.

Most of the other literature relating to the more recent discussion of the phenomenon of graduate overqualification in Germany may be divided into two categories: the first comprises highly specific surveys of graduates, differentiated by subject specialisation (most of these have been conducted by the University and College Information System (HIS) in Hanover) or even by specific departments of individual universities (this type of survey is conducted by ‘interested parties’, i.e. students in one of the departments in question, often as one of their degree papers); the other category comprises papers presented at conferences on the subject of graduate career prospects and subsequently published in the report of proceedings.

The HIS studies are reports on graduates in specific federal states or subjects, based on the system’s own surveys (see for example Minks, 1992 and 1996; Minks and Filaretow, 1993; Lewin et al., 1994a and b). One of the central problems with these studies, however, lies in the database, which only covers the first years of a graduate’s career.

This problem, of course, also arises for university- and subject-related studies of graduate employment. The utility of this type of study is undisputed, because it can give prospective students important information about future career prospects. Nevertheless, the scientific quality of the studies is generally below average, since they are compiled as a rule by people with no research background.

The important thing about the latest developments in this field is that the discussion about the future of graduate employment in Germany now focuses on overqualification and unemployment as closely related phenomena (see for example Schreyer, 1999, and Wissenschaftsrat, 1999). This represents a major step away from the narrow perspectives which had long prevailed, in which unemployment was only seen as an employment risk.

Studies on the overqualification of people with vocational diplomas are considerably less common than studies on graduate job matches. The most plausible explanation of this phenomenon may be that higher education is expanding more rapidly than vocational education. Accordingly, graduates may be regarded as more likely victims of labour-market imbalances.

Hofbauer and Nagel (1987) conducted a wide-ranging study of the risk facing skilled workers of occupational demotion to semi-skilled or unskilled status, examining the specific level of risk in various different trades, for example. The study by Neubäumer (1993), to which reference has already been made in section 3 above, is based on an unconventional approach. The authoress proceeds on the assumption that segmentation applies not only to the labour market but also to the market for training places in the dual system of classroom and on-the-job training. The study demonstrates that in those occupations where working conditions are poor, training is provided in excess of requirements as a means of coping with the loss of the better trainees, who move upmarket when they have served their apprenticeship. Those who complete their training in occupations with poor working conditions but do not find a job, either in the occupation for which they have trained or in

54 For a collection of graduate studies from various European countries, see Teichler (1988).
a market segment with better career prospects (assuming they are prepared to switch to another occupation) are generally compelled to settle for overqualification. Neubäumer's findings show that this phenomenon is undoubtedly empirically significant in Germany (see also Neubäumer (1997) and Neubäumer (forthcoming)).

A study by the present author (Büchel, 1994b) examines overqualification at the start of non-graduates' careers. What seemed astonishing at first sight was the higher incomes earned by the overqualified workers. This finding, which was also obtained by Hofbauer and Nagel (1987, pp.54-55), shows that monetary considerations are an important factor in the acceptance of an underskilled job, at least in this phase of a person's career (for a similar finding, see Neubäumer, 1993). Pay differentials to compensate for monotonous work and other disagreeable working conditions, such as the presence of noxious substances, could also play a part (cf. Lucas, 1997, p.557). This factor may be particularly significant in the case of trained craftsmen who subsequently take up semi-skilled jobs in manufacturing industry or do piecework. Even after a short time, however, those who started out with a good fit would be better placed, because their income would have risen more sharply. A similar approach is found in partial analyses such as Büchel and Weißhuhn (1995), Weißhuhn and Büchel (1998), or Büchel and Pannenberg (1997).

Pfeiffer and Blechinger (1995) and Blechinger and Pfeiffer (1999) examine the realisable value of vocational training in the labour market and observe diminishing returns in the course of people's careers.

The only general study relating to Germany that is exclusively devoted to the fit between vocational training and jobs was conducted, ironically enough, by two researchers from the United States (Witte and Kalleberg, 1995). The way in which they assess job/training matches, however, is somewhat questionable, for they assert (p.311) that only about 50% of men and 60% of women who have successfully completed their vocational training are in jobs that match their training [1].

An innovative study was compiled by von Henninges (1996), who investigated the persistent contention that technical progress, the globalisation of labour markets and other factors would lead to the gradual disappearance of unskilled jobs. In so doing, he addressed the methodological problem whereby, because of the restricted availability of data, most studies do not focus on the requirement levels for specific jobs but on the formal qualifications of the people in those jobs. As a result of the expansion of educational provision, there are indeed fewer and fewer workers with no formal qualifications; however, the fact that unskilled work is being performed by semi-skilled or skilled workers means that the rate at which unskilled jobs are being shed is being systematically overstated (p.78).

Lastly, the topic of overeducation was chosen as an example how to work efficiently with robust stochastic earnings frontiers (Jensen, 1999). This paper, however, has a stronger econometric focus than a substantial one.

Only a short time after the dissolution of the German Democratic Republic, special studies on eastern Germany began to appear. Von Henninges (1991) shows that, contrary to the ideological claims made by the regime, overqualification had already assumed epidemic proportions during the Communist era (see also Schwarze, 1993, Büchel, 1995, and Brinkmann and Wiedemann, 1995, p.330). Schwarze (1993) presents a comparison of the situation in eastern Germany before and after the demise of the East German state (1989 and 1991) and identifies income effects of overqualification.

The labour-market monitor for the new federal states proved to be an effective source of data for the investigation of overqualification. In thematically wide-ranging IAB studies on the development of the employment situation in eastern Germany, the phenomenon of

55 At this point, however, it should be mentioned that, irrespective of data restrictions, macro-economic surveys of the jobs that people do are far more difficult to conduct from a methodological point of view than surveys of employees' qualifications or occupational categories.
Overqualification is given special treatment (Bielenski et al., 1994 and 1995, and Brinkmann and Wiedemann, 1995 and 1997). The very structure of the 1995 study by Brinkmann and Wiedemann (p.323) testifies to the high priority that is attached to the phenomenon of overqualification in the empirical research of the IAB, at least in relation to eastern Germany, where the percentages of overqualified employees are very high; this emerges especially clearly from the special study on this subject by Brinkmann and Wiedemann (1997).

These, then, are the studies that focus specifically on eastern Germany.56

The extent to which foreigners in Germany are affected by overqualification is investigated in a study by Szydlik (1996a). However, the fact that the source data (from the GSOEP) only yield rudimentary information on foreigners' qualification levels (at least for those who were educated in their native country) must pose problems when it comes to assessing whether their jobs are commensurate with their training. Szydlik observes, for example, that more than half of the Turks working in Germany are overqualified for their jobs. If we bear in mind, however, that even today Turkey requires only five years' compulsory schooling of its young citizens and that there is effectively no institutional system of vocational training in the country, the validity of this finding appears dubious. Heinelt and Lohmann (1992) also elicit high overqualification rates for ethnic Germans who have moved to the Federal Republic from Eastern Europe; here too, there are problems with the validity of the measurement strategy.

The job/training fit for working women is examined in detail in one of the studies by Büchel and Weißenhuhn (1997c). Extending the basic approach adopted in Büchel and Weißenhuhn (1997a and 1998), the authors attach special importance to an examination of the socioeconomic background of the women who are affected by overqualification. This relates not only to the women's family circumstances (e.g. the number of children in the household and the arrangements made for their care) but also to their partner's employment status, his income situation, etc. The study establishes a strong link between the financial circumstances of the household and the need to accept underskilled work, although marked differences were observed between women with different qualification levels. The household structure and the number of children seem to be less significant factors, with the qualification that women who are lone parents exhibit a far higher risk of having to accept a second-best solution in the labour market.

Other countries of the European Union

In the United Kingdom, Sloane et al. (forthcoming – see also Sloane et al., 1996) were the first to devote a study to the subject of overqualification. Their work is based on the research approach adopted by Duncan and Hoffmann (1981) and delivers similarly structured findings.

The Dutch researcher Groot (1996) found that few British employees were overqualified for their jobs. His assessment of the job/education match, however, was based on what appears to be a somewhat arbitrary modification of the DOT system. An extension of this approach, based on the same assessment strategy, is found in Groot and Maassen van den Brink (1995).

Battu et al. (1998a and b) test the theory of differential overqualification (Frank, 1978b) and arrive at a negative result. In a longitudinal study, Battu et al. (1999) show that overqualification has adverse effects on job satisfaction and income. They produce the noteworthy finding that social background does not affect the probability of a mismatch.57

56 There are, however, other studies on the empirical situation in eastern Germany, such as those by Büchel and Weißenhuhn (1997a, 1997c and 1998) and by Szydlik (1997a, b and c). One remarkable point is the finding presented by Szydlik alone that underemployment is less widespread in eastern than in western Germany (see Szydlik, 1997b, Table 1, p.43, or the redundant findings in Szydlik, 1997c, Table 2, p.13).

Alpin et al. (1998) examine over- and underqualification in a wide-ranging study. Their ambitious quest to establish whether the overqualification of individuals is only a temporary phenomenon meets with little success, however, because they only have access to right-censored data on job duration. This question cannot be answered on the basis of such data. Finally, Battu and Sloane (forthcoming) find that displacement effects caused by overqualification do occur in the upper echelons of the labour market, but that unskilled workers in the United Kingdom are not being ousted to any great extent by overqualified recruits.

One of the more unusual longitudinal studies in the domain of overqualification research was presented by Dolton and Vignoles (1997). They observe that most employees who start their career in a job for which they are overqualified do not manage to make the transition to appropriate employment in the first six years. Dolton and Vignoles (forthcoming) arrive at similar findings to Sloane et al. (1996 and forthcoming) with regard to the returns to surplus years of schooling.

Alongside these microeconomic studies on overqualification there are also conventional studies which examine the aggregate effect produced by the expansion of the education system, such as the study by Mason (1996).

For France there are studies by Forget and Gautié (1997a and b), in which the percentages of over- and underqualified employees in the younger age brackets are assessed by qualification level and job duration for the years 1986 and 1995, as well as a study by Vincens (1995), which treats the problem of overqualification in a rather general fashion (pp. 149-150).

With regard to Spain, there are relevant studies by Alba-Ramirez (1993) and Beneito et al. (forthcoming). Alba-Ramirez finds evidence for the job-matching and career mobility theories. Beneito et al. examine the question whether surplus years of schooling should be regarded as complementary components of human capital or substitutes; their test shows that the latter is the more accurate assessment.

The Portuguese situation has been the subject of studies by Kiker et al. (1997) and by Mendes de Oliveira et al. (forthcoming). Kiker et al. adopt a similar approach to Duncan and Hoffmann (1981) and find that it confirms the allocation theory. Mendes de Oliveira et al. refine the same Duncan and Hoffmann approach and demonstrate that the returns to surplus and deficit years of schooling are heavily dependent on job duration.

In Greece, studies on overqualification have been produced by Patrinos (1995 and 1997). He arrives at similar overqualification rates for Greek graduates to those recorded in western Germany, for example. As might be expected, Patrinos finds evidence of wide divergences between academic disciplines. One especially noteworthy finding is that overqualification is disproportionately high among graduates from humbler backgrounds.58 Other studies are based on the idea of overeducation as an imbalance between the supply of higher qualifications and the demand for them, an idea that was widespread in the early days of the discussion (see subsection 5.1 above); these include works by Tsoucalas (1981), Psacharopoulos (1988), Glytsos (1990) and Lambropoulos and Psacharopoulos (1992).

For Austria there is a study on access to blue-collar occupations for apprentices when they complete their training (Ofner, 1994). Ofner finds that, two years after obtaining their certificate of apprenticeship, about one-third of the former apprentices who have jobs are overqualified.

This review of nationally focused literature on the subject of overqualification shows that this major problem has yet to arouse the interest of employment researchers in many countries of the European Union. We can but speculate on the reasons for this. The restricted availability of key data may be a sig-

---

58 This finding is consistent with that of the author (Büchel, 1997), who identifies a positive correlation between income prospects and the education level of the parental household, thereby challenging the oft-expressed view that a university degree is a social leveller.
significant factor, for a mismatch variable cannot be generated without an adequate range of relevant reliable data. Efforts must be made to ensure that data-gathering institutions show greater willingness than in the past to elicit the information that researchers need, such as the skill level required for individual jobs. This problem has already been recognised (ILO, 1998, p.90); a fair degree of patience is likely to be needed, however, before this aim is achieved.

5.2.3 International comparative studies

There are studies in which findings from various countries are put together and some in which the researchers' own empirical comparisons are drawn.

Examples of the first group are the publications by Suda (1979), Teichler (1988), Hofmann (1995) and more specifically those of Hartog (1997), Büchel and Weißhuhn (1997c), Borghans and de Grip (1999), Tesserling (1998), Büchel (1998b), and Groot and Maassen van den Brink (forthcoming). These studies provide quite general information on various research findings in an international context.

Studies in which direct international comparisons are drawn in the domain of overqualification have so far been limited to comparisons between the country in which the researchers are interested and the United States, which serves as the reference country. Almost all such studies compare Germany with the United States.

Buchtemann et al. (1993) presented a comparative study on career starts in Germany and the United States. Their study analyses data from the PSID and GSOEP. Matches and mismatches are only one aspect of this wider-ranging study. The study by Daly et al. (1997, revised in Daly et al. (forthcoming)) uses the same databases to examine the income effects of deficit and surplus components of human capital along with the returns to qualifications which are actually needed for a person's job. In so doing, it follows the approach established by Duncan and Hoffmann (1981). The authors are interested in ascertaining whether structural changes in the U.S. labour market have a greater impact on results than structural differences between the countries under examination. Astonishingly close analogies emerge in the findings for Germany and the United States; the key finding of the study is that similarities between the nations are more pronounced than the similarities between the U.S. findings for different points in the time series.

Büchel and Witte (1997) analyse the effects of overqualification in the initial phase of employees' careers. They use the longitudinal structure of the 'High-School & Beyond' data sets and the GSOEP. Here too, the two countries under scrutiny are remarkably similar in structural terms. The studies by Szydlik (1997b and c and, to a certain extent, a), are also based on information from the PSID and GSOEP. While the aforementioned studies arrive at similar overqualification rates in the United States, the identified percentages of underqualified workers are strikingly lower than those calculated by Daly et al. (1997, Table 1, p.27).

Szydlik (1998) examines the overqualification of immigrants in Germany and the United States. But this once again begs the question how, given the extremely wide divergence between national training systems in terms of quality, anyone can hope to achieve comparability between the formal vocational qualifications that immigrants have obtained in their own countries. Witte (1999) examines the development of overqualification among young people in Germany and the United States; unlike Büchel and Witte (1997), this study bases its analysis of the U.S. situation on PSID data. The study by Büchel and Weißhuhn (1997b) provides a summary in German of the main elements contained in the previous studies by Daly et al. (1997) and Büchel and Witte (1997).

Cohn and Ng (1999) as well as the more fully elaborated version of this study by Cohn et
Felix Büchel (1999) examine overqualification in a comparison between the United States and Hong Kong. What seems at first sight to be a rather exotic research project actually produces remarkable results. In fact, the standard pattern that is familiar to us from Western research literature also applies to Hong Kong: as a rule, overqualification is more frequently observed than underqualification, older employees are more often underqualified for their jobs, while younger employees are more likely to be overqualified, and the Duncan and Hoffmann findings on the returns to surplus and deficit years of schooling, which were first published in 1981 and have since been confirmed in numerous studies, are likewise found to hold true for Hong Kong.

The presentation of this literature survey has also shown up major research gaps. An important research perspective for the future relates to the need to achieve mutually compatible national data sets on mismatches and to analyse them on the basis of a standardised examination model. Only in this way can institutional and regional effects be satisfactorily isolated; a comparison between individual studies for various countries cannot achieve this because of the widely divergent measurement methods.

6. Overqualification and unemployment: The case of Germany

The purpose of this empirical section is to present some examples, with the aid of a few indicators, of links that exist between overqualified and unemployed status.

In subsection 1.2 above, a methodological affinity was highlighted between overqualified and unemployed status within the labour market. The essence of this affinity is that people in both situations are unable to capitalise fully on their certified vocational qualifications in the labour market. The 'skill spill' in the case of overqualified workers amounts to \( x \% \), where \( x \) is only indirectly determinable – by means of an income analysis, for example – but is substantially higher than zero.

In the case of jobseekers, the spillage factor is 100%. If we assume, for the sake of simplicity, that the skill spill in the case of an adequately employed person is 0%, the 'middle' ground of overqualification which lies between adequate employment and unemployment must be observable within those social categories that unemployment literature identifies as clearly disadvantaged.

6.1 Research approach

6.1.1 Database

The measurement strategy introduced in the following paragraphs is based on data from the German Socio-Economic Panel (GSOEP) administered by the German Institute for Economic Research (Deutsches Institut für Wirtschaftsforschung – DIW) in Berlin. This set of data, collected from representative samples of the population resident in the Federal Republic of Germany, contains a wealth of longitudinal information on households and individuals. The initial sample in 1984 comprised almost 6000 households. The head of each household was given a questionnaire covering the whole household. All members of the household aged 16 or over (more than 12000 individuals) were also given a separate personal questionnaire seeking factual information and opinions on many aspects of their lives, especially education and employment.

The households and individuals in this sample are surveyed at yearly intervals. The database is constantly being widened as household members leave to start new households, as new members move into panel households and as younger members of the household reach the survey year in which their 17th birthday falls.

Information on the education and training of foreigners

The vast majority of the foreign nationals who are GSOEP respondents are first-generation foreigners, in other words the 'guest workers'

\(^{60}\)For more extensive information, see Projektgruppe Panel, 1995.
who were encouraged to come and work in Germany. In the present context, these people form a special group in the sense that they underwent schooling and vocational training in their native countries. There is only rudimentary information available on their educational and training qualifications. This information is not comparable with the very precise details elicited by the questions that are addressed to German respondents about their education level. Moreover, the education systems of the various countries of origin are so highly disparate that identical response patterns can rarely be taken to mean equivalent levels of qualification.

The conclusion we must therefore draw from this situation is that it is impossible to measure the degree of mismatch for foreign workers if they have been trained in their native countries. The aforementioned heterogeneity of training courses in their countries of origin is not the only reason; another factor is that the GSOEP question equates the various levels of job requirement with German educational certificates. No very convincing attempts have yet been made to solve this compatibility and validity problem adequately (Szydlik 1996a); Szydlik's exorbitant assessment that around 60% of all 'qualified' foreigners are overqualified will certainly raise eyebrows at the very least (Szydlik, 1996a, p.667; see also Szydlik, 1997a, p.17).

In the light of these considerations, the categorisation of job/education matches in the following paragraphs will only apply to those foreigners who have undergone at least their vocational training in Germany. The problems outlined above with regard to information on immigrants' education levels also apply to other databases, but overqualification researchers have yet to respond to them with the necessary sensitivity (see the criticism in point 5.2.1 above of the methodology applied to immigrant studies).

General case selection

All members of the sample who were in the labour force at the time of observation are categorised. People in full-time employment, regular part-time employment, minimal employment, and involuntary unemployment (including the hidden labour reserve) are examined, except in cases where the employees are still in full-time education, since there will be no 'definitive' information on vocational qualification in such cases. For the same reason, internees, voluntary workers and people in similar occupational situations are excluded from the analysis, as are those of retirement age (65 and over). Since people who have no vocational qualifications at all cannot by definition be overqualified, they too are excluded from the categorisation (cf. Witte and Kalleberg, 1995, p. 308, for an analogous approach). With respect to the latter selection, an exception is made for the step of analysis resulting in Table 1.

The considerations described above form the basis of the condition that only people who have received vocational training and/or higher education in Germany are taken into account. Migrants who moved between East Germany and the Federal Republic are also excluded from the analysis. Because of the categorisation rules governing the assessment of overqualification (see point 6.1.2 below), it is also necessary to exclude those few people for whom no information on vocational qualification, job-requirement level or occupational status is available.

6.1.2 Categorisation of overqualification

Because of the superiority of the subjective approach to the 'objective' DOT/GED system, as discussed in point 4.1.2 above, the strategy presented below for the measurement of overqualification is based on the former. The

61 Szydlik writes, 'Admittedly, knowledge and skills acquired abroad cannot be unequivocally evaluated' (p.664); however, the continuation of his study, which compares the job/training matches of Germans and foreigners, is evidence of such an evaluation being undertaken in spite of this acknowledged obstacle; indeed, the evaluation is at the very heart of this particular study.

62 For the rationale behind this exclusion, see Büchel, 1998b.
strategy takes account of the objections that have been raised about the subjectivity of the collected information on job-requirement levels by validating reported information on occupational status.

This generation of the mismatch variables from three, rather than the usual two, initial indicators is what gives this categorisation system its innovative quality. It does, admittedly, create two additional categories: implausible combinations (of job-requirement level, formal qualification and occupational status) as well as a ‘grey area’ (Hecker) or ‘mixed category’ (Plicht et al., 1994), in which the three indicators referred to above cannot clearly signal a match or mismatch, even though there is nothing recognisably inconsistent in the data reported by the respondent.

One problem with the measurement strategy is therefore that the scope of this new mixed category scarcely lends itself to evaluation in the framework of overqualification research. This disadvantage is more than offset, however, by a sharper distinction between adequate employment and overqualification.

The GSOEP does not ask directly whether a respondent’s job is commensurate with his or her training but merely asks about the requirements of the person’s job. The question ‘What type of training is normally required for the job you do?’ is accompanied by the following graded response categories: ‘No special training required’, ‘Only a short induction on the job’, ‘A lengthy period of coaching at my place of work’, ‘Attendance at special theoretical or practical courses’, ‘A certificate of vocational training’ and ‘A university or college degree’. It is permissible to choose more than one response. Pre-tests, however, have shown that multiple responses, which are in any case quite rare, almost invariably involve a combination of ‘A certificate of vocational training’ and ‘A lengthy period of coaching at my place of work’ or else the requirement category ‘Attendance at special theoretical or practical courses’ in conjunction with any of the other options. This means that we can record the most demanding reported requirement without sacrificing any very significant information.

By means of a comparison with the acquired formal vocational-training qualification, the degree of congruence between job and education can be directly determined; the disparity between the employee’s formal qualification and the job requirements – at least for people with the same category of formal qualification – can then be graded, i.e. assigned to one of a number of bands in a ‘skill spill’ scale. Since the pre-tests that were conducted as part of the data-verification process high-

---

63 To define the mixed category, we must first conduct pre-tests (which are not documented here), using group-specific occupational and income information.

64 A further residual category, created by the presence of a missing value in one of the three indicators required to generate the mismatch variables, is no different in methodological terms to an equivalent category based on a conventional two-variable approach but is made somewhat larger by the addition of the third variable. The information on occupational status is not regarded as sensitive data and is seldom posted as a missing value in the GSOEP.

65 In conjunction with the income distribution for each category and the structure of the job classifications in each category (on the basis of the three-digit ISCO codes), summaries were produced in advance for each of the requirement levels. These pre-tests revealed, for example, that the occupational and income structure for the two requirement levels 'A certificate of vocational training' and 'Attendance at special theoretical or practical training courses' are similar, in the same way as the structures for 'No special training required' and 'Only a short induction on the job' resemble each other. For that reason, each of these response pairs is bracketed together.

66 Following similarly structured pre-tests, the levels of formal qualification are aggregated. The certificate of vocational training, which is the general category for those workers whose qualifications are non-academic, covers those who are qualified master craftsmen, as is common practice; graduates of universities and colleges of higher technical education (Fachhochschulen) are also bracketed together in the customary manner, which reflects the fact that no distinction is made between these two levels of qualification on the job-requirement side.
lighted individual borderline cases straddling two categories as well as a number of inconsistencies, other particularly detailed information on the respondents' occupational status from the GSOEP survey is included in order to determine the mismatch variables.

The following categories are thus created: ‘(definitely) overqualified’, ‘degree of mismatch not clearly determinable’ (a mixed category which is wisely excluded as a rule from evaluations of job content), ‘(definite) congruence between job and education’, ‘implausible combination of the three generating variables’ and ‘at least one missing value among the three generating variables’ (an indeterminable degree of mismatch is also classed as a missing value).67

The use of separate classification models for western and eastern Germany takes account of the different educational certificates in the former East and West Germany.68 The classification model for western Germany with the combinations of job requirement, formal qualification and occupational status is documented in Table 0 of the annex; for the classification models for eastern Germany, see Büchel, 1998b, Tables 4.2 and 4.3, pp.189 ff.

Identifying underqualification

Occasionally, when analysing the job/qualification fit, besides examining the category of adequate employment and that of overqualification, researchers also study a second misfit category, namely that of underqualification (see for example Daly et al. (forthcoming)). Such a situation occurs when a respondent does a job for which he or she does not possess adequate formal qualifications. This mismatch phenomenon occurs in a few exceptional ‘rags-to-riches’ careers, such as that of a dishwasher who works his way up to become a millionaire, but it has to be discussed on the basis of completely different premises to those that underlie the discussion of overqualification (cf. Alpin et al., 1998, pp.19-20). The theory of career mobility, for example, can explain overqualification but not overemployment; Sicherman (1991, p.109) explicitly addresses this point.69 If researchers wish to examine mismatches in general, they must accordingly analyse and discuss the categories ‘overqualification’ and ‘underqualification’ in strict segregation. If, on the other hand, the emphasis is on the phenomenon of overqualification, as it is here, underqualification and adequate qualification can be lumped together fairly easily (for a similar approach, see for example Groot, 1993a, p.302, and Groot, 1996). In the following paragraphs, therefore, underqualified workers are assigned to the ‘adequate employment’ category; their common quality that interests us in the present context is the fact that they are identified as not being overqualified.

The degree of overqualification

The aforementioned grading scale for data (recoded into categories) on formal vocational qualification and job requirement can also be used to interpret and grade the newly created information on the discrepancy between these job and training levels. However, when the categorisation is subjected to further differentiation in this way, since the original variables were already highly aggregated, the resultant lack of sharp divisions between the categories demands a certain amount of caution from anyone who develops such a classification model or who subsequently interprets the findings it produces.

67 For a treatment of the relatively small percentages that fall into this category and into those of ‘implausible combinations’ and ‘missing values’, see Büchel and Weißhuhn, 1997a, Tables A2-W/O-84, -91 and -93, as well as Büchel and Weißhuhn, 1998, Table A2-W/O-95.

68 For the rationale behind this division, see Büchel, 1998b.

69 Moreover, in European countries such as Germany, where certified vocational qualifications are major determinants of career prospects – in contrast to the United States, for example – underqualification is of minimal empirical significance. The 7% or so of German employees (1984 figure) whose educational certificates would not normally qualify them to pursue their current occupation have an average shortfall of only 0.7 years of schooling; the average qualification surplus for overqualified workers in 1984, on the other hand, exceeded two years (see Daly et al., 1997, Table 1, p.27).
While the division into appropriate employment and overqualification on the basis of the described categorisation system has certainly passed the validity test (cf. point 6.1.2 above), this cannot be said unreservedly of the degree of overqualification. Although there is no doubting the validity of the graded structure, the volume of the various skill spills cannot be determined with sufficient accuracy. For that reason the graded structure has only been used to obtain information on the volume of skill spillage in particular descriptive evaluations where incidence figures have been high (see for example Büchel, 1998b, Tables 5.1 to 5.3, pp.192 ff.).

For more ambitious research designs, such as the one illustrated in the present section, it therefore seems advisable to accept some loss of information for the sake of a more valid categorisation system; this, indeed, is done in most empirical studies on overqualification. Thus, if the sample is classified into valid categories, the result will be a dummy variable — overqualified: yes/no — for all workers with a formal vocational qualification or a university degree acquired in Germany.

Validity checking

The overqualification variable obtained on the basis of the categorisation principle described in the preceding paragraphs must be externally and internally validated before being used empirically.

The external validation is based on the comparability of the volume of underqualification revealed by one’s own findings with the figures produced by other studies with different underlying research strategies.

The most comprehensive empirical study of the incidence of overqualification in Germany which is not based on the categorisation strategy described above is that of Plicht et al. (1994), although it only examines university graduates. The study involves a mixed category, which results in wide margins of error; within this framework it identifies graduate overqualification ranging from 8% to 17% (western Germany, 1991). The author of the present study, eliminating the mixed category, arrived at a value of about 14% (see Büchel, 1998b, Table 5.2, p.193), which is of the same order as Plicht, Schober and Schreyer, even though they not only use a different database but also pursue an entirely different approach, based on occupational categories.

In studies on overqualification among university graduates, which is the main focus of attention in the German discussion, percentages of under 10% to 15% (Tessaring, 1994a, p.49, Buttler and Tessaring, 1993, p.470, and Szydlik, 1996b, p.304) are identified, although no details are given on any part of the operations used to arrive at these percentages. The figure of 25% advanced by the Donors' Association for the Promotion of Science and the Humanities in Germany (Stifterverband für die Deutsche Wissenschaft, 1993, p.4) is surely overestimated and must be seen in the light of the general pessimistic tone of that publication. So if we exclude this last outlier, the external validation seems to have been generally successful.

For the purpose of internal validation, the validity of the construct used to distinguish between the characteristics of jobs done by appropriately qualified workers and those whose incumbents are overqualified is tested. If the categories really are sharply defined, considerable differences should emerge in terms of quality.

Irrespective of its theoretical derivation, the expectation that overqualified workers would be considerably worse off than adequately employed workers with similar formal qualifications is observably fulfilled in a highly refined examination of some 50 items in virtually all dimensions (Table 1 in the annex). The pattern of these findings leaves no room for doubt about the validity of the categorisation model.

6.1.3 The evaluation process

The empirical evaluations are based on the German Socio-Economic Panel (GSOEP — see point 6.1.1 above). West and East Germany are examined separately. The cross-section evaluations are based on the year 1995, while the longitudinal analyses use the period from
1984 to 1995. Specific details of the analytical methodology are contained in the various paragraphs on the interpretation of findings. The findings that are presented are largely derived from the multivariate analyses. For further descriptive information on the various stages in the evaluation process, the reader is referred to Büchel, 1998b. Overqualification is identified on the basis of the strategy described here in subsection 6.1.2.

Subsection 6.2 examines four subjective indicators that produce inferior values for jobless people compared with employees in the field of unemployment research, refining this strategy by applying a division into three categories — 'unemployment/hidden reserves', 'overqualification' and 'adequate employment'. Subsections 6.3 and 6.4 go on to analyse transition patterns into and out of overqualification. Finally, section 6.5 examines the dynamics of income loss resulting from overqualification; the second part of this evaluation focuses on a comparison between periods of unemployment and periods of overqualification.

6.2 Subjective indicators: differences between adequate employment, overqualification and unemployment

6.2.1 Problem-solving capacity

In order to measure possible deprivation in people's everyday lives, the questionnaire asks respondents to what extent they agree with a number of statements, one of which is 'Things have become so complicated that I can barely cope'. Although this question has a recognisable dynamic component, which relates to external (social) development, the response can also apply to transitions from a socially secure status, such as training or adequate employment, to overqualification or unemployment and therefore seems to be a very suitable means of shedding light on the issue under examination here. The responses 'fully agree' and 'tend to agree' with the aforementioned statement are interpreted as indicative of limited problem-solving capacity. A probit model is used to identify the determinants of this limited capacity, special attention being focused on the three relevant categories of employment status.71

The findings set out in Table 2 of the annex show that the overqualified respondents' assessment of their own problem-solving capacity, controlled for important socioeconomic variables, including the level of formal education, actually places their expected 'middle' position far closer to that of jobseekers than to adequately employed workers. Although their problem-solving capacity is higher, on average, than that of jobseekers, the difference is not significant. By contrast, there are significant differentials between matched and mismatched employees. This finding is observable for both West and East Germany.

6.2.2 Morale

A person's awareness of a shortage or absence of demand in the labour market for his or her acquired vocational skills and qualifications will probably have an adverse effect on that person's morale, since the vast majority of people, or at least of those who wish to be economically active, place employment high on their list of priorities. For the purposes of the study, the sample is divided into those whose morale is high and others. In accordance with a strategy commonly used by the GSOEP to evaluate morale, based on an empirical distribution of responses on an eleven-point scale (0-10), people who rate themselves at points 8, 9 and 10 on the scale are defined as having high morale.72

71 The same type of econometric model is adopted in points 6.2.2 to 6.2.4 below.

72 American researchers occasionally display less sensitivity in their choice of evaluation model. Hersch (1991), for example, evaluates her satisfaction scale, which is graded in the same way as the GSOEP model, on the basis of a regression equation.
The following may be deduced from the findings set out in Table 3 of the annex: both in West and East Germany, overqualified workers report not only significantly higher morale than jobseekers but also significantly lower morale than those workers whose jobs match their qualification levels. Whereas the overqualified workers are roughly equidistant from the other two categories on the satisfaction scale for East Germany, the morale of overqualified workers in West Germany is far closer to that of adequately employed workers than to that of jobseekers.

6.2.3 People's concern about their own economic prospects

In order to measure the respondents' assessment of their own prospects for the future, the questionnaire asks whether they are worried about a number of things, one of which is their own economic situation. The responses 'very worried' and 'rather worried' are interpreted as pessimistic assessments of the respondents' own economic prospects.

The findings are set out in Table 4 of the annex. Both in West and East Germany, overqualified workers are significantly more optimistic about their expected economic development than jobseekers but significantly more pessimistic than workers with well-matched jobs. One interesting point is that the same pattern emerges as was observed for morale, with equal spacing between the middle category and each of the other two for East Germany, whereas overqualified workers in West Germany are distinctly closer to adequately employed workers than to jobseekers in their assessment of their own economic prospects.

6.2.4 Political involvement

An important observation in the domain of political science is that unemployed persons are liable to turn their backs on the world of politics because they feel betrayed (the 'political apathy' hypothesis; see Büchel and Falter, 1994). This is liable to lead to impaired functioning of the democratic system. Besides voting in elections, allegiance to a political party is regarded as an effective indicator of the extent of a person's political involvement. The purpose of these paragraphs is to extend the conventional examination of the connection between employment status and party allegiance to the category of unemployed workers.

The findings documented in Table 5 of the annex show that, controlling for major socio-economic characteristics, the identification of jobseekers with the party system does not differ significantly from that of overqualified workers. The latter, however, demonstrate significantly less party allegiance than workers with good job/qualification matches.

All in all, the findings of section 6.2 confirm the hypothesis that the redundancy of an individual's marketable skills does not only have an adverse effect on his or her social well-being in the case of total redundancy (i.e. unemployment). Even partial redundancy of a person's skills, as happens in the event of overqualification, results in a diminished - and sometimes drastically diminished - quality of life compared with that enjoyed by employees whose jobs are commensurate with their qualifications. While overqualified workers are significantly better placed than jobseekers and significantly worse off than their adequately employed counterparts in terms of morale and perception of their own economic prospects, once the relevant data has been controlled for important socio-economic characteristics, when it comes to their ability to cope with everyday life (at least for the time being) and their allegiance to political parties, however, overqualified workers demonstrate attitudes that are not far removed from those displayed by jobseekers, whereas people whose jobs fit their qualifications tend to be significantly closer to the 'social norm' in these respects.

6.3 Transition to inadequate employment

6.3.1 Preliminary remarks on the dynamics of individual overqualification

Following the presentation of the static perspective in the previous subsection (for a wider range of analyses see Büchel, 1998b),
the following paragraphs deal with the dynamics of changes of employment status at an individual level. Although in the medium term the percentage of overqualified employees in the German labour force has remained fairly stable (see Büchel and Weißhuhn, 1997a and 1998), we cannot rule out the possibility that, as with the phenomenon of unemployment, this overall picture of stability conceals a great deal of movement in and out of overqualification in the course of individual careers (cf. Groot and Maassen van den Brink, 1995, p.14).

Accordingly, the approaches adopted here are based on the longitudinal analyses that characterise modern unemployment research. This means that interest focuses on the phenomena of movements into and out of overqualification, which have seldom been dealt with in research literature, as well as on income effects of overqualification. The main points of interest are transfers in both directions between overqualification and the other main categories of employment status, namely work commensurate with qualifications, unemployment, other economic inactivity and full-time training. The main transition patterns are examined below.\(^{73}\) When choosing suitable evaluation procedures, we have to remember that the information on job/training congruence is only available for one point in the year, in other words the time of the survey. Since some of the observation periods are very short (1991 to 1995 for the area of the former East Germany, as against 1984 to 1995 for western Germany), the use of hazard-rate models, which is actually the best way to proceed when dealing with this sort of question, would be ill-advised, even for discrete modelling. The use of the panel approach to process the relevant data is also out of the question at almost every stage of the evaluation, since the observed changes of employment status will normally occur only once, if at all, for each person during the examination period. Accordingly, models that control for unobserved heterogeneity would exclude most transitions from the examination, since observations with only one occurrence do not serve any explanatory purpose in this type of model. For that reason, the research designs of the various stages in the evaluation process must be conceived in such a way that the analysis can be performed with conventional probit or regression models.

Our first step is to examine the process whereby individuals become overqualified. This transition is identified when a respondent reports overqualification in a questionnaire after having reported a different employment status the previous year. These situations from which individuals enter into overqualification are the focal point of the present subsection.

### 6.3.2 Descriptive findings

Table 6 in the annex shows the types of employment status previously held by overqualified workers, broken down into percentage columns by regional labour market, qualification level and sex.

An examination of the totals column shows that the most common previous status of overqualified workers in both East and West Germany is that of adequate employment (just over 40% in each case). Outdated expertise and declining productive capacity may be mooted as reasons for this.\(^{74}\) This transition pattern is far more characteristic of men than women, reaching a peak for highly qualified male workers in the former East Germany; this reflects a systematic downgrading process as part of the hierarchical 'cleansing' operation in the period following reunification. Nevertheless, this seems to refute the oft-repeated hypothesis that overqualification is chiefly a problem for married women who interrupt their careers for family reasons, with the result that their skills become rusty through lack of practice, leaving them no op-

\(^{73}\) For more findings see Büchel, 1998b.

\(^{74}\) See the analyses, broken down by age group, in Büchel and Weißhuhn, 1997a and 1998, which demonstrate a considerably higher percentage of overqualified employees in the oldest age bracket, especially among non-graduates in western Germany.
tion but to re-enter working life at a level for which they are overqualified; while this explains some overqualification, it is clearly not the only explanation.

In western Germany, almost a quarter of those who take up underskilled work are unemployed jobseekers. In the East, this percentage is considerably higher, with some 40% of overqualified recruits having been unemployed the year before. This demonstrates the nature of overqualification as an alternative to unemployed status; even though private placement services for unemployed people are gradually gaining in importance, this sizeable movement of labour from unemployment into overqualification is due not least to the restriction by the national employment authority of the jobseeker’s right to refuse job offers. The findings also testify to an abundance of flexibility on the part of jobseekers. They also reveal striking differences between regions and between levels of formal qualification; for example, underskilled jobs are a very important source of employment for East German workers with mid-range qualifications, whereas for West German graduates, especially males, overqualification has far less empirical significance.

‘Spontaneous’ transitions from economic inactivity to overqualification by people who are not actively seeking work (i.e. who are not registered as unemployed) are only made to any great extent by West German women with mid-range qualifications. West German women graduates lag far behind in second place. Among West German men and East Germans in general, this form of transition has only marginal significance.

Approximately one in eight people take up an underskilled job on completion of a training course. This is the case in both western and eastern Germany. This type of transition has become disturbingly common among West German graduates, both male and female. More than one in four West German graduates working overqualified took up his underskilled job immediately after obtaining their degrees; this situation is somewhat less common in eastern Germany and applies primarily to highly qualified women.

### 6.3.3 Multivariate findings

The reference category for our multivariate analysis was the length of time spent in one of the other types of employment status besides overqualification. The multivariate analysis of the descriptively acquired findings (Table 7 in the annex) produces a surprising picture in terms of the previous employment status of overqualified workers. Our first task, however, is to discuss the findings in relation to the control variables.

Clearly different behaviour patterns emerge for transitions to overqualification in eastern and western Germany.

In western Germany, first of all, more women than men take jobs for which they are overqualified. Reasons for this may be less employment-centred training courses, lower priority attached to careers, periods of economic inactivity for family reasons with the accompanying depreciation of human capital, etc. (see below). Older employees are seldom observed to make such a switch. It may be expected that, on losing jobs commensurate with their qualifications, for example, older employees may be more inclined to take advantage of early-retirement packages than to ‘struggle through’ to retirement in an underskilled job.

Transitions to overqualification are more frequently observed among individuals with poor school records than among those with better school qualifications. Training in a technical college (Fachschule), which has traditionally been employment-based, affords protection against overqualification, as does civil-service training, which is normally followed by appointment to an appropriate post in one of the public authorities. Individuals who have successfully completed an apprenticeship are also less liable to become overqualified than those who have undergone other forms of vocational training.

A surprising result emerges for graduates of higher technical colleges (Fachhochschulen), who are observed to be more prone to overqualification than holders of apprenticeship certificates. Respondents who attach low
priority to a successful career are also over-represented among the newly overqualified; the undemanding nature of their jobs corresponds to their own level of demand for professional success.

As the regional unemployment rate rises, the probability of a transition to overqualification is reduced. There are two conceivable ways of explaining this: either unskilled and semi-skilled jobs are disproportionately rare in a tight job market or else individuals who cannot obtain an appropriate job are more inclined simply to register as unemployed, the social stigma of unemployment being diminished as the local jobless rate increases.

In the territory of the former East Germany, the control variables exert an influence in several different ways. Besides older employees, those in the youngest age bracket also move into overqualification less frequently, which means that transitions into overqualification are typically made by workers in the middle age groups. While there are no gender-specific differences of the sort that exist in western Germany, people who only have the certificate awarded on the successful completion of eight years' schooling are also more likely to be overqualified. Another conspicuous feature is the over-representation of highly qualified employees, who were the victims of large-scale systematic downgrading. The reason given for this measure by employers is the discrepancy between the high level of employees' formal qualifications, which often depended on a certain degree of identification with the former Communist system, and the actual market value of these qualifications in a competitive economy. In eastern Germany too, transitions to overqualification tend to occur more frequently in areas with relatively low rates of unemployment. Moreover, such transitions are more common in rural than in urban areas, in contrast to the older federal states.

As for the previous employment status of overqualified workers, once the quite heterogeneous descriptive findings have been controlled for important socioeconomic characteristics, surprisingly similar structures emerge for eastern and western Germany. Compared with a transition from appropriate employment - the reference category - a switch from unemployment or the hidden labour reserve is a far more frequent occurrence. Direct transitions from training are also significantly more common than those from appropriate employment, albeit by a somewhat narrower margin. In the west of Germany, moreover, even transitions from other forms of economic inactivity happen more often than transitions from a matched to a mismatched job; in the eastern part of the country, however, other forms of economic inactivity play an insignificant role as a source of overqualified labour.

This shows that the descriptively identified 'typical' switch from a well-matched job to a mismatch correlates highly with major socioeconomic characteristics. Controlling for these, we see that this form of transition is actually rather untypical. Hence, overqualification in Germany does not primarily take the form of worker dequalification, for example in the wake of rapid technological change, with the accompanying devaluation of knowledge and skills; on the contrary, underskilled jobs tend to be accepted by those who are economically inactive in whatever form. The motives, which are surely many and varied, for taking such jobs are still uncertain at this stage of the analysis, but more precise information on these will emerge on further examination.

6.4 Selected transitions from overqualification

Our second step involved an examination of the process whereby individuals cease to be overqualified. Here too, the various forms of employment status that were discussed in connection with transitions to overqualification were the main focus of attention. Particular importance attached to the question whether overqualified workers manage to step up into jobs that are commensurate with their training or whether they are more likely to slip down into unemployment.

Descriptive findings

The findings presented in Table 8 of the appendix reveal considerable differences between eastern and western Germany.
The most commonly used exit door from overqualification in western Germany leads to appropriate employment. A conspicuously high number of male graduates make that transition. While this can be used as an indicator of the capacity of the career mobility theory to explain overqualification, it is not evidence in itself, since we are only looking here at those who move away from underskilled jobs, not at those who remain in them.

A very similar pattern emerges, albeit at a lower level, in eastern Germany, but this time the main exit route leads to involuntary economic inactivity, i.e. unemployment or a place in the hidden reserve of labour. This type of transition mainly affects people with mid-range qualifications as well as women with higher levels of qualification. In the west of Germany this downward transition is mainly observable among men with vocational diplomas; it hardly ever affects male graduates and seldom happens to female graduates.

There is also a wide East/West disparity in the case of transitions into voluntary economic inactivity. In western Germany, this transition is typically made by women who give up overqualified work. Irrespective of their level of qualification, some 40% of women who give up underskilled jobs move into voluntary economic inactivity. In eastern Germany, however, this type of transition is not very significant. Percentages vary little among the compared groups, reaching a peak of 10%.

A switch to full-time training is not a characteristic move for those who give up inadequate employment. Neither in the East nor in the West of Germany does this figure reach 10%. Whereas in eastern Germany women are more likely to make such a move, whereas in the West German labour market this transition is chiefly made by men, with holders of academic degrees more frequently being given the opportunity for full-time training (presumably in the form of a second degree course or professional training) than holders of vocational diplomas.

The following paragraphs will take a closer look at transitions from overqualification to the two types of status that are of most interest to us in the context of this study, namely unemployment and adequate employment. For more detailed analyses, see Büchel, 1998b.

6.4.1 Transition to unemployment

At this juncture a two-step evaluation was undertaken with a view to answering the following questions:

a) Do people in underskilled jobs run a greater risk of unemployment than those in appropriate jobs?

b) Does the acceptance of an underskilled job protect people who have lost an appropriate job from subsequent unemployment? Or, to put it another way, does overqualification offer such people a genuine alternative to unemployment in the longer term?

Transition to unemployment from inadequate or adequate employment

The aim here was to examine whether adequate employment affords better protection than overqualification against the risk of unemployment. In the model that was used, the alternative to a transition to unemployment was continued overqualification.

The findings set out in Table 9 of the annex reveal considerable differences between western and eastern Germany in terms of the risk of losing a job and becoming unemployed. They do concur, however, on one key point, namely that this risk is significantly higher for employees in underskilled jobs than for those whose jobs match their qualifications. The respective risk levels for these two groups diverge more widely in the East than in the West of Germany.

Transition from adequate employment to unemployment – directly or via overqualification

We wished to test whether the acceptance of an underskilled post by a person who had lost a job commensurate with his or her skills and qualifications was likely to protect that person against subsequent unemployment. To
paraphrase the question, we want to know whether overqualification is a genuine alternative to unemployment or whether it is liable only to postpone a descent into unemployment. Those people who remained in adequate employment over the observation period served as the reference category.

What the findings in Table 10 of the annex demonstrate is that people who take an underskilled job on losing an adequate job considerably reduce the risk of subsequent unemployment, particularly in western Germany. This may be deemed to indicate that acceptance of an underskilled job is a deliberate choice on the part of many people as an alternative to unemployment.

6.4.2 Transition to adequate employment

At this point a two-step evaluation was undertaken with a view to answering the following questions:

a) Are individuals more likely to obtain a job commensurate with their qualifications if they are overqualified or if they are unemployed?

b) Does an interim phase of overqualification make it easier for jobseekers to find a post that matches their qualifications?

Transition to adequate employment from overqualification or unemployment

The purpose of this stage in the evaluation process was to establish whether the fact that overqualified people already have one foot in the labour market gives them an advantage over their unemployed counterparts in the quest for adequate employment, assuming they are in competition for the same jobs. People who are economically inactive but not registered as unemployed or in the hidden reserve, or who have just completed a course of training were excluded from this evaluation. For unemployed jobseekers and overqualified workers together, we examined the probability of transition to adequate employment. The reference category comprised those who retained one status—unemployment or overqualification—throughout the observation period. Our primary interest was to discover whether and how a person’s original status influenced his or her chances of making the transition to adequate employment. The findings are presented in Table 11 of the annex.

Overqualified workers find adequate jobs less frequently than unemployed jobseekers. The same pattern applies in both parts of Germany. It does not seem easy to interpret these findings. It is conceivable that people in underskilled jobs are under less pressure to find appropriate jobs than those with no job at all, since the job they have, inadequate though it may be, probably provides them with an income above that of unemployed jobseekers. Moreover, as has been shown, the category of overqualified workers includes some people who attach low priority to a successful career; it is conceivable that such people may not be looking for a job that is more commensurate with their qualifications or at least that their efforts to find a better job may be less than wholehearted.

To put it simplistically, it may be said of unemployed jobseekers that their status tends to ‘testify’ to a disinclination to accept any old job—including, of course, underskilled jobs; it is therefore safe to assume a high degree of probability that their job search will be confined to educationally adequate employment, at least in the initial stages. What certainly emerges is that, when employers have job vacancies, they do not seem to let their choice of candidate be governed to any great extent by the stigmatisation effect of unemployment or by the positive signal of willingness to work ‘at all costs’ that is transmitted by applicants who are overqualified for their current jobs.

Transition from unemployment to adequate employment—directly or via overqualification

The next step was to undertake a more specific examination of the findings described in the previous paragraphs. To this end, jobseekers were studied with a view to ascertain-
ing whether they managed to find educationally adequate employment within a particular period – five years for western Germany and three years for the territory of the former East Germany. This means that transition patterns could be compared between the two parts of Germany but not the frequency of transitions. The question at the forefront of this examination was whether a transitional phase of overqualification is liable to serve as a ‘bridgehead’, in other words whether it helps jobseekers to gain a foothold in the labour market from where it is easier for them to move upmarket into the sort of job for which they are qualified (for a more general treatment of this question, see Büchel, 1994a).

The findings set out in Table 12 of the annex suggest that, if adequate employment is assumed to be the ultimate aim of a job search, a temporary ‘makeshift’ transition to overqualification tends, in both the East and the West of Germany, to be a ‘dead end’. The dimensions of the estimated parameters indicate that a high volume of state dependence ensues from this situation.

6.5 Income effects of overqualification

There is already sufficient statistical evidence that overqualified workers earn lower incomes than workers with equivalent qualifications whose jobs match those qualifications (see section 4 above), and this point need not be analysed any further here. What this subsection examines is the extent to which income growth differs between overqualified and appropriately employed workers.

6.5.1 Income growth among people who are initially overqualified

The first step was to compare the respondents’ first reported income in the observation period (broken down by degree of job/training match) with their last reported income; in the case of the latter figure, the match/mismatch question was no longer relevant, because the analysis took account of any upward mobility from underskilled jobs.

In the evaluation, the initial amount of income was taken into consideration so that we could control for the fact that the lowest earners automatically stand a better chance of improving their income levels. The ratio of the last to the first reported income was selected as the dependent variable; these values were plotted on a logarithmic scale to adapt them to the model. Given the nature of the dependent variables, extraneous control for the length of the observation period was also required. In the vast majority of cases, the duration of this period equalled the number of years spent in employment. To control for untypical career histories, intervening periods of unemployment and other forms of economic inactivity were taken into account as additional covariates, as were any years missing from the panel records.

The findings set forth in Table 13 of the annex present a very similar picture for eastern and western Germany in terms of the effect of adequate employment at the start of the observation period. Controlling for the initial income level, we see that the income curve for overqualified workers rises less steeply than for workers whose jobs match their training levels. So the former not only have to endure an income shortfall at any given time in respect of their unused skills and qualifications (see the literature cited in section 4 above or, for Germany, Büchel, 1998b, Table 5.30, p.238, for example); in addition, the gap between their earning power and that of their adequately employed colleagues widens with length of service.

6.5.2 Erosion of human capital through overqualification

The second step involved examining whether a period of overqualification has the same sort of effect in terms of depreciation of human capital as a phase of voluntary or involuntary economic inactivity. This hypothesised affinity is based on the fact that 100% of a person’s acquired human capital lies dormant during a phase of economic inactivity, while x% of it lies dormant during a phase of

76 In this context, ‘number of years’ means the number of annual surveys in which a particular employment status was reported.
Overqualification, $x$ being situated somewhere between 0 and 100. Accordingly, the rate of skill depreciation resulting from overqualification must lie somewhere between the depreciation rate for an economically inactive person and the rate for a person in adequate employment.

Clearly, this hypothesis can only be tested if figures for initial and final income from adequate employment are available and if a phase of overqualification is identifiable at some time between the beginning and end of the observation period. In order to permit a direct comparison with the standard reference value, i.e. a period of unemployment, people with a history of adequate employment followed by a period of unemployment or a period in the hidden labour reserve then another period of adequate employment were included in the analysis. As in the previous step, the reported data were controlled for intervening years of voluntary economic inactivity and for any years that were missing from the panel records.

The findings presented in Table 14 of the annex confirm the aforementioned hypothesis, at least for western Germany. In both parts of Germany, periods of overqualification sandwiched between periods of adequate employment adversely affect income growth. In the West, as expected, the depreciation rate is lower than that for voluntary inactivity (100% absence of training in occupational skills), which in turn is lower than the depreciation rate for unemployed jobseekers (100% non-use of skills plus additional downward pressure on wage demands). This accords with the expectations of the human-capital theory and may also be regarded as tending to confirm the typological affinity between overqualification and unemployment that was postulated in the introduction to the present study.

The unexpected findings for eastern Germany have to be interpreted in the light of the particular situation that still obtains in the labour market there.

### 7. Conclusions

#### 7.1 Methodological consequences for employment researchers

Conventional employment research, with its fixation on unemployment, underestimates the volume of skills and qualifications which education systems produce but for which there is no demand in the labour market. By including the hidden reserve of labour in analyses of this type, employment researchers have already taken one major step towards more effective assessment of the efficiency of education systems and of the coordination problem between education systems and labour markets. The purpose of the present study has been to highlight the apparent indispensability of another step, namely consideration of overqualification as an additional category in its own right.

While the category of the hidden reserve has now found its way into official and semi-official statistics and has secured a permanent place alongside registered unemployment (see for example OECD, 1995b, pp.45 ff.), either the overqualified percentage of the labour force is tacitly omitted (as in the official German employment statistics) or its omission is ascribed to unresolved measurement problems: 'Invisible underemployment [i.e. the percentage of the labour force who are overqualified for their jobs] ... by its very nature is difficult to measure. For this reason, it is not discussed' (OECD, 1995b, p.45).

A first attempt to close this unsatisfactory information gap was made by the German Ministry of Education, Science, Research and Technology, which began to commission biennial standardised reports on the extent and structure of overqualification in Germany (see Büchel and Weißhuhn, 1997a and 1998).

---

77 The unexpected findings for eastern Germany have to be interpreted in the light of the particular situation that still obtains in the labour market there.

78 In this context, however, employment researchers usually disregard the phenomenon of 'visible underemployment', i.e. the fact that numerous employees would like to work longer hours (see OECD, 1995a, p.45). This is another situation in which people are prevented from capitalising fully on their skills and qualifications.
The measurement strategy used in these reports, however, relates closely to the specific characteristics of the German education system and cannot answer Rumberger’s call for the development of an internationally comparable indicator (Rumberger, 1994, p.281). Given the wide diversity of national education systems, more could surely be achieved with measurement strategies (less precise though they would necessarily be) which were based on training duration and could therefore be integrated into an extended human-capital approach of the type described in Duncan and Hoffmann (1981).

The extensive omission of the phenomenon of overqualification from European employment research creates problems, some of which are critical, with regard to the validity of the applied examination method. This is especially conspicuous in research into the demand for skills and qualifications.

The problem lies in the almost universal practice of implicitly equating the level of skill required for a job with the formal qualification of the incumbent. A typical statement appears, for example, in iwd (1997): ‘Low-skilled workers are the great losers of structural change. Many unskilled and semi-skilled jobs in industry have already gone’ (p.6). This assimilation would only be valid if overqualification did not exist in the labour market. As long as it does exist – as it does in every industrialised nation of the Western world – and as long as the incidence of overqualification exceeds that of underqualification, there will be more unskilled jobs than unskilled workers. Disregarding this fact can lead to various miscalculations, for instance to overestimation of the dynamics of structural change and the accompanying loss of unskilled jobs. Likewise, the job prospects for unskilled and semi-skilled workers will be systematically presented in an excessively gloomy light. It must be remembered that, alongside unskilled and semi-skilled workers, there are also overqualified workers in semi-skilled and unskilled jobs; the total number of all these workers represents the actual number of unskilled and semi-skilled jobs in the labour market (and the economic demand for such jobs). At the same time, the demand for higher qualifications is systematically overestimated. Certainly the demand for overqualified workers proves that employers expect an overqualified worker to outperform an adequately qualified worker in an equivalent job. The fulfilment of this expectation can be demonstrated empirically (Büchel, 1999a). Nevertheless, it remains undisputed that, where two workers have the same qualifications, the one whose job matches those qualifications will normally be more productive than the one who is formally overqualified for his job.

Although it may be the case that technological progress and the accompanying structural change are raising the average skill level required for jobs in the European market, if the level of demand is deduced on the basis of employees’ formal qualifications, the education boom and the subsequent rise in the average educational attainment level of the labour force will inevitably be the source of misinterpretations unless due account is taken of overqualification. Many different sources of error affecting the accuracy of the predicted demand for labour were quickly recognised and discussed (see for example Tessaring, 1982, or, for a more general treatment, Mertens, 1982, pp.145ff. and pp.563 ff.). However, the serious prediction problems arising from the implicit assimilation of formal qualification and job requirement, problems with consequences for educational planning that must not be underestimated, especially in the domain of higher education, are still only being explicitly discussed in isolated studies (see Adamy and Bosch, 1990, p.118, von Henninges, 1996, p.78, and Weißhuhn 1996, p.86).

Conventional forecasts of educational requirements, i.e. predictions based on the ex post development of the labour force’s formal qualification structure and extrapolating future needs on that basis (see Tessaring, 1994b, Weißhuhn, 1996, and Weißhuhn et al, 1994) plainly cannot do enough to satisfy the need of prospective students and trainees for information on their future employment prospects. One alternative is the production of studies on the fate of graduates in each institution, broken down by disciplines. At least in the academic
field, the authors of these studies are gradually moving away from the practice of assessing educational success on the sole basis of the ‘employed/unemployed’ dichotomy and are giving increasing consideration to the quality of the jobs that employees do.

The body of literature on this subject, however, is still far from providing reliable and comprehensive information for prospective students and trainees, even though researchers did not take long to start thinking about strategies for the provision of such information (see Chaberny and Schober, 1982). There is no comprehensive reporting system on all possible training courses at every educational institution in Europe, nor are there any studies on the fate of graduates in the longer term or standardised measurement systems, without which the opportunities and risks of different training courses cannot be compared, while there is also a fairly general lack of academic quality among the few studies that are available at the present time (cf. point 5.2.2 above).

Moreover, even with the present research design, as in the case of conventional educational needs forecasts, it is only possible to draw reliable conclusions for the future from the past if the basic conditions remain constant in the medium term. The prospects of finding a job with a particular qualification are certainly a good example of the sort of information that cannot normally be provided because of changes in these basic conditions. Prospective students and trainees would generally be well advised to choose their courses on the basis of their intrinsic interests than to be guided by predicted labour requirements or the findings of studies on the employment status of previous graduates. Be that as it may, it is still a fact that demand predictions which do not address the problem of overqualification are plagued with an even greater degree of uncertainty than those which are adjusted for overqualification.

On the basis of a few classic questions from the field of unemployment research, the present study has shown that the phenomenon of overqualification, because of its typological affinity with unemployment, can be analysed effectively with the instruments of unemployment research. However, the quantitative evaluation of the representative data sets that are currently available in the field of employment research reaches its limits when it comes to examining precisely what induces employees and employers to consent to overqualification; the present study could only provide some initial leads. A qualitative approach emerged here as an effective means of evaluating the motivation of employees.

The findings of the only studies in which this type of approach was adopted (Schlegelmilch, 1982, 1983a, 1983b and 1987) cannot be generalised because they are restricted to one level of qualification and because their sample is unrepresentative and too small. None the less, the approach displays an interesting analytical thrust, which is able to offer insights that cannot be gleaned from the findings of conventional analyses; this makes it a suitable medium for imparting fresh momentum to quantitative research based on representative data by broadening the scope of surveys to include aspects such as the intrinsic motivation of people to do jobs for which they are overqualified. A first movement in this direction is made in Büchel, 1998b.

With regard to closer investigation of employers’ motivation to recruit overqualified job applicants, Haugrund (1990) has been the only author so far to highlight this specific research angle. However, the fact that his survey was limited to a few firms in a single industry and only examines technical staff with fairly high skill levels means that his findings are not amenable to generalisation either. More comprehensive future studies with a broader database, designed to follow up this preliminary work, could deliver important new information.

7.2 Implications for education and employment policies

7.2.1 Implications for education policy

The findings of this study give rise to different postulates for the domains of vocational education and higher education, because these two parts of the education system normally have widely different funding struc-
tures. The German Duales System of alternating practical and theoretical vocational training of apprentices is discussed in somewhat greater detail here, because it is often presented as a model system by numerous public policymakers in the field of vocational training in other European countries.

**Dual vocational training**

In relation to the German dual system, Neubäumer (1993) found that those industries which experience difficulties in recruiting skilled workers tend to train in excess of their needs. These are generally industries with largely unattractive and undemanding jobs. Many of the trainees who are surplus to requirements have no option but to move to underskilled jobs.

The findings of a study by the present author (Büchel, 1998b) confirm this effect, whereby individuals who have completed the basic level of secondary education and possess a certificate of apprenticeship run a disproportionately high risk of overqualification. This shows that the quality of training in the German dual system is far from being as uniform as the advocates of this very characteristically German system of vocational training frequently assert and as might be suggested by the annual discussion that takes place in late summer regarding the situation in the apprenticeship market, a discussion which tends to focus exclusively on the number of training places available and the demand for those places.

The same findings prove, as did those previously obtained by Hofbauer and Nagel (1987), for example, that the volume of skills and qualifications which the system produces but which the labour market does not use has assumed menacing proportions, whether this means that the jobs to which those skills and qualifications relate are insufficiently attractive or that there are simply no suitable jobs available. There is a need to identify the reasons for this inefficiency of the dual system and to seek ways of improving it.

First of all, the perennial criticism of excessive specialisation in the vocational-training system, reflected in a huge number of distinct trades, remains valid today. This specialisation makes it more difficult for individuals to use their acquired skills if they subsequently have to work outside the trade they have learned. It would make better sense if emphasis were placed on imparting selected key skills, which should certainly be relevant to groups of specific occupations; specialisation should be delayed until trainees have begun their careers, when the knowledge and skills required for the performance of specific tasks should be imparted through on-the-job training, as is done in the United States. This point has now been taken on board by education policymakers and initial moves have been made in the postulated direction.

In addition, training courses which are out of date and for which there is consequently little or no market demand should be discontinued, and at the same time courses should be developed in new marketable fields of activity. This process currently takes too long, not least because of the strictly regulated procedures and the large number of interest groups involved in decision-making. These problems are now the subject of critical discussion in Germany, and some very promising proposals have already emerged.

Another strategy focuses on the improvement of the existing information system regarding the marketability of the various training courses. The information provided by careers advice centres is all too frequently confined to a description of training curricula with no details of career prospects. The latter information should be provided before prospective trainees choose their courses. Hofbauer and Nagel (1987) recommend that advice should be available from the employment authorities in the final year of technical college (p.45), but this is clearly the wrong time. By then the fatal chain of events depicted by Neubäumer (1993) has already been set in motion; apprentices training for problem occupations realise too late that they have made the wrong choice.

If the information situation were improved, not only in terms of training curricula but also in terms of subsequent career opportunities,
in accordance with the strategy presented by Chaberny and Schober (1982), this would alter the training decisions of school-leavers, thereby influencing the content and quality of employers' training programmes and of the trainees' subsequent jobs. It must be borne in mind, however, that the effectiveness of such a strategy will diminish as the process of change on the demand side of the labour market gathers momentum.

The emphasis in the present study is on overqualification among non-graduates. However, the implications for this level of qualification cannot be identified in isolation, not least because the general public and the academic world closely associate mismatches in the labour market with overqualified university graduates. For this reason, the following paragraphs deal briefly with the implications of the overqualification problem for higher-education policy.

**Higher education**

In the domain of higher education, as in the dual system of vocational education and training, the risk of overqualification is observably dependent on the profession for which the student is training or the discipline he or she is studying (see for example Büchel and Matiaske, 1996, and Alpin et al., 1998). Although in Germany university graduates in general run a somewhat lower risk of overqualification than holders of vocational diplomas, for example, once the data have been controlled for the main personal characteristics the differences become insignificant. Indeed, graduates of higher technical colleges (Fachhochschulen) – again after controlling for personal characteristics – are significantly more prone to overqualification than holders of vocational diplomas (Büchel 1998b, Table 5.8, p.204). There is also evidence to suggest that the problem of overqualification will become more acute for German graduates – especially women graduates – in the future (see Büchel and Weißhuhn, 1997a and 1998, as well as Büchel, 1996a).

The overqualification situation described in this study gives rise to certain postulates with regard to education policy, but these cannot be formulated without reference to the specific discussion on graduate overqualification. The problems reflected in the findings that have been obtained are subject to widely varying interpretations, depending on the observer's perspective. Nevertheless, the question arises, at least in economic terms, as to whether the skills demanded by the labour market could not be provided by the education system with less effort and at less expense. This question sheds light on three of the main reasons for the present glut of academic qualifications.

First of all, the fact that higher education in the vast majority of European countries is largely funded from the public purse creates profound external effects. The excessive cheapness of university study by market standards systematically produces a surplus of qualifications; the introduction of tuition fees, which are of mere symbolic value when compared with the actual cost of university education, will do little to change this.

Secondly, an academic degree may be regarded as the most valuable formal qualification. According to the postulates underlying the job-competition model, it places graduates quite near the front of the labour queue. This sort of position remains sought after, even when the returns to education and employment prospects in general decline, for example because of a glut of academic qualifications or a drop in the standard of university education. The desire to secure the highest possible educational qualification in a discipline selected on the basis of personal preference therefore remains rational from an individual point of view, even in a climate of deteriorating career prospects (for a detailed treatment of this aspect, see Zwick (forthcoming)); the fact that the aggregate macro-economic effect of such a strategy may be to reduce the general level of well-being is unlikely to have any bearing on the educational decisions that individuals make.79

79 On the competing aims of the manpower-requirement approach and the social-demand approach, see Kühlewind and Tessaring, 1975.
Thirdly, the positive signal that is emitted by the highest vocational qualification is also very desirable in terms of a person’s social profile, irrespective of employment status, and this also stimulates demand.

Demand for the top educational qualifications may therefore be expected to keep on rising as long as the educational attainment seems to be ‘cheap’ in terms of the required personal effort and financial outlay. This raises the question as to how education policy can be used to combat the resultant excess demand for academic qualifications which is gradually leading more and more university graduates into overqualification.

A restrictive policy could begin with the introduction of tuition fees at market rates. These fees, however, would have to be based on the actual cost of training, unlike the models that are most often discussed at the present time. In terms of market economics, there is no logical reason why the same fee should be payable for a (cheap) law course as for a course in medicine, for example. In addition, the intended effect of reducing the level of demand for education can only be achieved in conjunction with an absolute repayment obligation which must apply irrespective of subsequent career success, although provision would certainly have to be made for a mechanism designed to avoid social hardship. The overall effect of such linkage between the demand for education and self-financing would be to reduce the size of the group of overqualified employees who report that a successful career ‘is not so important’.

This, however, raises the problem of the social acceptability of tuition fees at market rates, which, as the current public discussion has shown, is a tough nut to crack. A more realistic means of restricting the demand for education would seem to be a reform of the university course and examination regulations based on the modular acquisition of certificates (for a discussion of this option in the German context, see Büchel and Helberger, 1995).

As in the domain of non-graduate employment, the proposed academic reforms would have to be accompanied by a further improve-
likely to prove more effective. These measures are generally targeted at unemployed jobseekers at the present time. As part of the process of reducing the specialised component of curricula in the field of non-academic vocational training, consideration should be given to the possibility of extending such measures to overqualified workers and to devising some means of dividing the cost between employers and the government. Emphasis should be placed on training in a marketable job, in other words within the framework of a proper employment contract. While the current widespread implementation of job-creation schemes in Germany fulfils an important social function at the present time, when there is no suitable alternative, it does distort the market and means, for example, that the findings of conventional market studies, which are based on employees’ qualification levels and do not differentiate between workers on job-creation schemes and those in regular employment, send erroneous signals to the education system about the utility of the certificates it awards.

Limited regional mobility has proved to be an obstacle, at least in Germany, to people’s prospects of obtaining a job commensurate with their qualifications (Michel, 1998b, pp.143 ff.). The relevant findings show that greater efficiency could be achieved not only if individuals were willing to move house but even if they were prepared to commute. All measures designed to overcome this reluctance to move to places where work is available, a reluctance that has traditionally been far greater in Europe than in the United States, for example, will help to ensure a better return on investments in skills and qualifications and to enhance the efficiency of the labour market. There are many conceivable strategies that transcend the conventional mechanisms of employment policy, from structural measures such as improvement of the roads and transport infrastructure, including the development of local public transport services, to fiscal measures such as tax concessions to offset work-related removal costs.

Here too, however, within the narrower confines of employment policy, an information deficit has to be highlighted. A long-distance move in search of work presupposes knowledge of the employment opportunities at the new location. Adequate information has hitherto been reserved for the more highly qualified. The jobs that might interest them are normally advertised nationally. By contrast, there is a severe shortage of information on a national, let alone European, scale for jobseekers with no managerial qualifications. Employers traditionally recruit these employees locally. Given the identified benefits of regional mobility, the establishment of a European recruitment service on the Internet would certainly be a huge step forward.

The employment strategies described above are primarily designed to adjust the ratio of matches to mismatches. It is evident that employment policies also exert a strong influence on the ratio of overqualified workers to jobseekers. An employment policy can be used to motivate skilled jobseekers to accept jobs for which they are overqualified by cutting their unemployment benefit or by tightening the rules governing the definition of a reasonable job offer and by ensuring that the rules are enforced.

There are several grounds for suggesting that this sort of induced increase in overqualification at the expense of the unemployment rate would be economically sound. In some European countries, the percentage of low-paid jobs is judged by the OECD to be disproportionately small when compared with countries such as the United States. This is probably due to the fact that, depending on the type and composition of the household, state benefit from the European welfare systems, which are often corporatist in nature, may sometimes offer a higher income than an unskilled or semi-skilled job.

On the other hand, trade unions are gradually coming to realise that there is too much standardisation of wage rates at the lower end of the scale, which results in excessively high

---

81 The role of further education as a means of reducing the risk inherent in underemployment is discussed in Büchel, 1998b.
pay for unskilled and semi-skilled work. While greater differentiation of wage rates at the lower end of the pay scale, accompanied by a reduction in transfer payments, would certainly increase the number of jobs – especially in the service sector, with its high job-creation potential – we could also expect an increase in the numbers of the ‘working poor’, as has happened in the United States.

This strategy, however, can only operate within certain limits, which are set by social policy or by society itself. For example, most of the European population would surely feel rather uncomfortable with the idea that, as often happens in the United States, every store checkout would have an auxiliary – who might be overqualified for the job – standing by to pack customers’ shopping into bags and carry it to their cars, even though there might be a market for this service at a suitably low rate of pay. The introduction of a combined wage, made up of income from employment and transfer payments, which is currently under discussion, could be an effective means of creating more jobs.

The present study has shown that significant links exist between overqualification and unemployment. So the question whether the percentage of overqualification in a national economy is ‘too high’ or ‘too low’ must always be answered by reference to the unemployment rate. The ideal ratio between the overqualified and unemployed percentages of the labour force cannot be determined by a scientific study but needs to be established normatively in the light of society’s collective values. The same applies to the percentage of overqualified workers when considered in isolation. Overqualification must not be seen as an entirely bad thing; it also has positive effects, for example in the form of spillover effects in connection with the skill upgrading of certain occupations. It is conceivable that, like the rate of ‘natural’ unemployment, an optimum level of overqualification could be identified on the basis of structural models, although this too would surely spark off a discussion on the considerations that should determine whether the labour market is functioning at maximum efficiency.

Summary

Section 1 begins by setting out the purpose of the study, which is to investigate the reasons for the occurrence of overqualification and to address the problem of finding a valid means of identifying cases of overqualification. At the same time, the author takes the innovative step of trying to establish a typological affinity between overqualification and unemployment (including the hidden labour reserve). This affinity derives on the one hand from the fact that both situations involve a mismatch between qualifications and job requirements. It may be assumed that both phenomena impose a heavy financial burden on national economies, since economies do not operate at full capacity when part of their stock of human capital lies dormant. This implies that overqualification is a problem that needs to be addressed in the same way as unemployment, although there can be no disputing that unemployment is the more serious problem. In terms of the human capital theory, the analogy may be seen as follows: in the case of unemployment, 100% of a person’s acquired formal vocational qualifications remain unused; in the case of overqualification, x% of those qualifications are unused, x being a significant quantity which can certainly be measured empirically, for instance by means of income analyses.

Another common feature of the two situations is that they are potentially temporary in nature and that the vast majority of people in them are not there out of choice. It may also be assumed that people in either situation will tend to aspire to a move into employment commensurate with their level of qualification. This means that it is possible in principle to analyse the phenomenon of overqualification with the same dynamic research strategy that was developed in the seventies to study un-
employment. This standpoint, however, is still very rarely encountered in the field of employment research.

Section 2 deals with terminological matters. Even at this stage, overqualification research is complicated by an unwieldy mass of concepts.

Section 3 briefly presents the various theories with which researchers have tried to explain the persistence of overqualification in the labour market. Some unorthodox approaches are also outlined. Most of the theories can only claim to explain part of the phenomenon. This section also discusses sets of influential factors that have scarcely ever been treated in the existing body of literature: institutional conditions such as the rules governing the system of unemployment benefit, basic economic conditions such as the trade cycle or the situation in the regional labour market, the personal preferences of those who offer their labour, in terms of the utility they ascribe to career success, etc., and the productivity calculations of employers, who need to know whether overqualified workers are liable to outperform their less-qualified colleagues.

In section 4, the problem of identifying instances of overqualification is systematically discussed. The discussion starts with an explanation of the two main measurement strategies – the 'objective' and the 'subjective' approach – and their diverse variants; the presentation includes unorthodox measurement processes.

The so-called 'objective' approach identifies overqualification by comparing the employees' formal qualification levels with the reported information concerning their occupations. This approach depends on precise knowledge of the training that exists for particular occupations. Changes in the level of occupational requirements in the course of time, a high degree of variation between job requirements within the same occupational category and the typically high number of missing data on occupations that results from the conversion into ISCO codes of occupations that respondents are normally asked to report in words all pose considerable problems when this approach is adopted.

The so-called 'subjective' approach, on the other hand, compares the employees' formal qualification levels with their own subjective assessments of the qualifications required for their respective jobs. The disadvantage here is undoubtedly the greater element of uncertainty that always accompanies subjective assessments. A major advantage of this approach, however, lies in the assumption that the employees themselves are the best people to ask about the real requirements of their jobs. The methodological discussion that was largely conducted in U.S. research journals during the eighties essentially came to the conclusion that the subjective approach possessed greater validity than the objective approach. Accordingly, research designs based on the objective approach are hardly ever encountered in contemporary studies.

Once these strategies have been explained, the author's own refinement of the conventional subjective measurement strategy is described. This is principally based on the introduction of a third variable – occupational status – into the categorisation process. This variable serves to validate the standard comparison between the formal qualification and the employee's subjectively reported job-requirement level. The overqualification variable created by this measurement process, which still takes the dichotomous form 'overqualified? yes/no', turns out to be considerably more selective than the variable generated by the conventional two-variable process.

The validity of the construct was tested with the aid of job characteristics (about 50 items) of overqualified and adequately employed workers; differences – usually substantial – between these two categories were observed for almost every item. The only disadvantage is the emergence of two additional categories. The first of these covers cases that cannot be definitively assigned to either of the original categories, because the combination of the three input variables does not permit a clear classification as overqualification or adequate employment, while the second category cov-
ers cases where the combination of the three variable characteristics is implausible. These two categories are generally excluded from the empirical evaluation. The reduction in the total number of cases, however, is fairly small.

Section 5 provides a comprehensive review of the literature that deals with the subject of overqualification. Special emphasis is placed on the origins of this discussion in the wake of the expansion of education systems in the seventies and eighties. The beginnings of the academic investigation of the problem of overqualification are retraced for the United States first of all. This is the country from which the main contributions to this field of research have come, contributions which, above all else, set the methodological standard.

The early development of overqualification research outside the United States is described, the German situation being used as an example. Thereafter, more recent works from the United States and Europe — including international comparative studies — are presented. It emerges that European overqualification researchers have only begun in recent times to draw upon the methodological groundwork that was produced in the United States. It is also noticeable that, apart from the Dutch, British and German research, the work that has been done on overqualification in Europe is still at a very rudimentary stage.

In section 6, on the basis of German longitudinal data, some selected examples of issues in the field of overqualification research are examined empirically in the light of the postulated affinity between unemployment and overqualification.

It emerges first of all from cross-section analyses that, once the data have been controlled for the main social characteristics, overqualified workers do not differ significantly from jobseekers in their problem-solving capacity and level of political involvement but that both lag far behind workers whose jobs match their qualifications. In terms of morale and concerns about the future, the overqualified group is positioned halfway between the unemployed and adequately employed groups.

The second stage of the examination involves the use of the instruments of dynamic unemployment research to analyse overqualification. Firstly, transitions into overqualification from various other types of employment status are examined. The multivariate analyses show that, when the data are controlled for the respondents' socioeconomic background, unemployment is the status from which individuals most frequently move into overqualification. This is evidence of important exchange processes between these two types of employment status. Transitions from overqualification to unemployment (downward mobility) and to educationally adequate employment (upward mobility) are then analysed.

These analyses demonstrate that transitions into unemployment occur more frequently than transitions to adequate employment. This finding, which is consistent with the postulates of the segmentation approach, can be seen as further proof of exchange process between overqualification and unemployment. In an additional analysis, the study examines whether a phase of overqualification following a period of adequate employment is likely to afford protection against unemployment or whether it tends to be one step in a downward process. The former is the case, which indicates that employees with a strong desire to work who see their educationally adequate job at risk or who have already been made redundant will protect themselves against unemployment if they take a flexible approach and accept a second-best option in the form of overqualification.

A transition into adequate employment, however, is a more frequently observable occurrence among unemployed than overqualified individuals. An additional analysis also demonstrates that acceptance of an underskilled job does not bring jobseekers any closer to adequate employment. On the one hand, this may mean that many underskilled jobs can be regarded as dead-end jobs. On the other hand, this finding could indicate that a significant number of unemployed people are pursuing an inflexible job-search strategy and will only accept jobs commensurate with their qualifications. This possibility touches on the
question of the institutional rules governing unemployment benefit.

Lastly, longer-term income effects of overqualification are examined. It emerges that the incomes of overqualified workers grow more slowly than those of their adequately employed counterparts. This remains the case even after the basic income level has been controlled for numerous socioeconomic characteristics. A final additional analysis is then conducted to establish whether – as would be expected – a period spent in overqualification creates income effects that lie somewhere between those of adequate employment and those of unemployment. The expectations of the human capital theory are indeed fulfilled: if periods of overqualification or unemployment intervene in the course of a career spent mainly in adequate employment, while the phases of overqualification generate significant income losses by comparison with unbroken adequate employment, these losses are lower than those that result from a period of unemployment.

The study is rounded off in section 7 with methodological conclusions addressed to employment researchers and substantive implications for education and employment policies. The first postulate addressed to employment researchers is that the typological affinity between overqualification and unemployment should be recognised; this would result in far greater diversity of research strategies for the analysis of overqualification, particularly longitudinal analysis, than has hitherto been observable in the relevant literature. The second postulate is that predictions of future demand for labour should no longer be based, as has hitherto been customary, on a prolongation of the development of an employee’s level of qualification but rather on the development of the skill level required for his or her job. Neglecting the aspect of mismatch by disregarding the problem of overqualification could lead to glaring errors in the assessment of future labour requirements. The likelihood of such miscalculation will be greater if overqualification rates rise over a period of time.

A host of suggestions are made to policymakers in the fields of education and employment as to how the percentage of overqualified workers in the labour force can be reduced. These are largely extracted by means of partial analysis from the empirical findings set out in the available literature. For details of these suggestions, the reader is referred to the short subsection 7.2 of the study. Here too, the crux of the matter is that the problem of overqualification should be considered relevant in macroeconomic terms and that political pressure should be applied with a view to solving it; such pressure should be structured in the same way as the mechanisms used to combat unemployment, although lower priority will naturally be given to overqualification. Both overqualification and unemployment are signs of inadequate coordination within the labour market, in which the inefficiencies of the education system play a significant role. Accordingly, both problems lend themselves to treatment with similar sets of mechanisms.

ad: Adequate employment = congruence between job and education (including underqualification). A12
ov: Overqualification = underemployment.
+ : Degree of mismatch not clearly determinable.
- : Implausible combination.

1) including: Apprenticeship degree (Lehre); in former GDR: including Berufsausbildung/Facharbeiterabschluß, Master craftsman degree (former GDR) (Meister DDR), Full-time vocational school degree (Berufsfachschule), School of public health degree (Schule des Gesundheitswesens), Technical college degree (FRG) (Fachschule), School for civil servants (Beamtenausbildung), Other vocational degree (sonstiger berufsbildender Abschluß)

2) including: Technical college degree [former GDR] (Ingenieur-/Fachschule DDR), Post-sec. technical college degree (Fachhochschule), University degree (Hochschule/Universität)

Other qualification levels used in Tables 1 to 14: Lower general schooling (Hauptschulabschluß / 8. Klasse), Intermediate general schooling (Realschulabschluß / 10. Klasse, including Fachabitur), Higher general schooling (Abitur), For East German Classification see Büchel/Weißhuhn (1997a).

Source: Büchel/Weißhuhn (1997a).
Table 1: Workers broken down by formal vocational skills, the degree of congruence between job and education, and various job characteristics and group-related averages from these characteristic groups (West Germany and East Germany, 1995).

All percentages: column percentages (100% divergence rounded up to the next figure). All results weighted.

1) Potential gross monthly salary: In the case of part-time and minimum-time employees, the monthly equivalent, calculated over an agreed working period. Excluding minimum-time employees working less than five hours per week and the self-employed.

2) Excluding minimum-time employees working less than five hours per week and the self-employed.

3) Dependent employees = 100 percent.

4) Pay determined by length of service (as well as performance) "on a regular basis" or "sometimes".

5) Excluding the "don't know"s = 100 percent.

6) Including self-employed farmers and members of their family working on the farm.

7) The question was: "If you could choose the number of hours you worked, taking into account that your salary would be commensurate to the number of hours worked, how many hours a week would you prefer to work?" (Compare their answers with their actual working times.)

8) The question was: "It is not always so easy for workers to reconcile working time with family responsibilities and household tasks. Do you find that to be a problem?" The respondents answered: "yes".

9) Dependent employees = 100 percent.

10) Employees with a fixed workplace = 100 percent.

11) The respondents answered: "fully applies" or "partly applies".

12) On a scale from 0 ("totally unsatisfied") to 10 ("totally satisfied")

13) The question was: "Would you put in extra hours to finish off a task you had already begun, even if it meant working for another hour and would not be paid as overtime?" The respondents answered: "yes, of course".

14) The question was: "If you were to lose your current job, would it be easy, difficult or practically impossible for you to find at least one other job that was equivalent?" The respondents answered: "easy".

Only employees below the age of 65. Excluding interns, persons receiving training or further training, and migrants between East and West Germany since 1989. West Germany: excluding immigrants included in the °D° sample of the German Socio-Economic Panel (GSOEP).

Source: own evaluation carried out by the German Socio-Economic Panel (GSOEP).

Dependent variable: 1 = transition, from one observation year to the next, from underemployment or adequate employment to unemployment/the hidden labour reserve; 0 = (other).
Significance level: ** = p < 0.01, * = p < 0.05, + = p < 0.10.

1) Including persons living as a married couple.
2) "Slight"/"greatly" restricted on account of health reasons in carrying out daily tasks.
3) Including Fachabitur.
4) Only in combination with nonacademic vocational qualification.
7) "Professional success" is "not so important" or "quite unimportant", according to German nationals (foreigners were not asked).
8) West Germany: at regional level (BfLR data - [Bundesforschungsanstalt fuer Landeskunde und Raumordnung - Federal Research Institute for Regional Studies and Town and Country Planning]); East Germany: at Land level (relating to place of residence).
9) Number of inhabitants in place of residence < 50,000 inhabitants.
10) Alternative status: adequate employment.

Legend for German expressions: see table 0.

Covariates in brackets = reference category. Reference date for encoding the covariates: first year. Unweighted averages as model documentation.

Only persons having been underemployed or adequately employed in one observation year and interviewed the following year. One observation at the most per person (first occurrence of a possible movement). Only persons with a vocational qualification from Germany below the age of 65. Excluding internes, persons receiving training or further training, and migrants between East and West Germany since 1989. West Germany: excluding immigrants included in the "D" sample of the German Socio-Economic Panel (GSOEP).

Source: own evaluation carried out by the German Socio-Economic Panel (GSOEP).
Table 10: Determinants of the probability of transition from adequate employment within five years (three years for the former East Germany) to unemployment/the hidden labour reserve, depending on a possible interim phase of underemployment and other characteristics (West Germany and East Germany, 1984–1995 and 1991–1995, probit model)

Forecasting skill requirements at national and company levels

Rob A. Wilson

Abstract
The document reviews recent work on demand and supply forecasts at national level, broken down by sector, occupation and qualification, covering both European and other countries. This includes an assessment of forecasting approaches and results at regional and local levels. A review of the methods used and the results obtained at company level is also presented.

Labour market forecasts can be seen as having two prime roles: first to guide policy decisions made by the government and its representatives; and second, as a general aid to the individual actors operating within the labour market, providing them with information which can aid their own decision making. The fact that considerable efforts to conduct such forecast are going on all over the world suggests that, on balance, such activities are regarded as very useful and worth substantial investment by the public sector.

It is concluded, therefore, that forecasting of the labour market is inevitable. The only real question, is how this should be done. There appear to be two main possibilities:

a) centrally, in a transparent, logical, consistent and systematic fashion, recognising the 'public good' aspects of such work;

b) or in a decentralised, often ad hoc fashion, by individual actors or groups, frequently based on implicit rather than explicit assumptions.

A number of different approaches have been adopted to anticipate changing skill needs. The traditional approach has usually involved formal, quantitative methods, focusing mainly on occupations. More recently, other, rather less formal methods have been developed which have a strong qualitative emphasis. However, many exercises nowadays involve a mixture of both quantitative and qualitative methods, which are regarded as complementary. Increasingly, the focus is moving away from occupations to consider more general aspects of skill requirements.

Summary

In the first Cedefop report, Tessaring (1998) reviewed a number of quantitative forecasts of employment by sector, occupation and qualification for several European countries. This included Denmark, Finland, France, Germany, Ireland, the Netherlands and the UK. A prime objective of the current work is to update this review, focusing on new methods, approaches and results and extending the coverage to additional countries. As well as examining practice in Europe, the review also covers recent work conducted in a number of non-European countries, including the USA, Canada and Australia.

The paper focuses on the issue of ‘forecasting skills and requirements at national and company levels’. It begins with a review of recent work on demand and supply forecasts at national level, broken down by sector, occupation and qualification, covering both European and other countries. This includes an assessment of forecasting approaches and results at regional and local levels. It provides a comprehensive review of the different methods used and an assessment of their advantages and disadvantages. This includes the recent emphasis on changing generic skill requirements and the use of qualitative methodologies, as well as more traditional quantitative model-based approaches which focus on occupations. A review of the methods used and the results obtained at company level is also presented.

An eclectic methodological approach has been followed in undertaking this review, involving a range of techniques to locate relevant research being conducted in this area. This included a traditional literature search, a computerised literature search using digital databases including the internet and the use of various network contacts including Cedefop itself. A comprehensive bibliography of recent research throughout the Community and beyond has been produced.

The key hypotheses addressed are twofold:

a) first, is labour market forecasting necessary?

b) and second, if the answer to this question is yes, how should they be conducted?

Both the criticisms of forecasting and the counter arguments of its proponents are reviewed in detail.

There is a small, but at times vociferous, group of critics who have decried the value of such activities. They argue, variously, that it is unnecessary, impossible and/or irrelevant. It is argued in the review that most of these criticisms are misguided. In many cases, the criticisms have been constructive and have led directly to improvements in methods and approaches used, including the development of more qualitative methods. In other cases the practitioners involved in making projections have argued, convincingly in the opinion of the present author, that the criticisms are invalid.

There is a much larger body of opinion, therefore, that such forecasts can be of value to a broad range of potential users within a particular geographical area, be it a national economy or a much smaller local area. A strong case can be made that the provision of such projections can be regarded as a valuable public good, which should therefore be supported by central government. Labour market forecasts can be seen as having two prime roles: first to guide policy decisions made by the government and its representatives; and second, as a general aid to the individual actors operating within the labour market, providing them with information which can aid their own decision making.
Employers, education and training providers and, of course, individual students and workers themselves, all have an interest in trying to peer into the future in order to try to anticipate what may occur and to ensure that their own decisions result in the best possible outcomes (however these might be defined). The fact that considerable efforts to conduct such forecast are going on all over the world suggests that, on balance, such activities are regarded as very useful and worth substantial investment by the public sector.

It is concluded, therefore, that forecasting of the labour market is inevitable. The only real question, is how this should be done. There appear to be two main possibilities:

a) formally, in a transparent, logical, consistent and systematic fashion, recognising the 'public good' aspects of such work (often undertaken centrally);

b) or in an informal, often ad hoc fashion by individual actors or groups, frequently based on implicit rather than explicit assumptions.

A number of different approaches have been adopted to anticipate changing skill needs. The traditional approach has usually involved formal, quantitative methods, focusing mainly on occupations. More recently, other, rather less formal methods have been developed, which have a strong qualitative emphasis. Often this has reflected problems or lack of key data. However, most exercises nowadays involve a mixture of both quantitative and qualitative methods, which are regarded as complementary. Increasingly, the focus is moving away from occupations to consider more general aspects of skill requirements.

The present review of the main forecasting methodologies suggests that a formal, quantitative behavioural model is a very important foundation stone upon which such forecasting activity should be based. This should, in principle, enable a better understanding of the main factors influencing the supply of and demand for skills. However, it is important to go beyond the traditional 'manpower requirements model', with its focus on occupational employment levels. Most recent work has emphasised the need to consider replacement demands and not just to focus on projected levels of employment. In addition, other more qualitative methods, involving surveys, case study work, focus groups and other techniques have all been found to have the potential for 'adding value' to the more traditional methods. Finally, a key feature of much recent work has been the emphasis on key or generic skills which go beyond the straight-jacket imposed by traditional occupational classifications, to look at the skills needed to do various tasks.

It is clear that the political, institutional and legal context, have had a crucial influence in the systems for labour market forecasting which have been developed across the world. In particular, this is reflected in the statistical infrastructure within which the analyst has to operate, including the development of macroeconomic and labour market forecasting models. Most of the countries where fully developed systems are in operation have invested very heavily in such activities over a period of many years. The impact of IT in this area has been immense. In the USA, for example, the development of ALMIS the American Labour Market Information System has facilitated all kinds of research and commercial activities in the area of Labour Market Information (LMI) and labour market forecasting. It has also facilitated the development of local as well as national level forecasts as in the UK.

The main conclusion from the review is that employment projections can and do provide a useful aid to policy makers in making decisions about training, recruitment and the personnel issues. It can also provide very useful information to a broad range of other actors in the labour market, including employers, individuals and education and trainer providers. This includes the development of 'early warning systems' to avoid bottlenecks, shortages and imbalances, which have been regarded as a serious problem in many countries. However, it is important to be realistic about the accuracy with which this can be accomplished. The idea of indicative planning
of education and training systems has long been discarded by labour market forecasters.

The value of such exercises depend crucially on the quality of the data upon which they are based, as well as the validity of the various assumptions built into the forecasts. To some extent the latter will depend upon the degree of sophistication of the models adopted, the more sophisticated the model the more likely it is to be able to deal with the many subtle influences on changing employment structures. A substantial investment by the public sector is necessary to support such activity, both to provide the basic data (which may also have a variety of other uses) and to support the forecasting activity itself.

Despite all the various problems associated with such activity, the experience of many countries, particularly the USA, suggests that useful forecasting tools can be developed at European level. This experience suggests that such forecasts can provide helpful information to both labour market participants as well as for policy makers about the labour market environment they are likely to face. It is therefore recommended that a regular European wide labour market forecasting exercise should be undertaken, supported by central government funds. This should include detailed occupational forecasts but also focus more generally on the changing supply and demand for skills (by sector, occupation, region, etc).

1. Introduction

1.1 Background to the project

Tessaring (1998) provided a brief general review of the methodologies used in employment forecasting. The present contribution expands upon this review. It provides a much more comprehensive and in-depth coverage than the Tessaring paper, which was concerned with a rather broader range of issues to do with the future of work. The present review covers the literature on what has traditionally been termed 'manpower planning', including the various quantitative forecasting models used at national level in many countries. However, it also extends the focus to include a number of new approaches to anticipating changes in the pattern of the demand for skills. The aim has been to summarise some of the key methodological issues in employment forecasting. The review also addresses questions concerned with the rationale for forecasting as well as some of the problems and pitfalls associated with it.

1.2 Aims and objectives

The key aims of the review are to provide:

- a summary of recent work on demand and supply forecasts at national level, broken down by sector, occupation and qualification, covering both European and other countries;

- a corresponding assessment of forecasting approaches and results at regional level, including an assessment of the importance of focusing on the local level (which some argue is necessary if such forecasts are to attain full operational relevance) as well as the problems and pitfalls in doing this;

- a comprehensive review of the different methods used and an assessment of their advantages and disadvantages in both national and regional cases. This includes an assessment of the various new approaches being used to anticipate changing skill needs, which have been advocated in recent years as well as a considered review of the various criticisms which have been made of more traditional methods;

- a corresponding review of the methods used and results obtained from assessing the future skill requirements at company level.

2 Although this terminology appears increasingly outdated, given pressures towards equal opportunity and the use of non-sexist language, the term 'manpower' remains in regular use. The word planning has also come to be regarded in somewhat derogatory terms in some circles. The present review has adopted the alternative terminology of employment forecasting. This should be understood to refer to the analysis and management of all human resources.
level and their implications for the development of formal and informal skill training within companies;

- an assessment of the relevance of the forecasts for training provision, and the implementation of 'early warning systems' to avoid bottlenecks, shortages and labour market imbalances;

- an assessment of the need for a regular European forecasting activity concerning the supply and demand for skills (by sector, occupation, region, etc.).

1.3 Methodological approach to the review

An eclectic methodological approach has been followed in undertaking the literature search and review. This has involved various techniques to locate any relevant research being conducted in this area, including:

- a traditional literature search using bibliographical indexes;

- a computerised literature search using digital databases;

- use of network contacts:
  - based on the IER's established network, including members of the symposia held at the University of Warwick between 1989 and 1997,
  - contacts through an ongoing Leonardo project,
  - contacts through Cedefop;

- use of the world wide web to search for relevant sites and information;

- use of the IER's own website to attract interest and invite comment on the review as it is progressing.

The aim of all this effort has been to produce a comprehensive bibliography of recent research throughout the Community and beyond. The full bibliography, including subsections in Italian, German and Spanish, is attached to this report.

1.4 Outline of the report

Sections 2 and 3 provide a summary of the literature on general employment forecasting at national and regional levels. This discussion includes a review of the methodologies adopted as well as a summary of the main criticisms of the approach. The employment forecaster's responses to such criticism are also reviewed and an assessment of the benefits and limitations of such work is attempted. Recent changes in emphasis towards local forecasting and more qualitative approaches are discussed.

Section 4 extends the review to cover company level employment planning and forecasting. In parallel with the development of national employment models there was a growing interest during the 1960s in personnel planning at microeconomic level. Company employment planning began in earnest during the 1960s, although some institutions had undertaken this kind of exercise for many years before then. Much intellectual effort has been put into understanding the problems of wastage and recruitment to ensure that companies have the skills they require. Many very sophisticated statistical models have been developed, based on Markov methods. As at national level, the nature of such planning has changed over the years, with much less emphasis today on mechanistic manpower models. Nevertheless there is a considerable amount of effort devoted to forecasting wastage and assessing future recruitment needs. Most major companies and other large employing institutions are now well aware of the importance of human resource planning. Many now have personnel officers in quite senior positions whose main responsibilities are to deal with such problems.

Section 5 considers how the different political, legal and institutional frameworks in individual countries have shaped the kind of work which has been carried out in each case. A particularly important issue is how these factors have affected the statistical infrastructure in each country. This is dealt with
Forecasting skill requirements at national and company levels

separately in Section 6. The importance of development of standard systems of classification, the need for regular and detailed employer and household surveys on employment structure and the advantages of electronic access via the internet are discussed. Some of the key methodological issues in employment forecasting are reviewed in Section 7. These include: the limits to our understanding of socioeconomic systems; inadequacies in data; and ending with a brief discussion of various other technical, methodological problems. Finally, Section 8 contains the main conclusions.

2. A general review of employment forecasting

2.1 Background

Employment forecasting first became prominent during the early 1960s when economists were concerned about problems of both structural unemployment and labour shortages. Initially, it was hoped that governments would be able to intervene, especially on the supply side of the labour market, to ensure a balance between the demand for and supply of skills.

The initial optimism of the planners was soon dented, both by technical and practical problems in producing accurate forecasts, as well as a barrage of theoretical criticism, which questioned the whole rationale for employment forecasts. Although these criticisms have been rejected to some extent, the nature of the employment forecasting undertaken in the 1990s is now very different from that attempted in the 1960s. Forecasts of both the demand for (and in a few cases the supply of) skills at national level are regularly undertaken in most of the major OECD economies. However these assessments are very different from the indicative type planning exercises attempted by the pioneers of the 1960s. In particular, the attempt to develop a direct link between the changing pattern of demand for skills and the regulation of the intake into education and training courses has now been recognised as impractical in most countries.

Current labour market assessments emphasise the implications of past patterns of change for the future demand for skills, often using quite sophisticated econometric models. The aim is to present policy-makers with information on the labour market environment that they may face if such trends continue. They may also attempt to assess the effect of different courses of action. The information provided by such assessments is only one of the necessary inputs into decisions about the scale and content of different education and training programmes which government officials, education and training providers, companies and trade unions will need to use in developing their strategic thoughts.

However, current thinking, in most but still not all countries, is that the scale of education and training programmes needs to reflect the demand from individuals. In most market oriented economies, the latter are regarded as best placed to make choices based upon a vast range of micro as well as macroeconomic information, which a bureaucrat would not be able to take into account. It is felt in many such countries, that individuals need good labour market information to help them make the best choices.

In countries such as the USA and the Netherlands, very detailed information, including forecasts, are regarded as an essential part of this. In many others more general macro level projections are becoming more readily available and are seen as having an important role to play in making young people and others who make career choices aware of labour market trends. While it is recognised that such information may offer only a broad brush picture of the possibilities facing those making training and career development choices, it can provide an important input for use in vocational counselling and guidance by practitioners who are aware of its limitations.

In practice, such projections will often provide only general guidance on such matters, although in some countries much more detailed information is available. In many (if not most) cases, of course, the labour market prospects in a chosen career path will not be the major factor in an individual's decision. Nev-
Nevertheless, if such decisions are to be made efficiently, it is important that individuals have the best information available, even if they choose to discount it.

Nevertheless, it is important, right from the outset, to recognise the limitations of employment forecasting. It is important to avoid the pitfall of thinking that it is possible to develop computerised models which can provide accurate predictions of the future demand for training. The lessons from almost 40 years of research caution against this. Despite these caveats, the present author is firmly of the view that formal forecasts can provide useful information for policy-makers and the various actors in the labour market, as long as it is used in combination with other relevant information and its limitations are recognised.

2.2 Employment forecasting: a brief history

Employment forecasting has been undertaken, in one form or another, for many years. The literature in this area dates back at least to the 1950s. Ahamad and Blaug (1973) wrote of the need to review the previous 20 years of experience of manpower forecasting. In carrying out this review, they identified examples of forecasting for all occupations and for single categories of worker in several developed and developing economies around the world. There is now an enormous literature covering work at both a macro and micro level.

The previous work by Tessaring (1998) covered a limited range of work conducted at national level within a few major European countries. Tessaring (1998) referenced a large number of works, including some general reviews, which have explored these issues, such as Eijs (1994), Heijke (1994) and Youdi and Hinchliffe (1985).

A number of other useful reviews have been conducted, to which the interested reader is referred for more detailed discussion, see for example, Hopkins (1988), Hughes (1991), Colclough (1990), Smith and Bartholomew (1988), Meltz (1996), Haskell and Holt (1999) and, most recently, Strietska-Iliina (1999).

The document by Hughes (1991) contains a particularly comprehensive review of many of the technical issues, including details of work in the USA and Canada. Meltz (1996) reviews the position for Canada, while Heijke (1994) contains chapters by many of the leading European practitioners. Haskel and Holt (1999) have brought things up to date with a critical review of the merits and limitations of such work, albeit focusing on the UK experience.

Most recently Strietska-Iliina (1999) has provided a review of practices in France, Germany, Ireland and the Netherlands as well as a number of eastern European countries. The present section attempts to provide a summary of the main features of this literature.

During the 1960s employment forecasting became prominent at national level as economists attempted to advise governments on how to avoid imbalances between the supply and demand for skills, (whether appearing as structural unemployment or skill shortages impeding economic growth). One of the most influential works was done within the OECD-Mediterranean project in the early 1960s, Bombach (1965). At that time it was hoped that detailed employment plans could be developed which could be used to guide policy decisions relating to the provision of educational and training programmes at a very detailed level (i.e. for particular levels of qualifications or skill).

In practice the methods adopted at that time tended to be rather naive and mechanistic. As a result, these early forecasts were usually very inaccurate, especially on the supply side. The typical methods adopted involved linking the demand for particular skills to output projections for different industries, often via some form of input-output model (see for example Parnes 1962). The links were generally a series of fixed coefficients. This assumption was heavily criticised as failing to recognise the possibility of substitution of one factor of production (or skill) for another, (see for example, Ahamad and Blaug 1973).

3 In a paper prepared for the Skills Task Force, which has been set up to advise the UK Government's Secretary of State for Employment.
2.3 Criticisms of employment planning

Many of the early models used for employment forecasting were not explicitly specified in a quantitative form. Such forecasts could not be evaluated by statistical methods (see Ahamad and Blaug 1973). Where quantitative evaluation did prove possible there were often large errors in the forecasts for different occupations. As might have been expected, the errors tended to increase the longer the time horizon of the forecast. Most of the early demand forecasts were derived from fixed coefficient models which were prone to error. On the supply side the forecasts were highly simplistic, with no attempt to examine the implications of variable retirement or wastage rates.

A number of criticisms of the general manpower requirements approach have been offered (see, for example, Colclough 1990):

- that national level employment planning is irrelevant because markets will respond of their own accord to ensure that the correct skills are produced;
- that the fixed coefficient approach is invalid since it ignores the possibilities of economic substitution;
- that inaccuracies in the assumptions will be compounded making the projections of little value;
- that such approaches focused solely on economic considerations without reference to wider social implications;
- that past imbalances were often ignored and carried forward into the projections;
- that the approach did not allow for interaction between supply and demand factors.

Employment forecasters have rejected all these criticisms. With regard to the first criticism, they point to evidence of market failure (reflected in persistent skill shortages, which seem to be a feature in many countries) and to the long-lags in training (which can lead to temporary but long-lasting imbalances in occupational labour markets).

With regard to the second point they highlight empirical evidence that the elasticity of substitution for skills is low and argue that wage structures tend to exhibit stability over the long term. More recently, improvements in methodology have opened up the possibility of allowing for substitution possibilities explicitly in the econometric models which can be built (although this remains the exception rather than the rule).

The third criticism is rejected on the grounds that the problem of forecasting inaccuracy is not unique to employment forecasting but applies to any economic projections. Evidence does not suggest that employment forecasts are significantly more inaccurate than any others. Moreover, there is considerable evidence that policy makers have found these useful, (see Strietska-Ilina 1999, Borghans et al. 1998 and Meltz 1996).

The fourth point has been answered by introducing a broader range of disciplines into the process and recognising that economics is only one of a number of important considerations to be borne in mind. The fifth and sixth points have been addressed by attempts to deal with these limitations, taking such factors into account explicitly, in a manner which was not possible in the pioneering studies.

More recently, a more general criticism has been characterised by a quotation from a French manager who stated that 'the term planning is imbecilic; everything can change tomorrow' (Mintzberg 1994).

Occupational projections fell into disrepute in France during the 1970s when the fifth and sixth economic plans were blown off course by the oil crisis and subsequent sectoral readjustments. As a consequence, the seventh economic plan abandoned direct confrontation of detailed demand and supply projections, (see Paul 1985). Indeed, occupational projections were omitted altogether from the eighth economic plan. Nevertheless, the demand for occupational forecasts continued, with an in-

The kind of views expressed by the French manager implicitly assume that planning involves a quite mechanistic process based on the past, that it is more backward than forward looking. However, most practitioners have a much more open-ended view about what planning (and forecasting) can provide. Reilly (1996) sees the process as:

- conscious,
- explicit,
- analytical,
- purposive,
- forward looking,
- dynamic,
- aggregate (broad brush),
- quantitative.

Such a view is certainly characteristic of the philosophy behind much employment forecasting (see for example, Wilson 1994 and Lindley 1994). Indeed, some would argue that one of the main benefits of such activity is in posing the questions rather than providing precise answers (Pascale 1991).

2.4 Employment forecasting in the 1990s

As a consequence, employment planning at national level has continued to be practised, albeit in a less mechanistic and indicative fashion. During the 1990s a growing consensus developed that conventional manpower planning was too mechanistic and inflexible to meet changing economic conditions. Criticisms of conventional employment planning were advanced by Psacharopoulou (1991) and Castley (1996a, 1996b), amongst others. Psacharopoulou (1991) has advocated that manpower planning should embrace a much fuller labour market analysis which would include measurement of wages, wider use of household surveys and skill and educational profiling of the working population. The emphasis has moved away from employment planning towards more general labour market assessment and forecasting, with the emphasis on anticipating change.

Most developed countries now undertake regular labour market projections. However, these are used more as general aid to policy makers and labour market participants to illustrate the implications of a continuation of past patterns of economic and labour market behaviour for the future, rather than as an indicative input into educational planning. It is emphasised by most practitioners that such assessments should be regarded as a broad-brush guide to the sort of environment that labour market participants and policy-makers may face, rather than a crystal ball. It is notable, however, that in some of the far east ‘tiger’ economies there is greater adherence to the notion of indicative planning than in many western countries.

In some countries, such as the USA and the Netherlands, more detailed projections are still conducted although these are not carried out with the idea of supporting precise indicative planning of education to match changing demand patterns. There are also many recent examples of employment forecasting at below the nationwide level. These include the development of local area employment models and the production of detailed forecasts for key industrial sectors (e.g. the engineering industry) or important occupational subgroups (e.g. highly qualified workers).

Employment forecasts can be subject, of course, to wide margins of error but this does not invalidate them, any more than it does other economic forecasts. One of the key problems in all social science forecasting is that the forecast itself may alter behaviour and indeed this is often a key objective (see, for example, Wilson 1994 and Meltz 1996). In any event, as Cairncross (1969) notes, forecasts should not be taken too literally or as telling policy-makers or individuals what to do. They should be treated as one among many pieces of information, which is needed before taking decisions and which can be used to help evaluate the risks to be faced. Employment forecasts can contribute to the decisions which have to be taken with regard to education, training, and choice of occupation by provid-
ing, as Colclough (1990, p.20) argues, 'a detailed, consistent and plausible picture (if properly done) of how the future might look'.

More recently criticisms of employment forecasting have focused on the question of how relevant traditional occupational projections are for both policy-makers and other labour market participants. One criticism was that many such projections failed to recognise the significance of replacement demands (Dekker et al. 1994). More recently, there has been growing concern that the focus on occupations fails to get to grips with the skill requirements that employers have or the skills which individuals need to acquire to gain and retain employment. The response of the practitioners to these criticisms is discussed below (in Section 3.2.1) but essentially they have extended their analysis to include these elements.

3. Methodological approaches

3.1 Alternative methods

There are a number of different approaches that have been adopted to anticipate changing skill needs. Some, particularly the more traditional approaches, involve formal, quantitative methods. Others, especially some of the more recent attempts, are rather less formal and have a strong qualitative emphasis, involving the use of multidisciplinary methods. Such methods are not primarily concerned with precise quantitative measurement. All of the following have been used at different times and in different contexts. The main approaches that have been used are as follows:

a) quantitative methods:
   - mechanistic/extrapolative techniques,
   - behavioural/econometric models,
   - survey of employers' opinions,
   - skills audits;

b) qualitative approaches:
   - Delphi techniques (consultation of expert opinion),
   - case studies,
   - focus groups,
   - holistic modelling approaches.

3.2 Quantitative modelling

3.2.1 Traditional approaches to employment forecasting

For many years the dominant technique has been quantitative modelling, using a combination of behavioural/econometric models as well as more basic extrapolative techniques (where the data are inadequate to apply more sophisticated methods). Typically, quite sophisticated, behavioural models are used, with parameters estimated using econometric methods where the data are good enough to permit. This usually includes the macro-economic and sectoral employment aspects. More basic extrapolative techniques are used where the data are less adequate, notably for producing more detailed breakdowns of employment by occupation and qualification.

Pioneering work in this area was undertaken in the USA by the predecessors to the Bureau of Labour Statistics (see, for example, Department of Labor 1963 and 1965); in France, where the occupational dimension was included in the fourth economic plan for 1962-65; and in the OECD Mediterranean study (Bombach 1965). This was followed up by work in Canada by the Federal Department of Labour, in Germany by organisations such as the Institut für Arbeitsmarkt- und Berufsforschung (Institute for Employment Research – IAB) and in the UK by research conducted by the Institute for Employment Research (IER), funded by the Department for Education and Employment.4 The US approach is summarised in Figure 1, while a summary of the situation in the UK is given in Figure 2.

A detailed review of the German approach can be found in Tessaring (1997). This highlights the increasing diversity of methods and data sets that have been used to tackle the problem of anticipating labour market change in Germany. The combination of econometric,

---

4 When IER first started its work on occupational forecasting in 1975 it was known as the Manpower Research Group, while the DfEE's predecessor, the Manpower Services Commission, managed the research on behalf of the then Department of Employment.
survey and other approaches is typical of the way the methodology for undertaking employment projections has been developing over the past 10 to 20 years.

Similar work has been conducted in many other European countries. Strietska-Ilina (1999) describes the current positions in France, Ireland, the Netherlands as well as Germany. Tessaring's (1998) review also details models used in countries such as Finland, Germany, Ireland, the Netherlands and the UK. Recent reviews of the situation in France, Germany, Italy, Spain and the UK can also be found in a series of papers produced as part of an ADAPT project, (Blin 1999, Schultze and Reimers 1999, Vergani and Muscella 1999, Antonio 1999 and Wilson 1999).

Other countries have made only limited progress in this area. For example, in Austria the collation of key economic and employment statistics is carried out by the Austrian Central Office for Statistics (ÖSTAT) but this body does not carry out any forecasting work. Rather, organisations such as the Institute for Advanced Studies (IHS) do such research. They use a macroeconomic model (link model Austria, LIMA) to produce a set of highly aggregative forecasts. A second set of forecasts is produced by the Austrian Institute for Economic Research (WIFO) who use a model which is capable of some disaggregation into different sectors. The forecasts of these two institutes are critically important and they are presented regularly to government officials and Austrian social partners. Fuller details on the Austrian forecasting approach can be found in Lassnigg and Mayer (1999).

Important work has been carried out outside Europe and the USA. The main national economic model used to forecast employment in Australia and more recently adapted by South Africa, Pakistan, Thailand, Indonesia and China, amongst others, is the ORANI model. Work on this model began at Monash University in 1975 and the original specification of the multisectoral model was described in Dixon et al. (1982). The features of the original model were a facility for multiproduct industrial sectors, elasticities of substitution between domestic and imported goods and services, technical change variables for all commodities, very detailed treatment of key distribution and transport sectors and a regional dimension. This basic model format is published as ORANI-G (Horridge et al. 1998), where ‘G’ stands for the generic version of the model and details are now available on the internet (www.monash.edu.au/policy/oranig.htm).

The Australian model has been extensively revised and upgraded since its inception. The comparative-static framework has been replaced with dynamic equations arising from stock/flow accumulation between capital stocks and investment and also between foreign debts and trade deficits. Other extensions to the basic model have included systems of government accounts and fuller regional breakdown of model results. The present model contains 112 industries (defined according to the Australian standard industrial classification), which map into some 21 broader industrial groups. A variant on the ORANI is the version developed at Monash (Malakellis and Dixon 1994), which exhibits a higher degree of disaggregation for households, occupations, sectors and regions. In particular it yields employment forecasts for some 283 occupations across some 56 regions.

Improvements in modelling techniques have resulted from the significant investments made in IT equipment and data, as well as from the more general advance in economic scientific methods over this period. All of the governments mentioned above have supported such developments indirectly via their funding of academic research efforts in higher education. The latter has also been facilitated by the effects of the IT revolution on the ability to handle increasingly complex statistical problems with increasingly less effort. Statistical and econometric modelling techniques have been particular beneficiaries. In addition, the general process of scientific advance (which has benefited from the massive expansion of investment in education and research and development worldwide) has had a major impact.

The availability and accessibility of labour market data has gradually improved since the early 1970s, again linked to the IT revolution. This has again been a feature common to all
Forecasting skill requirements at national and company levels

Figure 1: The US approach to labour market forecasting

The US Bureau of Labor Statistics (BLS) has a long involvement with model-building to forecast employment by industry and occupation for at least 10 years forward. Bureau projections are based upon extensive detailed econometric modelling of output and employment relationships. Data are used from a number of different BLS surveys, current population surveys, Bureau of the Census surveys of business, as well as national income and interindustry accounts. Forecasts are produced for some 500 to 1,000 detailed occupations and some 240 industrial sectors (precise numbers vary with particular types of analysis). The results of the projection exercises are published in a number of journals (the key one being *Monthly Labor Review*), as well as on the internet (http://stats.bls.gov/emphone.htm).

A full up-to-date account of the BLS approach to employment forecasting is provided in *Bureau of Labor Statistics* (1997). They key component of the forecasts if the input-output accounts which are only updated periodically. The most recent set of US forecasts is based on the 1987 input-output matrix which is projected forward using RAS methodology. Similar problems arise in allocating the final demand product groups to detailed commodities and this exercise requires the use of an updated bridge table. The whole modelling exercise critically depends on the maintenance of regular and consistent time series observations on industry and commodity outputs, employment, hours worked, wages and salaries and critically, on occupational staffing patterns. The staffing information is derived from a series of surveys conducted by individual state employment security agencies. These data are complemented by occupational information provided by federal government employees as well as for self-employed workers, agricultural workers and for those employed in the private household sector.

The efficiency of the BLS forecasts is heavily dependent on the quality of its data inputs to the model. Improvements invariably require the development of new or refined data series. The available data is seen as the major limitation on the forecasting exercise. One of the latest developments in the US has been the coming on line of the O*NET system which has been designed to focus on skill needs in great detail and is intended to provide useful information for careers guidance.

these countries as well as to most other European countries. Although there have been some notable set backs, the overall position in the late 1990s is vastly better than when labour marketing forecasting first started.

A number of early national economic models which contained a significant employment forecasting dimension were reviewed by Hopkins (1988) for the International Labour Organisation. Amongst the models which were examined were the Cambridge multi-sectoral model for the UK, the French and Dutch equivalents, as well as the overall OECD interlink model, which was an attempt to tie together some major econometric models in use across the world. Table 1 provides a listing of the link participants in the early 1980s and so shows the international interest in employment forecasting at this date.

Some of the broad conclusions reached by Hopkins (1988) are worth noting, although developments since the early 1980s have served to invalidate some of the findings. The actual prediction records of the major models were found to be very mixed with the most inaccurate sets of forecasts arising from the interlink exercises. Most models were superior to very naive predictions but many did not inspire much confidence with regard to detailed projections. This of course, was a conclusion from many of the very early indicative planning exercises. Nevertheless, the forecasting models were found to be useful for exploring a range of alternative scenarios rather than for making precise predictions.

---

5 For example, in the UK, a number of major surveys, including the planned 1976 census, were cancelled and there have from time to time been significant cuts in expenditure on many key national data sets.
Figure 2: The UK experience of labour market forecasting

The first serious attempt at employment projections in the UK were produced in the late 1970s using a modified version of a static multisectoral macroeconomic model developed by Professor Richard Stone and his colleagues in the Cambridge Growth Project (CGP). Subsequent forecasts used improved versions of this model which was the subject of a continuous programme of development both by the CGP (and its successor, Cambridge Econometrics (CE), a private sector organisation) and the Institute for Employment Research (IER). National government funding from the Department for Education and Employment (DfEE) and its various predecessors supported this work.

More recently, the emphasis in the UK has changed to the local rather than national level. After 1988 the responsibility for delivering government training programmes for young people and the unemployed passed to the local level. Local organisations have often conducted their own surveys of employer's labour and training needs. Many also commission forecasts. Various software packages have been developed to exploit the data collected by DfEE and made available on National Online Manpower Information System (NOMIS).

Careers guidance companies in the UK have also recently been privatised (previously they were part of local government) and are now taking an active interest in anticipating future labour market conditions on behalf of the clients they advise. They also operate at local level. Moreover, education and learning suppliers (colleges, universities, etc.) have been charged with the responsibility of ensuring that the courses they provide are relevant to future labour market needs.

Recently, a new series of Industry Training Organisations (ITOs) have been set up in the UK, operating at national level. These include the Construction Industry Training Board (CITB) which is the ITO for construction and the Engineering and Marine Training Authority (EMTA) which covers engineering. Others cover areas such as agriculture, distribution and security services.

The Skills Task Force is a national body set up by the Secretary of State for Employment in 1998 to assess the UK's future skill needs. It has members from a broad range of companies although it is not intended to be representative. It has commissioned a number of research studies including a major project on skills deficiencies. This research is intended to identify the nature, causes and implications of skills deficiencies in the UK. It involves an eclectic set of research methodologies, including in-depth case studies, large-scale survey work and econometric analysis.

Specification in these early models varied quite markedly and it was subject to much change. Several models used a mixture of econometric modelling combined with expert subjective judgement. A strong case could be made for better specification and the incorporation of a fuller set of labour market variables. Estimation techniques have improved very significantly since the early 1980s and, taken together with greatly enhanced computing power, this has enabled far superior model specifications to be produced. Most of these models were restricted to macroeconomic and employment forecasting, by sectors, although a number have been extended to include further characteristics such as occupation and qualification.

During the 1970s and 1980s many of these countries' governments invested heavily in macroeconomic model development. In the USA and Canada, such work has been undertaken directly by the government. In Canada the work of the Federal Department of Labour...

has been carried forward by Human Resources Development Canada (HRDC), which is a part of the federal government. In the USA the BLS's work in this area has gone from strength to strength. In the UK, the Institute for Employment Research (IER) an academic research unit has conducted this work for most of the past 25 years, while in Germany and France a combination of academic and public research institutions have led the way.
The approaches to generating national projections have gradually been refined and improved in parallel with the development of macroeconomic modelling more generally. These improvements have resulted from:

- significant investments in methodological advances;
- improvements in techniques and understanding;
- huge increases in the ability to handle and process data;
- improvements in the availability and accessibility of data.

Many of these elements are interconnected and related to the general effects of the IT revolution.

3.2.2. Spatial disaggregation

The approaches adopted in most countries involved the development of national models covering all sectors. From an early stage such analyses have often also included a spatial (regional) dimension.

In the USA, separate results for individual states have been produced for many years. In Canada, although the initial work focused on the national level, demand for more local information soon led to the addition of regional/provincial dimensions (Meltz 1996). Many of the results for other countries, including France and Germany also include regional dimensions.

These developments reflect both institutional factors and data availability. In the case of the UK, for example, detailed analysis of the standard regions of the UK (which include Wales, Scotland and Northern Ireland as well as the nine regions of England have been conducted for many years. However, the UK regional projections only covered sector and not occupation until the early 1990s. The re-introduction of occupational projections at regional level in the UK reflected the shift in emphasis towards local provision of education and training programmes, with the introduction of the Training and Enterprise Councils (TECs and the corresponding LECs in Scotland). More recently this has led to the further narrowing of the geographical scope to a focus on the areas covered by the new regional development agencies.

In France, every region has, since the late 1980s, had a regional employment and training observatory (OREF). These were intended to develop decision-making tools to allow the linking of analysis, data and forecasting for education and training in support of decentralisation. In Germany, the importance of the local dimension has also long been recognised, the role of the Länder in education and training provision being critical. These examples highlight the importance of the political, institutional and legal contexts in shaping both what is regarded as desirable as well as what is feasible.

3.2.3. The ‘demand’ for skills

The demand side of employment forecasting has adopted a variety of different methods. The most common method involves some form of econometric macroeconomic model. In the early days the fixed coefficient, ‘Manpower requirements’ approach, was the most common method of dealing with the demand side. As noted above, this usually involved making a series of links from gross national product (GNP), or other measures of individual industry output, to employment. From there, further links to the demand for particular skills, were made, usually focusing on occupations. In most of the early employment models the latter links were all in the form of fixed coefficients. More recently the models used have been more sophisticated, allowing for changing coefficients and responses to economic variables such as prices and relative wages.

Details of the methods used have been summarised in Tessaring (1998) and in the earlier review by Hughes (1991), so they are not repeated here. It is perhaps worth noting that most of the early models concentrated on just two main dimensions: industry (or sector) and occupation. More recently, there has been

7 Having said that, many of the very early studies also had a focus on educational requirements, including qualifications.
more effort to add a third dimension relating to qualification, skill or educational requirements, although such efforts often remain constrained by lack of adequate data.

In the early 1990s criticisms of employment forecasting have focused on the question of how relevant traditional occupational projections are for both policy-makers and other labour market participants. One criticism was that such projections failed to recognise the significance of replacement demands (Dekker et al. 1994). It was emphasised that projections of occupational employment levels failed to recognise the need to replace those leaving the workforce for retirement and other reasons. This has now been remedied in many models (for example, the current models for the Netherlands, the USA, Canada and the UK all now deal with such matters explicitly).

More recently, a key feature of much work has been the focus on key or generic skills which go beyond the straight-jacket imposed by traditional occupational classifications, to look at the skills needed to do various tasks. There has been growing concern that the focus on occupations failed to get to grips with the skill requirements that employers have or the skills which individuals need to acquire to gain and retain employment. The Department of Labor in the USA has been developing the O*NET database, which identifies, defines and describes various aspects of occupations, including the various generic skills typically associated with each job. Much of this information has been made available on the Internet. In the UK the Skills Task Force has also been taking a strong interest in such issues and a number of recent studies have attempted to grapple with this issue (see, for example Haskell and Holt 1998). Green (1998) has tried to demonstrate the value of different types of key and generic skills using hedonic wage equations, while BSL (1998) have tried to apply such concepts directly, in a skills assessment exercise for Wales. In Germany the IAB has used employer surveys to get more detailed information on the nature of jobs but this has tended to focus more on functions, such as R&D, rather than key skills (such as IT skills).

Thus the simple notion of concentrating upon just two (or three) key dimensions (industry, occupation and possibly qualification) is now being superseded by a multidimensional approach. This involves the use of terms such as functions, tasks, abilities, personal attributes, characteristics and generic skills. In many cases the precise use of these terms has yet to be widely agreed. Until they have been standardised, as is the case for industry and occupation, these dimensions will remain difficult to operationalise. Nevertheless, there seems to be widespread agreement that the two or three dimensional approach adopted in most traditional forecasts, will become increasingly irrelevant to policy-makers and individual labour market actors alike.

3.2.4 Employer surveys

The main alternative approach to anticipating changing skill needs has involved surveys of employers. To many people, it seemed that the obvious way of assessing employers' future skill needs was to go out and ask them directly. In the early days of 'manpower planning' and up until the late 1960s and early 1970s, this was a very popular approach. However, it was the subject of especially strong criticism. This centred upon the lack of any firm theoretical foundation as well as the practical problems of ensuring that all respondents to the survey were adopting common assumptions about the future scenario and that their responses were mutually consistent. For example all the firms in an industry cannot increase their market share simultaneously (see for example Ahamad and Blaug 1973). It fell into disrepute when projections produced for organisations such as the UK's Engineering Industry training Board (EITB), relating to engineering skills, turned out to be highly misleading. Lack of consistency in the underlying assumptions adopted by the respondents, and in particular conflicting views about future market share, resulted in very inaccurate projections.

Rajan and Pearson (1986) revived such methods in the UK in the mid-1980s. Theirs was a major survey of companies at national level. It was as much concerned with reviewing current trends and their causes as making pre-
dictions for the future. It also took a more qualitative than quantitative emphasis than many of the previous survey studies. Their work showed that this approach could, if used with care, produce useful results. Their main value is where the available data are inadequate to build more sophisticated time series econometric models (and as such they are still widely used in developing countries).

This contrasts with the results from a number recent employer surveys commissioned by TECs in the UK to provide information and intelligence on key issues of concern to themselves and their local economic development partners. Some of these surveys have been of a very ad hoc nature and have produced data of dubious quality. Others have been conducted in a much more structured and thoughtful manner and have both avoided the worst pitfalls of such approaches and provided valuable insights. A good example of the latter in the UK is the London TEC's employer survey (London TEC Council 1998). This generated a range of information on current structure and performance and immediate future prospects. The results focus on size of firm as a key issue but also move well beyond simple issues of quantitative changes, attempting to discern what is driving the observed changes. Issues of location of plant and inward investment are a key focus. However, the general consensus has been that such surveys can only provide useful indications for a very short period ahead.

There has been something of a revival of interest in this approach in recent years in the UK, with many TECs conducting regular surveys of the employers which they serve. However, these surveys are concerned with a range of issues and often do not attempt to obtain hard quantitative data on future skill demands.

Such approaches have also been popular in a number of other European countries where data from national/official sources are inadequate or do not exist (see for example Vergani and Muscella 1999 and Antonio 1999). However, they can also be an important complementary element to more quantitative modelling approaches. For example, the work of Prognos and the IAB for Germany since the mid 1980s has also made use of such survey results (see Tessaring 1997). They also form an important element in the French approach (Giffard et al. 1999).

Although the value of the employer survey method for obtaining direct quantitative data on future requirements has been brought into considerable doubt, it can still have some value in obtaining a more qualitative picture about the state of a particular labour market. In such a guise it may have much in common with so-called ‘Delphi’ techniques used to assess future prospects in areas that are hard to quantify. This approach relies on obtaining a consensus of expert opinion. This method has seen renewed interest in the late 1990s as researchers and policy makers have sought to add value to the basic quantitative approaches based on econometrics. Another aspect which has been given considerable attention in recent years, is the use of such surveys to obtain data about detailed aspects of employers' skill requirements, including information on, so called, key generic skills (see for example Mori et al. 1998).

3.2.5 Modelling supply

On the supply side, the typical approach has been to develop simple stock-flow models relating the total stock of employment in period t to that in period t-1, using an accounting identity linking the main inflows and outflows to the stock. Supplementary models to determine the proportion of the stock that is economically active (and if it is a particular occupation that is of interest, the proportion actively engaged in that particular job) have also been used. The main outflows considered are those due to death, retirement and other exits from the workforce and emigration. The main inflows relate to the flow of new entrants (qualified as appropriate), reentrants to the workforce and migration. If the focus is on particular occupational categories, then interoccupational mobility also needs to be considered. These approaches drew upon micro level company planning procedures, where often very comprehensive and detailed data were available to estimate and model such flows and transitions.
At national level, quite sophisticated systems of demographic accounts began to be constructed in the 1960s in many countries. These were intended to parallel the national economic accounts. However, lack of government interest in most countries (with one or two notable exceptions, such as the Netherlands) has meant that these have not been developed to anything like the same extent as the economic and financial accounts. As a result employment models have not flourished to the same degree as the macroeconomic models based upon the economic data. Nevertheless, employment forecasters have made attempts to fill the information gaps from various ad hoc surveys and to build models which allow for some response in flow and activity rates to economic and other factors.

In the more sophisticated models, detailed econometric analysis of time series data has been undertaken to explain historical changes in rates of flow and economic activity rates, with a view to projecting them into the future. Where data are more limited these rates are assumed fixed or extrapolated from a few observations. Data limitations have meant that in most countries the more sophisticated models are restricted to particular occupational categories, where good information on the various stocks and flows are available (see for example the treatment of highly qualified occupations in Wilson et al. 1990). Only where particular emphasis has been placed on collecting and analysing such data have more general models been developed covering all occupations (see for example the work of Heijke 1994 and the contributions for Germany, Netherlands and the UK in this reader).

It is also worth mentioning that so called skills audits (generally based on surveys of qualifications held by individuals) have also been widely used in recent years to establish the stock of skills available in particular local areas. These are surveys of households rather than employers. They are primarily concerned with assessing the supply of skills rather than the demand side of the labour market. However, such surveys can play a useful part in obtaining a complete overview of the supply demand balance.

3.3 Qualitative Methods

A variety of different types of study and approaches can be considered under this heading. They share in common the fact that they are not primarily concerned with obtaining precise or comprehensive quantitative measures of employer's skill requirements but rather a broad brush assessment of current trends and future possibilities. At the same time such studies can often involve a very detailed analysis of the particular circumstances affecting the sectors or occupations under review. They can be very useful in situations where the statistical infrastructure is not good enough to support quantitative model building.

Such methods are being employed in many countries to complement more traditional quantitative approaches. In France, for example, Giffard et al. (1999) describe the use of a variety of techniques to monitor and anticipate change. These have been increasingly popular in France since the more mechanistic quantitative approaches to planning fell into disrepute after the oil crisis of the 1970s and early 1980s. They often involve the input from a number of social partners as well as labour market analysts.

Such methods have also been widely adopted in a number of southern European countries, which do not have such good labour market statistics as some of their northern neighbours (see for example, Vergani and Muscella 1999 and Antonio 1999). Such methods do have some advantages compared to more quantitative ones (which can sometimes give a misleading impression of precision). They have therefore also been used to complement the quantitative methods.

The Delphi approach to forecasting involves pooling the opinions of a number of people (possibly experts of some kind) in order to try to identify the key issues. This can be done in a variety of different ways. The classic method is to bring the experts together in a suitable forum to exchange views and hopefully to develop some form of consensus. Another approach is to interview people and discuss the matter, possibly in a structured fashion. This
can be used to develop 'case studies', which can have some general messages. In this case the researcher/interviewer may be the only one to hear all the views expressed. They have then to make sense of all this, sometimes conflicting, information.

The UK's National Institute for Economic and Social Research has established a long and distinguished track record of such work (see, for example, the various works of Prais, Mason and Steedman listed in the bibliography). Such studies tend to focus primarily on the current situation and often involve detailed international comparisons. Anticipation of future change is generally very qualitative. Nevertheless this can add important insights which complement and support the results of more quantitative projections. This kind of approach has also been adopted in a number of other countries.

Another method, which has become increasingly popular, is to arrange 'focus groups'. Discussion of the topic of interest is then arranged, possibly based around material submitted in advance and possibly involving some kind of facilitator to prompt and structure the discussion. This type of approach is a feature of an ongoing EC ADAPT project being conducted by the UK's Engineering and Marine Training Authority (EMTA 1998). This has also involved partners in other Europe. Many other projects of a similar nature are being conducted across Europe under the auspices of the ADAPT programme. This type of approach has also been adopted in many other studies such as the UK's Merseyside economic assessment (KPMG 1996).

### 3.4 Non-traditional modelling

A number of analysts have attempted to develop less quantitative, more holistic approaches to assessing long-term futures. Such work is often focused on the notion of sustainable development and social cohesion. In the UK, the Henley Centre study of the future of work in London is a good example (see London TEC Council 1998).

In the Henley Centre approach, local competitiveness is viewed as a function of social cultural and environmental factors as well as purely economic ones. Both long and short-term drivers of competitiveness, thus broadly defined, are distinguished. These are proxied by around 50 different indicators to operationalise the concept. The model does not deliver precise predictions of changes in levels of economic activity. Rather it represents a policy tool for exploring long range issues, developing various scenarios and strategies. Applying the model to London enables the different challenges facing each of its 33 boroughs to be identified and appropriate policy responses to be developed, including implications for skills.

### 3.5 Focus on local forecasts

As noted above, during the late 1980s and early 1990s, the emphasis in many countries has switched to a more local focus. In part this was supply driven. Improved access to local data, combined with ever increasing computing power, made development of local projections, linked to a national macroeconomic forecast, both easier to conduct and cheap. Much local research has attempted to replicate what is done at national level. However, what is practicable is clearly constrained by the data available. There has also been strong pressure demanding such local emphasis and involvement, many practitioners regarding this as essential if the results are to have practical value.

In France, the emphasis since the early 1980s has increasingly focused on the Regional Employment and Training Observatory (OREF) as a mechanism for analysis of current and future training needs. These observatories have developed a range of methodologies for translating from sectoral change, through occupations and qualifications to training needs. Much of this remains quantitative in approach, but the idea that indicative economic planning of educational needs can be achieved, has been abandoned in favour of a more qualitative multi-disciplinary approach to such issues (Giffard et al. 1999).

Initially, most local projections were fairly rudimentary. A typical approach was to simply apply employment growth rates taken from a national or regional economic forecast to some base year estimates of employment in the lo-
cality. In the UK, for example, such procedures were formalised by IER in the early 1990s with the development of a software package for local forecasting (Wilson et al. 1995). This package was designed to be run on a PC by the local operator. It could be used to develop a variety of employment scenarios for the locality, linked to a particular national/regional forecast produced by IER on an annual basis. Detailed sectoral data for the locality were based on official data, distinguishing around 50 industries. Default employment forecasts for each sector were based on the assumption that the local sector maintained a fixed relationship with the corresponding regional employment figure. Occupational results were spliced on to this by extrapolating the local area's occupational structure within each sector in line with national or regional trends. Various options were possible to enable the user to customise the results, taking into account local quantitative and qualitative information. A similar package based on a spreadsheet approach was developed by Portsmouth Polytechnic (Brettell and Jaffrey 1990). This also included a Leontief input output employment matrix, enabling rudimentary impact analyses to be conducted.

Rapid advances in computer technology and software, including the adoption of Microsoft Windows as a virtual standard, have facilitated the development of much more sophisticated approaches. In a joint operation with Cambridge Econometrics (CE), the IER developed the first version of the Local Economy Forecasting Model (LEFM) in 1993 (Wilson et al. 1995). This took the basic ideas embodied in the Fortec and the Portsmouth models forward on a number of fronts. The new package was designed to provide local users with a complete economic and labour market model for the local area, constructed as a mirror image of the models used by CE/IER at national level. LEFM provides a detailed disaggregated database, covering all of the usual economic and labour market indicators for the locality. These are all linked by the same kinds of technical and behavioural linkages which one would expect to find in a national model, including a full input output matrix. Corresponding data are also provided within the package for the region within which the local area sits and for the whole of the UK. Links between the local area and the rest of the world are dealt with by modelling the flow of goods and services and of people across the local boundary. The package operates in a Windows environment. It has been designed to be transparent and easy to operate. The results produced are readily accessible and designed for input directly into written reports such as the 'local labour market assessments' which TECs were legally obliged to produce.

LEFMs have been set up for over 100 local areas in the UK since the model was first developed. The main clientele has been TECs. However, the package has also been supplied to local authorities, careers guidance companies and a variety of other clients. It has been used to produce the economic and labour market forecasts which lie at the heart of many 'local labour market assessments' and related reports. Versions of LEFM have also been set up for countries outside the UK, including Germany and Spain. Emphasis on local forecasting has also been a feature of work in many other countries although this rarely has the same quantitative, model based, emphasis as the UK research.

4. Company level employment planning

4.1 Background

Companies and other employing institutions also have an obvious interest in monitoring their workforces and assessing the implications for recruitment of such factors as the age structure of the workforce, wastage rates, and changing patterns of demand. Indeed the genesis of national employment forecasting can be regarded as work carried out at individual company level. Company level 'manpower planning' (as it used to be termed or personnel planning to use a less sexist term) is now a well established management function. Larger companies and employing institutions often have a specialist personnel manager in quite a senior position to undertake this function.

At the company level, the range of models and methods is, of course, even broader ranging
from very simple rules of thumb to quite complex models paralleling the national level ones described above. These tend to focus more on the short-term than the national models, reflecting the different interests of governments and individual companies. The former are generally more concerned with the longer term development of the economy and the provision of education and training programmes, which involve long lags between entry and qualification. They are therefore much more interested in projections five to 10 years ahead. Companies, on the other hand, often tend to be more concerned with immediate problems connected with recruitment and wastage.

Where the focus is more upon the short term, the assumptions of fixed coefficients are more sustainable. However, the longer term the forecast being undertaken, the more important it is to recognise that such coefficients may be changing because of long-term trend influences as behaviour responds to changing economic circumstances.

There is an enormous literature covering these topics, much of which is far too specific to be of general value, given the aims of this particular review. Nevertheless, it is useful to provide a brief overview of some of the key issues.

4.2 Statistical methods in use

Bartholomew, Forbes and McClean (1995) give a comprehensive review of the various techniques in use to produce company manpower forecasts. This review greatly expands on the earlier work of Lewis (1969) in this area. A great deal of the literature is very mathematical in content, see Vajda (1978), and a large number of the papers appear in statistical or operations research journals. A good summary of the earlier work in company manpower planning is provided by Smith and Bartholomew (1988).

The starting point for most traditional company manpower models is the existing stock of labour resources and the wastage flow from their stock. The mathematics of Markov chains provide a ready modelling framework for predicting such flows. As personnel record systems have improved and new statistical developments in survival analysis have evolved, semi-Markov processes in continuous time have become established. An age-specific approach can be used, rather than just a job tenure-specific method and this model is used to explore alternative scenarios, when an analysis of career patterns is taken into account. The demand side of manpower forecasting calls for a different approach because it is primarily concerned with jobs rather than people. There is no clear-cut demand model to set alongside the Markov processes which are used to model the supply-side, because the demand determinants at company level are very diverse, depending on the organisation.

Marked differences are apparent between the demand for employment in the traded sector (e.g. manufacturing companies) and the non-traded sector (e.g. local government or the health services). There is now a huge body of work about planning in areas such as health services, education services and government administration. Much of this is in the public domain. However, it tends to focus on sector specific concerns. The work in companies operating in the traded sector is extremely diverse. Much of it is highly technical and falls within the boundaries of operational research rather than the broader economic and social science which underlie the national work. A problem in this area is that much of this research is not made public because of concerns about commercial confidentiality.

Where the time series of data is long enough and of sufficiently good quality, regression modelling can be used. Alternatively, if information on causal variables is lacking, a simple trend extrapolation approach can be applied. In its more sophisticated form the autoregressive moving average class of models (ARIMAs) developed by Box and Jenkins (1970) may be used. A common problem at company level remains the relatively short time series of consistent data on which such models can be based. As databases of employment records have developed, opportunities to build better demand-side models for specific company occupations have increased.
4.3 Other methods used to project company demand

Reilly (1996) has recently described some more general and less quantitative approaches to assessing company employment demand. Amongst the methods are work study, which establishes optimal levels of resourcing for planning levels of operation. Associated with this technique, is activity analysis, that can be used to identify the numbers of employees needed for specific tasks. Both methods presuppose the company can accurately determine its future scale of operations from market output forecasts.

Other approaches which could be used are ratio analyses, which assume a fixed relationship between sales volumes and the numbers employed in specific occupations. Such an approach could be amended to allow for productivity growth. Another method is to use benchmarking, whereby staffing in comparable factories and offices is used as the criteria for determining appropriate employment levels.

In many smaller companies demand forecasting (both for output and employment) is achieved by subjective judgement of the senior managers. The criteria for making such judgements is never made explicit, so that forecasting errors cannot be reviewed and there is little opportunity to improve predictive performance from past experience.

4.4 Evaluation and improvements in company employment planning models

Commercial confidentiality shrouds many of the models produced by the corporate sector and so, it is not possible to assess how well they perform in terms of predictive accuracy. As the sophistication of supply-side modelling has increased, the prediction of changes in the existing stock of employees is likely to have become more efficient. Difficulties remain with the models for forecasting demand changes and it seems likely that the shortcomings in this area will be similar to those encountered for the national employment forecasting approaches (see Section 2.2).

Company employment planning models continue to be a valuable tool for the planning of human resources and the development of suitable training and education strategies. The literature continues to produce papers from many different countries which demonstrate the evolution of models used for forecasting employment at varying levels of aggregation. Two recent such studies are the papers by Khoong (1996) and Kao and Lee (1998).

5. The importance of the political, institutional and legal contexts

It is important to recognise that there are significant differences between countries in the approaches to these issues. These differences reflect both different cultural, historical and institutional backgrounds (which influence the general approach to such problems), as well as more specific differences related to data availability (which can constrain what is feasible). It is notable that the availability of good labour market data tends to be positively correlated with levels of national income and wealth. Although it is clear that the higher are national income levels the easier it is to afford what can often be quite expensive data collection and processing activities, a case can also be made that causality may run in the other direction. In other words good labour market information can improve the operation of the labour market and thereby contribute to economic growth and the creation of wealth.

This is certainly a major part of the rationale for the very substantial investments in this area made by the Department of Labor and, in particular, the Bureau of Labour Statistics in the USA. Although the USA is perhaps the classic example of a modern, capitalist economy, both the federal and state governments see fit to invest very heavily in data collection, modelling and forecasting. The situation in many of the richer European countries is similar although few make such large investments as the USA. In other parts of the world, such as the Tiger economies of the Far East, many governments are also
putting considerable emphasis on planning for investments in human capital.

The quantitative, econometric model building approach to anticipating skill needs has probably been most popular and been developed to the greatest degree in English speaking countries. However, many of the countries in northern Europe have also placed considerable emphasis on this approach, including France, Germany, the Netherlands and a number of Scandinavian countries. In a number of cases, they have built on the experience of countries such as the USA, adding their own particular characteristics, reflecting the national institutional framework and the statistical database in their country. In many respects, this has resulted in unique developments, but ones which, in principle have important lessons for other countries.

In the Netherlands, for example, the work of the Research Centre for Education and the Labour Market (ROA) (see, for example, Heijke 1994 and Borghans et al. 1998), has been very innovative. However, it is closely tied to the particular data available in that country, much of which is not collected in the same form elsewhere. The emphasis in ROA's work has been on providing detailed careers advice to individuals. This has shaped its methods and models, resulting in a very detailed emphasis on occupations and educational levels.

In a number of countries in southern Europe, (for example, Italy, Spain and Greece) data systems have not been established to enable the kinds of modelling work conducted in other countries to be carried out, (see, for example, Vergani and Muscella 1999 and Antonio 1999). The approaches adopted there are therefore more qualitative, and based on ad hoc surveys and other methods of obtaining data.

In the UK, the national government has also supported the development of employment forecasting, albeit not in quite the same manner or to the same degree as in the USA or Canada. It provides a good example of how institutional and other constraints influence the nature of the work conducted. The Department for Education and Employment\(^8\) (DfEE) is the national government department responsible for labour market and related issues. It has for many years collected and analysed labour market data based on a range of different sources (unemployment statistics, estimates of employment vacancies, pay and other key labour market indicators)\(^9\).

The DfEE itself carries out some of the analysis of labour market data, but it has a long history of commissioning research on the labour market, including forecasts of future labour demand. Academics and commercial consultants have undertaken this work. In particular, the Institute for Employment Research (IER) received support for developing and running a sophisticated econometric model of the national economy over many years, starting in 1975. This resulted in the production by the IER of an annual review of the economy and employment which looked at future trends in the labour market. This programme of work is described in Figure 2 above. The UK National Skills Task Force has recently recommended that such work be carried out on a regular biennial basis, supported by public funds\(^10\).

---

\(^8\) Formerly the Department of Employment.

\(^9\) These are collated and published in Labour Market Trends (formerly The Employment Gazette) and related publications. In addition, the DfEE is responsible for commissioning the labour force survey (LFS) as well as various other evaluations of specific training programmes and policy initiatives. As in other European countries, the LFS was instigated in response to the need to provide statistical data for the European Commission. More recently, it has developed into one of the major sources or labour market data, which is widely used by a vast range of analysts as well as government officials.

\(^10\) There are, therefore, a variety of well-established mechanisms for analysing, identifying and forecasting labour market trends and skill needs in the UK. However, the reliability of estimates based on some of the national surveys (often adjusted to reflect regional conditions) may be questioned. Moreover, the fragmentation at local level means that the quality of information can vary a great deal from one locality to another. The position, in general, remains less well developed than in the USA.
6. The importance of statistical infrastructure

In addition to investment in general economic modelling techniques, through support of research in universities, various national governments have also provided technical support for anticipating skill needs in a number of other ways. The key elements here have been:

- the development of standard systems of classification;
- the introduction of regular national surveys of households and employers;
- the development of means of access to these datasets electronically.

In many countries attempts have been made to develop standard systems of classification for both occupations and qualifications. Such systems are an essential prerequisite for the development of the sound statistical databases which in turn are basic building blocks for robust modelling and forecasting work.

In the USA the current focus of attention is on developing systems for classifying generic skills such as numeracy, literacy, problem solving, social skills, etc. Such developments are in hand in the UK but at a less advanced state. Other European countries, including France, Germany, the Netherlands and Sweden, have seen similar developments.

Sectoral information lies at the core of most macroeconomic models used for employment forecasting. This requires data on employment, of course, but also a range of other data if a fully specified macroeconomic model is to be developed. In most countries, where they are available, such data are based on surveys of establishments. A key issue is whether such data are available at regional and local levels. Without such information development of subnational models and forecasts is greatly constrained. Some countries are well served with regard to such data. The BLS in the USA, for example, conducts a range of very detailed sectoral and occupational surveys. In Germany the Mikrozensus (labour force survey) and the establishment panel provide key inputs (cf., for example, Dostal 1999 and Bellmann, in this report).

Until recently, information on occupational structure was, in many other countries, only available from the Census of Population which is usually only conducted rather infrequently (typically every 10 years). For example, until the European labour force survey (LFS) was properly established, with reliable information on occupational employment, the main source of data on this topic in most European countries was the Census of Population (CoP). Other surveys may have contained occupational data but this was not their central purpose and they were inappropriate for many reasons. Even today there are severe problems of comparability both over time and between countries, despite moves towards the use of international standards such as ISCO. Perhaps the most problematic feature has been the lack of a standard system for classifying occupations. Considerable efforts have been made in many countries to standardise such systems across all major surveys, but at present the differences between countries remain significant.

The European LFS is conducted in a broadly similar fashion in all the countries of the European Union. The gradual improvement in the European LFS, and in particular its recent increase in sample size, mean that it is now a prime source of data on occupations. However, it is still limited in its ability to provide accurate data for small geographical areas. Compared to the huge survey of establishments conducted by the Bureau of Labour Statistics (BLS) for the USA, the European LFS provides a very fuzzy and erratic picture of trends in occupational structure. Further improvements will be needed here if models comparable to those described for the USA are to be developed across Europe.

Other data sets also need to be made more accessible and to move towards a standard system of classifying occupations. Such developments could dramatically improve the ability of researchers to monitor trends in occupational and related matters. However,
surveys available in most European countries remain inadequate compared to the much larger surveys conducted by the BLS in the USA which provide a much more accurate picture of skill mix and occupational earnings within sectors.

A major development in making labour market information (LMI) more accessible has been the introduction of systems such as the American Labour Market Information System (ALMIS)\textsuperscript{11}. Such national systems, funded by the government, are designed to allow analysts and others direct access to various datasets containing labour market information, via the internet. These datasets include censuses of population, surveys of employers, household surveys and surveys of earnings. The availability of ALMIS in the USA has led to a vast expansion of activity related to the processing and dissemination of LMI, including the development of a range of commercial services aimed at providing a forward look at the labour market, and an enormous growth of activities based on accessing, processing and disseminating these data.

7. Problems in labour market forecasting

It is important to recognise the limitations of what can be achieved using current best practice methods. Even the most sophisticated models available suffer from a range of problems. Some of these are, in principle, things which might eventually be solved. Others are likely to remain intractable for the foreseeable future. These problems can be discussed under three main headings:

a) limits to understanding,
b) data inadequacies,
c) methodological difficulties.

7.1 Limits to understanding

The world is a very complex place. Most socioeconomic variables are the outcome of the decisions and actions of many different individuals and institutions. Chance factors, acts of God, in addition to well laid plans influence the eventual outcome. In developing models to explain behaviour, the objective is to identify and isolate the key factors which are held to affect the variable of interest. This is often much easier said than done. It is often quite difficult to disentangle the various influences which are thought to be important.

Most models are set up on the basis that behaviour is fixed. This itself may be a questionable assumption, especially in the social sciences. Behaviour may alter in response to new events or changes in exogenous variables (that is variables whose own determination lies outside the system being modelled). In some cases behavioural relationships may lie hidden because previously unexperienced influences come into play. A good example of this was in macroeconomic models used to explain aggregate consumption during the 1970s. These failed to include inflation as an explanatory variable until inflation reached significant levels in the 1970s. Inflation had always been a potential influence but its effect remained hidden while it was not at a high level. Until this was recognised by the modellers, their models produced biased forecasts.

In producing any particular forecast a view must be taken about any exogenous factors that may be important. For example, government policy is frequently regarded as exogenous because of the difficulties in modelling the political process. This does not mean to say that such matters are unimportant. Typically, the sensitivity of the forecast to alternative assumptions about such matters is assessed by developing a range of scenarios rather than just a ‘fixed point’ forecast. Major economic traumas in the rest of the world economy may need to be dealt with in a simi-
lar fashion. Few national employment forecasters attempt to model explicitly what is going on in the world economy, even though it may be a key driver of domestic employment.

Some other, non-economic events, such as earthquakes, may also be regarded as 'unforeseeable' in the context of forecasting the labour market. Such 'acts of god' are regarded as inherently beyond the understanding of the model (although in another context geologists may make serious attempts to forecast such events).

7.2 Data inadequacies

A major problem area in much forecasting work relates to data. This may reflect lack of data on key variables, for example, accurate and detailed data on occupational employment and occupational earnings, as well as many important labour market inflows and outflows. It may also reflect inadequate data in terms of timeliness, accuracy and fitness for the purpose it is being used. Frequently the data available are lacking (for example, labour market flows). Often they have been collected for a different (often administrative) purpose and are therefore less than ideal for the development of a forecasting model. There is no substitute for good quality, regular information. Unfortunately it is often not until model building has begun that is possible to accurately identify data requirements. In the first instance, of course, it is necessary to do the best one can with whatever data are available. Data problems remain a key constraint to the development of employment forecasting tools in many countries. While a few, such as the USA, have very good systems, many others, including many European countries have to muddle through using what limited data are available. In other countries, even the basic data needed to build detailed multisectoral models (such as detailed measures of sectoral output and related economic accounts) remain a dream.

7.3 Methodological difficulties

Econometricians have identified a whole series of methodological problems in the development of time series models. This is not the place to go into such issues in detail. For this, the reader is referred to a standard econometrics textbook. However, it is helpful to rehearse some of the main problems. One class of problems comes under the heading of multicollinearity. Most variables in economics are highly trended it is therefore often very difficult to disentangle the separate influences of different - variable. It is also too easy to discover spurious relationships which simply reflect the fact that two unrelated variables are both trended (and therefore closely correlated) while in reality there is no relationship between them. A second class of problems relates to simultaneity. Variable X may depend on Y but Y may also depend on X. Technically Y is said to be an endogenous variable, that is a variable determined within the system that is being modelled. This contrasts with an exogenous variable which is entirely determined by factors outside the system being modelled. Considerable care is required in such circumstances if misleading inferences are not to be drawn. It is of course a truism that nothing is truly exogenous and that everything depends upon everything else. The trick is to identify which are the essentially exogenous variables in any system and which need to be treated as simultaneously determined.

Various other technical pitfalls await the unwary forecaster, such as serial correlation, heteroskedasticity and omitted variable bias. This is not the place to discuss such matters in detail. Suffice it to say that in developing a satisfactory forecasting model, due consideration needs to be given to avoiding falling into such traps, if the forecasts are not to mislead rather than guide policy-makers.

There have been numerous methodological advances in this area in recent years which have been aimed at addressing these technical problems. However, it is probably true to say that these lessons have yet to be fully implemented in the practices of most labour market forecasters. However, this is not a reflection of the failure of such analysts to recognise the need to improve their methods so much as the difficulty of applying these new techniques when dealing with so few time series observations.
8. Conclusions

8.1 Forecasts – Who needs them?

The world is an uncertain place. In this context, almost everyone is involved in planning and forecasting, even if this amounts, in practice, to assuming implicitly that there will be ‘no change’. It has been argued by employment forecasters, that since some forecasting of the labour market is inevitable, it is better that they be done in a logical, consistent and systematic fashion. There is a large body of opinion that such forecasts can be of value to a broad range of potential users within a particular geographical area, be it a national economy or a much smaller local area. At one level are policy makers charged with the responsibility of setting the institutional framework and delivering government policy. At another level are those concerned with providing goods and services, including education and training programmes. Employers, educationalists and, of course, individual students and workers themselves, all have an interest in trying to peer into the future and to ensure that their own decisions result in the best possible outcomes (however these might be defined).12

Forecasts can therefore be seen as having two prime roles: first to guide policy decisions made by the government and its representatives; and second, as a general aid to the individual actors operating within the labour market, providing them with information which can aid their own decision making. The degree of emphasis on these two elements differs quite significantly between countries.

Against this view must be set opinions of the smaller but at times vociferous group of critics, who have decried the value of such activities. They have argued, variously, that it is unnecessary, impossible and/or irrelevant to carry out employment forecasts. In many cases, however, their criticisms have been constructive and have led directly to improvements in methods and approaches used, including the development of more qualitative methods. In other cases the practitioners have argued, convincingly in the opinion of the present author, that the criticisms are invalid. The fact that considerable efforts to conduct such forecast are going on all over the world suggests that, on balance, such activities are generally regarded as very useful and are perceived as having real value.

8.2 Accuracy and limitations of forecasts

It is important, of course, to have a clear appreciation of the limitations of any forecast. Forecasters do not have a crystal ball and cannot foresee the future precisely. Nor are they concerned to ‘plan’ in an indicative sense. Rather, they try to map out the consequences of a series of assumptions about patterns of behaviour and policy stances for likely future developments.

As set out in Section 7 there are severe limitations in our ability to forecast. These include:

- data problems – there is often considerable difficulty in establishing the current position let alone forecasting the future. These difficulties may be especially acute at local level;
- limits to understanding – although the social sciences have made considerable strides over recent years there are still major gaps in our knowledge about how systems and individuals behave;
- past behaviour may not always be a good guide as to how things will develop in the future;
- there are technical difficulties in forecasting which are often ignored due to data limitations (multicollinearity, serial correlation, simultaneity bias, etc.);
- a final set of problems relates to the fact that many events are inherently unpredictable (such as earthquakes or other acts of god, political events, etc.).

12 This information may need to be processed and moderated by careers guidance counsellors in order to be of value in making individual training and career choices.
8.3 The benefits of conducting forecasts

The production of a formal forecast or set forecasts for a particular area should not be seen as an end in itself. Rather it is best regarded as part of a process of improving understanding about what is going on in the economy and the associated labour market. This understanding can then guide policy makers and other actors operating within the local economy (such as individual workers, students and employers) to better decisions. The main benefits can therefore be summarised as follows:

- the aims and objectives of intervention can be made clearer and the ability to evaluate policy can help to establish a virtuous circle;
- forecasts can provide a focus for discussion and cooperation ('posing questions') and may help to breakdown old misperceptions about labour markets;
- forecasts should enable those involved to take a more strategic, rather than a firefighting, approach to problems as the implications of current trends and outcomes for the future are explicitly explored;
- finally, forecasts can also provide important information and guidance to individuals enabling them to make better decisions about their own futures, although this may need to be moderated by expert careers guidance counsellors to be of most value.

8.4 Preferred methodologies

A number of different approaches have been adopted to anticipate changing skill needs. The traditional approach has usually involved formal, quantitative methods. More recently, other, rather less formal methods have been developed which have a strong qualitative emphasis. Often this has reflected problems or lack of key data. However, many exercises nowadays involve a mixture of both quantitative and qualitative methods, which are regarded as complementary.

With regard to quantitative methodologies, on the demand side, best practice increasingly involves more sophisticated econometric techniques, enabling quite complex behavioural models to be developed. Often this is now employed in conjunction with surveys of employers, asking them more or less directly about their future skill needs. Until recently, the latter had fallen into disrepute but is currently seeing something of a revival, albeit in a modified form.

On the supply side the main methods used usually involve a stock-flow approach. This projects future stocks from current levels by predicting inflows and outflows. In the early models this was usually done on the basis of assuming fixed rates of flow based on past data. However there is much evidence accumulating that such flows are dependent on economic and other variables. The focus of such models tends to be on the existing workforce, inflow rates and wastage rates. Better data are now becoming available enabling something approaching a full set of demographic accounts to be developed in some countries at the leading edge of such work. As such data are improved, this will facilitate the modelling of transition rates between the numerous states of training, employment, unemployment, etc.

Although the present review of the main forecasting methodologies suggests that a behavioural model is the most appropriate approach (which should, in principle, enable a better understanding of the main factors influencing the supply of and demand for skills), more basic time series models may also provide a useful supplement in situations where data limitations preclude the more sophisticated approach.

Most recent work has emphasised the need to consider replacement demands and not just to focus on projected levels of employment\(^\text{13}\). In addition, other more qualitative methods, involving surveys, case study work, focus

\(^{13}\) Although this has been done in some countries such as Germany since the 1970s, albeit not always in a detailed breakdown by single occupations or fields of study.
groups and other techniques have all been found to have the potential for 'adding value' to the more traditional methods. A key feature of much recent work has been the focus on key or generic skills which go beyond the straight-jacket imposed by traditional occupational classifications, to look at the skills needed to do various tasks.

8.5 The importance of the political and statistical infrastructure

When comparing the different approaches used to anticipate future skill needs in different countries, it is clear that the political, institutional and legal context, have had a crucial influence. In part, this is reflected in the statistical infrastructure within which the analyst has to operate. The latter has a particularly important influence. Without good data it is impossible to build some of the more sophisticated models. Statistics are of course only part of the story. The development of macro-economic and labour market forecasting models is a very slow and expensive business. Most of the countries where fully developed systems are in operation have invested very heavily in such activities over a period of many years. While new IT developments mean that it is now much easier to duplicate such effort and possibly to 'piggy-back' on what other countries have already achieved, it is less easy to suddenly invent a long time series database, which lies at the heart of most models.

The impact of IT in this area has been immense. In the USA the development of ALMIS the American Labour Market Information System has facilitated all kinds of research and commercial activities in the area of LMI and labour market forecasting. This has also been a feature in some European countries. For example, the DfEE has supported the development of the equivalent UK National Online Manpower Information System (NOMIS). This provides online access to labour market information via the internet to anyone with the appropriate technology. It includes all the major data sets for which DfEE is responsible\textsuperscript{14}. This has led directly to the development of many new local products and services.

8.6 Increasing emphasis on local forecasting

In recent years, there has been an increasing tendency towards devolving power to smaller geographical units in many developed economies. This has led to an increased demand for labour market information (LMI) and, in particular forecasts, at local level. As the perceived need for information at local level has grown, so the capacity of the databases and the power of equipment required to process data have increased. The information revolution has gathered pace over the 1980s and early 1990s and analysts and policy-makers now face the prospect of an enormous increase in the amount of information available. Data are becoming more easily available in many ways, with the introduction of on line databases, the increasing ease with which large survey databases, such as public censuses, can be accessed and the growing power of computers to process this information.

However, in some respects, there is a danger of being overwhelmed by the mass of data available and a key problem is to avoid information overload and to sort out the key messages. As at national level, local forecasts are intended to identify the key trends and to highlight the main issues that will be important in the future. In these circumstances, analysts have begun to develop tools, which bring together relevant information about the local economy and present it in an easily digestible form. At the same time, these tools can draw out the implication for the future of continuation of past trends as well as enabling 'what if' scenarios to be developed. A basic aim is to convert basic labour market information into useful intelligence, which can be used to guide important decisions. Another objective, in many cases is to empower the local analyst by providing them with the tools to undertake their own forecasts.

8.7 Main policy conclusions

The main policy conclusion from this review is that employment forecasting can and does

\textsuperscript{14} Charges are made for accessing these data and there are strict controls to ensure confidentiality.
provide a useful aid to policy-makers in making decisions about training, recruitment and the personnel issues. It can also provide very useful information to a broad range of other actors in the labour market. This includes employers, education and trainer providers as well as individuals, although the need for such information to be moderated by careers guidance counsellors and others is strongly emphasised in many countries.

However there are strong limitations to what such exercises can do and it is clear that they do not offer a crystal ball from which the precise details of the future can be gleaned. Rather they spell out the implications of a series of assumptions about future developments based on certain relationships representing a continuation of past patterns of behaviour. Appropriately done, they can provide a transparent, logical, consistent and systematic view of what the future might look like given these assumptions.

The value of such exercises depend crucially on the quality of the data upon which they are based, as well as the validity of the various assumptions built into the forecasts. To some extent the latter will depend upon the degree of sophistication of the models adopted, the more sophisticated the model the more likely it is to be able to deal with the many and subtle influences on changing employment structures. Naive, mechanistic models are, unless used very carefully, likely to mislead rather than inform. On the other hand, increasing detail, complexity and sophistication of some models can rapidly run into decreasing returns, unless backed up by data and analysis of equivalent quality. Increasing detail and complexity can also reduce transparency. It also makes it less easy to identify simple causes and effects, as for example, in econometric models with several thousands of equations. Some forecast evaluations suggest that 'native' models, at a more aggregate level, are not necessarily of lower accuracy than more complex and detailed ones.

It is also important to emphasise the many problems and difficulties that face many forecasting exercises of the kind reviewed here. Gaps and inadequacies in the database set limits on what is feasible. Methodological problems further compound the difficulties that the forecaster faces. The sheer complexity of the real world and the difficulty of identifying and isolating the key influences on the supply of and demand for skills must not be underestimated. A major reservation on forecasting is that despite all the effort on forecasting activities since the 1960s and 1970s, this has not been able to prevent unemployment and over-education. The jury remains out on whether this is because of the inadequacies of the projections themselves, or whether it reflects the fact that policy makers and others have ignored them (or possibly failed to act appropriately).

Despite all these caveats, the experience of many countries outside Europe, particularly the USA, suggests that useful forecasting tools can be developed at European level. This experience suggests that such forecasts can provide helpful information to both labour market participants as well as for policy-makers about the labour market environment they are likely to face. It is therefore recommended that the possibility of developing a regular European-wide labour market assessment, including detailed occupational forecasts, be given serious consideration.

Forecasting skill requirements at national and company levels

This is the background publication of the second report on vocational education and training (VET) research in Europe published by Cedefop in 2001. It contains a number of contributions on current research in the framework of generating and using skills and competences. The basic theories, methodologies and results are presented and the main implications for future research, policy and practice are discussed within each contribution.

Some key issues addressed include:
- steering VET systems, funding and the changing roles of VET professionals;
- learning and training within the context of lifelong and lifewide learning;
- training, employment and development of human resources from a company perspective;
- labour market dynamics and their impact on skills and competences;
- individual performance, social exclusion and transition from education/training to work;
- VET research in selected non-EU countries.

We hope that this publication coupled with the complementary synthesis report, will enhance understanding of research undertaken within Europe and contribute to closer cooperation between researchers and decision makers at all levels.

Abstract
Learning at school and university and also at the workplace has become more important in the knowledge-based economy. This paper provides a critical review of recent econometric work on the determinants and impacts of training in Europe. Training has non negligible positive effects for firms and trainees; for the group of non trainees potential negative effects has been found in some studies. The incidence and the impact of training depend on the national education and training system. However, selectivity, diversity of training, individual heterogeneity, self selection and general equilibrium effects seem to play an important role in all training systems.

* Sladjana Milentijevic and Jochen Möbert provided research assistance. Furthermore, I would like to thank Pascaline Descy, Manfred Tessaring and members of the CEDEFOP research network for many valuable comments and remarks. The usual disclaimer applies.

Summary

Learning at school and university and also at the workplace during working life has become more important in the knowledge-based economy due to economic and technological change. In some occupations and places of work, skill obsolescence due to technical change seems to be arriving more rapidly.

This raises questions on the importance of general versus more specific types of knowledge and skills, and the relative importance of classroom-based education versus self-organised forms of learning. In European Union countries, more people are better educated, more participate in continuous training and on-the-job learning. However, empirical knowledge on the determinants and effects of different methods of learning is still scarce, especially from a European viewpoint.

Although there is a widespread belief in a positive relationship between education, training and growth, the evidence provided so far is far from being complete. Aggregate figures for the European Union suggest a clear hierarchical pattern in the labour market: those who are better educated are on average better represented in the work force; have higher earnings; participate more frequently in formal continuous training; are less often unemployed; are more often self-employed; have a higher regional mobility, and work with newer and more high tech equipment. Job mobility on the other hand is negatively correlated with the amount of human capital invested in a specific occupation, since investment increases switching costs. The pattern seems to have been rather stable over the past few decades, although continuing skill-biased technological change is a challenge for VET policy in Europe.

These stylised facts do not necessarily mean that those who are better educated or have higher educational qualifications also have a higher lifetime income or utility, because in the investment period they often have higher costs and there may be substantial comparative advantages for different educational pathways (for example, more cognitive or more mechanistic skills) for different people. Assuming heterogeneous individuals, there are individuals at the margin, whose lifetime utility is rather similar in different pathways and there are individuals who receive higher utilities either with lower or higher educational qualifications.

What one would really like to know for policy analysis is the value of the lifetime utility of a person for different educational pathways under different educational standards and regulations. However, these values are not observable and estimates available are far from being conclusive in all respects.

The critical review of more specific econometric work in this study indicates that training is beneficial for both firms and individuals. The benefits are not negligible, in fact they are sometimes rather large. The fact that training has positive effects is, however, no guideline per se for government activity. There is evidence that self-selection on the one hand and general equilibrium effects on the other are at work. As a rule, training has positive effects and net benefits for trainees. However, there is some evidence that net effects for non-trainees might not be positive. In these cases, training might be a bad investment for the respective people, firms and – from the viewpoint of economic efficiency – for society.

In addition, non-negligible parts of observed differences in outcome variables such as earnings, wages, hours of work or career satisfaction cannot be attributed to education and training. Innate abilities, heterogeneity of abilities and preferences, family background, political events (for example the fall of the Berlin wall on 9 November 1989 had significant impact on the East Germans), luck and the path of economic and technological development are factors which are all important. Selectivity, diversity of training, selection and general equilibrium effects seem to play an important role in all training systems as well.

The empirical results suggest that the more structured the whole training system is and the more investment in general human capital acquired while a person is young, the lower the returns to continuous training are after
this high initial investment. If education is centralised and compulsory school attendance is expanded, then all people should achieve higher levels of education and formal skill levels. Selection into different career pathways transmitted through labour markets begins after compulsory school attendance. If the level of more general types of skills learned in schools is high, training at the workplace plays a different role and is no longer responsible for building up these more general types of skills. Such mechanisms seem to be responsible for the lower returns to continuous training in countries such as Germany and France compared to the United Kingdom. Conversely, the less structured the training system is, the higher the measured returns of continuous training seem to be.

European training systems differ. The different types of investment in VET and the spacing of these investments over an individual's life and the role of the State will depend on differences in prices for education, expected wage profiles, the skill structure of the workforce, tradition and technological factors. Success at school and other training institutions is not the only factor explaining work-related success and careers. Labour market regulations and institutions might lead to insider power and create entry barriers and waiting queues for young workers, despite higher education and greater investment in training. Such mechanisms seem to be present in most European countries, although to different degrees.

Some of the findings are a major challenge to the role of government in training. Obviously, formal education and training are not omnipotent weapons against all storms of life for all people, but they may be very strong weapons when used at the right time, to the right extent and with the right content. At other times in an individual's working life, other weapons such as non-formal learning, regional, firm or occupational mobility might be more helpful.

Centralisation, in the sense of generally acknowledged educational certificates (trades in the German dual vocational training system, for example) might be helpful for some occupations and especially when larger investments in educational qualifications are considered. However, there seem to be limits to such strategies.

Firstly, the German apprenticeship system sometimes seems to react very slowly to rapid economic or technical change (Blechinger and Pfeiffer 2000) with the consequence that training curricula are old fashioned and skill obsolescence becomes a problem for firms and workers, which they try to overcome by additional and costly continuous training. Secondly, the set up and running costs of such a system can be rather high. More decentralised, deregulated and flexible systems, similar to those in the United Kingdom or the United States which depend to a higher degree on market signals, might have an advantage in times of rapid and unpredictable technical change. However, there may be other benefits in a more centralised system with compulsory school attendance. Youth unemployment is low in Germany and participation rates in VET are high. Imperfect capital markets, which can create entry barriers for poor young individuals in market economies do not play a major role. One single optimal VET system does not exist. Policy-makers have to attach weight to different policy objectives when policy changes are considered.

Key qualifications and more general human capital cannot be acquired in a short time. If technologies change, key qualifications will also change – to some extent at least. They have to be acquired through a long and continuing process (Weinert 1997) which presumably will have a sustainable impact when people are young or very young. The older individuals become, the more important non-formal and self-organised types of learning become. Mobility between occupations, regions and firms might also be valuable strategies for improving the career position of workers.

For improving VET policies an adequate, systematic and regular research design ex ante would be helpful, to allow greater understanding of the relationship between specific VET activities and the actual, secondary and desired results. Due to tight public budgets, the need for evidence of impact and efficiency of
new and existing programmes will increase in future. A research design that takes diversity of situations, heterogeneity of individuals, differences in training systems, governments, markets, etc. into account is, however, expensive and takes time. If, for example, a unified European survey on VET would be conducted in the year 2000, the results of the analysis would only be available between 2001 and 2004 or even later. If one wished to compare the results over a longer time span, for example over a period of 30 years (compare the National Child Development Study – NCDS – from the United Kingdom which started 1958) results would not be available until 2030.

Besides research based on microdata which allows one to investigate the determinants and partial impacts of VET at individual level, general equilibrium effects should also be investigated using time series or panel data. Research on VET based on microdata might be improved if it were more regularly and systematically based on European wide conducted data sets, such as ELFS, European Household Panel or IALS. Despite methodological problems, international surveys should have the advantage that the most interesting human capital and training variables are defined in comparable ways. Empirical results for different regions might be more comparable and differences in results might help to identify the different impacts of national VET policies.

National VET programmes and policies dominate Europe. It is therefore necessary to evaluate specific VET programmes on a regional or national basis. There is no need for standardised and European-wide evaluations if national VET programmes dominate. Most firms hold formal or more informal training programmes. Therefore, there are markets for training and these programmes seem to provide returns to investment which are as high as other investments in machines or research. However, the author is not aware of systematic research on the returns on training investment by private firms. This would be an additional source of extremely valuable knowledge and information for assessing public VET policies.

From the author’s point of view, future research could be directed towards the following questions to improve the understanding of the impact of VET policies at both individual and aggregate levels, and optimise policy reactions to technology and other shocks. The questions are interrelated.

1. Research on specific public VET programmes should be intensified to learn about partial impacts at individual level and efficiency of programmes. This type of research is usually based on microdata if the programmes are not too large. A partial evaluation design ignoring general equilibrium effects should suffice.

2. Research on public VET systems should also be intensified. This type of research should evaluate the whole system and also take into account general equilibrium effects, financial efficiency and labour market institutions. Research on this topic is usually based on aggregate time series data, individual panel data and official data on programme costs.

3. Research on the returns of VET for non-participants should be intensified. Should governments help non-participants and especially individuals with low skills to participate in VET or CT, or are other measures, for example wage subsidies, better for improving the labour market position of the low skilled?

4. It is not fully understood, whether there are cumulative negative or positive relationships of public VET policies of different types transmitted through labour markets. Therefore, research on the question of whether public promotion of higher education in the past 30 years had a negative impact on wages and labour market prospects of individuals with vocational education should be intensified to avoid negative relationships in future and improve coordination between educational and labour market policies.

5. How efficient will educational policies and relative higher and secondary education for the next 50 years be for young people en-
tering national training systems in the next five or 10 years? What is the optimal portfolio for different types of education? Should it be more general or more specific in nature, and should it be for individuals, firms, regions or Europe?

1. Introduction

Learning at school and university and also in the workplace during working life has become more important in the knowledge-based economy. In some occupations and places of work, skill obsolescence due to technical change seems to be arriving more rapidly. This raises questions on the importance of general versus more specific types of knowledge and skills, and the relative importance of classroom-based education versus self-organised forms of learning. In European Union countries, more people are better educated, more participate in continuous training and on-the-job learning. However, empirical knowledge on the determinants and effects of different methods of learning is still scarce, especially from a European viewpoint.

In this article, the relationship between learning, training and individual performance is discussed from a theoretical and empirical point of view, based on scientific research on the determinants and impact of training in the past decade. The main question is who participates in training and for what reasons, and what the effects are with respect to productivity, wages, job search, employment, job duration, mobility, careers and other variables. These questions can be applied to all agents involved in the training process, namely for individuals, firms, training institutions as well as governments. The research task is to measure the training incidence and outcome and to look behind the mechanism which may help to explain the results. Since governments in Europe are increasingly involved in educational policies and active labour market programmes for improving the skill level of the unemployed, and public budgets are tied, evidence on the effectiveness and efficiency of such policies becomes more important.

In Europe, there is a great variety of training measures in terms of their content, duration, financing and direction, depending among other things on the changing historical and cultural role of the State in the education and training process. Thus, the determinants and outcome of training are also characterised by a considerable amount of heterogeneity. For some individuals, training has a positive impact under particular conditions, for others it seems to have no or even a negative impact. Although there is widespread belief in a positive relationship between education, training and growth, evidence provided so far is far from complete.

In this study, attention will be restricted to a microeconometric analysis of the determinants and effects of initial and continuous training in European countries or selected regions in Europe. The goal is to quantify different factors determining training and its outcomes. It rests on theoretical and statistical models and ideally allows the testing of conflicting hypothesis or alternative explanations. Due to the increased availability of microdata and to an increased use of microeconometric models in the past 10 to 20 years, this is a dynamic and growing field of research. It was not possible to review all of the work done in this field.¹

The report concentrates on quite recent works carried out using data from European countries. Furthermore, there is focus on economic aspects of training, namely on incentive and investment issues. This does not mean that other aspects are irrelevant. Social and cultural aspects are also of great importance (see Cedefop's first report on vocational training in Europe: Tessaring 1999). However, there

¹ I apologise if all available research is not mentioned and discussed according to its relevance. The selection of studies used for this report is the result of an electronic search strategy and a manual search in selected journals, the European Economic Review, Labour Economics, Oxford Economic Papers, The Journal of Human Resources, Journal of Economic Literature and The Journal of Labour Economics. In addition, recent research on the determinants and effects of training for German employees and the self-employed has been incorporated (Pfeiffer and Reize 2000).
exists a trade-off between in-depth discussions of specific aspects of training from an economic viewpoint and a general discussion covering all aspects of training. This is not an issue for this study, since it favours a more specific discussion.

Although the main discussion centres around VET, some studies also refer to higher education at universities. This is important since in labour markets different types of skills may be substitutes or complements, depending on labour market institutions and technology. Recent research on skilled-biased technological change in industrial countries seems to indicate that skilled workers with higher secondary education are substitutes rather than complements for skilled workers with higher education (Machin and van Reenen 1998). In the process of technical change in particular, the share of skilled workers with secondary education is declining. Technical change seems to be biased to more cognitive and theoretical skills. The bias seems to depend not only on technological factors but also on labour market institutions. Therefore, extending the focus can help improve understanding of the basis for economic incentive and investment issues in education and training.

This chapter is organised as follows. The next part provides selected indicators showing the relationship between VET and economic performance in the European Union from a highly aggregated point of view using official data. Part three contains theoretical considerations on the relationship between ability, education and mobility. Individual or firm data sets are introduced in the next part, followed by a discussion of the theoretical and empirical methods underlying the empirical work and some issues with respect to the measurement of training and outcomes. There is virtually no unified data source that has been utilised for all countries of European Union and there is great variety in data, empirical methods and measurement of training. In part five, different results of these studies are compared and discussed. In the last part, conclusions are drawn with respect to future research and VET policy in Europe.

2. VET and economic performance – selected indicators

This part provides an overview of selected empirical relationships between the amount of education and training a person received and his/her position in the labour market. The figures presented in Table 1 are based on highly aggregated numbers for the 15 Member States (EUR15, taken from Eurostat 1998 and the European Commission 1997) and, in the case of earnings, on 12 European member countries (taken from OECD 1998a).

In line with the discussion in Cedefop's first report on vocational training (Tessaring 1999) VET is identified with ISCED 3 (higher secondary education) and compared to ISCED 0,1,2 (preprimary, primary and lower secondary education) and ISCED 5,6,7 (higher education). The data collected refer to employment, unemployment and self-employment, to continuous training and earnings in 1995 or 1997, in EUR 15 or in 12 European countries.

It is shown in the first row of Table 1 that roughly 76% of those belonging to ISCED 3 aged 25 to 59 were employed, compared to 85% of those belonging to ISCED 5,6,7 and 59% of those belonging to ISCED 0,1,2. There is a monotonously positive relationship between levels of employment and the level of education, while unemployment rates are monotonously negatively correlated. Depending on the definition of unemployment, 7.3% or 8.8% of all those belonging to group ISCED 3 in EUR 15 had been unemployed in 1997, compared to 5.3% or 5.8% of those belonging to ISCED 5,6,7 and 8.4% or 12.5% of those belonging to ISCED 0,1,2.2

Youth unemployment rates in Europe are much higher than those for middle-aged people. However, again, there is a negative correlation between the level of education and

2 The different numbers are the result of different definitions of unemployment. The lower numbers refer to the ILO definitions, the higher are based on the number of persons officially registered as unemployed.
the level of unemployment or the threat of unemployment. Those young people who have invested in an education comparable to a higher secondary education are less hit by unemployment than those who have invested less.

It is also clear from the numbers in the table that the higher the level of education, the higher the ratio of continuous training (CT). While roughly 6% of the European medium-skilled labour force participated in CT during the past four weeks, only 3% of the low-skilled did so.

What is not as obvious and well documented is that self-employment rates (the figures in the table are based on the group of self-employed without employees) are positively correlated with the level of skills. The positive correlation is even more pronounced for the self-employed with employees, since qualification matters even more if the self-employed recruit employees and have larger firms (Pfeiffer and Falk 1999).

Education and earnings in the 12 European countries are also positively correlated. There are significant differences in the relative earnings position of VET earnings, but in every country they earn more than employed people with a lower level of education on average and less than employed people with a higher level of education. The wage distribution is more even in Scandinavian countries, but even less, for example, in Portugal, where low-skilled workers earn about 60% of medium-skilled workers and high-skilled workers earn about 183% of medium-skilled workers.

To summarise: aggregate figures for the European Union by and large show a positive correlation between investment in human capital and employment, earnings, self-employment and further investment in human capital and a negative correlation between human capital and unemployment.

There also seems to be a positive relationship between human capital, regional mobility and the use of high-tech machines at the workplace, as is reported by Pfeiffer (1997) for Germany, Entorf and Kramarz (1997) for France, or Blundell et al. (1997) for the United Kingdom. Occupational mobility on the other hand is negatively related with the amount of human capital invested in a specific occupation, since the costs of switching between occupations rise with former investments in human capital (Pfeiffer 1997).

A closer look at individual countries reveals different numbers in all these indicators but, by and large, the same pattern can be observed. The country numbers are documented in official reports of the European Commission and it is not necessary to repeat them in the current paper. The empirical relationship between training and other indicators differs between countries, with differences being the results of many factors, among them the economic and demographic composition of the labour force, the capital and technology intensity of firms and the industry, as well as differences in the governmental framework and policies of the individual European countries (Tessaring 1999; Muller and Shavit, 1998, OECD, 1998 b).

3. Theoretical considerations: education, innate abilities and mobility

According to a well-known distinction, there are two types of human capital: specific and general (Becker 1964). While general human capital is valuable in the whole economy, specific human capital is valuable only in a firm, region, or in conjunction with a special technology. Since resources such as time and money are scarce, individuals, firms, training institutions and governments have to make decisions about the composition of different types of investment in human capital. Findings from the aggregate level seem to suggest that there are different solutions to the trade-off between investment in either more specific or more general VET (Levhari and Weiss 1974) depending on the pace of cultural, economic and technical progress where the individual lives.

The trade-off is a result of at least two conflicting factors. More general skills and hu-
Man capital can be used in many different occupations and can help to reduce the cost of further education and learning, for example at the workplace. A large and rising degree of specialisation at the workplace, however, also requires very specific skills. People with these skills presumably start with higher productivity when entering a new workplace compared to people with more general skills. In times of more rapid technical change or increased uncertainty about the future of economic development, investment in more general skills can be a better strategy, because demand for specific skills in the future is uncertain and the risk of skill obsolescence higher. In times of reduced levels of uncertainty about the path of economic and technological development, investment in more specific skills might be a better strategy.

Larger amounts of investment in more general skills in all European countries over the past few decades can be explained as a reaction to increased levels of uncertainty about economic and technological developments. Although more people are better educated ('educational revolution'), the numbers and figures in Table 1 seem to indicate a clear hierarchical pattern in the labour market: those who are better educated are, on average, more often part of the workforce, have higher earnings, participate more frequently in training and are unemployed less often. In the past 20 years in most European countries, the percentage of workers with an academic degree has doubled (BMBF 1999). The percentage of workers with higher secondary education has also risen, but only slightly. Nevertheless, the hierarchical patterns seem to have been rather stable in recent decades. According to Mayer (1996), the hierarchical pattern has been stable in Germany for the past 50 years. However, the interrelated impact of educational revolution on the one hand and skilled-biased technological change on the other, might have far reaching consequences for the future of VET, a topic which will be discussed again.

The numbers presented in Table 1 are of a descriptive nature and are taken from aggregate statistics. The relationship may not be true any longer at individual level. A positive correlation between earnings and years of education in the aggregate is, for example, compatible with the observation that there are people with 18 years' education who do not earn more than people with only nine years' education. Furthermore, it is not possible to conclude on the basis of the numbers that the observed relationships and earnings differentials are the direct result of training or VET.

First, the differences in the outcome variables such as earnings may also be the result of other factors not under investigation in Table 1, for example age, gender or occupation. Differences in the age structure of the workforce may explain part of the positive relationship between levels of education and earnings, since investment in human capital typically takes time and is therefore positively correlated with age.

Second, people may put themselves into different training routes according to their preferences and innate abilities, factors which typically are not observed very well in empirical research. People take part in training because they expect higher net benefits, which might be difficult to observe for researchers. Innate differences in abilities, for example, can explain 50% of the variance of intellectual capacities of young people in Germany (Weinert 1997, Weinert and Schneider 1998). Furthermore, the ability differentials seem to stay rather constant over long periods and might not change in schools. A statistical correlation between schooling and training variables, and outcome variables such as earnings, might therefore be biased due to omitted variables such as innate abilities or ambitions, i.e. due to self-selection. The bias can be in both directions.

In economic terms, this is part of the human-capital versus signalling debate (Cohn and Geske 1990, Tessaring 1999, Weiss 1995, Wolpin 1977). The positive correlation between higher earnings and level of education may not be the result of investment in human capital, but higher investment in human capital might just be a signal of higher innate abilities. In the most extreme form of this screening hypothesis, schooling serves

only to identify those individuals who are more productive in the market, the proposition being that an individual's productivity is unaffected by the formal schooling process.' (Wolpin 1977:950).

This debate is also relevant for CT, although the incentive and investment character of decisions in CT differ. Firms already know their workers and the information problem has therefore been solved and can no longer be the central issue if we look at firm and work-related training. However, training and promotion schemes are highly interrelated (Prendergast 1993) and the causal relevance of training for promotion can be questioned. Training at the workplace might rather be a consequence of promotion than promotion...
being a consequence of training. In that case, research on the determinants of promotion becomes as important as research on the determinants of training.

For the purpose of this study, training is defined as an investment by individuals, firms or the government. While the costs of training have to be born today, benefits will manifest themselves in the future. The outcome of training is uncertain to different degrees depending, for example, on the quality of the training institution, the path of technical change and economic growth, but also on the size of cohorts and demographic change (Tessaring 1999).

Investment in training is not the only relevant decision for any involved party, namely individuals, firms or governments. Firms, for example, have to decide on products, product quality, capital investment and innovations. Some of these decisions are highly interrelated to training decisions, such as introducing new products or new processes for improving the firm's position in the market. Firms have the option to hire skilled labour without training, which might lead to negative external poaching (Hocquet 2000) and insufficient training in a private economy.

The term 'training' should not be restricted to formal training activities, especially when one looks at CT (Weiss 1994, Pfeiffer and Reize 2000). Learning by doing, that is informal training at the work place, has important economic implications as well. Arrow (1962) assumes that the productivity of a firm depends on the total experience of all firms (measured by accumulated gross capital investment). In the course of time the same output will be produced with less and less labour ('learning curve'). The productivity effect arises solely from the process of learning through production ('learning by doing'), and the common knowledge character of experience ('knowledge spillovers').

Individuals also have to choose between several alternatives and actions. They can choose to change their firm to get higher wages, or they can choose to participate in privately financed training programmes. For individuals, to undergo VET is an important and far-reaching decision, and they should therefore be careful when making this decision. Expectations about the outcome of training, taking into account that other people may also decide to train, do indeed play a measurable role in individual behaviour (Heckman, Lochner and Taber 1999).

One general aspect to consider for all parties is the topic of timing of investments in human capital. Among other things, timing depends on compulsory school regulation, individual abilities, labour market regulations and career plans. This consideration suggests that the decision to undergo a particular training measure is part of a larger set of economic activities of firms, training institutions and individuals. Therefore, it does not always make sense to talk about the effect of training isolated from its context, since training is one of several simultaneous economic activities.

The determinants and effects of training depend on labour market institutions and the path of economic and technological development. They also depend on national education and training systems. That is, they depend on how and by whom education and training is financed, on its content, qualification and assessment. Training systems in Europe vary to a great extent with respect to all of these factors, as has been documented in the first report on vocational training. Comparing outcomes of different training types in the different systems in Europe may help to understand the complex interrelationships between education, training and outcomes. It may also provide a guideline for the optimal spacing of investment in training throughout life and improve the understanding of the role of government in optimising content, finance, assessment, qualification and participation.

Since training is viewed as an investment in this study, there should be a parallel between the cost and benefits of training (Lynch 1994, Booth and Snower 1996). According to the distinction of Becker, individuals receive a large part of the return of investment in general skills and human capital themselves. They should therefore bear a large part of the...
costs. This system works if, after making the investment, individual productivity is higher and wages on average are higher for trainees thus providing an incentive for the investment. Furthermore, this system only works if individuals can borrow money to finance their general training or if wages are lower during the training period. If capital markets are not perfect, that is, if there are credit constraints, not all those wishing to participate in training for reasons of efficiency might be able to do so. This can be an important issue for privately funded education systems and usually serves as one rationale for government interventions; another rationale is positive externalities of education, because they may also lead to insufficient investment in human capital in a free market economy (Booth and Snower 1996). If government subsidises general training, private returns in the form of higher wages can, in principle, be lower than in the case of training which is purely privately financed.

Changes in wages are not only determined by training, but also by a larger set of factors (Hamermesh 1993), among them the amount of investment in machines and human capital investments in the population. If the amount of training in the population is considerable, which is the case in all European countries, it is necessary to take general equilibrium effects of training into account. The returns to training can differ depending on whether one looks from a partial or general equilibrium view (Heckman and Lochner 1998). In a general equilibrium view, the cost of training and the longer-term impact on the economy-wide wage structure should be taken into consideration.

The benefits of more specific types of training may lie in higher productivity gains for firms. Therefore, firms should bear the costs of more specific training and wages may not change after training. The relationship between the optimal amount of investment in general and specific human capital depends among other things on individual preferences and abilities, the capital and technology intensity of firms and costs and financing arrangements. The returns on more specific human capital may additionally depend on the amount of general human capital that a person has acquired. Thus, education, initial and continuous training are interrelated and the incidence and impact of training depends on the training system of a society as a whole.

Over-education or coordination failure between several types of training may arise in an economy. An example of coordination failure seems to be the German training system, where general university education is largely paid for by the government, while vocational training is not. Recent trends in the demand for labour suggest that due to rapid technological change, vocational skills are becoming obsolete at an increasingly faster rate, which favours cognitive and more academic skills (skill-biased technical change, see Blechinger and Pfeiffer 2000, Machin 1996, Machin and van Reenen 1998). The bias in favour of skilled labour depends furthermore on labour market institutions. The more rigid the wage structure is, the faster upskilling will be during the computer revolution (Blechinger et al. 1997).

Labour markets in Spain might serve as another example of situations where labour market regulations also have secondary undesired effects. One reason for the very high unemployment rates for young people in Spain is the employment protection rules for older workers. The Spain youth labour market has therefore been characterised as a high-skilled bad job labour market, since high skilled individuals end up in low skilled jobs, crowding out low skilled individuals (Dolado et al. 1999).

For other authors, the problem of underinvestment in general skills might be a serious problem for economic development. There might be a complementarity between general human capital and technological development (Acemoglu 1996). A lack of basic skills might hamper the speed of innovation. Firms who want to innovate have to train their workforce, which means additional costs of innovation for the firms and therefore less innovation and productivity gains. This can theoretically lead to the vicious circle of 'bad skills – bad jobs' or 'low innovation – low training' equilibria (Snower 1996).
Individuals, firms, educational arrangements and labour and product markets are characterised by a large degree of heterogeneity, where VET and CT play different roles. The rest of the paper is devoted to looking more closely into the relationship between VET, CT and outcomes in the labour market using data sets from firms and individuals. The following part introduces the potential and limitations of data sets, the methods used, as well as measurement problems with training variables and main explanatory variables.

4. Econometric methods, data and measurement issues

4.1 Econometric methods

Most studies reviewed below use econometric methods to quantify the determinants of training and its impact on wages, hours of work, duration of job search, duration of employment and other outcomes. Most of the studies explicitly take care of the self-selection problem in quantifying the impact of training. They model the decision to train and the outcome of training simultaneously.

The problem of impact measurements in social sciences when compared with natural sciences is that social programmes cannot be easily isolated from real life processes (with the exception of psychological experiments). Social programmes such as public VET policy are embedded in real life. The main task of research is to measure the impact of the programme despite the fact that many other factors simultaneously influence participating individuals or firms and thus the desired outcomes. These influences stem from individual, social, economic and policy factors.

The coefficients of econometric works based on single equation outcome models with some training indicators as an explanatory variable, can be seriously biased by self- and/or programme-selection. Participants in training do not usually constitute a random sample of the workforce or the population of unemployed people. Those who see comparative advantages and higher net benefits in training might have higher probabilities of participation. Comparative advantages may result from lower costs of training or higher expected returns, or there might be special preferences towards training.

There is an ongoing scientific debate on the question of selectivity, individual heterogeneity and the role of institutions. If selectivity is empirically relevant, then simple comparisons of means of outcome variables between non-participants and participants in training and the coefficients of single equation models might be seriously biased. More complex econometric models would often be needed to solve the so-called 'comparison problem'. It is not possible to observe the outcome of an individual participating in training and the outcome of the same individual in the case where he/she would not have participated in that training. On the other hand, the difference between the mean earnings of non-participants and participants in training can be a misleading guide for assessing the impact of training. This is the case, for example, when participants in training programmes are more highly motivated or have higher innate abilities than non-participants. In such cases, earnings, working hours, or other outcome variables of interest may have already been higher before the participation in training and training may have no impact at all.

The advantages of training are usually identified by the difference between the two outcomes, one observed, and the other not observable. To assess the impact of training, one has to rely on estimates which can be based on a group of people without training. Obviously this group of people should be identical with
the people participating in training with respect to all relevant characteristics (whether they are observed or not) of the people and the environment in which they live. The comparison problem is to find such a control group. The precision and accuracy of the estimate will depend on the precision and accuracy of the control group. While some researchers believe that the comparison problem can only be resolved by means of social experiments, others have developed statistical and econometric tools for unbiased estimates of the impact of training with the help of non-experimental data.

In classical experiments, prospective programme participants have been randomly divided into one experimental and one control group. Given this research design, the difference between the outcome in both groups must be a result of the programme if all other conditions are similar. The other approach uses information from participants and non-participants of actual programmes. In this case, the individuals participating in a programme have been selected systematically, either by themselves or by specific programme rules. Since social experiments are rare in Europe, current research into the determinants and impact of training in Europe depends on non-experimental data and adequate econometric tools.

One possible solution is the comparison of the individual outcome variable before and after participation in VET in the framework of an econometric model (see Blundell et al. 1997, Pannenberg 1997 and Pischke 1996 for such a procedure). This information is, however, often not available, for example when people are young and have no labour market experience before entering VET. Pfeiffer and Reize (2000) use the concept of the comparison group in two ways. On the one hand, they compare trainees and non-trainees, taking care of the selection problem with econometric methods. This is a common way of taking advantage of non-experimental comparison groups.

Furthermore, the determinants and impacts of continuous work-related training between employees and the self-employed are compared. In this case, the self-employed group serves as a comparison group for assessing the relevance of estimated effects of CT for the group of employees. The self-employed decide for themselves concerning the amount of investment in training. In the case of employees, firms decide who participate in their work-related training programmes. The decision process is therefore more complex for employees, and aspects such as poaching externalities, funding or promotion ladders become important. Therefore, the estimated impact of training in the self-employed group provides a sort of benchmark value for assessing the role of human-capital for training in the group of employees (see Cohn and Geske 1990 for a survey on former studies based on differences between self-employment and wage work).

There might be intentional and unintentional outcomes of training, or the lack of it, which are either favourable or unfavourable for the individual, firm, region or industry, or the whole economy. Most econometric studies investigating training analyse the direct intended impact at personal or company level for some favourable variables such as wages, productivity, employment prospects, etc. Secondary, sometimes undesirable effects occurring to other individuals, or at other firms or industries, might be important (so-called general equilibrium effects), although they are seldom investigated in empirical research. Examples of research which addresses these issues in a more indirect manner are the aforementioned studies on skilled-biased technological change and on over-education (Hartog 2000).

Secondary effects cannot be excluded empirically a priori. If some firms, for example, provide excellent training for their employees and thus are more competitive, other firms might lose market share, or their employees may have a higher probability of being dismissed. Such negative indirect effects are, however, difficult to trace, and their assessment often requires costly research designs. One important general equilibrium effect stems from the fact that government promotion of VET has to be financed and therefore affects the budgets and welfare of taxpayers.
4.2 Microdata on VET

The aim of microeconometric studies on education and training is to investigate the determinants of training and assess its impact on subsequent working careers taking into account observed factors such as age, gender, labour market conditions as well as unobserved factors such as motivation or innate abilities. These studies are based on microdata. The units of observation are either individuals, firms or both. The aim and scope of data differs considerably. Not all were, for example, collected for studying VET-related issues exclusively. This part provides an introduction to the empirical basis which should be helpful for a critical understanding of the results. The data belong to one of the following four types (see Table 2):

a) cohort data (CD);
b) cross sections (CS);
c) repeated cross sections (RCS);
d) panel data (PD).

CD consists of all persons or a sample of persons born for example in 1958 in England. These persons are either interviewed once in a retroperspective manner which is the case with the German Life History Study (GLHS), the Brabant Survey (BRAS), the Norway Survey (NORS) and the Lancashire Career Data Survey (LCSD), or are followed during their life on a regular basis. An example for the latter is the English National Child Development Study (NCDS).

The four cross-section data (CS) survey samples of persons or firms from a well-defined population at a point in time. The Dutch wave of the International Adult Literary Survey (DIALS) is a survey based on a sample of the whole Dutch population in 1995; the French Survey on Education and Qualifications (FDQ) is based on a sample of the adult French population; the Company Training in Ireland (CTIRE) data survey firms from Ireland in 1993, and the Community Innovation Survey (CIS) surveys firms from manufacturing in 12 European countries in 1993.

If survey data for well-defined populations are produced regularly without being connected individually, they are called repeated cross sections (RCS). Examples of this type of data are the German Qualification and Career (Q&C) data, a representative sample of employees surveyed in 1979, 1985 and 1991; the German Labour Force Survey (GLFS), a representative sample of the population surveyed every year (since 1991 GLFS has been part of the European Labour Force Survey), and the Swedish Level of Living Survey (SLLS), a representative sample of the Swedish population surveyed in 1968, 1974, 1981 and 1991.

The last type of data sets is termed panel data (PD). The same units of observations are surveyed at different time points again and again. Six studies rely on panel data, three on individual panel data (Dutch Biannual Labour Supply (OSA), annually since 1992; German Socio Economic Panel (GSOEP), annually since 1984; Norwegian social insurance data (KIRUT) since 1989), three on firm panel data (Collective Bargaining in Large Firms (NCGE) in Spain since 1979, the Hannover Firm Panel (HFS) covering industrial firms in Lower Saxony, Germany since 1993 and the German Plant Panel (GPP) covering plants in Germany since 1993).

In a recent Employment Outlook (OECD, June 1999), the determinants and wage impacts of continuous training in seven OECD countries are studied: Australia, Canada, France, Germany, United Kingdom, Italy, the Netherlands also based on microdata. For European countries, they used the 1993 cross section of the German Socio Economic Panel, the French Survey on Education and Qualifications of 1993, the 1996 cross section of the British Household Panel of 1996, the 1991 Bank of Italy survey and the 1994 cross section of the Socio Economic Panel of the Netherlands. For a description of the last three data sets, which look quite promising for microeconometric research on training issues and which are not mentioned in Table 2, see OECD (1999).

* Type: CD = cohort data; CS = cross sections; RCS = repeated cross sections; PD = panel data; **Aims: A = the main objectives are the determinants and the impact of education and training; B = the main objectives are related to education and training; C = the main objectives focus on other topics, but meaningful questions on education and training are included.

Source: own composition.
The remaining data designs differ according to the main focus of the surveys (see Table 2). While some aim directly at analysing training issues, others have different aims or should best be characterised by a multitude of aims. Nevertheless, these data have been used for analysing the determinants and impact of training. It is necessary to keep the main focus of the data sets in mind when interpreting the results or discussing policy implications.

The following categories of aims can be distinguished (see also Table 2):

a) the main objectives are the study of the determinants and impact of education and training (CTIRE, GLHS, FDQ, LCSD, Q&C);

b) the main objectives are also related to education and training (BRAS, DIALS, GSOEP, GLFS, NCDS, NORS, OSA, SLSS);

c) the objectives focus on a different set of topics; meaningful questions on education and training are included (CIS, GPP, HFP, KIRUT NCGE).

From the 18 data sets under consideration, five belong to category A, which was originally designed to provide an understanding of the relationship between training and the outcome of training, for example the performance of the labour market. Eight belong to the second group, where the study of training is one among several aims. As an example, the German or European labour force surveys should be mentioned, which aim at investigating issues such as participation, family situation, unemployment, social insurance and so on, and also continuous training. Five sets of data belong to the last category. They provide meaningful information on training, but have different aims. An example for this category is the 'Collective Bargaining in Large Firms' (NCGE) study from Spain, which aims at investigating wage-setting in large Spanish firms, but nevertheless provides meaningful information on firms' investment in training.

The types of data have specific advantages and disadvantages for investigating VET-related themes. Below, some of them will be sketched very briefly. Cohort data provide valuable information for a well-defined cohort of persons, but no information on individuals of other cohorts. Interactions between cohorts on the labour market cannot be studied. With cross section data it is, on the other hand, not possible to disentangle age and cohort effects. Earnings equations based on cross sections presuppose constant age-education-earnings relationships over time, which might be questionable in a dynamic world.

Longitudinal studies based on panel data or repeated cross sections are constructed to overcome these restrictions. Aspects of individual biographies, such as lifetime-earnings-profiles or education and training histories can, in principle, be investigated if the time period is long enough. The GSOEP, for example, started in 1984 and contains a biographical annex for all persons surveyed for the first time in 1984. In principle, longer life histories can be reconstructed with such a design.

However, longitudinal data might be plagued by the problem of comparison of variables and other information over time and might be affected by fluctuations in the business cycle or political and other events. Changes in the definitions of earnings, working conditions and hierarchies over longer time periods might lead to spurious correlations in empirical work.

The lessons to be learned from empirical work seem to be that there is no single ideal data set for all research problems. An ideal data set will depend on the goal under investigation and on financial resources as well, since conducting surveys is expensive.

Recently, in OECD countries and/or European countries, four surveys have been conducted to provide harmonised training statistics for OECD or European countries (OECD 1999): the International Adult Literacy Survey (IALS) 1994-95, the European Labour Force Survey (ELFS) 1997, the OECD/INES (Indicators of Education Systems) data on continuing training 1991-96, and Eurostat's Continuing Vocational Training Survey (CVTS) 1994. These surveys provide valuable insights into training among the different countries. Com-

Comparative research on VET in different countries based on cross section data now becomes possible.

However, measured participation rates in CT differ significantly between the four surveys (OECD 1999:142, 144), which is presumably a result of different definitions of training between the surveys and, furthermore, of sample sizes. To give the reader a numerical example of the diverging participation rates in career or job-related training: in Germany this rate amounts to 20% according to the IALS, 4.2% according to the ELFS, 33.3% according to the OECD/INES, and 24% according to the CVTS (OECD 1999:Table 3.2). That seems to indicate that harmonisation of surveys to provide harmonised statistics might not always be a superior strategy of data collection.

Some of these surveys have been used for microeconometric work in some countries. The IALS data have been used for investigating training in the Netherlands (Oosterbeek 1998), the ELFS data for investigating training in Germany (Pfeiffer 1997). Although these surveys seem to have specific problems as mentioned above, VET-related research could be improved if the data were to be used more systematically for all countries.

### 4.3 The measurement of training and outcomes

Training, like human capital, has several dimensions. In empirical research, it is necessary to measure the dimension of training. There are qualitative and quantitative dimensions. The following dimensions have been investigated, some of them overlapping (see Table 3). Besides more qualitative dimensions such as training in a classroom, at or outside the workplace, or training with or without a qualification certificate, there are some quantitative dimensions, such as the hours, days or years of training, or the cost of training. The studies presented all use slightly different definitions of training and none include comprehensive information on all dimensions of training.

Furthermore, it is necessary to measure the impact of training, which may reveal further
dimensions (see Table 4). There must be a close relationship between the aim of a training programme and the measurement of outcome variables. In empirical literature, outcome measures include wages, earnings, productivity, hours of work, time of search for the first job after VET, length of duration of the first job, mobility (regional, occupational), upward mobility, employment/unemployment, further training, others (health, fertility, democratic values, etc. not investigated here).

Source: own composition.

While some types of vocational training aim explicitly at providing more general skills in the sense of transferable knowledge (transferable between firms, technologies and over time) such as the German dual vocational training system, others aim at providing rather specialised skills (such as large parts of CT) to master specific aspects of everyday work, for example a two-day training course to understand a new version of an internet browser. There are even more different types of training which aim at reintegrating people into the regular labour market, which applies for most active labour market programmes.

Furthermore, training programmes might have undesired secondary effects. This leads to a distinction between the direct impact of training at individual or firm level and indirect impact, sometimes termed ‘general equilibrium impact’. For example: if an increasing number of people are trained with specific skills, the returns to this type of training may decline, or the number of people trained with more general skills may have an impact on the demand for labour in a different skill group.

4.4 The set of explaining factors

The task of the research is to assess the determinants and the isolated impacts of VET. Researchers try to quantify the direct impact of training, which is the difference between the outcome variable before and after training within the framework of econometric mod-
Often the determinants of participation in VET and its outcomes are modelled simultaneously, which seems a natural way of tackling the issue, since training is chosen individually or by firms through its impact on desirable outcomes. The set of explanatory factors explaining training usually includes all or some of the following categories of variables:

- Socio-demographic background and work history (age, gender, experience, periods of unemployment, ...);
- Family background information (education of parents, place of residence, ...);
- Educational background and ability variables (intelligence scores, educational degrees, ...);
- Information on former or current labour market conditions (regional unemployment rate, ...) and characteristics of the firm (if training was or is provided in a firm);
- Information on the training institution (type of school, qualifications, ...).

The set of explanatory factors explaining the impact of training includes variables which also belong to the above categories of variables as well as training indicators.

5. Discussion of results

5.1 Summary

The determinants and effects of training depend on individual characteristics, labour market institutions and the path of economic and technological development. Furthermore, they depend on national education and training systems. Education and initial and continuous training are interrelated, and the incidence and impact of training depends on the training system of society as a whole.

Critical review of empirical literature seems to indicate that the more structured the whole VET system is through institutional arrangements and State regulation, and the higher the amount of more general investment in human capital provided in the early years of life or of an employment relationship is, the lower the measured returns to continuous training are after the high initial investment. Conversely, the less structured the training system, the higher the measured returns of continuous training seem to be.

Furthermore, selectivity plays an important, but different role in training systems. It seems as if the more people or workers are trained to reach a higher level of general vocational skills, for example through State-financed training systems, the greater impact selectivity has on the labour market after finishing VET at schools and/or firms. The role of CT then changes: worker promotion becomes more important and those who are promoted are trained as well. However, if the government-regulated training system provides less general human capital during the early stages of an individual's life, selection for training at the workplace becomes important and the aim of training lies in providing specific or general skills.

5.2 The determinants of training

The discussion of results starts with the question of who participates in VET and CT? While in some countries such as Germany, the difference between initial VET and CT is rather clear cut, in other countries such as the United Kingdom, the difference is not so clear. In Germany, young people who do not enter the university system have to participate in the dual vocational training system. Young people either start a regular two-and-a-half to three-and-a-half year apprenticeship training scheme with a firm, or if they do not find an apprenticeship training place, they have to go to special VET schools until the age of 18. After finishing that phase of education and training, continuous training can start. In the United Kingdom, statutory schooling ends at the age of 16. Thereafter, there are three main qualification pathways (job-specific training, general vocational education, general education, OECD 1998b, Chapter five). One difference from the German system seems to be a higher degree of freedom and less institu-
Training and individual performance: evidence from microeconometric studies

Regulations with respect to choices of individuals and firms. Therefore, the boundaries between initial and continuous training are sometimes less obvious.

Evidence from empirical work (which has been put together in Table 5) can be summarised as follows:

- Family background, school quality and ability (measured for example with mathematics scores) are important determinants of participation in VET and CT;
- CT first increases in parallel with experience and begins to decrease after 10 to 20 years;
- Higher educational qualifications or vocational skills seem to increase the probability of receiving CT; there seems to be a correlation between the occupation chosen in initial and further training;
- Former participation in CT also seems to raise the probability of CT;
- Women do not have higher probabilities of participation than men and in some studies probabilities are lower;
- Self-employed persons have a lower probability of participation than employed workers;
- Minority groups, for example immigrants, have a lower probability of receiving training;
- Part-time workers receive less training than full-time workers;
- Larger firms provide more training than smaller firms;
- Training probabilities in growing and in high-tech industries are higher;
- Training probabilities are higher in more unionised industries and union members receive more training than non-union members;
- The probability of training decreases with job tenure, although the pattern in the first 20 years is far from being monotonous; workers staying in the firm where they received initial training have a lower probability of training than other workers;
- Public sector establishments provide more training than private sector establishments;
- For the self-employed, non-formal CT seems to be more important than formal CT;
- Initial training and CT seem to be substitutes in part.

These results indicate that selection and selectivity are important issues in the determinants of training. Training does not seem to be a random element of human economic activity. However, not all the results shown in the list are found in all of the studies. It is these differences that can help obtain a deeper understanding of the forces underlying training. The following issues are discussed in greater detail: the relationship between initial and continuous training, the role of gender and the determinants of initial training.

Although there is some need for more differentiation, most of the studies seem to confirm the positive relationship between the amount of human capital received in initial education and training and continuous training which becomes clear from the aggregate data (see Table 1) in a multivariate statistical framework. For studies based on personal data, see Arulampalam and Booth (1997), Blundell et al. (1997, 1999), Goux and Maurin (1998), Groot (1995), Pannenberg (1995, 1997, 1998), Schömann and Becker (1995) and OECD (1999); for studies based on firm data, see Alba-Ramirez (1994), Gerlach and Jirjahn (1998).

Oosterbeek (1998), who examined supply and demand factors in terms of training determinants, was able to show that while for firms (the demand side) education is insignificant, it is not for individuals. He suggests that the positive correlation between education and CT found in most of the studies is the result of omitted ability variables or self-selection. Furthermore, he argues that this finding is not a result of selectivity effects from the demand side. For firms, it does not matter whether they train better educated or less educated workers, but for individuals there are differences in the payoff of training, with a higher payoff for the better educated. There-

Source: own composition.
fore, more better educated people are more likely to participate in training.

Pfeiffer and Brade (1995), who processed detailed information on the subject of university education (engineers, natural scientists, employees in administration, economists and others), find that there is no monotonous positive correlation between education and CT. Their findings suggest that workers with a university degree in engineering or natural sciences have no higher probability of participating in CT than workers with apprenticeship training. Conversely, teachers and other workers with a degree in social sciences had a much higher probability of participating in CT. The authors conclude that in the age of natural science, engineers and natural scientists are the main producers of new knowledge and new products, and that the activity of this group of workers generates the need of CT for other staff. Therefore, engineers do not have the highest probability of participating in CT.

Findings suggest that education is not the only factor of the positive relationship between initial and further training. The activities of an employee, that is his or her position and tasks within the firm, have some explanatory power, too. Most of the studies cited only give some broad information on education and are therefore not suited as a basis for a deeper discussion of this question. One further exception is the study of Pfeiffer and Reize (2000) which indicates that in Germany the determinants of training for workers with an apprenticeship degree are higher if the type of apprenticeship belongs to the electro-technology or commerce industries compared to other trades. Such differences point to occupation-specific differences in skill needs resulting from technological change, or in differences in the quality of initial training in different trades.

A comparison between employed and self-employed people to identify the determinants of self-employment indicates that for the self-employed, the negative gender effects are not significant (Pfeiffer and Reize 2000). Since the self-employed decide on CT on their own, this says something about the role of the worker-firm relationship in the selection of participation in CT. It is not that women do not want to undergo training, but that firms seem to prefer men. A similar finding and argument is reported by Oosterbeek (1998), who argues that this behaviour may be the result of a higher investment risk, since women have a higher probability of career interruptions than men. The OECD (1999) study also found no significant gender differences in participation rates based on recent surveys.

Focusing on the determinants of participation in initial VET, evidence suggests that school quality and innate abilities have some explanatory power. The family background (parents’ educational attainment) and the alternatives available to the individual also seem to be important for explaining participation in VET. There is by and large a positive relationship between parents’ educational qualifications and the educational qualifications of children, although during the educational revolution a larger number of children from parents with lower educational qualifications entered universities (for Germany see Pfeiffer 1997). Innate differences in abilities can explain 50% of the variance of intellectual capacities of young people (Weinert 1997). Furthermore, the ability differentials stay rather constant over long periods and seem to be unaffected by schooling.

The study of Andrews and Bradley (1997) gives insights for a region in Britain. The results seem to indicate that a higher academic level reduces the probability of participating in VET after compulsory school and increases the probability of attending a university. The same is true for young people’s occupational preferences and associated expected lifetime earnings. Judging from that variable, non-vocational continuing education is preferred to continuing vocational training, which again is preferred to the remaining alternatives (youth training schemes, working and on-the-job training, unemployment).

School type and quality seem to matter, although this is an ongoing debate. Dearden, Ferri and Meghir (1997) provide a summary of the research on school quality, educational attainment and wages, a large part of which has been carried out in the USA. Andrews and
Bradley (1997: 399), for example, differentiate between standard schools maintained by local authorities, a 'voluntary/grant' category and 'special' schools, 'which cater mainly for the needs of young people with learning difficulties'.

These variables have some explanatory power for explaining the long-term career choices of pupils. For example, school leavers from special schools have a higher probability of joining youth training schemes, while those from the first category have a higher probability of joining non-vocational continuing education. School size can also have an influence on the probability of non-vocational continuing education, where the greater the school size, the greater the negative influence.

Andrews and Bradley (1997: 408) conclude: 'Moreover, the estimates ... suggest a clear ranking of outcomes, where the most able end up following non-vocational continuing education, and the least able end up either unemployed or with jobs with only on-the-job training... ' It is not clear how valid this statement is for different countries in Europe and for different types of training systems.

5.3 The effects of training

Does training have a positive impact, for example on productivity, job search duration and mobility and if so, what is its quantitative magnitude? Which part of the observed differences in wages or wage growth, in hours of work, or job duration can be attributed to training? Most econometric studies have investigated the effects on wages, on earnings or corporate productivity.

One should bear in mind that in standard earnings equations (so-called Mincer earnings equations) in cross-sections, 25 to 50% of the variance of earnings or wages can be explained by human capital variables such as years of education or educational qualification, training, age, professional experience, occupational status, technology and gender. The rest remains unexplained. This demonstrates that a quite substantial part of earnings variation among workers remains unexplained by the standard human capital approach. Other studies investigate the effect of training on job search duration, length of job duration, hours of work, post training firm job mobility and upward mobility, and the impact on employment probability. Although training and other human capital variables often have some explanatory power, again a large part of the individual variations in these outcomes variables remains unexplained by empirical research.

The findings of the econometric studies, which have been put together in Table 6, can be summarised as follows:

- there is a positive correlation between VET and wages (found in all studies with the exception of one study for Norway, where the effect is zero, Elias et al. 1994; in the other Norwegian study, the coefficient is positive, Bratberg and Nilsen 1998); the positive relationship between VET and wages depends on the type of VET, the country and the group of individuals under investigation; the estimated returns range between 0 and 40%;

- family background and ability have measurable effects on earnings (Blundell et al. 1997, 1999);

- the estimated returns to training are by and large positive for the group of participants; there are examples where the estimated returns turned out to be negative for the group of non-participants (Groot 1995, Groot et al. 1994, Oosterbeek 1998). This suggests the existence of comparative advantages, general equilibrium effects and self-selection;

- there is evidence that the returns for employed workers are higher than those for the self-employed (Pfeiffer and Reize 2000);

- there is evidence that the returns to CT are higher if they are financed by individuals instead of firms (Pannenberg 1997);

- there is evidence that informal CT has returns (Weiss 1994) as well and that these returns are lower than those of formal CT (Pfeiffer and Reize 2000); there is further
evidence that the degree of formalisation matters (Pfeiffer and Reize 2000), as well as school quality (Dearden et al. 1997, not cited in Table 6);

- there is evidence that the returns from CT depend on the educational qualification and on gender (Blanchflower and Lynch 1994, Blundell et al. 1997, Elias et al. 1994 and OECD 1999, not cited in Table 6); the evidence for gender seems to be mixed, as well as the evidence with respect to educational qualification (Jonker et al. 1997); while former studies sometimes found a negative relationship between educational qualification and returns to CT, new studies with different econometric methods seem to challenge these findings (Abadie et al. 1999, not cited in Table 6);

- there is evidence that the returns from CT depend on the educational qualification and on gender (Blanchflower and Lynch 1994, Blundell et al. 1997, Elias et al. 1994 and OECD 1999, not cited in Table 6); the evidence for gender seems to be mixed, as well as the evidence with respect to educational qualification (Jonker et al. 1997); while former studies sometimes found a negative relationship between educational qualification and returns to CT, new studies with different econometric methods seem to challenge these findings (Abadie et al. 1999, not cited in Table 6);

- there is evidence that hours of work are positively correlated with CT (Pfeiffer and Brade 1995);

- there is evidence that upward mobility rises parallel to CT and educational qualification (Schröder and Blomskog 1997, Goux and Maurin 1998, Pannenberg 1997);

- there is evidence that employment prospects increase with educational qualification and firm-related CT (Blundell et al. 1997, Bratberg and Nilsen 1998, Mayer and Carroll 1987);

- there is evidence that job search duration after initial education and length of job spells in the first job rise with educational qualification (Bratberg and Nilsen 1998) and with the amount of human capital the firm invested in apprentices (Fränz and Zimmermann 1999, not cited in Table 6);

- productivity of firms rises parallel to training (Alba-Ramirez 1994, Gerlach and Jirjahn 1998);

- there is evidence which suggests the existence of poaching externalities (Hocquet 2000);

- there is evidence that firms not only gain from specific investment in human capital (specialised training), but also from more general investment in human capital (general training) (Barnett and O'Connell 1998).

Although considerable methodological and data problems remain to be solved — the result stems from different countries, different data, estimators and methods used, and often the main objective of these studies is rather positive than normative analysis — these are interesting results which are especially important for VET policy.

First, results indicate that classroom education, work-related and more general types of training are beneficial for both firms and individuals. These benefits are not negligible and are sometimes rather large. Benefits from education, learning and training seem to occur to a great extent between individuals, firms and regions. Individual heterogeneity, differences in the education and training systems, are important factors behind these differences.

Second, the result that education and training has positive benefits does not mean that policy has been optimal or that publicly provided VET should be enhanced. There is rather a lot of evidence for positive impacts of VET on participants and comparably less evidence on the impacts of VET in the group of non-participants. In fact, there is evidence that self-selection on the one hand and general equilibrium effects on the other are at work. Training has positive effects and net benefits for the group of trainees. However, there is also some evidence that for non-trainees, net benefits might not in fact be positive. From the viewpoint of economic efficiency for these individuals, training might be a bad investment for firms, individuals and society. Furthermore, most of the studies reviewed do not investigate the costs of VET.

Third, any benefits of CT seem to decrease with the level of educational qualification. The lower the amount of initial training, the lower the incidence of CT, but the higher the measured returns in terms of any increase in wage. The benefits of CT for those who already have a high educational qualification seem to be

Source: own composition.
related to rising wages to a much less extent than for those with a lower level of qualification. However, it is currently too early to conclude on the basis of these findings and on economic efficiency reasons that people with a lower educational qualification should receive more training because their returns to training are higher (this seems to be one conclusion of the OECD employment outlook report, OECD 1999). The positive VET impacts for low educated people found in cross-sections (OECD 1999) might not stay constant in panel studies, hinting at unobserved heterogeneity problems in the cross-section studies (Abadie et al. 1999).

A refined version of the hypothesis seems to be more in line with the evidence. To a certain extent, VET and CT can be substitutes. In those countries where individuals invest a comparably large amount in initial VET (for example workers in Germany), returns to CT are lower than in those countries where people invest a comparably smaller amount in initial training, for example workers in the United Kingdom (compare Blundell et al. 1999 and Pfeiffer and Reize 2000 or Pischke 1996) or in the United States, where returns to continuous training also seem to be rather high (Lynch 1994). The refined hypothesis therefore postulates that returns to training after education are smaller if more people have received more initial education.

Fourth, government intervention in the training process of firms certainly has effects, which should be carefully investigated. There is some evidence that the French system provides more workers with training, because it is compulsory for firms to do so. However, in this system returns to training seem to be zero, even for those participating in training (Goux and Maurin 1998). Government interventions into private training processes might therefore have unintended negative secondary effects, which should be understood carefully for rational policy reasons.

Fifth, returns to CT seem to be higher for employed workers than for the self-employed (Pfeiffer and Reize 2000). From this result, one can conclude that human capital aspects in the narrow sense of productivity enhancement only constitute one part of the training story. CT is the result of complex negotiations between workers and firms. Self-selection, firm selection, industrial relations, and internal promotion ladders are important factors in the process of training. Training often seems to be the result of a pre-selection process where workers are matched to hierarchical positions. It is not always training which leads to higher wages but rather the selection process which is the driving force behind an increase in wage. After selection for higher positions has taken place, workers are trained and receive higher wages. So, if we observe that a person has been trained, we often merely observe that he has been promoted. This is the case in the United Kingdom, Germany and other countries. However, in the United Kingdom, returns to training seem to be higher than in Germany and investment in initial training is lower than in Germany. In France however, where firms have to provide training, returns equal zero. Therefore, training in the French system seems to be no indicator for internal promotion.

Sixth, in the papers reviewed there is no clear picture of market or government failure. While some findings can be interpreted as evidence of market failure ('poaching externalities', Hocquet 2000), others suggest that market forces work in the 'right' direction. An example for the latter statement is that returns to employer-provided CT have turned out to be lower than those of individually provided CT which seems to be in line with forecasts from the human capital theory of G.S. Becker (Pannenberg 1997). Yet another example is the zero return result for France (Goux and Maurin 1998), which could be interpreted as government failure since it is compulsory for firms to provide training, whether it is efficient for them to do so, or not. But overall, the studies surveyed cannot be used to draw strong conclusions on the relevance of market or government failures.

Seventh, training in a competitive environment may have positive effects on some individuals and some firms, while it may have negative or positive effects on other individuals or firms at the same time, or later. Trained workers might crowd non-trained workers out
of the labour force or out of jobs, and firms which provide more training and more innovative might crowd other firms out of product markets, because staff of the former are better motivated and they have innovative products. These negative, indirect effects cannot be ruled out in market economy. Good firms with superior technologies or lower costs have higher survival probabilities than other firms. However, if training is subsidised by government, assessment of VET programmes should take care of such indirect negative impacts. Some recent theoretical work is based on the assumption of positive external effects of VET (Acemoglu 1996, Lucas 1988). In the case of positive technological external effects, the productivity of trained workers in one firm is higher if the workers of other firms are also trained. Unfortunately, there is not yet enough empirical evidence on these issues with respect to training to be able to answer whether and under what circumstances training has a positive or negative secondary overall impact on society.

Eighth, there seems to be a large heterogeneity with respect to the determinants and effects of training. The estimated effects seem to differ between individuals, regions, over time and even between researchers and methods. This is true even if the same data are used, as can be seen by a comparison of the numerous studies performed by the British NCDS or the German GSOEP data. From the evidence surveyed in this paper and the diversity of it, it is not possible to draw strong and very specific conclusions with respect to VET policies. However, it is possible to draw some broader conclusions with respect to VET-related policy and research issues, which is carried out in the next part.

5. Conclusions

Although there is widespread belief in a positive relationship between education, training and growth, the evidence provided so far is far from complete. Aggregate figures for the European Union suggest a clear hierarchical pattern in the labour market: those who are better educated are on average more frequently found in the work force, have higher earnings, participate more often in formal continuous training, are less often unemployed, are more often self-employed, have a higher regional mobility, and work with newer and more high tech equipment. Job mobility on the other hand is negatively correlated with the amount of human capital invested in a specific occupation, since investment increases switching costs. The pattern seems to have been rather stable over the past few decades, although continuing skill-biased technological change provides a challenge for VET policy in Europe.

These stylised facts do not necessarily mean that those who are better educated or have higher educational qualifications also have a higher lifetime income or utility, because they often have higher costs in the investment period and there may be substantial comparative advantages for different educational pathways (for example, more cognitive or more mechanistic skills) for different people. Regarding heterogeneous individuals, there are individuals at the margin, whose lifetime utility is rather similar in different pathways, and there are individuals who receive higher utilities either with lower or higher educational qualifications.

What one would really like to know for policy analysis, is the value of the lifetime utility of a person for different educational pathways under different educational standards and regulations. However, these values are not observable and estimates available are far from being conclusive in all respects.

The critical review of more specific econometric work in this study indicates that training is indeed beneficial for both firms and individuals. The benefits are not negligible, in fact they are sometimes rather large. The fact that training has positive effects is however no guideline per se for government activity. There is evidence that self-selection on the one hand and general equilibrium effects on the other are at work. As a rule, training does have positive effects and net benefits for trainees. However, there is some evidence that net effects for non-trainees might not be positive. In these cases, training might be a bad investment for the respective people, firms and

1093
— from the viewpoint of economic efficiency — for society.

In addition, non-negligible parts of observed differences in outcome variables such as earnings, wages, hours of work or career satisfaction cannot be attributed to education and training. Innate abilities, heterogeneity of abilities and preferences, family background, political events (for example the fall of the Berlin wall on 9 November 1989 had significant impact on the East Germans), luck and the path of economic and technological development are all factors which are important. Selectivity, selection and general equilibrium effects also seem to play an important role in all training systems.

By and large, empirical results suggest that the more structured the whole training system is, and the more investment in general human capital is acquired while a person is young, the lower the returns to continuous training are after this high initial investment. If education is centralised and compulsory school attendance is expanded, then all people should achieve higher levels of education and formal skill levels. Selection into different career pathways transmitted through labour markets only begins after compulsory school attendance. If the level of more general types of skills learned in schools is high, training at the workplace plays a different role and is no longer responsible for building up these more general types of skills. Such mechanisms seem to be responsible for lower returns to continuous training in countries such as Germany and France compared to the United Kingdom. Conversely, the less structured the training system is, the higher the measured returns of continuous training seem to be.

European training systems differ. The different types of investment in VET, the spacing of these investments over an individual’s life and the role of the State will depend on differences in prices for education, expected wage profiles, the skill structure of the workforce, tradition and technological factors. Success in schools and other training institutions is not the only factor explaining work-related success and careers. Labour market regulations and institutions might lead to insider power and create entry barriers and waiting queues for young workers, despite higher education and more investment in training. Such mechanisms seem to be present in most European countries, although to different degrees.

Some of the findings are a major challenge to the role of government in training. Obviously formal education and training are not omnipotent weapons against all storms of life for all people, but they may be very strong weapons when used at the right time, to the right extent and with the right content. At other times in an individual’s working life, other weapons such as non-formal learning, regional, firm or occupational mobility might be more helpful.

Centralisation in the sense of generally acknowledged educational certificates (for example, trades in the German dual vocational training system) might be helpful for some occupations and especially when larger investments in educational qualifications are considered. However, there seem to be limits to such strategies.

First, the German apprenticeship system sometimes seems to react very slowly to rapid economic or technical changes (Blechinger and Pfeiffer 2000) with the consequence that training curricula are old fashioned and skill obsolescence becomes a problem for firms and workers, which they try to overcome by additional and costly continuous training. Second, the set up and running costs of such a system can be rather high. More decentralised, deregulated and flexible systems such as those in the United Kingdom or the United States, which depend to a higher degree on market signals, might therefore have an advantage in times of rapid and unpredictable technical change. However, there may be other benefits of a more centralised system with compulsory school attendance. Youth unemployment is low in Germany and participation rates in VET is high. Imperfect capital markets, which can create entry barriers for poor young individuals in market economies, do not play a major role. No single optimal VET system exists. Policy-makers have
Training and individual performance: evidence from microeconometric studies

to put weight behind different policy objectives when policy changes are considered.

Key qualifications and more general human capital cannot be acquired in a short period of time. If technologies change, key qualifications will also change, at least to some extent. They have to be acquired through a long and continuing process (Weinert 1997) which presumably will have a sustainable impact when people are young or very young. The older individuals become, the more important non-formal and self-organised types of learning become. Mobility between occupations, regions and firms might also be valuable strategies for improving the career position of workers.

For improving VET policies an adequate, systematic and regular research design ex ante would be helpful, allowing greater understanding of the relationship between specific VET activities carried out and its actual, secondary and desired results. Due to tight public budgets, evidence of impacts and efficiency of new and existing programmes will grow in the future. A research design that takes diversity of situations, heterogeneity of individuals, differences in training systems, governments, markets, etc. into account is, however, expensive and takes time. If, for example, a unified European survey on VET were to be conducted in the year 2000, the results of the analysis would be available between 2001 and 2004 or even later. If one wished to compare the results over a longer horizon, for example, over a period of 30 years (see the NCDS data), results would not be available until 2030.

Besides research based on microdata which allows one to investigate the determinants and partial impacts of VET at individual level, general equilibrium effects should also be investigated using time series or panel data. Research on VET based on microdata might be improved if it would be more regularly and systematically based on Europe-wide data sets, such as the ELFS, European Household Panel or the IALS. Despite remaining methodological problems, international surveys should have the advantage that the most interesting human capital and training variables are defined in comparable ways. Empirical results for different regions might be more comparable and differences in results might help to identify different impacts of national VET policies.

National VET programmes and policies dominate in Europe. It is therefore necessary to evaluate specific VET programmes on a regional or national basis. There is no need for standardised and Europe-wide evaluations if national VET programmes dominate. Most firms sometimes hold formal or more informal training programmes. There are, therefore, markets for training and these programmes seem to provide returns on investment which are as high as other investments in machines or research. However, the author is not aware of systematic research on returns to training investment by private firms. This would be an additional source of extremely valuable knowledge and information for assessing public VET policies.

From the authors point of view, future research could be directed towards the following questions to improve understanding of the impacts of VET policies both on the individual and aggregate levels and optimise policy reactions to technology and other shocks. The questions are interrelated.

First: Research on specific public VET programmes should be intensified to learn about partial impacts at individual level and efficiency of programmes. This type of research would usually be based on microdata if the programmes are not too large. A partial evaluation design ignoring general equilibrium effects should suffice.

Second: Research on public VET systems should also be intensified. This type of research should evaluate the whole system and should take into account general equilibrium effects, financial efficiency and labour markets institutions as well. Research on this topic will usually be based on aggregate time series data, individual panel data and official data on programme costs.

Third: Research on returns to VET for non-participants should be intensified. Should
governments help non-participants and especially individuals with low skills to participate in VET or CT, or are other measures, for example wage subsidies, better for improving the labour market position of the low skilled?

Fourth: It is not fully understood, whether there are cumulative negative or positive relationships of public VET policies of different types transmitted through labour markets. Therefore research on the question of whether the public promotion of higher education in the past 30 years has had negative impacts on wages and labour market prospects of individuals with vocational education should be intensified to avoid the possibility of negative relationships in the future and improve coordination between educational and labour market policies.

Fifth: What is the efficiency of educational policies and the relative efficiency of higher and secondary education for the next 50 years for the cohort of young people entering the national training systems in the next five or 10 years? What is the optimal portfolio of different types of education, more general or more specific in nature for individuals, firms, regions or Europe?

The effect of national institutional differences on education/training to work transitions in Europe: a comparative research project (CATEWE) under the TSER programme

Damian F. Hannan et al.¹

Abstract
The paper presents a comparative empirical study on school to work transitions in a range of European countries. The project (CATEWE, 1996-2000) is funded by the TSER programme. Discussed are the main conceptual and methodological approaches, empirical data bases, progress to date with the study and some initial results from a related earlier research project carried out under the Leonardo da Vinci programme.

The main objectives of the CATEWE project are to:

a) develop a comparative conceptual framework to study school to work transitions in EU countries with different institutional systems, and

b) apply that model to both comparative stock analyses of labour force surveys (LFS) in most EU countries, and comparative flow analyses of school to work transition surveys (SLS) in five EU countries – France, Ireland, the Netherlands, Scotland and Sweden.

To do this effectively we need to develop

c) a set of comparatively defined variables which adequately capture the complexities of school to work transitions in France, Ireland, the Netherlands, Scotland and Sweden – as measured both by 'flow statistics' in their national school to work transition surveys and as 'stock' statistics in their national labour force surveys.

¹ The ESRI coordinates the project. The following are the main researchers and research centres in each country: participants D.F. Hannan and E. Smyth, ESRI, Dublin; D.Raffe, CES, Edinburgh; H. Rutjes, DESAN, Amsterdam; R. van der Velden, ROA, Maastricht; M. Mansuy and P. Werquin, CEREQ, Marseilles; W. Mueller, MZES, Mannheim.

1. Introduction

The main reason why comparative research on education/training to work transitions in European countries is important is its unique ability to assess the extent to which education, training and labour market integration processes are similar or different across EU national boundaries. If the same market and institutional processes operate in the same way and with the same outcomes and relationships across all countries there would be no need for comparative research. If, however, there are important national systemic differences in the complex relationships between individuals' social characteristics, education/training achievements and labour market outcomes then it is important for both research and policy purposes that these national differences be elucidated. The main purpose of the CATEWE research project is to do this.

The project builds on previous efforts in this field to develop a more sophisticated and comprehensive conceptual framework for this purpose. It constructs and uses a more comprehensive and standardised set of databases, and sets out to analyse these in more detail than previous efforts.

Four themes of that analysis appear most relevant to the aims of Cedefop's second report on vocational training research in Europe: the issue of educational and employment exclusion (point 7); detailed longitudinal surveys of education/training to work transitions (point 8); and the extent of 'matching' between education/training contents and levels and employment/occupational outcomes (point 9), with particular reference to low-skilled or poorly qualified school leavers (point 11).

The project is a comparative sociological and economic, empirical study on school to work transitions in a range of European countries. It is funded by former DG12 under the TSER programme (the CATEWE project, 1996-2000). This paper describes the main conceptual and methodological approaches to the study, the empirical databases used, progress to date with the study and some initial results from a related earlier research project carried out under the Leonardo (DG22) programme. Since the research only started in December 1997 (to December 2000) and we have just started the analyses of the integrated, comparative databases we have no findings to report from these analyses. However we do provide some preliminary results from an earlier related comparative research project on early school leaving carried out under the Leonardo, DG22 programme (1997-98).

The main objectives of the CATEWE project are to:

1) develop a comparative conceptual framework to study school to work transitions in EU countries with different institutional systems, and

2) apply that model to both comparative stock analyses of labour force surveys (LFS) in most EU countries, and comparative flow analyses of school to work transition surveys (SLS) in five EU countries – France, Ireland, the Netherlands, Scotland and Sweden.

3) To do this effectively we need to develop a set of comparatively defined variables which adequately capture the complexities of school to work transitions in France, Ireland, the Netherlands, Scotland and Sweden – as measured both by 'flow statistics' in their national school to work transition surveys and as 'stock' statistics in their national labour force surveys.

The cross-national databases on national school leavers surveys contain almost 100 comparatively defined variables – though with many missing variable cells for some countries. These cover social background, initial and continuing educational/training variables, initial labour market experience vari-

3 Directorate General 22, since 2000: Directorate General 'Education and Culture'
ables. In addition to analyses of current school leavers’ and labour force surveys a limited time series analyses of these school leavers’ surveys will be carried out for Ireland and Scotland (1980–96) and for the Netherlands since 1988. In addition limited analyses will also be carried out on a comparative database of six-year follow-up surveys (1992-98) carried out in France and Ireland, and for a shorter period of observation in Sweden.

This paper is divided into five sections:

a) the conceptual framework,

b) study design and construction of comparative databases,

c) progress to date,

d) discussion of some relevant results from an earlier related study, and

e) conclusions.

2. **A conceptual framework for comparative research on education/training to work transitions in Europe**

Considering the varying institutional structure of European education/training systems and the varying national structure of education/training (ET) and labour market (LM) links, comparative European research on education to work transition is underdeveloped. We have only an incomplete and imprecise knowledge of the nature of the varying relationships across the different European countries, and we do not sufficiently understand the similarities and differences in these respects between EU countries, nor the mechanisms that can explain them. In the following section we will briefly discuss the major lines of research that have been pursued, highlighting the main gaps in existing knowledge.

The most influential conceptual approach has been that of Maurice, Sellier and Silvestre (1982). They conducted a detailed analysis of work organisation, job recruitment and occupational career patterns in a small number of selected French and German enterprises. Proposing a theory of societial effects they argued that the different kinds of qualifications which are produced in the German and French educational systems, and their use by German and French employers, result in complex system-specific relationships between qualifications and jobs. They describe Germany as a system patterned along a qualificational space, while France is considered to be patterned along an organisational space. In Germany, a rather differentiated set of widely recognised ET qualification outcomes are produced in a bipolar educational/training system (the dual system), and these courses and qualifications are used by employers both to organise jobs/occupations and to allocate suitably qualified people to them. In France, formal education is much less vocationally oriented and less closely related to the kind of work to be subsequently taken up. Skills and qualifications required for specific work tasks are mostly obtained (both formally and informally) through on-the-job training and are thus specifically tied to the needs of individual firms. Such organisation-specific qualifications have a less convertible value when workers move between firms. The association between ET qualifications achieved and LM positions subsequently achieved is, therefore, institutionally weaker in France than in Germany.

More recent studies based on this national institutional approach have generalised it by using the more general theory of segmented labour markets, rather than conceiving cross-national differences as idiosyncratic ‘societal effects’. Countries have been typified according to the predominance of either occupational labour markets (OLMs), as in Germany, or the predominance of (firm) internal labour markets (ILMs), as in France or Britain. Equally there are substantial national differences in the relative importance of organised interest groups, and nationally agreed corporate interest mediation arrangements between employers, trade unions and governments, in agreeing the curricula, examination processes and qualification arrangements for ET provision systems – and the content of vocational
The effect of national institutional differences on ET to work transitions in Europe

education in particular. Systems where such agreed upon education/training system arrangements are institutionally linked to 'matched', occupationalised labour market arrangements, are obviously quite different from others where the ET system is quite autonomously organised and occupational labour markets are weak (see Marsden 1990; Marsden and Ryan 1990; Ryan, Edwards and Garonna 1991; Eyraud, Marsden and Silvestre 1990). Soskice (1990; 1993) extended these analyses by showing how institutional variables beyond the labour market itself help to explain the emergence of, and reliance on, occupational qualifications that are of general value beyond the individual firm. His comparative work emphasises the impact of the structure of coordination existing in an economy between the State, employers and unions. He distinguishes between liberal market economies (mainly the English speaking countries) with rather decoupled educational systems and inefficient systems of vocational training, industry coordinated systems (Germany and the Scandinavian countries), and group oriented market economies (mostly Japan).

Most of this work has been carried out within the broader field of industrial sociology and labour economics and is methodologically marked by traditions most characteristic of these fields. Most of the studies are based on comparisons of a rather limited number of, usually 'core', countries and are often restricted to small samples of firms in selected industries or locations. While this allows an in-depth analysis of the processes across two or three counties, or that operate within individual firms or workplaces across countries, the results of this approach can rarely be widely generalised.

An alternative conceptual and methodological approach has generally been pursued in studies more closely tied to the sociology of social stratification or education. These studies are usually based on national samples of individuals, representative of the adult population or of selected birth cohorts. The information collected generally includes social background data on individuals, the type and level of education and training received, and characteristics of jobs and occupational careers. The most notable examples of such life history studies have been done in the 1970s in the US, Norway, and Poland, from 1980 onwards in Germany, and most recently also in the Netherlands and Sweden. Two comparative analyses from this tradition of research are of particular interest for the topic of this proposal: the studies of Allmendinger (1989) and studies done in the context of the CASMIN project. (See also Blossfeld and Shavit (eds.) 1993; Shavit and Müller (eds.) 1998.)

Allmendinger (1989) studies the effects of two specific aspects of educational systems – stratification and standardisation – on transition into employment and on patterns of associated work careers. Stratification refers to the extent of segmentation of the educational system into various tracks and their hierarchical organisation. Standardisation refers to the degree of comparability of specific educational qualifications within a given country in terms of the structure and content of curricula, examination standards as well as certification procedures. In countries like the USA both educational differentiation/stratification and national standardisation are low, while Germany is almost at the opposite extreme. Both dimensions contribute to the extent to which ET qualifications are used by employers as screening devices in selecting workers and allocating jobs to them. In her comparative study, based on life history data from Germany, Norway and the US, Allmendinger finds that stratification contributes to a closer link between the hierarchical levels of educational systems and various levels of work/occupational hierarchies, whereas standardisation contributes to early work career stability and less job search activity.

The main relevant contributions of the CASMIN project are its successful attempt to develop a unified conceptual framework and a classification schema for educational and vocational qualifications comparable for nine European countries with different educational systems, and its analyse of the relationships between such educational qualifications and occupational and class positions in the labour market (Müller et al. 1990; Müller and Karle 1993; Ishida, Müller and Ridge 1995). The
schema of educational qualifications is based on the twofold distinction between hierarchical levels of education on the one hand and the general (academic) or vocational nature of the qualification obtained on the other. While the empirical results indicate significant national similarities amongst the nations studied in the relationships between educational qualifications and labour market positions, they also show substantial national variations apparently due to specific national peculiarities of educational systems with their different historical roots as well as specific State policy interventions (particularly in the two east European countries analysed). The analyses also show the varying roles that education plays in intergenerational social mobility in the various countries.

An even more recent study in that research tradition (Müller and Shavit 1998) shows how varying national ET systems shape occupational attainment. In a comparative study of 13 European and other countries they find considerable between-country variation in the patterns of associations between educational qualifications and labour market outcomes. On the one hand, the strength of the association between educational qualification and occupational destinations appears to be clearly stronger in countries with higher degrees of stratification and vocational specificity in the ET system. On the other hand, the association appears to be weaker in countries with more general educational systems and larger proportions of the youth cohort achieving tertiary qualifications. While the study marks a significant advance the authors, however, point to several of its limitations. Its design is based on 'side by side' comparisons rather than on integrated and fully comparable data sets. It is somewhat limited in its analyses of the school to work transition process, being cross-sectional in nature, and labour market outcomes are measured mainly in terms of first stable jobs. The study is also limited in its coverage of important variables in the school to work transition process leading to stable employment.

While research discussed so far mainly attempts to elaborate and explain similarities and differences between countries in objective patterns of ET-LM relationships, a few comparative studies have also addressed the varying subjective experiences and motivations of individuals in their transitions from school to work in various institutional and societal context. Although the empirical base using this biographical approach is still very limited a number of studies compare school to work transitions in England and Germany (Bynner and Roberts 1991; Evans and Heinz 1994; Roberts, Clark and Wallace 1994) and another study compares Canada and the United Kingdom (Ashton 1988; Ashton, Green and Lowe 1993). The evidence shows how significantly individual perceptions and people's life histories are affected by the different institutional arrangements and societal conditions which structure this crucial transition in different societies.

The main conclusions, therefore, one can draw from available studies is that the nature of both ET and LM systems, as well as the nature of the link between them, varies across European countries. In addition, it is clear that these national institutional differences have significant effects on socioeconomic inequalities in educational achievements, on labour market outcomes and on individual life course trajectories. The following appear to be the most important dimensions of national variation in these respects.

2.1 The degree of institutional standardisation of ET systems

National ET systems vary in the extent to which centralised and standardised national curricula and examination systems exist, or are 'quality controlled'; and are then used for selection/progression purposes for further education or for labour market entry. In some countries (e.g., Ireland), both curricula and examination are nationally standardised, and a pronounced emphasis is placed on educational level and on grades achieved in selection for third level education and in access to paid employment (Breen, Hannan and O'Leary 1995). In other countries (such as the United States), curricula and exams are not nationally standardised at second level, grades are awarded on a school or district basis and are therefore much less relevant in
selection for further education or subsequent labour market chances (see Rosenbaum and Kariya 1991). It should be noted that the different levels of the ET system within a country may differ from each other in these respects. For example, second level education may be relatively unstandardised while third level education may be highly standardised.

2.2 The extent and nature of differentiation within ET systems

Differentiation within ET systems concern

a) the extent of division between general and vocational education, and the age and degree of selection into such different tracks/streams;

b) the extent of formal differentiation or grading of educational achievement outcomes - at each stage/level of education; the degree of hierarchical ranking of educational achievement and the nature and degree of selection for progression to higher stages.

The degree of differentiation between academic and vocational 'tracks', courses or routes varies widely across countries (see Allmendinger 1989). The German and Dutch systems of education/training, for example, are highly differentiated institutionally with parents/pupils choosing from the age of 11 onwards what type of school and educational path is to be followed. In contrast, the Irish and Scottish systems are much more general and comprehensive, with relatively weak curricular tracking at second level (particularly lower second level), although pupils may specialise to some degree in particular types of subjects (see Hannan et al. 1993). One of the objectives of the proposed research will be to examine the extent to which such curricular specialisations in the latter countries - such as in vocational/technical subjects - have any equivalent LM effects which correspond to the strongly differentiated Dutch and German systems. These national institutional variations have obvious implications for access to appropriate vocational training and for the degree of matching ('content congruence') between type of training and type of occupation subsequently achieved.

The relative degree of hierarchical stratification of levels of educational achievement, or the relative significance of levels of education achieved versus other aspects of educational achievement, appears to be more significant in non-differentiated systems such as in the Irish case; though in all systems 'level of education' achieved is expected to be one of the most important variables in labour market integration. Related to such hierarchical ordering of achievements is the extent to which grades achieved in examinations are elaborated (and are used in selection) - varying from minimal 'pass'/fail' distinctions to A to D, E, F distinctions in each subject in all examinations in Ireland and Scotland (see Breen et al. 1995).

These different aspects of differentiation vary across EU countries - with maximal influence of vocational/general differentiation in the dual system countries and the Netherlands, while in the Irish and to a lesser extent the British and French cases the importance of both level of education and grades achieved in examinations are likely to be far more important in educational progression decisions and in selection for employment. These macro-level characteristics of ET systems are likely not only to affect the educational progression decisions of students and their parents but the nature of the whole ET-employment relationship.

The research will therefore pay particular attention to micro-level variables which reflect three aspects of educational differentiation: the highest stage/level of education achieved, educational/vocational track or degree of specialisation involved, and curricular level taken and grades achieved in examinations.

2.3 The links between ET and LM systems

Employers' use of level and type of ET qualifications in employment decisions vary across countries and, within countries, between sectors and occupations. Employers' evaluations of ET outputs impact on labour market entrants in two ways: first, in opportunities to obtain employment and, second, in the nature
and level of the job obtained: whether regular or temporary, full-time or part-time, occupational status and level of pay. The nature of the link between ET and LM entry can vary substantially: from situations of complete isolation, or 'decoupling' of the ET system from the LM system (in 'liberal and open' market economies) to one where both systems are highly interconnected. Drawing on a typology developed by Hannan, Raffe and Smyth, (1996) and presented in Figure 1, we can conceptualise these links as follows:

a) strong and direct, shared interlink: Where employers and schools/trainers are jointly involved in the provision and delivery of training for young people, and where both employers and ET providers jointly agree on education/training requirements for specified occupations. This pattern is particularly evident in the German-speaking countries and Denmark where there is strong 'content' and 'level congruence' between educational outputs and labour market intake (see Konietzka and Solga 1995);

b) collinear linkage: Here a substantial occupational labour market exists, training for specific occupational positions takes place in second-level schools, but there is little or no joint delivery of training for young people moving from school to the labour force. In the Netherlands, for example, over 1,000 detailed occupational categories, and over 120 occupational groups can be distinguished on the basis of the level and type of education required for entry. As a result, there is a highly developed occupational labour market served by a large and diversified set of education/training programmes provided on a full-time basis, with a moderate to high degree of congruence between course content and occupational position. Elements of such a collinear link exist in other systems. In most countries, for instance, there is a range of professional and higher technical positions where specified educational programmes at third level are required for entry;

c) no direct link but strong market signals from schools: Although employers are not directly involved in schooling or training, school achievement outcomes (examinations and qualifications) are publicly certified and used by employers in making recruitment decisions. Education systems are highly standardised but tend to be less differentiated in terms of school type or curricular tracking. There is a high degree of 'level congruence' between educational outputs and labour market outcomes, but little regulated 'content congruence'. In addition to 'levels', examination grades may be widely used in access to employment (see Breen, Hannan and O'Leary 1995). Such reliable measurements of 'general human capital' are, not unexpectedly, widely used in employment decisions. With the exception of the American and Canadian second-level systems, most of the English-speaking countries fall into this category, as does France and many of the Scandinavian countries;

d) school placement function: a somewhat stronger version of (c) exists in countries like Japan, where besides open market 'reading' and matching of educational outputs to job offers, employers may be directly linked to schools by the school guidance service effectively acting as job placement officers in the employment system. This arrangement may be supported by, and officially acting in place of, the State employment service, as in Japan (Nakajima 1990; Rosenbaum and Kariya 1991);

e) no direct link and weak market signals: the USA is the exemplar here. There is no national standardisation of the educational system at first or second level, and second-level education tends to be comprehensive and relatively undifferentiated. There also tends to be limited post-school training of those high school graduates or dropouts who do not go on to third level, compared to Germany for instance (Schupp et al. 1994). On the other hand, a much higher proportion of the cohort complete upper second level education and go on to third-level (or other further) education in the USA and Canada; and the third-level systems there appear to be much more open

and flexible in terms of part-time and ‘second chance’ participation than is true for Germany, the UK (see Ashton et al. 1993) or for Japan (Nakajima 1990). In these cases, there appears to be both weak ‘content congruence’ and weak ‘level congruence’, though high school graduates tend to be at some advantage in relation to school drop-outs, and third-level graduates have clear advantages over high school graduates (Rosenbaum and Kariya 1991).

Using the above three dimensions of national educational systems – standardisation, differentiation and ET/LM links – and crudely dichotomising each one we can derive the following typology of national ET systems.

As indicated there appear to be few differences between European countries in the degree of standardisation of their ET systems at second level – at least relative to the United States. Although substantial differences do exist in how this is achieved and the extent to which it is centralised, for this initial purpose we can regard them as standardised. The dual system countries are highly standardised and differentiated, with strong and highly institutionalised relationships between ET systems and employers, etc. – particularly through the apprenticeship system. At the other extreme is the American system – relatively unstandardised, undifferentiated and with little if any institutionalised link between the ET and the employment systems. Most north and western European countries fit within the standardised and moderately to lowly differentiated box – though within this there are substantial differences in the extent of differentiation – particularly at up-
per second level, and also in the relative importance of apprenticeship/'alternance' arrangements in vocational training and labour market integration. The importance of these institutionalised differences between national systems in Europe will be explored below in the section on hypotheses.

Aside from such national ET system differences ET and LM relationships are also affected by labour market – particularly youth – characteristics.

2.4 Labour market contexts and employment decisions

The extent of differences between the adult and youth labour markets varies across countries. In some countries, the distinctions are more marked with young people disproportionately concentrated in particular occupations, industries or types of firms. Points of entry into particular occupations or internal labour markets can be aged-based with certain segments disproportionately filled by younger workers (Ashton 1988; Ashton, Maguire and Spilsbury 1990). In other systems such ‘youth jobs’ segmentation is very limited. Segmentation can occur along a number of dimensions:

The main axes of segmentation are in terms of occupation, industry, firm size. These dimensions vary both within and between countries. Earlier conceptualisations of labour market segmentation posited a dualistic division between a primary sector (with higher paying and more secure positions) and a secondary sector (with relatively low paid unstable jobs) (see for example, Doeringer and Piore 1971; Averitt 1968). More recent approaches have moved away from this ideal type to emphasise the complexity of labour market segmentation (see, for example, Rubery and Wilkinson 1994). The approach adopted in our study draws upon these more sophisticated accounts, focusing on the diversity of labour market structures rather than positing a dualistic division.

The relative balance between occupational (OLMs) and internal labour markets (ILMs) is an important dimension of labour market structure which also varies across societies (see, for example, Marsden and Ryan 1990). Occupational labour markets (OLMs) refer to labour market sectors where jobs are clearly defined in terms of content and have high levels of consistency across firms and industries. Workers in OLMs usually have educational qualifications or skills that are transferable from one employer to another (see Edwards 1979). In contrast, in internal labour markets (ILMs) only lower grade jobs are usually filled from outside the firm with mobility into most higher grade positions taking place after a period of training. Training tends to be firm-specific, taking place on-the-job, and consequently skills are not generally transferable to other firms (see Doeringer and Piore 1971). Occupational and internal labour markets may coexist within the same national system but the relative balance between the two forms varies between countries. OLMs tend to be more prevalent in Germany and the Netherlands and less prevalent in France, Italy and Ireland; Britain occupies an intermediate position, with considerable variation across sectors, but with a general decline in OLMs (Maurice, Sellier and Silvestre 1982; Marsden and Ryan 1990). However, even in countries where ILMs are prevalent, occupational labour markets tend to operate for more desirable LM positions, in particular professional employment.

The relative significance of occupational and internal labour markets is not only likely to be closely related to education/training systems but it is also likely to impact on the processes through which school leavers become integrated into stable employment. In a general and comprehensively oriented ET system and in an ILM-dominated labour market structure, new entrants to the labour market mainly learn relevant skills on-the-job. They are therefore more likely to enter the labour market at lower levels of occupational achievement, and are at a competitive disadvantage compared to insiders for higher responsibility posts, etc. In OLM systems a high proportion of entrants are more likely to find work which fits their occupationally specific qualifications. One would, therefore, expect that in the former case it is more difficult for school leavers – particularly the more poorly
qualified – to find stable employment: more job search time, more job shifting, less secure jobs; with unemployment more concentrated among new entrants (Esping-Andersen 1993). In these systems, the formation of a disadvantaged youth labour market segment becomes more likely, in particular under conditions in which demand for labour is low.

The youth labour supply is, therefore, differentiated by varying levels and types of educational and training experiences and qualifications, and the different social backgrounds of entrants. It is the way in which employers take account of these initial differences between potential young workers in making employment decisions that transforms these differences into enduring labour market opportunities. Thus, a crucial element in analysing the nature of labour market differentiation is to determine the factors used by employers in recruitment (and subsequent promotion) decisions to different labour market positions. In our analyses we pay particular attention to two general aspects of new job applicants’ characteristics: their educational/training characteristics, as already discussed; and their ascribed, social background characteristics – particularly gender and social class.

3. Methods: design of study

An ideal research design would involve both stock analyses of labour force surveys – to study the ET and labour market relationships; and flow analyses of school to work transition surveys, as well as longer, panel surveys of early labour market histories. Existing labour force surveys contain a lot of information on current labour force status and more limited information on educational/training achievements; but very little information on educational/training or labour market history. Nevertheless they provide the best sources of uniform information on education/training and labour market relationships in all EU countries. There are no equivalent data sources on the flows from education/training into the labour market across EU countries, although a small number of EU countries carry out regular surveys of large samples of young people who have left the educational system and entered the labour market, supplemented by follow-up surveys of their subsequent labour market and education/training histories. Ideally one would like such surveys to have much the same design and to have a large set of comparably defined variables/measurements for all countries of interest. However, data sources of this nature do not yet exist.

The labour force surveys (LFS) provide broadly comparable information on education/training and labour market characteristics across all EU countries. As such, the LFS is extremely useful in assessing the relationship between ET and LM systems across Europe. However, its usefulness as a data source for analysing transition behaviour is limited in a number of respects. First, most of the conventional labour force surveys have only limited information on education and training characteristics, and the categories used may also obscure important cross-national variations in education/training and labour market integration systems. Second, many such surveys have little or no information on the first jobs of young entrants to the labour market or subsequent detailed work histories. Third, because the sample covers all age groups, this may result in a very small number of labour market entrants in any given year. This makes it impossible to analyse country differences in the nature of the initial transition process. Fourth, these surveys rarely have information on the social background of respondents, thus obscuring variation between different groups of young people in the nature of the transition process. However, the national coverage of these surveys, their large sample sizes and comparable variable definitions mean that detailed comparative analyses can be carried out on the relationships between educational/training qualifications and current labour market statuses for different age/sex groupings in all EU countries. This kind of comparative analysis allows us to ground our SLS flow analyses of five EU countries within the wider EU system.

Surveys of school (or third-level) leavers (SLS) have much more potential for the analysis of
school to work transitions. These surveys allow us to examine in detail the relationship between social background, education/training characteristics and early labour market experience. This information can be supplemented by analyses of youth cohort or follow-up surveys, which give a more complete picture of the impact of education/training on longer periods of labour market experience. Since countries vary significantly in the pace, timing and patterns of the transition process, it is important to use longitudinal data to analyse the complexity of life histories among young people. In addition, changes in education/training policy and secular shifts in the economy will result in differences between cohorts of young people in their employment chances, access to further education and training, and so on. The school leavers' surveys are available for several points in time, allowing us to study the differences between cohorts of young people. However, such regular national school leavers' surveys are only carried out in a limited number of countries: France, the Netherlands, Ireland, the United Kingdom (Scotland), Sweden.

Although these surveys have not been designed to be comparable, they have substantial similarities. The five surveys comprise a year-group survey (Sweden), a labour market entrants' survey (France) and three follow-up school leavers' surveys – Ireland, Scotland and the Netherlands. Four of these surveys cover a cross-section of young people; the fifth (French) survey is targeted on leavers from specific courses. The surveys vary in the number and timing of follow-ups, and in the data they collect. For example, the most recent comparable surveys cover:

a) Scotland: young people who left 'general' secondary education in 1993-94 (although some may have taken up various mixtures of general and vocational courses), surveyed in the spring of 1995. Vocational courses (FE colleges), apprenticeships and training schemes, as well as higher education, all count as destinations;

b) Ireland: young people who left secondary education in 1995-96, surveyed in autumn 1997. This includes those who left Junior or Leaving Certificate (including vocational and applied) and post-leaving certificate courses in 1995-96. Other (post-secondary) vocational courses count as destinations, together with apprenticeships, training schemes and third level education;

c) France: young people who left general or vocational full-time (excluding general baccalaureat and agricultural courses) or apprenticeships in 1993-94. The survey was conducted in spring 1997 but the destinations in the data set refer to autumn 1996. Unlike the other surveys, the French (CEREQ) survey is based on labour market entry groups and does not include those who continued in the education system – for example, at university (see Becker et al. 1999);

d) The Netherlands: young people who left secondary education (including MBO) courses in 1995-96, surveyed in autumn 1997. The data set excludes those who reentered another form of secondary education (e.g. those who entered MBO). Apprenticeships count as destinations, together with higher education;

e) Sweden: young people who completed lower-secondary education in 1993, surveyed in spring 1997. Since most upper-secondary courses lasted two or three years, most sample members who entered upper-secondary education had left by the time of the survey, but a few were still there.

Therefore, while each survey covers a sample of young people in a given period after making a transition, the length of this period and, more importantly, the destination definitions of the transition, vary across countries. However, each survey effectively covers the school-to-work transition process – either prospectively or retrospectively – and therefore provide relatively sound comparable databases.

An inherent defect of the proposed study will be that its design neglects the direct observation of the behaviour of one crucial group of actors decisively influencing the ET-LM rela-
tionship on the side of labour demand: the strategies and selection preferences of employers in their personnel recruitment and job allocation decisions, which—as we have outlined above—are very likely to vary across countries. We recognise the importance of such information on the demand side of the labour market, and we will draw on research done by others on these issues insofar as this is possible.

The research maximises the potential of the labour force survey to ground our specific analysis in the broader European context, and uses the school leavers’ surveys in the five countries to develop a conceptual and methodological framework for analysing youth transitions across Europe. One aspired objective of our research is to help move the existing national surveys towards greater comparability, as well as to help the development of such surveys in other EU countries initiating surveys of school leavers—for example, in Belgium and Portugal.

This research develops upon a substantial body of comparative research already carried out by the project partners. The network made an exploratory attempt to construct a common dataset, using a small number of variables for the Dutch, Irish and Scottish data on school leavers at one point in time (1991) (Hannan et al. 1993). In addition, a common dataset covering a range of variables has been developed for the Irish and Scottish surveys over the period 1980 to 1991 (Smyth and Surridge 1995; 1996). Two of the project partners (CES and ESRI) have carried out research for OECD on developing a conceptual framework for examining school to work transitions and have been involved in planning meetings for the OECD’s current Thematic review on transitions from initial education to working life (see Hannan, Raffe and Smyth 1996). In addition four of the project partners (CES, Edinburgh; ESRI, Dublin; DESAN, Amsterdam; CEREQ, Marseilles) have completed a four nation comparative study on early school leaving for DG22 under the Leonardo surveys and analysis programme (1996-98.). This comparative research is based on a four-nation comparative dataset of school leavers’ surveys in France, Ireland, the Netherlands and Scotland. Some results from this comparative study are given at the end of this paper.

The following figure broadly indicates the type of information which will be used from the school leavers’ surveys.

| Data sources: |
| School leavers’ surveys for France, Ireland, Netherlands, Scotland, Sweden. Integration of three to five year follow-up surveys where available. |
| Sample characteristics: |
| National samples of secondary level school system leavers. |
| Education and training characteristics: |
| Level achieved; type of school/curriculum; general versus vocational education; vocational speciality; examination outcomes. |
| Individual and background characteristics: |
| Age, gender, age of completion of education; parental socio-economic status and education for some national surveys. |
| Labour market entry characteristics: |
| Labour force characteristics for first year in the labour market. Work careers available in follow-up surveys for three to six years in the labour force for France, Ireland and Sweden. |
| Labour market ‘success’: |
| Employment status; type of job (full or part-time); occupation; industry, wages. |
| Periods covered: |
| Other outcomes: |
| Household status; marital status; migration characteristics, etc. |

Country selection

The selection of countries included in the study is partly based on the fact that these are the main countries that carry out school leavers’ surveys on a regular basis and that researchers from these countries have been cooperating to explore their potential for comparative analyses. (Pottier 1993; Raffe 1993; Hannan et al. 1993; Smyth and Surridge 1995; 1996; Hannan, Raffe and Smyth 1996). The countries included do not represent all
the important dimensions of variation in ET and LM links in Europe but do differ substantially in these respects.

Ireland is perhaps at one extreme of the continuum where the second-level educational system is dominated by the vertically organised 'general education model', with a low level of horizontal, curricular/examination differentiation. Most schools are privately owned and managed, though highly State regulated. The curriculum and examination system is highly centralised and standardised (by State regulation), with State examination results being the main 'market signals'. The development of more general rather than specific (vocational) human capital is emphasised. The second level ET system is neither institutionally linked to employers nor formally differentiated to cater for occupational labour markets, although there has been some recent expansion of vocational training courses at upper second level. Although there are practically no institutional links between schools and labour markets, third level entry requirements and employment selection procedures pay particular attention both to level of examination taken as to grades in such examinations (Breen et al. 1995), with apparently little attention to vocationally specific specialisations, except in a limited range of craft and professional occupations.

In Scotland second school schools are State-run and comprehensive (except for a very small private sector). The curriculum is general and follows national guidelines. There are vocational elements in the curriculum, but they are integrated into the general curriculum. There is no occupational specialisation or tracking as in some continental countries. Schools may have links with employers – for example, in the provision of 'work experience' which all secondary pupils are expected to obtain – but these tend to support the broadly general objectives of schools. This relative absence of formal curricular differentiation means that in Scottish, as in Irish, schools the vertical dimension is dominant. Progression either into further education or into the labour market is strongly influenced by the level of attainment in 'academic' examinations taken at the ages of 16, 17 and 18. In the past, the main exception was that younger (16-year-old) school leavers sometimes had an advantage compared to older school leavers, because of their opportunity to enter age-restricted apprenticeships or training opportunities. These opportunities have declined, and a majority of young people now stay at school beyond 16.

In contrast to Ireland, the Scottish system offers vocational alternatives to school at the upper-secondary level. Further education (FE) colleges provide full-time courses, typically in broad occupational areas or in 'transferable' skill areas such as catering or business and administration. Many younger school leavers enter work-based training programmes (apprenticeships or youth training programmes known as 'skillseekers') which may include part-time studying at FE colleges. This training is typically occupation- (or employer-) specific. It is based on standards which are, in principle, 'employer-led'. Within this work-based sector 'horizontal' differentiation is more important (Raffe 1992). As in the rest of the UK, the labour market in Scotland is weakly regulated and structurally diverse; it is not easily classified in terms of ILMs or OLMs, although some studies (such as Marsden and Ryan 1990) characterise the UK in terms of decaying OLMs.

Traditionally, the educational system in France was strongly dominated by schools of general orientation with little formal vocational training. Since World War II, France has developed a vocational training system at all levels, which is closely connected to the general education system: training of workers and employees at the end of the first cycle (CAP, BEP), technical baccalaureate, then further training as technicians (BTS, DUT). Today more than 40% of school leavers have a technical or vocational diploma. Whereas general education is of greater value within the education system, technical and vocational diplomas have better recognition on the labour market. In large French firms, the predominance of internal labour markets has led to poor qualification/occupational 'matching' at entry level and to a late articulation between qualifications and job classifications. However, the current employment crisis has
mostly penalised young people and led public authorities to promote measures developing sequences of school-based and in-company training courses alternately (e.g. BAC professional, apprenticeships extended to technical and engineering training, and a range of work/school based training arrangements).

With the growing shortage of jobs, decision-makers adopted a certain number of measures supporting labour-market entry. These interventions are focused strongly on the interface between the educational system and the labour market which has two important consequences. The first one is that the very existence and content of these measures, often based on 'alternance' models, reveals apparent deficiencies in the existing educational and training system. The second consequence is that some of these programmes designed to assist labour-market entry, based on alternance training approaches, have had feedback effects on initial education/training, encouraging further reorganisation according to the new public model. All processes at work in France attest to a significant change in the conception of the aims of the educational system, now vested with a double mission: the traditional one of transmitting knowledge, and the more recent one of fulfilling a broader social function through the development of more vocationally relevant and effective education/training for labour-market entry, especially amongst young people with particular difficulties.

In some respects, the Netherlands is similar to Germany. The Dutch educational system is highly differentiated and standardised. It also has a strong vocational component, which at the same time is strongly segmented horizontally in many vocational specialities and a similar degree of stratification of general education. In contrast to Germany, however, the vocational training system of the Netherlands is school-based, has a low degree of overlap with workplaces and also much lower employer involvement. Besides school-based vocational training, it also has a system of apprenticeship, although small in comparison to Germany. This has, of course, consequences for the structure of the labour market. Recent research shows that ILMs and OLMs have almost equal shares in the Dutch economy (Dekker, de Grip and Heijke 1994).

These characterisations of countries will probably need revision with further analyses. At this stage, however, they may be sufficient to indicate the variation across the countries in the main variables and outcomes of interest.

4. Progress to date: construction of the comparative databases.

Four main issues arose in constructing a comparative database from five national school leavers' surveys:

a) definition of populations and samples;

b) timing of interviews – in terms of years in which school leavers were sampled and in terms of post-school labour market exposure;

c) variable definitions and specifications; and

d) overall design of database.

Population/samples. The population aimed at is all full-time initial second level system leavers – rather than school leavers. The concept of second level system leavers is used because of possible confusion where some potential respondents leave one school or school type, and enter another second level one – particularly in highly differentiated systems such as the Netherlands where national surveys made this possible. Such 'reentry' school leavers are excluded from the comparatively defined population/sample. They are included only when they subsequently exit the total system. We therefore aimed only to include those who leave the full-time second level system for the first time ('initial' leavers). Those who leave but who continue in post-school, part-time education or training are, however, included – this generally 'mixed status' being regarded as a 'post-school' destination.

The selection of samples for the national surveys may be from national registration lists or through a process of initially sampling schools/systems and then 'school leavers'
within these schools. In most cases the sample is designed to cover all those who left the full-time second level system in the preceding academic year – i.e. those sampled and interviewed in May 1998 would have completed their initial full-time second level education in the academic year 1996/97. Most are then in a 'post-school' status (usually on the labour market or in further education or training) for at least nine months to a year. Interviews at that point are designed to measure respondents' 'post-school' education, training and labour market outcomes and experiences subsequent to leaving school.

For the most recently surveyed, the samples include all those who left (completed course or left during course) their initial full-time (second level) education in the 1993/94 session in France and Scotland, and the 1995/96 educational session in Ireland and the Netherlands. The samples of respondents selected were interviewed between one year to one and a half years subsequent to their completion of second level education. The surveys were carried out by personal interviews in Ireland, by mailed questionnaires in France and Scotland and mostly by telephone interviews in the Netherlands.

4.1 Variable list and definitions in common database

Essentially we need as much detailed comparative information as possible on five areas;

a) the social background of school leavers;
b) household status and, to a limited extent, migration status (about 5 variables);
c) educational background/achievement (about 12 variables);
d) post-school education, training achieved (about 26 variables);
e) current employment status characteristics (about 20 variables);
f) labour force history characteristics since leaving full-time education (about 20 variables). See Appendix for details of common variables.

Clarifying these definitions and concepts took some time and intensive discussion; and in coming to common definitions we lost some important information. For instance, because the Irish and Scottish surveys covered only school leavers' defined in a conventional way, all post-school youth training and further education (in, e.g. further education colleges) is defined as a 'destination' for school leavers and, since a significant proportion of these are still in training or further education at the time of the interview (a year later) we have no information on their subsequent labour market outcomes. One way to correct this is to follow up such initial school leavers for a number of years (five or six) to measure such long-term outcomes. This is done periodically in a number of countries (UK – including Scotland, France, Ireland, the Netherlands and Sweden).

National surveys varied significantly in the nature and extent of social background data gathered. While the usual socio-demographic data (age, sex, age of completion of schooling) is present, there is a lot of missing data on social class of origin (for only two countries), ethnicity (for one country only), educational level of parents (two countries), employment status of parents (three countries). The more complex, multivariate analyses using these variables cannot, therefore, be as comprehensive as we would have wished. One of the main aims of future collaboration would be to increase the comprehensiveness and comparability of variables covered.

Educational experiences and achievements are generally well covered in most surveys: type of school and curricular track, highest level of
education achieved (CASMIN and ISCED measures); type of qualification achieved – vocational/technical or academic/general; grades/awards achieved in examinations and/or detailed educational achievement levels – i.e. from incomplete lower second level, ‘failed’ lower second level, ‘passed’ lower second level examination, to ‘passed’ or got ‘honours’ in upper second level examination. (See Appendix for details of variables covered by country).

4.1.1 Post-second level education and training

Extent and nature of participation, type and level of course; full-time or part-time, degree of vocational/occupational specificity of course, length of course, whether successfully completed, type and level of qualification achieved, etc. Extent to which education involved work experience and nature of work experience; apprenticeship training; extent and nature of involvement in ‘mixed statuses’ – (work and education). There is significant variation in variable coverage by country.

4.1.2 Labour market outcomes

Labour market entry outcomes: initial and current employment status. Extent of employment/unemployment; characteristics of jobs – occupation, industry, earnings, etc.; location of first and current job, etc. Details of the combined variable list are in the Appendix.

4.2 Time series

The most extensive information is available for the current (1993/94 to 1996/97) SLS databases. France (CEREQ) has carried out school leavers’ surveys since the early and mid 1970s. Most of these, however, are only partial samples of the population of leavers – the French samples are excluded from the time series. For Ireland and Scotland such national school leavers’ surveys have been carried out since 1970/71 in Scotland and 1980 in Ireland – and in both cases sampling is national and covers all second level leavers. The first national sample for the Netherlands is available from 1988 only. The Dutch sample is very large, is nationwide and comprehensive but is not initially selected as a national sample. Since it, however, covers all institutional distinctions, all regions and all levels of second level leavers it can be reweighted to approximate a national sample. The following table indicates the time series being used.

As already indicated the current, late 1990s, comparative data set has been constructed. The time series was constructed in September 1999, and analyses have started on the current database.

4.3 Construction of comparative labour force survey (LFS) datasets (coordinated by MZES, Mannheim)

Two data sources are used for LFS analyses: the EU community LFS through data requests to Eurostat in Luxembourg, and national micro data sets for Germany and the SLS project countries (France, Ireland, the Netherlands, United Kingdom, SW) and some other EU countries (Denmark, Spain, Italy, Austria and Portugal). LFS surveys for two time points will be used for most of these countries (from early 1980s and mid-1990s). Both cross-sectional stock analyses and some restricted synthetic ‘flow analyses’ will be carried out – using expected minimum age of completion of highest level of education achieved, and consequent estimate of amount
of time in the labour force. The European Community LFS (CLFS) provides a common database for the most important labour force characteristics for all EU countries. It is limited in its coverage of educational and training variables, and has very limited retrospective data. Access to individual level micro data is only by request to Eurostat. The individual national labour force surveys generally have much more information – though variable coverage and cross-national comparability of variables differs widely. In most cases, however, anonymised micro data sets are available from national census offices. In the CATEWE project, these micro data sets are now available at MZES, Mannheim – with the full set of comparable variable specifications to be completed shortly. Obviously much more complex analyses can be carried out on such a comparative European micro data set.

4.4 Progress on analyses of LFS and SLS surveys

Substantial progress has already (June 1999) been made in the analyses of the CLFS, and in both assembling and aligning the country level LFS micro data sets. Analyses of the CLFS has already commenced and – papers are being prepared for the September transition in youth (ITY) conference in September 1999 in Oslo. First drafts of five papers reporting analyses have already been discussed and critiqued (June 1999):

a) changes in educational participation and qualifications over time in EU countries;

b) national differences in youth labour markets and in transition trajectories;

c) ‘gradualism’ in labour market entry: double statuses in transitions;

d) labour market segmentation and the structure of youth employment in EU countries;

e) educational achievement and initial labour market outcomes: national and institutional contextual effects.

Reanalyses and redrafts of these papers were prepared and second and more comprehensive drafts were given at the European ITY conference in September 1999. It is hoped to publish the contents of these papers in journal articles as soon as possible thereafter. These analyses of the European Community LFS (CLFS), dealing as they do with all EU countries, will set the wider context for both the more detailed analyses possible with the individual country LFS micro data sets as well as the five country SLS data analyses. These later micro data LFS studies started in late 1999 and are to be completed by mid-2000. The analyses of the current SLS has already started and analyses of the time series and comparative follow-up surveys started in September 1999.

4.5 Analyses of school leavers surveys

The four country comparative database (France, Ireland, the Netherlands, Scotland) of current (1995-97) school leavers surveys was constructed by the end of March 1999. Swedish data was added in August 1999.

Construction of the time series data sets has started but will not be completed until end of June 1999. The construction of the French-Irish six year follow-up comparative data set has also started but will not be completed until September 1999.

Analyses of the current four-nation data set started in May 1999. A division of labour on analyses has been agreed, with first drafts of papers reporting results to be completed by

4 The European network on Transitions in Youth (ITY) has been holding annual European research workshops/conferences on education/work relationships and transitions since 1993. Initially funded by the European Science Foundation (1994-96) the subsequent workshops have been partly supported by national funding in Ireland, Scotland and in 1999 in Norway. Copies of workshop papers up to 1996 are available from the ESF in Strasbourg, from 1996 from CEREQ Marseilles, from 1997 from the ESRI Dublin, from the CES, University of Edinburgh in 1998.

6 This paper refers to the project results available until mid-1999.
September 1\textsuperscript{st} in time for the September TIY international workshop:

i) Comparative analyses of the relationships between initial educational/training achievements and ‘post-school’ educational and training outcomes;

ii) Comparative analyses of the relationship between educational/training achievements and post-school labour market outcomes;

iii) Comparative analyses of the relationships between initial educational/training outcomes, initial labour market integration processes and the extent to which State training/employment schemes mediate difficulties in transition;

iv) Comparative analyses of gender and social class inequalities in educational achievements and in education-to-work transitions;

v) Comparative analyses of both youth/adult and general labour market segmentation processes in the five countries;

vi) Comparative analyses of the nature and extent of labour market exclusionary processes amongst the least qualified.

As of mid 1999 there were no results from these analyses. But the papers were subsequently revised and are now available as CATEWE working papers.\textsuperscript{7}

One clear result, however, is the fact that it has proved possible to construct cross-nationally comparable microdatabases from both national labour force surveys and school leavers surveys. Although there are serious missing data problems for some important variables (particularly social background variables) in the school leavers’ surveys this database is still a very rich one for research and policy purposes. The earlier Leonardo study, reporting analyses of a more restricted cross-national data set based on the same type of surveys, however, indicated some important policy relevant results and conclusions. Some of these will be discussed next.

5. Results and conclusions

Although there are as yet no results from our analyses of the CATEWE comparative databases some conclusions from our work on comparative database construction are important. In addition some results and conclusions from an earlier, though more restricted, comparative study of school to work transitions amongst early school leavers, under the Leonardo surveys and analyses programme, (1997-98, VTLMT\textsuperscript{8}) appear very relevant.

Two comparative micro data sets on school to work transitions have been or are being constructed using existing national surveys. The first is based on national labour force surveys for most European countries. The Eurostat Community LFS data set is available only for a limited set of variables, and in any case is not directly accessible to the research community – although Eurostat has been very helpful in making detailed cross-tabulations available. The national data sets are generally much more comprehensive and, for most EU countries, are available as anonymised data sets to the research community. So a comparatively defined LFS data set is being set up for the majority of EU States. The initial work on the CLFS (Eurostat) database indicates not just the value of cross-sectional analyses of the existing variables, but also the value of constructing and using other more complex variables – for instance, in using expected ages of graduation and entry to the labour market in identifying recent (young) entrants to the labour market – to estimate differences in labour market outcomes for

\textsuperscript{7} Available as a CATEWE working paper from the ESRI, 4 Burlington Rd., Dublin 4, April 2000.

\textsuperscript{8} Vocational Training and Labour Market Transitions. This was a project funded under the Leonardo ‘Surveys and Analyses’ programme, DG22, 1996-98. Contract N\textsuperscript{o} – IRL/96/1/10074/EA/III.2.a/FP1. Final report Dec. 1998. The research project was based on comparative analyses of school leavers surveys in France, Ireland, the Netherlands and Scotland – primarily focusing on the education–labour market relationship amongst those who left full-time education before completing upper second level. The project was coordinated by ESRI, Dublin in partnership with CES, University of Edinburgh; DESAN, Amsterdam; and CEREQ Marseilles.
young versus older labour market entrants. These analyses show clearly the underutilised value of the existing labour force surveys for research and policy analyses purposes.

The second main methodological finding is that the existing national school leavers' surveys carried out in five EU countries (France, Ireland, the Netherlands, United Kingdom (Scotland), Sweden) – and prospectively in Belgium (Flanders) and Portugal – provide a rich comparative database for studying the longitudinal/panel aspects of school to work transition processes in a range of EU countries. These mainly cover the post-school education/training and labour market history characteristics of school leavers for one to one and a half years after they complete their second level education. Combined with the cross-sectional LFS analyses of current status characteristics of individuals these detailed 'flow data' on educational and labour market history provide for very comprehensive analyses of school to work transitions across the European Union.

Although there are many sample and variable comparability problems arising from constructing a comparative database from such national surveys – with many 'missing data' gaps, for instance – both the process itself of constructing such a database and the initial raw results illustrate clearly the advantages of such approaches. In constructing comparatively defined, meaningful variables – which capture both the common and, as far as possible, the unique in each system – overarching concepts and variables need to be specified in ways that are not otherwise obvious. For instance the concept of 'level of education' does not always make clear whether the person reaching level 'x' has actually taken and 'passed' the relevant examination at that level. Equally, differences in the significance of different national ways of measuring educational achievement – whether, for instance, grades achieved in examinations, or 'levels' taken in courses/curricula are important/relevant – have to be dealt with in ways that are not always revealed in cross-national surveys where the lowest common denominator approach to variable definitions is often used.

Besides these comparative data construction issues, one of the main advantages of such cross-cultural (or cross-national institutional) studies is the classically stated advantage of additional insight into national characteristics gained from comparing one national system to another quite different one. By shedding normal ethnocentric conceptualisations engendered by national studies or even by limited comparisons with similar type systems, intensive comparative studies much more clearly reveal national differences. For instance, the overarching significance of 'grades achieved' in examinations in the Irish, and to a lesser extent in the Scottish system, in selection/progression to higher levels of education/training and into the labour market – and their apparent lesser significance in the Dutch or French systems – illustrate clear national system differences in educational assessment and selection. The relative significance of these different kinds of selection mechanisms becomes very obvious in any detailed comparisons – but they are very easy to miss in less detailed ones. The necessity to specify a wider range of social background, educational, training and labour market variables to capture the most relevant aspects of each national system, while at the same time trying to integrate these into an overarching, common set of concepts/measures is one of the main tasks of such detailed comparative analyses. Hopefully, these initial findings will show more insight and lead to a more comprehensive comparative analyses than would otherwise be the case.

The Leonardo VTLMT study – 1997-98

The earlier comparative European study of school to work transitions using school leavers surveys was funded under the DG22 Leonardo (Surveys and Analyses) programme (VTLMT9 1996 to 1998). The empirical analyses were based on a comparative data set based on school leavers' surveys in France (1995), Ireland, the Netherlands and Scotland (1993).

Vocational training and labour market transitions in Europe – coordinated by ESRI, Dublin in partnership with CES, University of Edinburgh; DESAN, Amsterdam; CEREQ, Marseilles.
The main focus of the study was on the relationships between initial educational/training outcomes and qualifications amongst school leavers and subsequent, post-school, labour market and education/training outcomes. In this case the main interest was in 'early school leavers' or those who left the educational system with no or poor qualifications. The final results and conclusions are included in the final VTLMT report to DG22 in December 1998, and are to be published as separate journal articles.

Four main hypotheses guided the analyses:

1. gender and social class inequalities in the type and level of educational achievement are greater in the Netherlands – the country with the most differentiated and selective ET system (Blossfeld and Shavit 1993);

2. the educational qualification distinctions amongst ‘early school leavers’ (or, more technically, lower second level leavers) – in terms of examination grades or ‘pass’/’fail’ distinctions – will almost have the same effect on labour market entry as the distinction between lower and upper second level leavers (Breen, Hannan and O'Leary 1995);

3. controlling for educational level and grades achieved in examinations, it is expected that those specialising in vocational/technical curricular ‘tracks’ will have significant labour market advantages over those in general tracks (Shavit and Mueller 1998);

4. the labour market effects of educational failure (early ‘dropout’ or ‘fail’ in lower second level examinations) are expected to be greater in national systems with less differentiated ET systems and less ‘occupationalised’ labour markets; i.e. more serious in Ireland and less serious in the Netherlands.

Main results

While the proportion of those leaving school in Scotland with only a lower second level qualification or less (40%) were almost twice as high as in the other three countries, the extent of post-school education/training participation rates were much higher there – so reducing national differences considerably. Such post-school provision and participation for the most poorly qualified was lowest in Ireland – with less than one in four of early school leavers entering alternative education/training pathways compared to almost one in two for their Scottish counterparts. There are then substantial national differences in the provision for and participation in such post-school ET interventions.

Gender and class of origin differences in levels of educational achievement are much greater in Ireland than in the Netherlands or Scotland. Irish lower level leavers, particularly those without qualifications, are more likely to be male, working class and have parents that are unemployed. At least in terms of the first major educational transition therefore, our main hypothesis is not supported: the least differentiated system – though one with strong inter-school competitive effects (Smyth 1999) – is the most gender and class discriminatory. The Irish system is also the most highly unidimensionally stratified – a highly hierarchical general system. It appears as if the highly differentiated and early selective Dutch ET systems have both lower initial educational failure rates amongst the total school entry cohort, but also class and gender selectivity appears to be lower at that basic level. Of course in terms of type of education/training and in terms of later progressive transitions – such as to the completion of upper second level or entry to third level – these national differences may be reversed.

The four countries differ substantially in the level and quality of post-school ‘corrective’ ET and active labour market provision. Labour market entry (whether at work or looking for work) is most likely to be almost the only opportunity available in Ireland for those not going on to third level. There is a much more elaborated, State funded and better organised set of both ET and work-based training/employment scheme provision in Scotland. Employment chances are maximised in the Netherlands but alternatives to unemployment through apprenticeships and State training/
employment schemes are much richer. France equally, although with the lowest employment chances for early leavers, has the most elaborated and best funded system of post-school training. The extent and nature of State intervention in the labour market for early and poorly qualified school leavers is, therefore, one of the most variable aspects of school to work interventions.

What effect has examination performance on labour market access or access to more valuable post-school ET pathways? In fact ‘passing’ lower second level examinations – so distinguishing between those who either left school before taking the examination or having ‘failed’ the examination and others who at least got a ‘passing grade’ in such lower second level examinations – has a significant positive effect on employment chances in all four countries; and in all except France on access to apprenticeships also. For other less valuable traineeships or post-school training/employment schemes the effects are negative for Ireland only – a not unexpected result given that recruitment to these schemes is targeted on the more poorly qualified with the poorest employment histories in Ireland.

What is significant here as in some other research (see Breen, Hannan and O’Leary 1995) is that level of performance in lower second level examinations is almost as important in labour market access as proceeding to upper second level, particularly amongst those with below average educational performance.

A State policy geared to maximising upper second level educational participation, without paying equal attention to improving the basic educational performance levels at primary and early post-primary levels, appears therefore to be a seriously mistaken one. There is little added value in keeping young people with poor performance histories in school up to 17 or 18 unless basic educational achievement levels significantly improve. Improving the basic educational and personal and social development skills of the lower performing 10 to 20% of the cohort at lower second level is a far more fundamental educational goal than just increasing the compulsory ages of attendance to 17 or 18. The second hypothesis is, therefore, strongly supported.

Are there effective alternatives to vocation/technical tracks or post-school vocational training programmes – such as apprenticeships – in non-differentiated systems such as the Irish or British ones up to age 16? Recent research has corrected for earlier negative assessments of assignment to vocational/technical ‘tracks’ within the more general and more comprehensive systems of the English-speaking countries – particularly for ‘non-college’ bound youth – (Shavit and Mueller 1998; Kerckhoff et al. 1998 Hannan and O’Riain 1996). Effectively these results indicate that although such vocational/technical ‘tracking’ may divert a significant proportion of working class children away from proceeding to upper second and into third level education (and so increase social class inequality at these higher levels) successfully completing such programmes does in most (though not all) cases increase access to skilled manual and service employment – or in escaping from the lower skilled and less secure sectors of the youth labour market. Our results strongly support the latter view. Such specialisation in second level, vocational/technical subjects significantly increases access to skilled manual occupations for males in all four countries – though it has no effect on employment access as such, controlling for the effects of most other relevant variables. Again this hypothesis is strongly supported, though for males only.

There is no evidence, however, that the relative effects of educational ‘failure’ – no qualifications or ‘failed’ qualifications – on employment chances are any higher in Ireland, though the extent to which this occurs is greater in Ireland and Scotland. The fourth hypothesis is not, therefore, supported, although this hypothesis is harder to test given

---

10 ‘passing’ in this sense has a clear meaning in the French and Dutch systems; but in the Irish and Scottish systems has to be somewhat arbitrary – so the older definitions are used as in the Irish case where a minimum of five Ds in the junior certificate (and equivalent in the Scottish GCSE) examination is regarded as required to get a pass.
the various different interpretations of educational 'failure' in Ireland and Scotland versus France and the Netherlands.

The results of this initial study of early school leavers encourage optimism about the future results of the larger CATEWE project. Combining both LFS analyses of education/training and labour market relationships in all countries, with more detailed analyses of school-to-work transitions in a smaller number of countries – using both time series and longitudinal analyses – the project should yield valuable comparative European analyses of education/training and labour market relationships by the end of the year 2000.

Education and labour market change:
The dynamics of education to work transitions in Europe*
A review of the TSER Programme

Damian F. Hannan, Patrick Werquin

Abstract
The education/employment relationship and the transition from school to work has been the subject of substantial research over the last decade. This is mainly because of its priority in policy making for a number of reasons (see paper).

One of the main policy research questions remains whether there is one or a number of different and equally effective solutions to these problems in different EU countries.

The underlying sources of these difficulties in different country labour markets within the EU are difficult to disentangle. They are not equally serious in all countries. They also tend to have different patterns in different countries, and there is no agreement on the exact source of the relative lack of job vacancies for young people.

Successful policy interventions also tend to differ across countries. Not all EU countries reacted the same way to the crisis, nor do or can they have the same kind of effective policy solutions: the seriousness and nature of the problem varies across countries; countries have different youth/age profiles, somewhat different economies, and clearly different institutional systems.

In these circumstances comparative cross-country research is of particular interest to learn to what extent and why some policies appear to be generalisable, while others appear to be effective only in particular country/institutional contexts.

This requires that research should aim at a clear understanding of the impact(s) of institutional contexts on education and training (ET) and labour market (LM) outcomes.

* The quality and comprehensiveness of this paper is a result mainly of the critiques and suggestions of our colleagues funded on TSER projects, who attended a preliminary meeting in Brussels at DGXII on Nov., 19th 1998. Any remaining inadequacies or faults in the paper are due entirely to the authors. Our particular thanks are due to T.F. Brandsma, University Twente, Enschede; P. 1. Introduction

This paper has three main objectives:

- a) It reviews the main research findings, conclusions and general direction of the Targeted Socio-Economic Research (TSER) Programme under the Fourth Framework Programme of DG12, dealing with research on education/employment relationships and, in particular, transitions from education to work in Europe and places it in the context of the wider research literature and policy priorities in the area;

- b) It highlights the main areas where policy needs are well served by research, and other areas where research is poorly developed;

- c) It suggests the main areas of research and policy analyses that need to be addressed in the next 5th Framework (TSER) Programme (1998-2002), particularly under the Horizontal Programme for Improving the Human Research Potential and the socio-economic research base. (O.J. c506/99, 13.01.1999).

The paper does not attempt to evaluate nor comprehensively review the main TSER research on education-employment relationships, but to summarise the main findings in the context of comparative European research and related policy preoccupations on the relationships between education/training system outputs and labour market entrants and outcomes at an individual and system level.

The education/employment relationship and the transition from school to work has been the subject of substantial research over the last decade. This is mainly because of its priority in policy making for a number of reasons. Firstly, most European countries have had persistent high youth unemployment rates for almost two decades, with the time between leaving full time education and securing a regular job also increasing significantly. With a substantial proportion of young people entering the labour market (LM) either never finding secure employment or being intermittently unemployed – particularly amongst the least educationally qualified – both policy makers and researchers have focused a lot of attention on the initial school-to-work transition process. Initially substantial state investments occurred in LM interventions such as state employment and training programmes, but gradually shifted to more active and more effective labour market interventions as the long-term secular rather than temporary nature of the labour market problem became increasingly apparent. As a result, in many EU/OECD countries participation in such state programmes became a regular feature of many young people’s transition between leaving full time initial education and either getting a regular job or effectively withdrawing from active participation in the labour market. Besides the immediate social consequences of such effects, these issues are of continuing policy relevance since, when economic growth resumes, countries will need a full working population complement in a situation of generally low replacement rates. Even in present circumstances labour shortages have emerged in some countries such as the Netherlands, so that state and European Union (EU) policy needs to be geared to address the medium to long term effects of declining demographic trends with improving economic growth.

Besides the current employment crisis, a rapid upgrading of education and training (ET) is required in most EU countries given the poor competitive position of EU countries for low skilled production and high global competitiveness for high skilled production and services, particularly from the USA and Japan. Given these policy priorities, transition from school to work has become a very important policy issue in most EU countries. One of the main policy research questions remains whether there is one or a number of different and equally effective solutions to these problems in different EU countries.

The underlying sources of these difficulties in different country labour markets within the EU are difficult to disentangle. They are not equally serious in all countries. They also tend to have different patterns in different countries, and there is no agreement on the exact source of the relative lack of job vacancies for...
young people. Successful policy interventions also tend to differ across countries. Not all EU countries reacted the same way to the crisis, nor do or can they have the same kind of effective policy solutions: the seriousness and nature of the problem varies across countries; countries have different youth/age profiles, somewhat different economies, and clearly different institutional systems. In these circumstances comparative cross-country research is of particular interest to learn to what extent and why some policies appear to be generalisable, while others appear to be effective only in particular country/institutional contexts. This requires that research should aim at a clear understanding of the impact(s) of institutional contexts on education and training (ET) and labour market (LM) outcomes. The main aim of this paper is to summarise some of the main lines of comparative European research on school-to-work transitions, with particular attention to research on these issues funded by the European Commission under the Targeted Socio-Economic Research (TSER) Programme of DGXII.

This paper has 8 sections:

1) The wider economic and policy context within which research on education to work transitions takes place.

2) A set of categories is proposed to define between country difference in national institutional arrangements.

3) The nature and extent of change in economic or labour market demands for different kinds and levels of education/training or skills/knowledge; as well as the extent these might vary across different labour market systems.

4) Changes in education/training outputs and the relationships and linkages between the ET system and changing labour markets and employers/firm behaviour; as well as the extent to which these also might vary across different national ET institutional systems.

5) Comparative analyses of the nature, extent and severity of educational and labour market failure/exclusion and the associated social exclusionary processes; as well as the relative effects of national institutional systems on such processes and relative effectiveness of interventions.

6) Research on the effectiveness of education/training programmes and of labour market intervention programmes.

7) Gender and class inequalities.

1.1 The policy contexts of education to work transitions

Increasing globalisation and competitive pressures combined with rapid technological change have, according to conventional economic wisdom, made education and training – human capital growth – of increasing if not paramount importance in securing modern economic growth.

State policy responses to the growing unemployment crises of the 1980s and early 1990s gradually changed over time to a recognition that the problem was not only cyclical and, therefore, could be adequately handled by temporary employment/training measures, but was also structural: with rapid technological change and increasing competitive pressures bringing about long term secular declines in certain industries and unskilled and semiskilled occupations. This realisation shifted policy emphases to supply side meas-

---

1 Research on youth unemployment has largely used the fact that minimum wage has been lowered in the Netherlands without any clear evidence of success in terms of unemployment. The idea of the labour being too expensive for young people does not seem to work from the Dutch experience.

2 See comprehensive review by Lundvall and Borrás (1997).
ures in education and training and to active labour market programmes. The main concerns were not only that the ET system was not changing fast enough to keep pace with rapid economic and technological change, but that changes in the organisation of production itself would also be necessary to guarantee continuing competitiveness. (Janoski, 1996; OECD, 1995; EU, 1994; O'Connell and McGinnity, 1997).

The European Commission's White Paper (1993) on Growth, Competitiveness and Employment, following on the Copenhagen summit, proposed a number of policies to tackle the EU economy's slowdown, with increasing unemployment and declining competitiveness. This White Paper was more innovative than preceding EU documents. Three chapters appear most relevant: Chapter 7 deals with education and training system, chapter 8 on the link between job creation and economic growth, and chapter 9 on labour costs (see also Meulders, 1998).

With an increasingly more knowledge-based economy, an accelerating pace of technological change—and consequent changes in jobs, firms and ET requirements—the necessity for substantial change in ET policy was proposed. This was proposed as necessary both to increase the level of knowledge/skills of the youth labour force, but also to change radically the nature of the ‘once-and-for-all’ full-time ET provider systems, toward a more open and more flexible one.

This was seen as necessary both to increase the chances of returning to post-school education/training and to orient systems of ET provision more toward life long learning and continuing re-education/re-training (p. 16). In addition the White Paper emphasised the necessity to substantially reduce the level of educational failure/underachievement amongst school leavers in most European countries and to improve transitions to work. In pointing to the very negative unemployment and other economic and social marginalisation effects of educational failure, and the subsequent difficulty in re-integrating such poorly educated youth back into the society, the White Paper prioritised the need for effective educational interventions (p. 124). Besides these obvious negative effects of educational failure and the necessity to effectively tackle its causes, the overall rapid pace of economic/technological change required much more forward planning than previously; hence the priority placed on research and new knowledge on occupational/work changes and attendant ET requirements. The increasing dynamic relationships between the ET system and the employment system in modern economies also required much greater levels of co-operation between them. But also much greater responsiveness and flexibility in instructional/learning and qualification systems to the changing economic/employment needs; as well as to the individuals needs for re-education and re-training over the life-course.

The White Paper also suggested the necessity for improvements in the fit between the tax and social protection system and employment in order to encourage job creation: suggesting, for instance, a decrease by 2% in social insurance contributions, and targeting it on youth and low skilled employment. It also suggested policies to reduce the disincentive effects of unemployment benefit on job search—though a clear disincentive effect of unemployment benefit has never been proved.

In addition to increasing the sensitivity of tax/insurance systems to LM needs, increased LM flexibility and less regulation is suggested to help creation of part-time and temporary contracts etc. as well as workers' temporary withdrawal on a voluntary basis from the LM (e.g. for sabbaticals, training etc.). In addition improvements in active labour market policies and in employment/job placement processes/agencies are suggested.

In addition to lowering tax/insurance contributions, a slowdown in wage increases was suggested, with wages not allowed to increase more than the increase in productivity. The level of wages appeared to be perceived to be one of the main reasons of low job creation, with minimum wage regulation/legislation also perceived as constraining employment growth. Again, none of these policy recommendations have any solid basis in the research/econometric literature. On the contrary, in the
meantime, recent OECD publications (Employment Outlook, 1998) have been more than cautious about the minimum wage as a general brake on jobs creation.

Following along the lines of the White Paper suggestions, the Essen Summit (1994) adopted five priorities in December 1994:

a) Improving the employability of the labour force through the promotion of investments in vocational training. Young people to be especially targeted.

b) Increasing job creation associated with economic growth through a greater flexibility of the labour force, by increasing wages by less than productivity growth and by encouraging regional and local initiatives, especially in the fields of new jobs (environment, social services etc.).

c) Reducing the labour cost, especially for unskilled jobs.

d) Improving the efficiency of public employment policies by switching from passive to active policies.

e) Improving the targeting of intervention programmes for those most affected by unemployment: young people, long term unemployed, unemployed female and older unemployed people.

The White Paper of the European Commission (1994) on Education and Training: Toward the Learning Society, proposed four main policy priorities. Firstly it indicated the necessity to have a balanced set of ET policies which both emphasised the necessity for increasing levels of general education combined with an increasing mix of employment linked vocational training in ways that minimise the dominating status/ethos of the former. In addition the White Paper (1994) recommended the creation of new and bridging curricular/course and assessment/certification arrangements between the two, normally divorced, education and training provider systems. The creation of new and more effectively integrated pathways between the different education and training systems, and the creation of a more open and flexible life long learning system is one of the main policy aims of the paper. Thirdly the necessity to anticipate and to adequately provide for new knowledge/skill needs was emphasised, as technological change accelerates and the necessity for constant upgrading of the workforce requires substantial changes in both the state and EU policy and ET provider systems. Fourthly the necessity for state and EU policy making, and budget allocation, as well as private sector employers, to more adequately recognise the necessity to treat human capital investment with the same priority as physical capital investment was emphasised. Finally the White Paper emphasised the necessity for states and the EU to prioritise interventions to radically reduce the level of educational failure and the resultant high levels of unemployment and social exclusion characteristic of most EU states.

After the Essen summit the next step was the Amsterdam summit in June 1997. A new chapter on employment appeared in the New Treaty for Europe; unemployment becoming one of the main policy priorities for the EU. Following the Amsterdam Treaty, the first European Summit for Employment was held in Luxembourg in November 1997. At this occasion, 4 guidelines were adopted:

a) Improving employability. This guideline follows previous White Papers' ideas on training and active LM policies.

b) Encouraging entrepreneurial activity: by simplifying regulations, improving access to funding, tax reductions etc., and by developing local initiatives.

c) Improving the adjustment capability of employers and employees: by modernising work organisations through increased flexibility, reduction of the number of hours worked; reducing over-time and increasing part time work; facilitating temporary withdrawal from the labour force and encouragement of retraining and life long learning etc.

d) Strengthening gender equality in the labour force; and improving the linkages between family life and working activity.
The Targeted Socio-Economic Research Programme (1994-1998) proposed by DGXII invited proposals for research from the European research community on three main areas of economic and social research: in science and technology policy, ET and LM integration, and social integration and social exclusion. The increasingly severe economic and social problems facing European societies required a more co-ordinated and better funded and targeted research and policy response than hitherto. Increasing global competitive pressures, the necessity for continuing productivity growth, the consequent need to expand and improve the effectiveness of European ET systems and the necessity for ET systems and enterprises to adapt readily and effectively to rapid technological and economic change to ensure sustainable long term growth, all indicate the necessity for co-ordinated, effective comparative research for national and European policy making.

EU economic growth increasingly depends on scientific/technological development, education/training systems which encapsulate this into human capital growth, and the development of a market and institutional framework which effectively integrates both into modern productive economies and welfare enhancing civil societies. To do this research needs to be of high scientific quality, comparative, have significant added value and help develop comparative data bases and effective and comparative conceptual/theoretical models and methodologies (TSER programme).

Besides the economic growth imperative high levels of persistent unemployment and associated economic and social exclusionary pressures in most EU countries also emphasise the necessity for high quality comparative economic and social research on national similarities and differences in the effectiveness of economic and social policies in tackling such exclusionary processes (TSER, 1996). The threats to equality of opportunity and to economic and social cohesion not only place European civil society under increasing pressures, but directly breach some of the central values and goals of European integration.

The main objective of the TSER (1994-1998) research programme was to build up both the knowledge base and research infrastructure for high quality, policy relevant, comparative European socio-economic research at both national and Community level. In Area II, education and training, the objective is to help link advances in science and technology and rapid economic/technological change to the effectiveness of the linkage/relationship between ET systems – in building up human capital stock – and labour market entry and in-firm insertion/training processes in attracting and using high quality labour. Within this broad area of research the Programme had three main objectives – to strengthen the European research base and improve communication and networking amongst European researchers, to develop and strengthen the knowledge base and to improve its quality and comparability, and help apply it to the challenges facing European economies and societies.

There are three main objectives of TSER Area II (Research in Education and Training):

1) the nature and extent of skill change and of labour demand in the economy and the effectiveness and nature of the responsiveness of ET systems to these changes;

2) The development of ET effectiveness/evaluation models and methodologies – both in terms of conventional schooling/training as well as in life long learning/instructional arrangements;

3) Transitions from school to work, and the nature and extent to which ET systems and their relationships to employment systems positively or negatively affect inclusionary or exclusionary processes.

Even before EU and OECD prompting, most European states had instituted substantial changes in educational and training arrangements and in the level and length of participation in initial full-time education and training. So substantial expansion in educational participation at upper second level and third level had occurred in all EU countries, though significant national differences still exist in
the nature, pace and extent of change in all these respects. In many countries the rapid increase in the level of education of the youth labour force has outdistanced the changes in occupational demand as previously defined – with significant ‘educational upgrading’ of many low and medium skilled occupations (Robinson 1997; and work of Ciretoq network); with most of the upward shift in the educational level of the work force occurring within existing occupations rather than in the expansion of new or more technologically advanced ones. Besides the concern about under-qualification, therefore, some concern has also been expressed about the extent of ‘overqualification’ amongst the young work force, and under-utilisation by firms of this newly up-skilled and better educated young labour (Krahn, 1997; Ashton and Green, 1996; 1997). The extent to which and the effectiveness with which employers use the substantial recent improvement in human capital in their recruitment, training, work allocation and promotion policies, and in their general human resource management and innovation processes, deserves equal attention in policy and research agendas as do ET policies and practices.

To conclude then, the TSER research programme (Area II) has substantial complementarity with the policy priorities of the various EU White Papers on education/training and labour market integration policy. Despite the evident weakness of research/policy institutional linkages at EU level – compared to its national or OECD equivalents – at least the content of economic and social research promoted by TSER (DGXII) appears relatively closely linked to EU policy priorities.

1.2 Demographic and economic context

The demographic and economic context within which change is occurring is now described according to the main usual sources such as Eurostat and OECD, as well as a number of TSER funded projects.

The economic and socio-demographic contexts within which school-to-work transitions occur within Europe have changed significantly over time, and these changes also vary significantly from country to country. Four aspects of these appear most relevant:

1) relative youth/adult demographic and unemployment rates and characteristics;

2) significant increases over time in the median ages of entry to the labour market, as young people stay longer in full-time education and search longer for a permanent acceptable job, but also increasing variances in the age of entering the labour market;

4) Finally there is a significant growth in the extent to which ‘mixed statuses’ (e.g. work and education) occur, particularly amongst those completing upper second level education/training as well as those going on to third level education.

Not only is the demographic and economic context within which transitions are being negotiated rapidly changing over time and highly variable across countries, but the shape and nature of that transition itself is also radically altering. It is significantly lengthening, and the socio-cultural and institutional context within which that lengthening socialisation occurs is also rapidly changing. Transition is no longer easily conceptualised as a ‘rite of passage’, or relatively unproblematic status change from dependent youth to independent adult statuses. It is now one in which the ‘youth stage’ is continuously being extended, mostly outside familial control; and in which educational and work roles are increasingly intermixed and negotiated or constructed over a much longer time period in the more family-independent contexts of educational institutions, stronger peer groups and part-time work roles. This ‘youth/adult’ stage of intensive socialisation, now less culturally reproduced than in previous generations, occurs in a much less predictable and controlled environment than previously. Besides these more general socialisation trends in transition, there are however very significant differences in the demographic and economic contexts within which such youth/
adult transitions occur in most European countries.

There is very wide national variation in the proportion of 15-29 year olds in the total population, as well as the relative size of youth inflows into the labour force across the European Union. This age group comprises only 22-23 percent of the population in Germany and Finland, but over 32 percent in Ireland (Freysson, 1996). So the relative size of the youth inflow into the labour force has different economic and policy implications in different countries; particularly so if one also includes in the equation the extent to which the older outflow on retirement comes from economic sectors – like agriculture – which are not being reproduced (as in Portugal, Spain, Greece and Ireland, for instance).

Allied to the demographic variable is the relative difficulty of access to the workforce faced by young people, or the relative ease of job loss, compared to older people. This also varies substantially across the Community: with the relative youth/age unemployment risk for Ireland for instance being twice that of Germany or Austria (Freysson, 1996). It is hypothesised that the extended apprenticeship arrangements of the former countries provide a more highly institutionalised, segmented, ‘protected’ and secure labour market access route for young job seekers (Müller and Shavit, 1998).

Finally the rate of return – in employment terms – to increasing educational levels also varies substantially across countries for youth entry cohorts: from around a 4/1 unemployment ratio between those with third level qualifications and those with less than upper secondary level in Ireland, to 3/1 for Germany and Denmark and less than 2/1 for the Mediterranean countries (OECD, 1997; Freysson, 1996; Eurostat, 1997). These differential employment returns to increasing levels of education are not highly correlated with national rates of completion of upper second level education (i.e. with their relative scarcity) as one might expect, with these rates being maximised in Germany, the Benelux, Scandinavian countries or France, and lowest in Portugal and intermediate in the UK or Spain. In the former countries, however, such qualification rates had already been very high by the mid 1980s, while quite dramatic changes have occurred in the level of education of youth cohorts in Portugal, France, Ireland and the Mediterranean countries. These rapid changes imply substantial young/old employee replacement issues within firms and between old and young industries etc. in these latter countries, with the consequent implications for human resource development and management within firms.

2. National institutional differences

There are substantial differences amongst countries in how they responded to this unemployment crisis and to secular economic change – not unexpectedly given the substantial economic and institutional differences amongst European countries, not only in their ET systems but more importantly in the interconnections or linkages between the latter and the main economic agents. In addition not all EU and OECD countries have moved in the same direction or at the same speed toward to a high skill and high value added production system (Ashton and Green, 1997; Steedman, 1997; Steedman and Wagner, 1987, 1989).

There are least three respects in which national differences in education/training systems in Europe make it unlikely that the same policy priorities can be implemented in the same way in all countries:

a) Their degree of institutional differentiation – at both lower and upper second level, with very clear ‘tracking’ from ages 11/12 onwards in Germany and the Netherlands for instance, and comprehensive systems at least up to age 15/16 in France, Britain and Ireland;

b) The extent of institutional linkage between the ET system and the employment system. This may be highly linked/coupled as in the German dual system – with a substantial degree of ET provision being jointly provided in the apprenticeship system. At the other extreme, the ET and LM
systems may be completely 'de-coupled'; with an institutionally separate educational system providing educational outputs or qualifications which are then 'marketed' in a separate labour market.

At one extreme the German dual system – provides a model of a highly differentiated ET system from the beginning of second level education, which at the same time provides the strongest connection/linkage between employers and education/training providers in the apprenticeship system. At the other extreme are the comprehensive and relatively undifferentiated ET systems of some of the Scandinavian countries, or more weakly (at upper second level education) as in Britain, Ireland and France. Here there is a much weaker linkage with the labour market.

c) Finally, compared to the American/Canadian ET systems most European systems are highly centralised and standardised (in curricular/pedagogical and examination/certification terms). In these respects the significance of examinations/qualifications, and of examination grades, are likely to be far greater in European countries than in the unstandardised American second level system (Rosenbaum and Kariya, 1991; Kerchoff, 1990, 1995; Breen, Hannan and O'Leary, 1995). Some significant differences amongst European countries, however, exist in both the nature and degree of differentiation of examination/certification, and in their significance in the labour market: the extent of differentiation in examination grades, for instance, being highly variable, as well as their use/significance in selection for further education/training and entry to the labour market (Breen, Hannan et al., 1995). Recent work also shows that such standardised and certified examination grades are important to employers even amongst lower level school leavers (Hannan et al., Leonardo, (VTLMT), Final Report, Dec. 1998; Smyth, 1998; Becker and Rutjes, 1998).

Given these wide institutional differences amongst EU countries in their ET systems and in the nature and degree of interconnection between the ET systems and their LMs, we do not assume in this paper that one system is necessarily more effective than another in terms of either generating high levels of human capital or of inserting it into the labour market: i.e. that functionally equivalent mechanisms of both generating and integrating human capital into the economy are likely to occur across the different EU countries. What seems to be crucial in building up and maintaining a high skills, high value added production system, is the construction of strong systemic relationships between the education/training provider system and the main economic actors (individual or corporate) – but that there are many different institutionalised ways in which this can occur. This may be done by the highly regulated German dual system model, or by the semi-corporatist and formalised Dutch model of high ‘occupationalisation’ of the labour market dependent on a supply of specifically educated/trained labour from the full time educational institutions; or the almost equally corporatist but more informal linkages of the Japanese models (see Hannan, Raffe, Smyth, OECD, 1996; OECD, Employment Outlook, 1997). And, given the success of the American model – with an almost completely de-coupled ET system with minimal standardisation at primary and second level, obviously there is something they are doing right – though most analyses would suggest that this occurs mainly at third level. Successful European type models appear to be characterised by a much higher level of integration/co-ordination between the state, education/training providers and employers – particularly for countries that are ‘late starters’ or those rapidly adjusting to modern economic competitiveness. Significant government planning, regulation, investment in and co-ordination of education/training, combined with corporate agreements with employers, education/training providers and trade unions etc. appears to characterise many of the most successful European economies, particularly as economies move into high value added production. (Ashton and Green, 1996). Recent research throws a lot of cold water on the older orthodox neo-liberal economic theories of economic development, showing no clear relationship between neo liberal or modern (European
Education and labour market change

Type) corporatist models of state/economy relationships and economic or employment growth. (OECD, Employment Outlook, 1997): that both are equally likely to be effective, though in substantively different national cultural, institutional and historical contexts.

If we assume the continuing significance of national institutional differences in ET and LM systems, which most current studies support (Shavit and Müller, 1998) - though with some growing similarities as mass educational participation extends to third level and increasing global competition forces adaptation - then the 'dual system' and Dutch education/training (ideal type) models will remain quite different from those countries with more 'general education' type ET and LM models: where most specific occupationally relevant training takes place within firms. If this remains the case then the greater degree of both 'level congruence' and 'content congruence' (Almendinger, 1989) between ET outputs and labour market integration outcomes, will continue to remain much stronger in the former countries. (Shavit and Müller, 1998). However, it is important to get clearer conceptualisation and measurement of these educational/working relationships. It is clear, for instance, that there are analogues or 'functional alternatives' to the greater 'content congruence' of 'dual system' countries existing in the more general educational/training systems; but these may not be measured by conventional variables. For instance, it is clear that those students who do choose to take a greater concentration of vocational/technical subjects at second level do appear to increase their probability of escaping low skilled and insecure employment, controlling for other educational achievement differences. (Müller and Shavit, 1998; Hannan et al., VTLMT, Leonardo final report, Dec. 1998). However, it is also appears clear that greater labour market competition occurs between school/college leavers for the same occupational niches in the more general educational countries, particularly at the beginning of the occupational career and particularly for low skilled jobs (Borghans, Hughes and Smits, 1998; Hannan, Raffe and Smyth, 1996; Hannan and McCabe, 1998).

As will become clear in the next section, if most secular change in the technical characteristics of work - and therefore in its educational/training requirements - occurs within occupations, and by and large within firms rather than between firms, then it appears reasonable to conclude that the more closely linked the ET and employer systems are the more adaptable the overall system. However, the opposite conclusion has also been proposed: that the more general educational systems - providing higher levels of initial general education - give a better base to further in-firm training and retraining; though most existing cross-national data (OECD, Education at a Glance, 1997,1998) generally indicate higher levels of in-firm training in dual system countries. This is an area however, where good quality cross-nationally comparable data are very poor, and research rather limited.

3. Changes in labour market, skill demands and relationship to education/training outputs

To what extent does economic and social research lend support to the hypothesis of rapid technological, economic and occupational change underlying the substantial increase in the skill education/training requirements of the European work-force?

Research work carried out by LIRHE (University of Toulouse) and funded by Cedefop, and other work funded by Cedefop 34 shows clearly that the rapid growth in the supply of workers with higher educational levels across most EU countries has not been equalled by an equally rapid growth in those occupations which 'require' - or had previously required - such high levels of education/training (Bédouwé and Espinasse, 1997; Monacorda

3 Bédouwé et al.

4 This study was funded by Cedefop and directed by L. Mallet, Univ. of Toulouse. A brief summary is given in Bédouwé and Espinasse, 1996. See also work by Ciretoq network also partly funded by Cedefop - e.g. Borghans et al., 1998.
Considered over the decade from the early 1980s onwards, upward shifts in educational qualifications had been general throughout Europe, but most educational change over the period had in fact occurred within 'old' occupations rather than in new occupations, or growth in occupations that had previously required a high level of education. So, if we measure technological change as reflected in equivalent change in occupations with higher technological/training requirements, most of the educational change had not been due to technological/occupational changes in demand, but to changes in the relative supply of more highly educated labour.

This research, therefore, gives no support to the demand driven 'technological change' hypothesis: one that appears to underlie most of the EU and national policy documents. The alternative, 'credentialist' hypothesis – of an over-supply of highly educated labour being absorbed in occupations for which they are not in reality required, on the other hand – receives some support in these studies: provided one assumes that the task complexity, 'difficulty' and degree of responsibility of work tasks within similarly named occupations remains the same over time – say a 10 to 20 year period.

Most educational/training growth, in fact, appears driven mainly by other considerations, however: underlying, economic, political, institutional and socio-cultural factors such as higher youth unemployment and rapid expansion in upper second and third level educational provision partly driven by the necessity of keeping young people out of the labour market for as long as possible; some undoubted upward shifts in skill demands as well as high individual rates of return to increasing levels of education, and the obvious strong relationship between low levels of education and high unemployment/exclusion rates. In addition in many countries rapidly increasing levels of parental education also increase demand – the result of rapid expansion in second level education in the 1960s and 1970s in most OECD countries. So, at a minimum there is no evidence in these studies that skill shortages or skill deficits in general has significantly constrained higher/skilled occupational expansion (though this may well be the case in particular occupational/industrial sectors); and that such skill shortages have been significant in educational expansion. Indeed the opposite proposition is given significant support – that an increasing supply of highly educated labour has substantially outstripped conventional occupational demand (Ciretoq network research; Bédewé et al., 1998; Robinson and Manacorda, 1997; Steedman et al., TSER research 'Newskills'; Sofer et al., TSER research 'STT').

However, these studies do not show any decline in the individual earnings rate of return to more highly educated labour – as one might expect if the increase in higher qualifications were diffused evenly throughout the occupational distribution. Indeed there is significant evidence that educational inequalities in earnings returns have in fact increased in some countries over time (Robinson, 1997). Analyses of occupational/industrial differences in rates of return in earnings indicate that in the modern expanding corporate managerial and professional-technical occupations sectors, the rates of return to higher levels of education have in fact increased. In those intermediate (status) occupational niches, however, particularly in the services sector, where there has also been a substantial upgrading in the level of education/training of the workforce, there is some evidence of a relative decline in earnings returns to higher level qualifications. Some evidence, therefore, exists that it may well be the increasing supply of more highly educated la-
bour that has facilitated such recruitment — particularly in occupations in the services sector where not previously required — and where such a recruitment choice would significantly decrease training costs for employers (Robinson, 1997; OECD, 1996, 1997 and 1998). No evidence here, therefore, in wage rates at least, of increasing productivity and technological sophistication within these intermediate service occupations, but more of a rational response by employers to an oversupply of more qualified labour where the relative price of such labour has decreased. Of course, as will be discussed later, the time that young ‘over-qualified’ people spend in such jobs may be restricted to a short period at the beginning of work life.

In a number of longitudinal/panel research studies on labour market transitions of school/college leavers over a 3-5 year; a majority of the more highly educated who initially took up lower status occupations, for which they were clearly ‘over-qualified’, subsequently became upwardly mobile out of them; with the rate of ‘overqualification’ declining rapidly with time in the work force. (See Hannan et al., 1998). Not only have employers upgraded their recruitment ‘requirements’ for intermediate and lower status occupations, but many of them — particularly in the ‘secondary sector’ — have transformed these occupations into temporary and part-time jobs, recruiting more highly educated school/college leavers on a temporary basis and ‘churning’ these jobs over for succeeding cohorts of school/college leavers as well as substituting older and more highly educated women workers returning to the labour force on a part-time basis (Green, Ashton et al., 1997; Hannan et al., 1998). Not only have employers upgraded their recruitment ‘requirements’ for intermediate and lower status occupations, but many of them — particularly in the ‘secondary sector’ — have transformed these occupations into temporary and part-time jobs, recruiting more highly educated school/college leavers on a temporary basis and ‘churning’ these jobs over for succeeding cohorts of school/college leavers — as well as substituting older and more highly educated women workers returning to the labour force on a part-time basis (Green, Ashton et al., 1997; Hannan et al., 1998). In periods of high youth unemployment, particularly in open economies — as in the English speaking countries, employers disproportionately pick young employees ‘off the top’ of labour queues. So, with increasing competition for non-skilled jobs from the more highly qualified, the less qualified tend to be disproportionately excluded from the work force in times of high youth unemployment. This process however does not appear to occur to the same extent in Mediterranean countries — where unemployment rates for recent graduates appear particularly high (OECD, EAG, 1996 to 1998; Schizzerotto and Cobalti, 1998).

There is some evidence for Britain and France that the ‘closeness of fit’ between level of education and occupational status of first job has declined over time (Heath and Cheung, 1998; Goux and Maurin, 1998). This however does not appear to be the case for Germany, Müller, Steinmann and Ell, 1998). In addition there is clear evidence that the correlation between educational level and occupational status varies significantly across countries — particularly for first jobs: apparently greater in the more educationally differentiated and more ‘occupationalised’ labour markets (Shavit, Müller, 1998).

Of course occupational categories, especially highly aggregated one, include a wide range of work and firm situations. As a result many workers who may appear (statistically) to be ‘over-educated’ for their jobs/occupations may in fact be jobs that do demand their level of education/training. However, most studies on the earnings of people in jobs in which there are ‘over-qualified’ indicate a much lower rate of return to increased educational credentials than in ‘matched’ jobs. See review by Groot et al, 1998 in the STT, TSER project; Cohn and Khan, 1995; van der Velden and van Smoorenburg, 1997).

These changes in employers’ recruitment behaviour and in patterns of access to employment are proposed to have a number of significant economic and social effects:

- Increasing levels of ‘qualification inflation’ and of competition for low status occupations from the more highly qualified have increased the labour market exclusionary pressures on the least qualified; particularly in the context of a decreasing supply of unskilled and semiskilled manual and service occupations. (These effects however appear to be nationally and institutionally sensitive).

- Lowering of rates of return to more highly qualified labour markets entrants to intermediate/low status occupations in non goods-producing sectors.
Potential lowering of upward – career and inter-firm – mobility chances amongst older and less poorly educated workers as the rate of increase of educational/training qualifications of the younger work-force disproportionately increases (Béduwé and Espinasse, 1997)

Many studies of occupational/educational change and increasing ‘overqualification’ levels assume, however, that the same occupational titles/categories retain their content/meaning over time. However, a number of sociological studies of perceived skill requirements for jobs, both within and across occupations/industries, indicate that these assumptions may be invalid. (Ashton, Green et al., 1997). These studies have shown significant growth over time in required skill levels within occupations, both for occupational entry and to carry out work tasks: i.e. in skills/qualifications to get jobs, skills/qualifications necessary to carry out the work, extent of training needed to effectively carry out work tasks etc. (Gallie, 1991; Ashton, Green et al., 1997). With minor exceptions this growth in skill requirements, qualifications and training – and a set of social and other cross-curricular skills such as problem solving, communication and interpersonal skills, etc. – appeared to occur in a wide range of occupations, at least in Britain. Partly as a consequence of such change in skill requirements within occupations there was no evidence of increased levels of experienced/perceived ‘overeducation’ in jobs from the mid 1980s to the late 1990s – despite the clear evidence that most qualification growth in that period took place within occupations rather than in new occupational niches or in niches previously requiring higher levels of education/qualifications (Ashton, Green et al., 1997). These increases in skill requirements were experienced across most occupations/industries, with the exception of some industries in the non-exposed sectors.

Some of the comparative European research on this issue shows substantial inter-country variations in the linkages between educational level (and type) and occupational level or status achieved. British and French studies, for instance, show a significant decline over time in the correlation between level of education and the occupational standing or status of first job (Heath and Cheung, 1998; Goux and Maurin, 1998). German studies on the other hand not only show a substantially higher correlation between the occupational status of first and educational level achieved, but also show no evidence of any decline in returns to third level education – though a clear decline in returns to the completion of upper second level (Abitur) appears to have occurred (Müller, Steinmann and Ell, 1998). The institutional structure of education/work relationships in the German dual system countries not only appears to lead to much higher levels of correlation between the level and type of education achieved and the status and type of first job entered, it also appears not only to have led to much lower youth/adult unemployment ratios than in other systems but also to much less change over time – or economic cycles – in the returns to higher levels of education. (Konietzka and Solga, 1995; Müller et al. 1998; Shavit and Müller, 1998).

A significant number of TSER research projects directly address these issues of the relationship between growth in the level of skills and educational levels of the European workforce and concomitant occupational change.

These and other recent studies of ‘over-qualifications’ and of competition between school/college leavers of different educational levels for the same occupational openings, repeat old themes from American research on the extent to which third level graduates take up ‘high school’ jobs. They also indicate however the necessity for fieldwork and research designs in studies of transitions to the labour market from third level education, for instance, to be based on samples of graduates from both third level and lower educational levels.

The partially completed work of the network of European researchers – from the UK, the Netherlands, Portugal, Sweden and France – working on the ‘New Skills’, TSER project (Steedman, 1997) includes analyses of:

a) the nature and extent of change in labour market demands in Europe,

b) the extent to which supply or provision of skills/competencies is changing to meet that demand.

c) Later work will explore the extent to which it is possible to specify a ‘minimum learning platform’ for EU countries.

Using LFS and IALS, individual level country data on occupations and wages etc., a series of 6 different across-country comparative research projects are carried out around three themes:

1) Changes in the demand for low skilled jobs (LFS), as well as other demand change in skill levels etc., particularly for new jobs/hirings;

2) Changes in the supply of more highly educated/trained labour, and particularly changes in post-compulsory educational participation; and

3) Earnings inequalities.

Three aspects of the findings are of particular importance:

i) There has been a significant decline in low skilled jobs over time, though this is not apparent in new hirings (in the UK).

ii) New hirings/jobs tend to have declined in relative terms over time – though this ratio is highly sensitive to the business cycle – and to be of lower skill and job complexity levels. Since these ‘new jobs’ are disproportionately concentrated amongst young school/college leaver entrants to the labour market there appears to have been a relative decline in the quality of such entry jobs over time – or at least from the early 1980s to the mid 1990s. New job tenures, for instance, appear to be fewer than the US, and appear to have decreased in relative terms since the mid 1980s.

iii) In relative terms wage rates for new hirings amongst younger workers have declined; with ‘wage drops’ more severe. So greater inequality in earnings have opened up over time; and in general a growth in poorer quality entry level jobs – more part-time and more temporary and a greater extent to which both of these are involuntary (Steedman, 1997).

Given these changes in the nature of demand, particularly for young entrants to the labour market, how has the supply of different educational levels been changing? Again the work of the ‘New Skills’ TSER project is revealing (Murray and Steedman, 1997). The analyses of the European Labour Force Surveys shows that all countries show substantial growth in educational participation rates at upper secondary level and higher, but that there are significant inter-country differences: the UK and Portugal have significantly lower upper secondary and higher education completion rates in the 26-28 year old age group. In Germany, France and the Netherlands on the other hand both state policy and institutional provision has been geared to maximise at least upper second level education and training provision/participation.

But even within these three countries very different policies and institutional arrangements underlie these provisions. Apprenticeships and other occupationally specific vocational education/training, shared instruction/training provision between employers and ET providers characterises the German dual system countries. An almost equally high degree of institutionalised agreement exists between both of these partners on both the content and quality of ET provision for a wide range of occupations in the Netherlands; though most education/training is provided in the full-time ET system. In both cases also a high degree of educational differentiation occurs at a very early stage in schooling – where students are allocated to different curricular tracks. Such occupationally specific education or vocational training assumes a high degree of concomitant ‘occupationalisation’ in the work place: of agreement amongst employers within industries of the division of labour and the broad content of different occupations etc. – as well,
of course, as the minimisation of ‘free riders’ in sharing training costs for the agreed set of occupations. In these training/employment contexts occupationally relevant ‘qualifications’, which are tradable across companies are the norm (Maurice, Sellier and Silvestre, 1986). France and Britain on the other hand show little if any educational differentiation at lower second level, and significantly less occupationally specific vocational training at upper second level – within the full time system. French policy and practice, however, is clearly geared to maximising upper second level, full-time education. Although with some vocationally relevant tracking at upper second level most vocationally relevant vocational training in France takes place within firms – with qualifications less tradable across firm boundaries. Britain, on the other hand, has geared a substantial proportion of post-compulsory educational and training policy toward both in-firm and other out-of-school provision for a substantial proportion of each youth cohort: though a much smaller proportion of this post-school and in-firm training appears to be tradable across company boundaries than in the German case. In all cases third level provision/participation has increased substantially over the past two decades.

Germany, the Netherlands and France have, therefore, clearly changed policy and ET provision and practice to a high skilled/educated young workforce, while other countries – like the UK and Portugal – have not to the same extent, with projections for 2020 showing these national differences continuing (Steedman, 1997; Steedman and Wagner 1987, 1989). Why do such national differences persist? Are they determined by governmental policy in terms of the provision/funding of places/institutions, or to what extent institutional or cultural – in choices made by families and pupils amongst the educational/occupational opportunities available? Obviously state policy, extent of resource provision, the extent and nature of alternative opportunities, but also the way parents and children react to or use the opportunities available, all affect outcomes. Such familial/pupil choices may be quite constrained as to whether one can freely go on to a comprehensively provided full-time education/

4. Conceptualising and measuring skills, ‘skills gaps’, changing skills requirements; and corresponding educational/training qualification levels

A large number of recent research studies, including ones financed by the TSER programme, deal with the conceptualisation, measurement and certification of knowledge/skill levels and types; and the way in which these are inserted into the labour market. Conventional schooling/training qualification/certification frameworks – mostly based on achievements in specific curricula/course assessments, have expanded to cover more general and more cross-curricular skills, less based on formal instructional/assessment processes. In addition the processes by which the skills/qualifications of those leaving full-time education/training and entering the labour market are matched up with subsequent jobs/occupations need to be studied in detail: from the purely ‘open market matching’ proc-
Education and labour market change

oss characteristic of most entrants to the labour market in most of the English speaking countries, to the quite closely linked or 'matched' education/training and job entry processes characteristic of the German dual system countries (CATEWE project proposal, TSER, 1997). In the former case job offers and employers (buyers) decisions amongst those looking/searching for jobs (sellers) is a relatively autonomous decision making process in which the task complexity, responsibility and 'difficulty' of the job is matched with the 'required' knowledge/skills and competencies of job seekers through a generally unequal bargaining process – particularly in periods of high unemployment. With the exception of a minority of apprenticeship positions and of professionalised occupations or those with high levels of technical skill, this 'at arms length' and open market model would generally hold for the majority of such initial 'job search' transactions in English speaking countries and to a lesser extent in France. Here the education/training systems are largely institutionally de-coupled from the employment/production system. This is quite different to the German dual system, or the high degree of institutionalised employer/pro-vider agreements in the Netherlands which underlie the provision of specific educational/vocational training for a large proportion of occupational entry positions.

The main starting point in sociology to this kind of research was the seminal work by Maurice, Sellier and Silvestre (1986) which, in comparing the French and German education/training and labour market systems, distinguished the high 'qualification space' relevance of education/training qualifications in the German system – a high degree of occupationally specific education/training linked with an equivalent 'occupationalisation' of its labour market (an 'Occupational Labour Market'); and the low degree of such cross-firm occupational specification of work in the French system, combined with a high degree of in-firm training and a more substantial in-firm career structure – 'organisational space' within internal labour markets.

A substantial amount of research work within this tradition has been carried out on the extent and nature of 'matching' between both the level and content of education/training received in full-time education and the subsequent extent it was 'matched' to the job/occupation entered. The sociological research refers both to the extent to which the 'level' of education and the level/status/difficulty' of occupation entered was correlated – the extent and nature of 'level congruence' between education/training and jobs/occupations, as well as the extent and nature of 'content congruence' between the content of education/training received and jobs subsequently taken up (Almendinger, 1989 and 1997; Schupp et al., 1994; Konietzka and Solga, 1995; Müller and Shavit, 1998; Hannan et al., 1998). The main cross-nationally applicable hypotheses guiding the research is the significance of linked ET and LM institutional arrangements: i.e. in maximising both types of 'matching' in the German 'dual system' countries and the Netherlands (Müller and Shavit, 1998; Müller, Steinmann and Ell, 1998); and the relative dominance of 'level of education' in job entry and occupational selection in the more 'open labour market' economies with minimal 'occupational labour markets' (Hannan, Raffe and Smyth, 1996; CATEWE TSER proposal, 1997, and 6 monthly report, June, 1998). The significance of these national institutional distinctions is clearly evident, particularly in the German/British and German/American comparisons – with the correlation between both level and type of education and occupational status and type being much greater in the German case – particularly for first jobs. (Müller, Steinmann and Ell, 1998; Heath and Cheung, 1998).

These national institutional differences in ET systems and their linkages to the labour market obviously have other effects which have also been studied in some detail though the quality of cross-national data sets to adequately test the relevant hypotheses is rather limited. There are important policy areas where this research is very relevant:

- That both 'content' and 'level congruence' rates are greater in those countries with more differentiated/selective ET systems than in those with more vertically integrated systems (Almendinger, 1989 and 1997; Müller and Shavit, 1998). The matching of ET qualifi-
ations with occupations is more efficient when institutionally mediated.

- That social class and gender inequalities in upper levels of educational achievement and in the quality of labour market opportunities are greater in more selective and differentiated systems. Early selection into different educational tracks, with their associated occupational outcomes, increases the overall degree of class and gender selection into upper levels of educational achievement. (Blossfeld and Shavit, 1993).

- However, this does not necessarily hold for educational and employment/social exclusion. Here the main hypothesis is that economic and social exclusionary processes — for those with lowest or no qualifications — are more severe in national systems were the educational systems are more general/comprehensive and labour markets are less occupationalised (Hannan et al., 1995; CATEWE proposal, 1997, and 6 monthly June report, 1998).

This is hypothesised to occur for two reasons. Firstly in differentiated ET systems with strong vocational/technical options, early selection into such differentiated curricular tracks, although increasing the probability of working class children taking such options and consequently increasing class inequality at upper levels of educational achievement, does significantly increase the vocational qualifications and employment chances of such working class youth. In addition such vocationally relevant qualifications increase the chances of access to skilled occupations and secure job opportunities — significantly decreasing the probability of channelling into low skilled and insecure job sectors. (Arum and Shavit, 1995; Blossfeld, 1994; Shavit and Müller, 1998).

Within general ET systems on the other hand, with low occupationally specific vocational training and minimal occupational labour markets, competition between job seekers with different levels of education for low skilled jobs is maximised — particularly at times of high youth unemployment. In the former countries the pronounced institutionalised connections between ET qualifications and occupational entry requirements significantly reduces competition from the more highly qualified for such low skilled jobs. The correlation, for instance, between level of education and occupational status of first job is much higher in Germany than in Britain or France. (Müller et al., 1998; Heath and Cheung, 1998). Although overall class and gender inequalities in educational/occupational achievement tend to be greater in the German system, the greater institutional strength of ET/Occupational equivalencies there tends to protect low skilled market entrants from competition from the more highly educated to a greater extent (Blossfeld, 1994; Arum and Shavit, 1995; Shavit and Müller, 1998).

Besides the issue of ‘matching’ educational outputs with labour market inputs the explicit study of skills and skills needs has been the subject of a lot of research (Green, Ashton et al., 1997). Two of the recently TSER funded research projects deal explicitly with this issue: ‘COMPETE’, Competence Evaluation and Training for Europe: Assessing ‘Skills Gaps’ led by the Tavistock Institute, London; and NATCCC-PS, New Assessment Tools for Cross-Curricular Competencies, Federal Ministry for Education, Luxembourg, 1998.

8 Contract Number: ERB-SOE2-CT98-2038.

9 Contract Number: ERB-SOE2-CT98-2042.
but also the often equally important implicit skills which are learned informally and that cross curricular/course and occupational boundaries. The returns to apprenticeship in Germany for instance, even in occupations for which not matched, suggest high returns to such cross-curricular and non occupationally specific in-firm learning. The issues of how to measure, accredit and certify such skills require attention (European Commission, 1995). A rough categorisation of such general skills is proposed in the 'COMPETE', TSER project: basic or foundation skills, as well as learning models/orientations that lead to effective learning/re-learning; basic vocationally specific skills – such as basic literacy and numeracy; the effective use of modern information technology skills etc.; problem solving skills; complex social-technical skills – of how to work in the complex work environment – or skills in the application or operationalisation of knowledge in the workplace; plus a set of more general/implicit skills: – like social interaction and interpersonal relationship skills, personal resource management skills etc.

What are the likely effects of national/local ET institutional arrangements or national/local ‘learning patrimonies’ on both the effectiveness of learning of these skills and their integration into work life? These national instructional/learning systems reflect long historical processes which are sometimes very difficult to change. Besides the need for good comparative research and monitoring/evaluation of the outputs of the different EU educational and training systems\(^\text{10}\) there is a clear need for further comparative research work on more general ‘core skills’ and cross-curricular competencies – such as the TSER project carried out under the co-ordination of Reef (Luxembourg) (ERB-SOE2 – CT98-2042).

Even in states with relatively de-coupled ET systems there tends to be strong reciprocal relationships between the educational/training systems and certain industries and firms – of skills growth and science/technology partnerships – particularly in industries subject to more rapid technological change as in chemicals, pharmaceuticals and computers etc.; less in the non competitive services where most small firms are located. However, there are clear national institutional differences in these respects, with much stronger ET and LM linkages in the dual system countries; particularly at the intermediate skills level. Obviously the way in which firms/industries divide up work into jobs/occupations, and how they define, assess, develop and use the ‘skills’ of their workforces will vary enormously. Some of variation is national – in the sense that the degree of cross-firm ‘occupationalisation’ of work will be greater in countries like Germany or the Netherlands – where there is also a high degree of occupational vocationalisation of education and training (Shavit and Müller, 1998).

The British vs. German, and Irish vs. Dutch and Danish studies on manufacturing industry and firm specific skills (Birnie and Hitchens, 1994; Steedman and Wagner, 1987 and 1989; Daly, Hitchens and Wagner, 1984) clearly indicate a much higher degree of manual skill precision and of supervisory/management skills in ‘dual system’ countries where both prior education/training and in-firm training is both more focused and more prolonged. However these studies cover a limited range of industries and firms. It appears that technological change can be built into training and retraining more easily and more formally in the dual system countries. On the other hand the dependence on higher levels of more general education in France, Ireland and to a lesser extent in Britain may mean a more flexible and more effective re-learning system in these firms – though the comparative data on in-firm training show much lower levels in both Ireland and Britain (OECD, EAG, 1995 to 1998; O’Connell, OECD, 1997).

\(^{10}\) The European Network for educational research on Assessment, Effectiveness and Innovation (EU-AEI), in which all EU countries participate, has developed a framework on which all participants agree that the major areas in which monitoring of educational progress should be focussed. Initial statistics for most European countries are available on the Network’s Web site. The final report of the network identifies three areas for urgent attention: a European instrument bank for educational indicators, development of measures of ‘added value’ in educational achievement, development and improvement of valid and culture fair tests of student achievement.
5. Education to work transitions

5.1 Conceptual and methodological approaches

Transition may be best considered at the individual, school leaver level as a configuration or sequence – without any implication of necessary order – of status changes over time through which young people move from participation in initial full-time education to a subsequent point at which they have achieved a stable status/position in the labour market – or have withdrawn permanently from participating in it. These status changes are not necessarily progressive or irreversible. One can, for instance, leave school at an early age, enter the labour market, become unemployed and again re-enter full-time education 5 to 10 years later.

The concept has its origins in the anthropological literature on 'status passages', or rites of passage, with previously dependent young people incorporated as independent adults into the tribe/community, usually through a highly ritualised ceremony. The older ideas presumed that both 'childhood' and 'adulthood' were unproblematic statuses which, in the more modern/industrialised cultures of the time, had a short intervening 'adolescent' period of revolt/growth before young people were successfully incorporated into adult society. The problem is that all these relatively stable 'stages' of being human obviously no longer exist in most industrialised cultures. Economies, cultures/ideologies keeps changing, what it is to be 'adult' keeps changing. School to work transitions, access to stable employment, sexual activity, courtship, living together arrangements, marriage and new household formation are no longer ordered/structured in the same way – or in the same order. (See Buck et al., 1994). The relationship of sexual activity and procreation to stable and institutionalised marriage relationships, for instance, is no longer structured in the same way; or the meanings, feelings and norms associated with these status changes are no longer socially constructed in such a consensual way as appeared to have been traditionally the case. Educational, cultural/normative and economic change – and even more substantial change in the relationship between the sexes – have so dramatically shifted the 'rules of the game', or the underlying principles of order, that these transition sequences have both become more individualised, and more variable than previously.

If one starts off from a position of a young person still in full-time education and we study only school-to-work transitions, at any one time subsequent to school/college leaving a person may be in any one of 5 broad statuses: initial job search, employed or unemployed, in full-time education, or left the labour force and not in full-time education. If we continue the sequence until the person has achieved a full-time 'permanent' job, or appears to have achieved another stable status (such as unemployment or withdrawal from the labour force), there can obviously be quite a wide range of status sequences – each status of varying length and order.

Figure 1 below briefly illustrates the possibilities with 3 years observation after full time education.

Statistical methods to analyse such transition sequences have become very sophisticated – from the older adaptations of factor and cluster analyses methods (to initially cluster/aggregate the total set of sequences into a smaller manageable group of categories), to 'event history models', to the newer optimal matching analyses models (Halpin and Chan, 1998).

At an individual level such variation in status sequences tends to be highly structured by level and type of education and training, with the more highly educated generally having shorter and more direct transitions to secure and status congruent employment (OECD, Employment Outlook, 1997, 1998). Exceptions being in Spain and other Mediterranean countries – though with long term high returns to the successful completion of university education (Sofer et al., TSER, TSS project11; Breen

et al., 1998; Minguez, 1998). Access to employment after a (generally) short period of job search is the usual situation for the majority of school/College leavers – particularly for the better educated (though mainly in Northern European countries), and particularly in periods of low unemployment. Unstable employment interspersed with periods of unemployment and periods on government funded training/employment schemes is a normal situation for the unqualified. Return to education is least characteristic of the initially poorly qualified. Withdrawal from the labour force is most characteristic of poorly qualified females with poor labour market histories.

Accompanying, and highly interrelated with, these basically economic status changes are changes in other important statuses: movement out of home and migration, new household formation – including housing rental/ownership status as well as in household property and consumption patterns, changes in sexual behaviour and relationships and in the establishment of stable unions or marriages and subsequent procreation behaviour, etc. Only a minority of studies have researched these patterns of change in detail (See British ESRC studies, Buck et al 1994; Iedema et al., 1997). There are significant national differences in these transition sequences – with such household formation changes sensitive to third level educational policy (in terms of expansion and so encouraging young people to leave home at an early age, for instance), but also to state family support policy – with young women for instance less likely to leave the labour force for family formation reasons in countries where family and child support policies help women to combine work and family and child-rearing roles (Iedema et al., 1997; Trappe, 1995; Trappe and Rosenfeld, 1998).

Theoretical developments have not kept pace in either economics or sociology with such methodological advances – at least not in the empirical literature. Underlying most of economic analyses in the area have been ‘Human Capital’ theories (Becker, 1973), which in the case of transitions essentially applies utilitarian neo-classical theory to explaining the motivations of learners – as to what and how much education/training they purchase, and the way in which the supply/demand relationship in the market between job-seekers and employers works out. Such theories are at two levels, the first being individual based and the second one at a more macro-economic level. They are not necessarily opposing – with the general lack of job vacancies (labour demand side factors), for instance, usually put forward well before individual skills and competencies (supply side factors) are put forward as causes of low job growth and high youth unemployment.

Sociological theories tend to be at a lower level of abstraction, quite applied to the research task at hand, with little even middle range
theorising – except at a higher (and usually non-operationalisable) level of abstraction. Many of the hypotheses flowing from the older functionalist modernisation theories have been rejected by the evidence, while many of the newer ‘partial theories’ – such as the ‘increasing individualisation’ hypotheses are not unambiguously supported by the evidence. (Furlong et al., 1997, 1998; Shavit and Müller, 1998; Iedema et al., 1997).

In its attempt to be universally generalisable human capital theories essentially ignore national differences in education/training institutions and in labour market institutional arrangements. The sociological literature has almost the opposite set of fault lines, tending even at its most sophisticated to be too focused on understanding and explaining national institutional differences, without successfully tackling the essential cross-country similarities in social patterns of education/training and labour market integration and in subsequent career mobility patterns (See Erikson and Goldthorpe, 1992; Shavit and Müller (eds.), 1998).

The set of theories relying on individual approaches start from a strong differentiation between individual job seekers. This individual level heterogeneity is usually advanced as the main cause of varying levels of access to work in a full-employment economy, or to high levels of unemployment when economic crises occur. In the latter case, employers are facing an abundance of job seekers and they may hire whomever they wish according to observed/perceived productivity characteristics – using their standards/norms of jobs/qualifications matches. One may note three main consequences of this individual oriented point of view:

a) Because none of the solutions used in the various European labour market interventions have proved to be really effective in tackling unemployment, public policy has more often than not focused on the definition of high ‘at risk’ target groups. Applied economists and sociologists have thus shown great ingenuity and ability in developing tools to both identify and help test the effectiveness of interventions with these ‘at risk’ groups; using highly sophisticated statistical or econometric tools. Equally the improvement of research designs and data collection, with the greater availability of longitudinal data particularly, has characterised research activities.

b) The bias towards individual level research is somewhat misleading, however, in terms of overall public policy: giving the impression that, since research is mainly targeted at the individual level, the main cause of unemployment are individual characteristics – and that public interventions should, therefore, be individually oriented. Initial education, training, improved circulation of information on availability of jobs, improved job experience and job search skills etc., are all very relevant, of course, but the overall lack of jobs is given by macro-economic conditions, and developing/changing individuals abilities merely shift the burden of unemployment around. Even if all young people were provided with adequate training and up-to-date skills, this would take quite some time to shift overall labour demand from the current situation to a full-employment one: even if such positive macro level employment effects were to occur.

c) The main rational economic reason for state intervention in giving young people access to such effective training or work experience – besides the equity arguments and the minimisation of the negative social effects of long term unemployment – is that, when economic growth resumes, countries may well need all the labour force available, given the downward youth labour supply curves in most EU countries. In other words, any response to unemployment based on correcting for an individual levels of heterogeneity of skill/competency – particularly for those with very low competency – although only initially leading to a re-shuffle of employment/unemployment, the policy does allow such otherwise excluded young people to learn more, to be more educated/trained and qualified and to have more work experience. As a consequence it does allow such young people not only to increase employment chances for
them—though at a minimum this may merely shuffle the available jobs around—and reduce unemployment but also increases their employment chances when economic growth resumes.

Thinking in terms of individual difference, one may note that there is no uncontested evidence of a segmented youth/adult labour market. While there is evidence of a disproportionate concentration of young workers in low skilled service employment in most though not all EU countries (OECD, Employment Outlook, 1997,1998), it is also obvious that most of them appear to be upwardly mobile out of such employment in subsequent years—though a significant proportion of such low skilled service jobs appear to be continuously ‘churned’ amongst succeeding cohorts of young people: with the consequent employment exclusionary effects on the least qualified as they continue to fight for non-skilled jobs with succeeding cohorts of job entrants with higher levels of education (Hannan, Raffe et al., 1998).

Two related, recent theoretical orientations in sociology (Breen and Goldthorpe, 1997; Goldthorpe, 1998) have suggested some useful guiding theoretical orientations. Both distinguish between structure and agency. Structural variables index both the pre-established or ascribed order of distribution of resources/constraints of social background, schools attended and associated rule governed behaviours—or constraints on behaviour—that govern educational provision and its relationship to further education/training and labour market entry. In addition labour market opportunity structures tend to be structurally given, particularly for young people who do not migrate. There are substantial international differences in both the nature and structure of educational-training systems and their relationships to local, regional and national employment systems. The Anglo-German comparisons are particularly revealing in these respects (see Bynner and Roberts (eds.),1991; Shavit and Muller,1998; CATEWE, TSER, project proposal and June 1998 report).

‘Agency’ refers to individual choices within the constraints (resources, opportunities) established. It is only within the constraints of local/regional educational, training provision and opportunity structures can individual behavioural strategies or individual/group ‘strategic action’ take place. The degrees of freedom which bound individual’s or family’s knowledgeable, planned, motivated action to achieve pre-planned goals—which transformation actions’ which change otherwise apparently pre-determined outcomes—are severely constrained (Bynner and Roberts, op.cit.). The authors study of the extent to which such personal motivations/expectations, and planned actions to achieve these objectives revealed that they were only of an great significance for those going on to University and entering professional or higher technical/managerial positions. The relative significance of such ‘transformation acts’ was minimised for those entering most clerical, skilled manual and most lower skilled manual and service jobs. This study, however, refers only to Britain where, at that time, the proportions going on to complete upper second level education and going on to third level were rather low compared, for instance, to the much longer periods of extra-familial and extra communal (of origin) socialisation characteristic of the USA and of many other European countries. Here the degrees of freedom in access to other non-familial resources and other supports for non-traditional choices may be much more elaborated.

Using rational action theory, Breen and Goldthorpe (1997) and Goldthorpe (1998) suggest that individuals exercise of rational choice, utility maximising, behaviour can only occur within the constraints of the resource levels they possess, the alternative opportunities open to them at particular choice points—which again might be tightly institutionally constrained, and the costs of these different alternative courses of action. Ascribed class background factors determine the resources available. Macro level, institutional factors, for instance, may also tightly constrain or ration choices amongst alternative pathways within a highly differentiated education/training system even by age 11 or 12. The relative costs of these pathways and—and ability/resources to take them up—may again be tightly constrained by class differ-
ences amongst families. The Shavit and Blossfeld (eds., 1993) studies clearly indicate substantial inter-country differences in class inequalities in educational achievement which appear to be highly correlated to these highly institutionalised national differences in ET systems.

At a macro, overall systems, level the relationship between education/training systems and labour markets is perhaps best thought of as a medium to long term secular and reciprocal one – in terms either of the supply/demand relationships, but also of the changing effect on firms behaviour and productivity of an increasingly more highly educated labour supply; as well as the consequence effects of such gradually cumulating level of human capital on firm productivity, behaviour and subsequent labour demand. The way in which employers/firms react to this increasingly more highly educated/trained labour force – and the apparent differences between different sectors and firms in this respect (Green, Ashton et al, 1997) – is a crucial aspect of economic and social research in terms of the productivity and competitiveness growth of European firms and industries.

5.2 State strategy

Relevant state strategy appears to vary widely – from countries where worries of ‘oversupply’ and attention to issues of more balance in supply and demand for differently educated labour – or the issue of ‘adéquatisme’ in the French case (‘adéquatisme’ refers to the idea that the ET system produces as many graduates as necessary for each level of qualification¹²). This indicates an underlying assumption of a relatively stable equilibrated state of supply/demand – where a system might well be producing too many more highly educated young school/college leavers in one area and too little in others. In other words, the number of graduates is given by the LM and the adequate provision is made by the

¹² Lower level leavers would become unskilled workers, intermediate vocational training leavers skilled workers, higher vocational leavers technicians and so on.

ET system. This had been a strong assumption for over a decade in the ‘70s in many other countries. Research tends to show, however, that this view of ‘adéquatisme’ ignores the way/extent to which enterprises train their own recruits: many of them hiring young people of good general educational levels and then giving them specific training, and continuing to re-train them over their life cycle in the firm. As a consequence, executive or responsibility positions are mostly filled through an internal process of acquiring skills and competencies and consequent promotions. Within such an ‘internal labour market’ perspective, ‘adéquatisme’ appears too strong a term to describe the nature of demand and supply on the LM. Such views also ignore the extent to which firms/industries adapt to technological change and to a rapidly increasing level of education of their younger workers. Given the pace of technological and economic change, therefore, it makes more sense for states to plan (or to assume as necessary) for a current ‘oversupply’ of more educated school/College leavers – as judged by historical standards.

However, in at least one respect ‘adéquatisme’ still makes a fair amount of sense: in training fields that are highly technical, where demand is relatively stable and where such training is very expensive – as in some highly professionalised areas where increased supply, for instance, merely increases overall costs without any evidence of increased competition leading to lower costs and where there is no apparent overall social benefit. In these areas it is obviously necessary to closely monitor, and control the demand/supply balances.

In other respects, however, many countries appear to have taken a strategic decision to constantly increase the supply of more highly educated youth – irrespective of current demand/supply imbalances. This most often appears to be done on the assumption that supply will, over time, change demand; and increasing education and potential productivity of new workers will, over time, significantly improve labour productivity – irrespective of immediate issues of ‘overeducation’. However, there is a very clear shortage of com-
Comparative research work in this area – particularly in the context of the substantial institutional differences between national systems within the EU. The crucial role that firms play in converting that rapidly increasing human capital into increased productivity and increased levels of innovation and market competitiveness, as well as the way this interacts with national institutional variation needs to be studied in detail.

A number of TSER research projects deal directly with these issues, particularly

i) *Schooling, Training and Transitions (STT)*, co-ordinated by C. Sofer, Univ of Orleans (contract number ERB-SOE2-CT95-2012);

ii) the CATEWE\(^{13}\) research project; as well as some aspects of the NEWSKILLS, project (contract no. ERB-SOE-CT95-2006).

A summary of the results to the intermediate stage of the 3 year STT project on comparative economic research on European schooling and transition systems focused on three issues:

a) A meta-analyses of studies on ‘overeducation’. This showed that the extent of overeducation in Europe was no higher than in the United States, and that its prevalence appear to have stabilised if not declined over time: a finding which appears to contradict other research reported here. It also noted that the rate of return to higher levels of education also appeared to have increased over time (Groot et al., 1998).

b) A second hypothesis explored was that: higher educational investments (mostly state) would be positively associated with higher educational achievement levels and higher returns to education. Analyses of British data did not support either hypothesis – a not surprising results to sociologists, where such resource allocations, per se, have been shown by research since the 1960s not be associated with improved educational outcomes. The nature and effectiveness of the use of such resources appears to be the crucial variables, not the amount per se (see Mortimore et al., 1998).

c) The third controversial hypothesis – to institutional economists or sociologists – is that national institutional differences in ET systems and ET and LM relationships are irrelevant to educational outcomes, once resources are held constant; and that market forces not institutions determine educational outputs.

Another set of STT papers deals with school-to-work transitions. They are considered either as a discrete and sequential process of movement from one full-time status stage to another, or as a possible jointly occurring set of changes in statuses as persons move from full time education – with part-time work – to a joint work/employment-training status (in apprenticeship for instance) to, perhaps, finally into a full time job and part time education. One of the main questions explored is whether there is any additional advantages to such ‘mixed statuses’, such as part-time work while in full-time education or in more formalised apprenticeship type arrangements? The results of three studies are reported for France and the Netherlands. Results appear to indicate that for France those with pre-BAC educational qualifications, apprenticeship improves employment chances and job security over those with school level vocational education only – even though there is some negative selection amongst apprentices (Bonal et al. 1999; Sollogoub and Ullrich, 1999). Apprentices appear, however, to have a higher probability of exiting from initial unemployment.

Youth unemployment rates in Spain are the highest in Europe and twice as high as adult unemployment in Spain, as they are also in France and, up to recently, in Ireland. However on initial entry to the labour market there appear to be comparatively low returns (in terms of employment chances particularly) to higher educational qualifications in Spain (OECD, EAG, 1996 to

---

\(^{13}\)Comparative Analyses of Transition of Education to Work in Europe, (CATEWE), co-ordinated by ESRI, Dublin and directly involving 7 EU countries.
In the long term, however, there are substantial labour market returns in (both employment and occupational status and wages) to higher levels of education in Spain – but the period of transition for third level graduates seems extraordinarily long by other European standards, with the exception of Italy: almost one year to enter the labour market to first job and almost three years to first permanent job (Minguez, 1998; Jurado-Guerrero, 1997, see also Schizzerotto and Cobalti, 1998). The role of family/kinship status systems in maintaining and supporting children in ‘holding out’ for a higher status and more ‘level matched’ jobs appears to be much stronger in both Spain and Italy than in most other European countries (Schizzerotto et al., op.cit.).

In some respects the Italian labour market entry system behaves in a similar way to the German one – although for quite different institutional, and underlying cultural reasons. Access to many non-manual occupations depends on educational qualifications and is regulated by law. Contractual arrangements and labour legislation make for a high degree of labour market regulation and make it unrewarding to hire third level graduates for temporary and poorly paid work. And both sets of influences, combined with a high degree of status maintenance pressures at a family and local informal level, make for high levels of correspondence between educational status and occupational status achieved due both to expectational and informal pressures to maintain status levels as well for formal lab our market regulation reasons. Combined with apparently stronger family/kinship support levels – in the much higher rates of staying at home amongst 20 to 30 year old Italians, for instance – these institutional and status maintenance processes lead to much longer periods of initial job search and initial unemployment rates amongst third level graduates in Italy – as well as in Spain than in other European countries (Schizzerotto and Cobalti, 1998). Over time however the occupational and earning returns to University education in both countries appear particularly high.

The main objectives of the CATEWE, TSER project (1998-2000) are to study the mediating effects of national institutional differences on school to work transitions in northern and western EU countries – France, Germany, Ireland, the Netherlands, Scotland and Sweden. Using both ‘stock’ (Labour Force Survey) and ‘flow’ (school leavers’ surveys and follow up surveys) data sources the study’s objectives are to analyse the mediating effects of national institutional factors on:

a) the extent and nature of ‘matching’ between educational/training qualifications (qualification type and level) and subsequent occupational/industrial locations;

b) the extent to which educational/employment exclusionary processes vary by institutional arrangements – particularly the way in which they are class and gender structured; and

c) the way in which social origin (class and gender) are mediated by institutional arrangements. The project is yet only at a data construction phase and initial results will not be available until mid 1999.

What appears clear from this short overview of research in this area is that it is mainly concentrated at the individual level of analyses and mostly focuses on the ‘supply side’: of individuals exiting educational/training systems and entering the labour market. There are very few studies of the ‘demand side’: the recruitment and promotion practices of firms, changes in their organisational arrangements, their utilisation of the constantly increasing level of human capital amongst young entrants to the labour market etc. Under what conditions (of industry and firm) does it lead to increasing labour productivity, to increased or decreased in-firm training and increased adaptability, flexibility and growing productivity of the work force?

6. Evaluation and effectiveness research

There is a long tradition of school/organisational effectiveness/evaluation research within sociology and social-psychology – at least back to the 1950s, perhaps at the earliest best typi-
fied by Coleman's (1966) famous study of the effects of schools on educational inequality in the United States. He effectively concluded that schools and the level of resources at teacher/school level had no mediating effect on educational achievement or reduction of educational inequalities — whether race, gender or social class. Later work, however, which focused specifically on school and teacher/instructional organisational processes, and the way in which and the effectiveness with which resources were used by schools, did find clear though modest school effectiveness outcomes on educational achievement as well as mediating social origin effects.

This tradition of research is well typified by the work of the European Network for Educational Research on Assessments, Effectiveness and Innovation (EU-AEI), funded by the TSER programme (contract ERB-SOE2-CT85-2001:1996-1998). The EU-AEI network also focuses on European educational and school organisational monitoring, supporting cross-national comparative research on these issues and providing comparative data bases for their comparative analyses — both in terms of constructing 'bottom up' comparative surveys — from individual country studies, as well as encouraging 'top down' international empirical studies on in-school instructional/learning processes.

The Brandsma et al. project (TSER project, SOE2-CT95-2003, 1996-1998) is an analysis of the factors influencing the effectiveness of vocational training interventions for the long term unemployed in seven EU countries. A very sophisticated conceptual/theoretical model is used; including a lot of the necessary social background, organisational and curricular/instructional processual data, data on the interface with local employers and labour markets, and importantly the nature/quality of the relationship (guidance/counselling) of the training organisation (TO) to the individual trainee. The method is based on surveys of selected 'case study' TOs — including interviews with trainees, trainers, and employers etc. Preliminary results indicate some positive effects of very focussed guidance/counselling — toward developing competency in problem solving, handling interpersonal conflicts and work disciplines, and job search training situated near the point of market entry.

There is a large body of research work in both economics and sociology on the effectiveness of training and on the appropriate and effective methodology in cases where the trainees may be a highly selective group (Ryan, 1997). The unavailability of experimental approaches (particularly random assignment to the 'treated' and untreated group) toward evaluation in Europe, as compared to American studies, means that researchers have to be extremely careful and cautious in assessing the effectiveness of training programmes (Ryan op cit.; O'Connell and McGinnity, 1997). However, the research on this issue is much less sophisticated, both conceptually and methodologically than the research on school effectiveness — with equal pupil/school selectivity problems. More of the work also has been put into developing sophisticated statistical models — to try and take care of both selectivity biases and unobserved variables for instance — and much less attention to the effects of curricula, instructional arrangements and pedagogy, learning reward systems etc. as well as the quality of provision/instruction (see O'Connell and McGinnity for review).

Related to — and indeed included within — this type of research is that focusing both on the nature, effects and effectiveness of the different ways in which pupil achievement within courses of study are assessed and certified; as well as the nature, manner and effectiveness with which schools and Colleges themselves are assessed. EVALUE (ERB-SOE2-CT 95-2004; 95-98) is a French led TSER study of the nature/patterns, effectiveness, and effects of new ways of evaluating Universities in 8 European countries and in five aspects of their operation — evaluation of their instructional/learning systems, of research output, of teachers/instructors, of university organisation itself, and of college/university and employer/industry relationships.

Universities have radically changed their functions as they shifted from elite to mass educational providers. They have become much larger and much more complex in their
objectives and their organisation. Such increasing complexity of function and structure has been allied to substantial changes in their relationships to the state – as the main funder/developer, to the older professional, academic and scientific communities, but mainly to employer and market forces. As the proportion of their graduates having privileged access to the professions and public employment declined, for example, and as their potential significance as centres of new knowledge/skills generation grew as well as potential development centres for their localities/regions – at least in public debate – so difficulties in managing these often contradictory roles also grew. The necessity to maintain academic autonomy while at the same time having to adjust to substantially greater state and market pressures created great difficulties for universities. The way in which this pressure is managed, while maintaining standards, is one of the main aims of the EVALUE research.

The university–employer/industry relationship is one of the main topics of the research (pp. 85-98 of final report, 1998), and is more developed in two 'ideal types' of universities identified – in universities (or other equivalent technological colleges) specialising in applied science, business studies and educational studies and ones established with a strong economic/employment development logic. The employment/occupational integration of graduates of such colleges – and the role and responsibility of university authorities and lecturers to maximums such employment possibilities – appears to be highly variable; even to the extent to which the latter take such responsibilities seriously. The more traditional 'elite' universities, of a more academic character, are much less concerned with such employment outcomes.

The university/regional relationship is also studied in the EVALUE project. The project studies the complex relationships between third level colleges, established specifically for regional development purposes, and local/regional authorities and employers – in terms both of the expectations and support of the latter for such colleges, as well as the reciprocal expectations and behaviour of college authorities and lecturers etc. – and the strength and effectiveness of the partnership between the colleges and local/regional communities. The expected potential of such new colleges for regional development needs to be studied in detail – in terms of increasing local human capital resources, of decreased out-migration, the potential contribution of such increasing human capital to regional productivity growth – as well of course as the direct local returns to the increased employment created by the presence of the college itself. Some of the British and Irish studies in this area, however, are at best neutral in their conclusions about such local/regional returns to such educational investments.

The DELILAH TSER project (ERB-SOE2-CT95-2002) on Designing and Evaluation of Learning Innovations had three main objectives: develop a new conceptual/methodological approach to innovations in ET – particularly the idea of 'learning patrimonies'; carry out case studies in four ET sectors in Germany and Britain; and draw out the implications and policy conclusions.

The qualitative research indicated both the difficulties and different dynamics of change and innovation in the different institutional systems. First is the relationship of the state to schools – in, for instance, the increase in school autonomy that has occurred in some systems (such as the British), making them more responsive to both state (in effectiveness audits) and market pressures. At the same time increasing managerial control within the school reduces the autonomy of the professional role of teachers, creating countervailing pressures.

The study raises some important questions about the main purposes of education, particularly the potential negative effects of increasing instrumentalism and financial pressures on schools in a situation where the significance of familial socialisation is declining; and the ideational, identificational, normative and general socio-cultural roles of schools have probably become more significant. As other institutions like the family and community systems realign and decline in relative significance the effect of increased
instrumentalism on overall socialisation/school effectiveness needs to be studied in detail.

Although the evidence appears somewhat thin and not sensitive to varying institutional contexts this research does have some important messages, if not clear conclusions:

- The demand for increased educational levels has increased faster than the school system can effectively adapt. As a result, as those who previously could get unskilled jobs with no/poor qualifications declined substantially, schools did not adapt fast enough or effectively enough to cope with this problem. Most interventions with this educationally deprived group have occurred at a post-school level. The serious dangers in focusing interventions on such post-school interventions, usually in non-formal and temporarily organised arrangements, mostly dependent on year to year precarious funding, has become obvious in most EU countries where this occurred. More fundamental in-school innovations appear necessary – at pre-school, early in-school, and early second level school levels in order to reduce the incidence of in-school failure, which although relatively small in percentage terms (less than 10 percent in most systems), appears to have equally serious labour market integration effects on the lowest qualified in most systems. (Smyth et al., 1998; Martin and Raffe, 1998; Becker and Rutjes, 1998; Recotille and Werquin 1998, final Leonardo, VTLMT, report, 1998).

- Overemphasis on instrumentalism, and market readiness, not paying sufficient attention to general education or the particular personal/social development needs of educationally and socially damaged adolescents.

- The new political economy of schooling may very well lead to increasing class inequalities as funding arrangements change in some systems to be more school competitive and market sensitive (as in the UK), and such modern technological aids as IT and self learning etc. become increasingly important in schools without compensating resource allocation – with the middle class more likely to gain advantages.

7. Class and gender inequalities and social exclusion

The major secular shifts in economic structure in western industrialised countries over the past 20 to 30 years have led to substantial changes in occupational/class structures – particularly a decline in lower working class (particularly unskilled manual) positions, and substantial growth in middle and upper/middle class positions. This change in the nature of flow of children out of families into schools, combined with equally rapid changes in the structure and costs of schooling – with free education gradually being extended in most cases up to the end of upper second level, with substantial growth also in the importance of education in occupational allocation and promotion was all expected to have significantly reduced class origin inequalities and greater equality of opportunity in levels of education achieved (Boudon, 1974). Yet most of the international research on this issue indicates that despite substantial growth in average levels of education, and of greater relative growth in participation by children from working class origins at the lower levels of achievement in most countries, there is little evidence of overall decline in class inequalities in educational achievement levels – particularly at upper second level and at third level (Blossfeld and Shavit, 1993). Raftery and Hout (1993) proposed a radical hypothesis to explain this phenomenon – that inequality in educational opportunity is maximally maintained – with effects of social origin at all levels of education maintained to the point where the participation of advantaged groups is maximised and further expansion in participation can only come from those with lower working class origins. At this point the more advantaged groups push for further expansion of ever higher levels of education in order to maintain their advantage. So many international studies show positive effects of educational expansion at lower levels of education on equality of opportunity, but little change in class inequality at higher levels.
Little consistent change over time in class inequalities in educational achievement in most countries—with some notable exceptions such as Sweden and the Netherlands. In both cases, this decline appeared to be due more to an equalisation of life conditions between the different social classes than to any educational policy changes (Blossfeld and Shavit, 1993; Erikson and Johnson, 1996). In most countries, therefore, where social selection was most severe at the beginning of the educational career, the point of selection has been pushed further up the educational ladder.

Gender differences in educational achievement on the other hand show a much greater equalisation over time—with in some cases, the gender gap being reversed, with girls doing better particularly those from working class origins. Gender differences also appear to be greater in more differentiated systems at lower or upper secondary level—as in Germany and UK, whereas in France, Sweden, Portugal and Ireland it is the other way around (Freysson, 1996); mainly it appears because of the dominance of general educational models in the latter countries.

One of the main hypotheses of the CATEWE project (TSER, CT-97-2019, 1997-2000) relates not so much to overall class inequality effects on educational achievement, but on the effects of national institutional ET differences on educational/employment exclusion processes. The hypothesis is that such educational and labour market exclusionary processes are both more severe and more class origin biased in countries with less selective and less differentiated systems—Ireland and, to a lesser extent, Britain and France; or that it will be less severe in selective/differentiated systems as in the Netherlands and Germany, despite their greater class differentiating effects in overall educational achievement. In the latter cases early differentiation into selective educational/vocational tracks are closely linked to accessing segmented labour market outlets, segments/occupations with significantly lower levels of competition from the more highly educated. This is suggested to be particularly true for non-skilled manual/service occupational positions. The expected effects of this would be to leave more uncontested ‘room’ in the labour market for poorly educated youth, with the consequent effect of higher employment expectations motivating in-school learning. Shavit et al. (1993), for instance, find positive effects of vocational tracks on access to skilled occupational outlets and avoidance of low skilled and insecure employment.

Initial results, however, from a related Leonardo-da-Vinci project (VTLMT, DGXXII, 1996-98; Final Report, Dec. 1998; Martin and Raffe, 1998; Smyth et al. 1998; Becker and Rutjes 1998; Recotillet and Werquin, 1998) indicate ambiguous support only for the initial hypothesis on exclusionary effects—with the most poorly qualified in the Netherlands suffering almost equally high levels of employment exclusion as in Scotland, France and Ireland. However in other respects the results support the conclusions on the positive effects of vocational/technical qualifications on employment chances, but also indicated the almost equal importance of ‘passing grades’ in lower second level examinations in accessing the labour market. Access to apprenticeships, however, tend to be negatively selective in the Netherlands and France while it is positive in Ireland and Scotland (Smyth et al., 1998).

There are also quite substantial country differences in occupational allocation amongst these 4 countries—with a much higher proportion of lower second level leavers in non-manual jobs in Scotland (who have ‘passed’ their lower level examinations—at 16) than in the other countries. These latter differences appear not only to be due to national differences in the availability of such jobs to school leavers in general—a function of both the economic cycle and the extent to which public expenditure funds such occupations, but also the relative proportion of all school/College leavers entering the labour market who only have lower second level qualifications. This tends to be much higher in Scotland (Smyth and Surridge, 1995 and 1997). But in the latter case a much higher proportion of such early leavers are in alternative learning routes—apprenticeships, Youth Training and other full and part-time educational courses outside the conventional school system. The Scottish and British system then maximises out-of-school education and training for the
post compulsory years whereas the French, Dutch and Irish systems maximise full-time educational attendance up to the end of upper second level education (Martin and Raffe, 1998). Whether the increased level of education and postponement of labour market entry – as in the latter countries – has the moderating effects on class and gender inequalities in educational achievement and labour market success, as has been proposed and found in other research (Blossfeld and Shavit, 1993; Shavit and Müller, 1998) has to await further research.

Such lower level leaving is highly gendered and class differentiated in all countries: predominantly male, and predominantly from lower working class or unemployed family backgrounds, with parents having lower levels of education. Even given the large institutional differences between, for instance, the highly vocationally differentiated Dutch system and the more general educationally based and undifferentiated Irish one, it appears that the extent and nature of social class selectivity of successful educational progression in both countries appears remarkably similar; though paradoxically gender differentiation (positively) and class selectivity (negatively) factors appear more pronounced in Ireland. This would accord with our hypothesis – though the statistical significance of these inter-country differences has not yet been tested (Martin and Raffe, 1998).

Lindblad et al. TSER research proposal (SOE2-CT97-2028, 1997/8 – 2000) main proposition is that increased economic/political pressure on schools/universities, and increased ‘marketisation’ of resource allocation, evaluation, etc. significantly change the organisational characteristics of the school/College away from its public service functions/practices as a ‘rule governed’ to a market led system. As a result this makes it more difficult for the school/college to meet its new targets/objectives on reducing social exclusion. This will be investigated in 8 countries. Their method is to review the research literature, carry out comparative analyses through individual country ‘case studies’ of governance structures of schools/colleges – including ‘discourse analyses’ of existing policy etc. papers. Evaluations of national experiences with new governance structures, and research on national data/studies of social exclusion and class inequalities is also to be carried out. Implications of governance changes for social class inequalities and evaluations of new programmes of intervention targeted to improve the situation are to be carried out. This study in nine or ten countries appears to be inductively based, generalising from comparative national case studies of what interventions work or do not work in different contexts.

The ways in which, and the organisational effectiveness with which, schools/colleges are organised and managed do have significant impacts on student outcomes. (Mortimore et al., 1998; Smyth, 1999). It may well be that modern state led concerns about school management effectiveness and changes in their operating and governing arrangements toward ‘market led’ rather than ‘rule governed’ behaviour would have significant negative impacts as hypothesised here. Certainly the original British ‘market led’ arrangements for publishing crude examination results by individual school and the use of state vouchers in purchasing school places – expected to increase inter-school competition and overall school effectiveness by improving families/pupils choices between ‘effective’ and ‘ineffective’ schools – would neither have positive system effectiveness outcomes and would certainly increase class inequalities.

Nevertheless as third level educational participation becomes more ‘universal’ substantial changes are required in the way the originally elite and autonomous universities are run – and in many European countries the rallying cry of negative ‘marketisation’ appears far too self interested; with new instruments to ensure effective responsiveness to economic and societal needs badly required.

8. Conclusions and issues to address in the next TSER programme

There are four main themes in the “Improving Human Potential” part of the Fifth Framework Programme (1999-2002):
Three of these are clearly related to our theme — (i), (ii) and (iv).

The issues of school to work transitions, labour market integration, human capital ‘creation’ in education and training systems and its effective integration into the economy, variations across EU regions in their ET and LM institutional arrangements and their differential effects on labour market integration etc. fit clearly within these themes but need to be spelled out and applied to the new Vth Framework Programme. There appear to be at least five broad areas where high quality comparative economic and social research is urgently needed and would fit within the broad remit of the Vth FP:

a) Since the relationships between rapid technological change, education/training provision changes and economic/occupational changes are very complex — and not readily ‘read off’ from technological change — there is an urgent need for high quality comparative European research on these issues. There are wide national, industrial and between-firm differences in how, and how well, workers with higher levels of education/training and new technology are inserted or used within firms/industries. The way in which both technical and educational changes are related to firm/industry strategies of adaptation to rapid market changes should be a priority in future research. Current research on these issues has to depend too often on inferring such firm/industrial behaviour and strategies from data on individual workers’ labour market histories.

b) The issue of new development models and economic/employment growth — a main theme of the new research Programme — needs to be explored in depth on a comparative national basis across the EU. The wide national institutional differences in ET systems, their varying labour market integration processes and the extent/nature of their openness to life long learning processes, suggest substantial national differences in economic and employment growth models. There are large national differences in, for instance, the extent and nature of provision for life long learning systems, and in the way they are integrated with employment/work systems. These national differences are likely to be strongly related to both the participation rate and the effects of life long learning opportunities: with some national systems being highly ‘user friendly’ over the life course, highly integrated with both work life and careers. Other ET systems appear inflexible and unrelated to life long individual career and firm/industry re-skilling and up-skilling needs. The issue of ‘life long learning’, of its linkages to in-firm training and to the institutional flexibility of educational providers and qualification frameworks — to effectively optimise such ‘re-learning’ occurring over the life cycle, though such a dominating theme in EU policy documents, has received little comparative European attention; though significant cross-national differences do exist in the extent to which it occurs.

c) Equally comparative research at a firm and industrial level on the human resource management of increasing levels of education/training amongst young work forces is urgently needed. Given rapid market and technical change the extent and nature of adaptations by firms and industries needs as much study as has been given to the behaviour of individuals in their transitions from school to work.

d) Equality of opportunity in education, occupational achievement and earnings — by gender, social class of origin, ethnic group etc. — as well as the equally important issue of educational and labour market exclusion appears to be quite sensitive to both
economic/technological change as well as the way in which the national ET systems for initial and continuing re-education/training effectively provide opportunities. Again single national models appear unlikely to be generalisable to the whole Community - given the deeply rooted institutional differences involved. Besides the obvious injustice of high levels of inequality and its obvious negative social effects, the systemic and often deeply institutionalised nature of the under-utilisation of human capital involved - particularly amongst the most educationally/economically excluded - appears glaringly inefficient in both economic and social terms. The need for good quality comparative research on this issue appears obvious.

e) Comparative European Data: Besides the Eurostat data bases (particularly the Labour Force Surveys and Community Household Panel surveys) there are very limited comparative European data bases available on some of the most important education, training and labour market integration policy research issues that affect the European Community. Compared to the United States, for instance, or to a majority of EU states, there are no comparative surveys or data bases on longitudinal (flow statistics) on educational/training processes and outcomes and education to work transitions, no comparative data on life long learning processes or adaptation of firms/industries to rapid technological and human capital changes etc. Improvements in Eurostat surveys - including the new, year 2000 transition module on transitions - will be some help in correcting for this deficit, but in a very limited way. In addition there appear to be far more serious constraints in making such (suitably anonymised) Eurostat data sets available to the research community than is true of most individual countries within the EU. These issues will be discussed in more detail below.

8.1 Educational level and labour market success

Although variable cross-nationally there is generally a close relationship between level of education, employment chances and level of occupation (status or quality) achieved; i.e. a moderate to high level of 'level congruence'. However there is a substantial (though varying) degree of overlap within educational levels of occupational statuses achieved in all systems; i.e. of 'overqualification' of workers within occupations or 'under-utilisation' of education/skills by employers, varying considerably cross-nationally. (see Shavit and Müller, 1998; Borghans, Hughes and Smits, 1998). The degree of occupational 'overlap' between different educational levels, or the degree of labour market competition between them, obviously reflects national institutional differences, cyclical employment rates as well as life cycle factors - being greater in periods of high unemployment and at initial stages in the labour market. The varying nature of such 'overlaps' and their effects on labour market flexibility, labour productivity and turnover, employment exclusionary processes etc. all need to be studied in more detail.

Further cross-national study is also needed on the extent to which the content/level/difficulty of 'within-occupational/industry' categories remains the same over time or, as Green et al. (1997) study indicates for Britain, or the extent to which technical change/upgrading also occurs within occupations; or the extent to which occupational boundaries remain impermeable. In addition the extent and nature of productivity growth and organisational and technological 'response effectiveness' of firms/industries to the constantly improving quality of labour market entrants, needs detailed study. The 'under-utilisation' of skills by firms/industries needs as much attention as the 'overqualification' of young workers.

8.2 The content of education/training and occupational/job congruity

The issue of 'content congruence' (Almdinger, 1989 and 1997) has not received much comparative research in the EU. This may be a more relevant question in some countries such as Germany and the Netherlands or other countries with extensive occupational labour markets. To measure the nature and extent of the linkage between the content of what young people learn in initial education/
training and what knowledge/skills they actually use at work has usually been studied by linking field of study to the nature of the work/occupation taken up – either where institutionalised linkages exist as in apprenticeships, professional/technical occupations or otherwise where the educational/occupational connection can easily be estimated. More subjective approaches have also been used – by asking individuals in specific jobs/occupations to what extent they use their ET gained knowledge/skills in their work etc. However, in neither case is the research methodology without fault – with little cross-national comparability. In addition it is clear that a lot of occupationally relevant learning is implicit and unmeasured by educational/training qualifications – e.g. the significant advantages of apprentices in some cases in the labour market even in areas in which they have not been trained. The nature and significance of such non-formal and currently non-certified learning at home, in school and at work is recognised in some current cross national projects both in terms of content and learning style and motivation (Reef, Coord. of TSER project on cross-curricular competencies CT98-2042); with some evidence that some aspects of learning style – particularly the conformist and reproduction oriented style – may be functional for educational achievement in some settings but dysfunctional for subsequent labour market success. (Semeijn, van der Velden et al., 1997; Semeijn and van der Velden, 1998).

To over-value a narrow concept of ‘content congruence’, therefore, would be unwise: while initially functional for the overall system it may well have serious negative consequences for individuals’ career mobility and, if education and training is too narrow, also limit firm re-training and firm adaptability.

Additionally the discrepancy between the education/training provision of a national system and the needs of the productive system can be estimated (Kirsch and Werquin, 1995): the French idea of ‘adequatisme’. Because many French firms recruit young people at a given level and then train them within the firm – paying attention to the general educational level on appointment – the older ‘manpower planning’ idea of ‘adequatisme’ does not work. The most recent and relevant issue about ‘adequatisme’ is about what other, often implicit and informal, things young people learn while in school and what they use at work. The example of the German car producer which recruited most of the apprentice/trainee bakers in the region indicates that while the training system was not efficient in terms of field of vocational preparation it was obviously effective in other respects that were very relevant to car makers (for example work disciplines and shift/night working etc.). The informal/implicit learning of work relevant skills that are transferable to other occupational/industrial settings needs much more research.

Another example comes from Kirsch and Werquin (1995). They have shown than in France, most young people exiting the training system at the BEP level – first vocational level – did not use their specific skills and competencies in the first jobs they got, when/ if they got one. Even taking subsequent occupational mobility into consideration they are not generally mobile into jobs directly connected with their first vocational preparation subjects. There is need for further comparative research of the nature of both the explicit (certified) and implicit training/education provision/socialisation provided by the ET system, and the interpretation/use made of it by the employer/productive system.

Informal transferable skills – or personal and interpersonal skills which are the result of non-formal learning experiences both in the formal schooling setting as well as in related interpersonal socialisation, which are not measured and certified by schools, and which may therefore be less institution and country specific than formal schooling outcomes, is now the subject of a lot of research (e.g. OECDs, new PISA programme; COST Action AII etc.; Reef et al., TSER project, 1998).

8.3 Youth schemes, evaluation and selectivity biases

One of the most relevant aspects of youth schemes is their function in handling the increasing duration of job search and higher
rates of unemployment between the end of initial education/training and the first permanent job. As young people's status in the labour market dis-improved most States strongly intervened with various types of training/employment schemes. Many evaluation studies of the effectiveness of these schemes have taken place at the national and EU level (see Brandsma et al., TSER project CT95-2003, 1995-1998). The issue of selection bias in that evaluation is critical. Most such youth schemes are designed to ease transition from school to work for those with poorest qualifications and those least likely to be perceived as productive within an enterprise. Of course recruitment and progression within such schemes may be selective on both measured an unmeasured (usually social-psychological) variables. And since firm recruitment from such schemes is highly selective even amongst those employers think are the 'better' amongst applicants, selectivity bias may be quite high. In theory training schemes are designed to help young people who need further education/training. In practice, even if there is no selection by such schemes, employers selection may only take those who otherwise would have got the job anyway – the scheme has high 'deadweight'. Ways both to measure and control for these selectivity biases have been developed, but their applicability and validity need much more development and evaluation in comparative cross-national work.

There is therefore an urgent need for effective comparative evaluation of the effectiveness of these schemes in different EU countries (Grubb and Ryan, 1997). Heckman and Smith's (1995) dictum that 'The fundamental evaluation problem arises from the the impossibility of observing what would happen to a given person in both the state where s/he receives a treatment and the state where s/he does not. If a person could be observed in both states, the impact of the treatment could be calculated by comparing his or her outcomes in the two states, and the evaluation problem could be solved'. Given that participants are not observed in both states, a large literature has been developed to help control of the consequent selectivity biases. The use of experimental methods (in the random assignment of participants to treatment and control groups, for instance) to control for such biases has been very limited in Europe.

However before proceeding to such experimental methods it might be more advantageous to increase the conceptual, measurement and analytical sophistication of the evaluation research in this area to that characteristic of the older tradition of related research in 'school effectiveness' – paying much more attention to the nature of the curriculum and pedagogy, course organisational characteristics – including sensitivity to the often quite different social psychological characteristics and needs of the lesser qualified youth that take up such training courses. There is a need to get beyond the question 'do these programmes work' to the question of what kinds of programmes work with what kind of 'clients' – curricula, pedagogy – including the quality and relevance of both, the nature and quality of linkages to firms/employers and real work situations (see O’Connell and McGinnity, 1997; Ryan, 1998; Brandsma, Coord. TSER project CT95-2004).

Cost-benefit analysis has become the dominant mode of evaluation in the United States. This method has some limitations, however: arbitrary shadow pricing for valuing many costs and benefits, inadequate duration of measurement of outcomes, relative neglect of the variance of outcomes and the underlying reasons for these and so on. It tends to neglect, for instance many of the social, social psychological and even educational outcomes of interventions in focussing only on labour market outcomes. And it overemphasises the efficiency criterion, and often under-emphasises the equity/egalitarian criterion – a much greater priority in most European studies.

Besides the effectiveness and costs/benefits of such schemes little comparative work has been done on the institutional, organisational and curricular-pedagogical characteristics (including the content effectiveness) of these schemes (but see Brandsma et al., TSER, SOE2-CT952003). The relationship of such post-school schemes to initial education, the extent to which they are designed to correct for initial educational failure – and whether
the original system remains unchanged, the extent to which the organisations delivering such schemes are linked to the ET system – providing pathways back to it or in cooperation with it, and the extent to which linked in with employer and labour market systems. Since policy on state/EU interventions on transitions from school to working life are political imperatives in most countries, but such interventions cannot rely on solid, comprehensive and efficient theoretical or conceptual models – or a solid research base, the filling of this theoretical and research lacuna should be a priority issue for future research.

Besides the transition between education/training and the labour market, as well as transitions from and into unemployment, there are many other important transition issues that need investigation: returns (occupational/earnings) to different types and levels of education/training, migration and job search, movement out of the labour market and its relationship to new household formation – particularly for poorly educated young women, housing changes, changes in living together and marriage arrangements and so on. Studies of labour force withdrawal of young women, for instance, appears to take place in some countries only after a significant period of initial employment difficulty (Hannan and O Riain, 1993), but in other countries entry to the labour force itself upon completing education particularly amongst females with low levels of education – appears to be much more problematic (Canada Vicinay et al., STT Working Paper 07-98, 1998).

8.4 Earnings
Most of the research being done in the field of school-to-work transitions has been focussed on the probability of getting a job. Given the high unemployment rate across Europe this is not surprising. Job search is important not only in terms of its length and difficulty but also in terms of the quality of the match between school leaver and job – whether in terms of ‘content and level congruence’, the extent to which it is a marginal job, its occupational status and subsequent career mobility chances, wages and wage growth etc. (Atkinson and Micklewright, 1991). Wages also need to be studied in greater detail for other important reasons: The issue of minimum wages and of minimum wage legislation, unemployment benefit, wages on state programmes etc. The issue of the relative effectiveness of different active labour market programmes and the role played in labour market demand for young and older workers in a situation of overall low demand needs also be studied in more detail.

Finally wages have to do with the cost of labour which is often decried as too expensive as far as the low qualified labour force is concerned. The issue to address here is clearly whether Europe should lower the wage of poorly qualified young people or increase their skills through training, and what effect either policy would have on overall economic effectiveness. In addition the extent to which similar policies have similar effects in different national/institutional contexts also needs to be studied in detail.

8.5 Data issues
One of the main issues that arise in testing cross-national hypotheses is research/data quality. Usually the phenomena being dealt with are very complex and linked in complex ways to several origin, process and outcome variables: initial ‘ability’ and family background variables, ethnicity and gender; differences in the nature of educational/training programmes and processes and outcomes; differences in labour market history as well as opportunity characteristics; and personal outcome differences in terms of cognitive, affective and behavioural characteristics. Given this complexity and the different national systems within the EU it is difficult to answer many important research and policy questions with existing data sets. The following data questions appear very important for future research work:

- While obviously rational to build on existing data sources at an EU level (such as the Labour Force Surveys –LFS- and the European Community Household Panel Survey), as well as on relatively comparable national data sources such as the follow-up school/College leavers’ surveys –
carried out in six countries, the weakness of EU data sources on educational/labour-market relationships compared to that of our main competitors such as the USA needs to be corrected. Even where cross-national databases exist crucial variables are often 'missing' and comparative measurement difficulties arise where systems vary widely.

- Most of the current TSER quantitative research, for instance, is based on existing national and international data bases. There are some exceptions, such as the study of graduate employment in Europe (CT2023, 1997/8-2000). All of the evidence suggests the necessity to build comparative European data bases on the central policy/research issues involved; rather like those already existing in the Europanel and LFS household income/expenditure data bases.

- The significant improvements planned in the coverage and comparability of the Eurostat LFS data base, and particularly the additional information on transitions planned to be available from the 2000 LFS, potentially means that a lot of new comparative research work can be carried out; provided of course that 'public use' files, at the individual level, are made available to the research community as already happens in most of the EU countries. The development of more liberal Eurostat access regulations, such as those governing researchers access to such data sets at national level in most EU countries, is an important research and policy analysis priority.

- Besides the 'stock data' available from the LFS, good comparative 'flow data' on school/college to work transitions over the first 1 to 5 years or so in the labour market are urgently needed. These could be based initially on the current school leavers' surveys carried out in six EU countries (CATEWE, TSER project, CT97-2019), as well as the TSER funded third level leavers, follow-up surveys in 12 countries (Teichler et al, TSER contract CT-2023). However in the former case these studies cover a small set of countries and vary significantly from each other in sample definitions and variable coverage etc., though sufficient similarity exists to yield rich comparative sources of information on transitions. (Final Leonardo VTLMT report, Dec. 1998 available as an ESRI Working Paper, Dublin). One data strategy would be to improve the comparability of these surveys and increase their country coverage. The alternative, however, of 'top down' surveys either based on the planned, year 2000, Eurostat LFS module on transitions – though the planned set of variables is very restricted – or on new occasional cross-national surveys (such as the 'Teichler survey') should be actively explored.

- EU strategies on European data bases should, therefore, be as much concerned with 'making data European' as with creating new European data banks: with maximising the cross-national comparability of current national and international surveys on specific issues (such as the OECD and IEA co-ordinated studies), as well as creating new policy/research data sources for priority areas where this is necessary. Such a strategy would require a comprehensive assay of current and projected surveys, as well as determining areas where important data is missing or non-comparable.

The work of the TSER funded CATEWE project and the EU-AEI network shows both the importance and the possibilities for building on existing national and international surveys. The continuing work of the latter indicates, for instance, the necessity of continuing assessment of changing national objectives, strategies, contents and outcomes of educational interventions. Current methods for doing appear highly inadequate, with a need for European wide methods – for educational indicators, methods for measuring 'added value' and development of reliable and cross-nationally valid and culture fair tests etc. on an equivalent basis to that provided, for instance, by the United states or indeed other developed countries within the OECD system of monitoring educational and labour market changes; comparable for example, to
the work of Networks A to C within the OECD educational directorate, for instance.\textsuperscript{15}

The two main players in the area of international educational comparative educational assessment/testing research for instance are the OECD and the IEA (International Association for the Evaluation of Educational Achievement). Besides the issue of ensuring that cross-cultural reliability and validity of the instruments as well as their national institutional sensitivity (by ensuring that EU countries are adequately represented on the planning committees etc.), these organisations also normally allow participants to add so-called national options to their ongoing international survey instruments. The European ‘added value’ of such surveys would be greatly enhanced if the EU Commission would co-ordinate national efforts, ensuring that such instruments are adequately generalisable across EU systems, and that they provide data that is attuned to the main policy and research questions in the area (see Reef et al, TSER project, 1998).

In addition many national surveys are carried out on the same set of themes, and with much the same set of objectives by individual countries. The EU wide utility of these national surveys on educational achievement and labour market entry could be significantly improved if an ‘added value’ EU comparability dimensions were developed for the important variables. The costs involved would be marginal (to total costs) but the ‘added value’ return would more than compensate.

\textsuperscript{15}The work of the EU-AEI network for instance, shows the need for continuous assessment of the status and trends of educational objectives, contents and achieved competencies at primary and secondary educational levels. The conclusions of this, partly TSER funded, network are the existing tools for this are inadequate and that it is necessary to:

i) set up a European instrument bank for educational indicators;

ii) develop adequate methods for measuring added value in educational achievement;

iii) develop reliable and valid methods and instruments for culture fair testing on a comparative European basis for both student achievement as well as, for instance, for adult literacy testing.

The national longitudinal studies (in at least 6 EU countries) which follow young people from an early age (e.g. 15) in the ET system to a point in their labour market career where their status has stabilised (usually 3-5 years after entering the labour market) provide invaluable information on transitions which is not available from other sources. Usually these surveys include not only labour market history information but also the crucial social background characteristics and educational formation data on individuals. Since educational and labour market history itineraries are increasingly prolonged and individualised, cross-sectional, snapshot surveys give a highly inadequate picture of transition dynamics – or transition difficulties or success. Such longitudinal surveys should ideally follow young people for five to six years after leaving school, a minimum period to estimate ‘final’ transition outcomes (Werquin, 1997).

A good final benchmark to use is the age at which the unemployment rate of the cohort equals the adult one. Although the cost of such surveys is high and they cover a longer period of observation before results become available many EU countries already carry them out for their own policy purposes (France, the Netherlands, the UK, Ireland, Sweden and now Flanders), while partial or regional surveys are carried out in many other countries. Although there are some serious ‘missing data’ problems for some countries and other methodological difficulties the results of analyses of these comparative sets appear important and quite robust (Leonardo final VTLMT report 1998; and CATEWE, TSER project 1997-2000). An EU policy of ‘adding value’ to these national surveys (by increasing their variable coverage and data/sampling definitions for instance), and encouraging their expansion to other countries, would be a very cost effective method of increasing the availability of valuable comparative European data.

Besides such ‘objective’ and standardised surveys further comparative studies of individual strategies for, and experiences of, transition need to be carried out, such as in the Anglo-German studies (Bynner et al.,
Comparative research of other important policy issues also appear important. The issue of guidance and counselling, for instance, urgently needs attention – particularly as it relates to the transition of the less academically able students within school; and the general finding that in most countries such in-school services appear comparatively irrelevant to the great majority of school leavers in transition (Hannan et al., 1983; Becker and Rutjes, 1998). This contrasts sharply with the situation in many other countries – particularly Japan – as well as perhaps in vocational training and other educational programmes which have a large element of work placement/experience – which require close contact between schools and employers.

The Fifth Framework Programme – particularly the Key Action – Improving the Socio-Economic Knowledge Base – could thus be more focussed on some central economic and social policy issues: education/training and labour market relationships, the issue of technical/educational and firm industry change, the issue of state training/employment initiatives in the context of high youth unemployment, the issue of educational and life chance inequalities and educational/social exclusion, and the micro-macro issues of the relationships between educational/training change and rapid technical and market change at both firm/industrial and individual levels. Cross-national comparative research on these and other related issues should be a high priority for the new Vth FP.

Selection, social exclusion and training offers for target groups

Jan Vranken, Mieke Frans

Abstract
This paper discusses the key concepts of social exclusion and inclusion, the potential target groups and their specific problems. Target groups are underrepresented in labour market and training programmes. The crucial factors of exclusion are analysed from an institutional, an economic, a psychological, a socio-cultural and a policy perspective.

Discussed are the accessibility of programmes and the difficulties to comply with administrative selection criteria. The most important factor of exclusion programmes is the need for efficiency that is imposed on the programmes and their organisers. The shift towards privatisation and the tightening of the funding requirements results in creaming off effects and reduces training to a short-term solution. Any gap between restricted selection possibilities and strict output targets creates a 'double bind tension' for the training organisation that has negative consequences for the trainees.

Policy recommendations refer to:

- efforts to re-integrate the 'hard core' target groups by using their problems as benchmarks;
- taking account of the cultural dimension by the development of clearly defined 'management cultures' or 'organisational cultures';
- decreasing the gap that separates the employment situation from the training situation, directly through financial and other support and indirectly through a secure job perspective;
- the development of the long-term dimension of 'trajectory guidance'.

Introduction

This contribution addresses exclusion from the labour market and the role of certain forms of vocational training in promoting inclusion into the labour market. This implies that we will focus on the role of specific training offers in preparing socially excluded persons for a job. The field of inquiry is restricted to

- forms of training with a strong vocational focus;
- forms of training that are specifically organised for persons outside the labour market;
- external training initiatives. Training at the workplace is taken into account insofar as it is linked to external training offers. Social economy initiatives, however, also are included because of their importance for our target groups.

Our approach is rather conceptual and theoretical. Although it was one of the aims at the onset of this contribution, the situation and policies of different EU countries are not described. Neither did we include empirical data concerning participants in training programmes or national evaluations of measures. On the very specific strand of vocational training that is the subject of this contribution no overall data are available, even not at the national level, mainly because of the extremely large array of types of initiatives and the fact that they are often very locally embedded. In Belgium alone, 141 schemes to facilitate the transfer to the labour market have been identified and most of them imply some kind of vocational training. General data on participation of target groups and evaluation of measures relate to 'traditional' forms of vocational training. They were discussed by Nicaise and Bollens (1998) in their contribution to the 1998 background reports.

How will we proceed?

- Firstly, a coherent conceptual framework that focuses on the concepts of social exclusion and social inclusion is developed.
- Secondly, the groups affected by social exclusion, paying special attention to the labour market dimension, are discussed, taking account of institutional and other contextual factors such as the selection procedures. Special attention is paid to employment niches for target groups, especially the social economy sector.
- Thirdly, a general typology of these measures is elaborated, taking account of economic, psychological, sociological and institutional variables.
- Fourthly, the conditions for a framework to coordinate policies at several levels will be discussed.
- Lastly, activation policies are discussed in terms of their possible impact on vocational training. It is quite clear that they will constitute the intellectual and policy-making framework for future training programmes or policies.

1. The context

1.1 From social exclusion to social inclusion

The concepts of social exclusion and social inclusion are relevant at the theoretical and the policy-making level, particularly with respect to the relationship between the labour market and vocational training.

1.1.1 Social exclusion

Two main definitions of social exclusion are commonly used. One is inspired by the Anglo-Saxon tradition of citizenship, the other by the continental idea of societal gaps. From the first perspective, social exclusion is described 'in terms of denial or non-realisation of social rights (Room, 1991: 5), such as 'the right to a certain standard of living' or, more specifically, the right to labour, to housing and to educa-
tion. Social exclusion, then, implies that access to these rights is, knowingly or unknowingly, restricted by the manner in which social services are organised or by the vulnerable economic, social and political position of certain citizens.

For the other, continental, tradition the notion of social exclusion concerns the gap that exists between situations or groups in one or more areas of social life. This notion of social exclusion can refer to situations and processes such as polarisation, discrimination, poverty, and inaccessibility. In order for society to arrive at such a situation, it must be structured according to a centre/periphery relationship, while society’s means (economic, social and cultural capital) must be distributed unevenly. Of crucial importance in this respect is, of course, the fault line, which may manifest itself as a gap, a wall, or a barrier.

The distinction between relational, spatial and societal fault lines (Vranken, 1997) is an answer to what is probably the most crucial question with regard to social exclusion, namely exclusion from what? (see among others Silver, 1995: 60). Indeed, the reference points of social exclusion are situated at the micro-level (of individuals and their networks), at the meso level (of groups, institutions) and at the macro-level (of society).

The first reference point is that of the individuals and their networks. Relational fault lines refer to the fact that poor people’s networks provide no, or very limited, access to important social commodities (or to economic, social and cultural capital). Social exclusion may, then, be seen as the result of exclusion from the exchange in relationships that is part of participation in social networks. ‘Gatekeepers’ have the power to decide whether or not to allow through the flow of commodities persons or institutions, because they occupy a central position within a social network. By depriving people or groups (the lowly qualified, immigrants, the homeless) from social commodities (employment, housing, education, income, status, power) they create social exclusion (see also Vranken, Steenssens and Pultau, 1996: 57). With respect to the labour market, we are referring to personnel managers, labour exchange administrators, project managers, vocational trainers. Although they are bound to existing legal and administrative rules, many ways remain open to exercise a determining impact on selection processes and procedures regarding training, such as regarding the information that is provided, the linking of particular persons or groups to job opportunities, etc.

A second reference point is groups or group-like phenomena. Social closure is the process whereby social groups attempt to acquire, increase, or maintain rewards by restricting access to sources or opportunities to a small circle of a happy few. The purpose is to monopolise opportunities in life which others too find desirable, i.e. the closure of such opportunities to outsiders (Weber, 1922/1956: 201). Groups which fail to achieve any monopoly must compete with each other on the open market and are subjected to its levelling effects. The groups thus excluded often respond by imposing boundaries on even weaker groups, which results in so-called ‘dual closure’ (Parkin, 1974). The consequence is twofold: the creation of an uneven distribution of opportunities in life and of closed social relations and communities. This form of social exclusion is not unknown on the labour market; some ‘closed shop’ strategies or forms of ethnic discrimination are illustrative.

The third point of reference concerns societal structures and processes. The central question in case of societal fault lines is whether society as a whole or important areas of it are divided into subsocieties. Illustrations are the dual labour market or the increasing opposition between ‘earned’ income versus ‘welfare’ income, in terms of power and status.

1.1.2 Social inclusion

Inclusion, as with social exclusion, is a multidimensional concept. A high density of co-operation within the group, a strong identification with the group, and a large set of shared values and orientations are usually taken as signs of inclusion. Active participation is also a crucial issue; it implies a socialisation process, which incorporates individuals and groups at different levels of society. These
forms of social inclusion already refer to more than mere bonds between the individuals and include relationships between individuals and institutions.

Inclusion in society takes place through different sets of roles. The first set is related to the roles that people adopt from their position as producers. The second set refers to their position as consumers. The third concerns their position as citizens and the fourth their position in different 'public' social networks (such as associations, but not family networks). It is commonly accepted that overall social inclusion is fundamentally rooted in labour market inclusion (or economic inclusion in a larger sense).

Different forms of social inclusion are present in these sets of roles: cultural, normative, communicative and functional inclusion (see also Landecker, 1951). Cultural inclusion is about the concordance between different cultural standards (such as between that of the labour market and that of the long-term unemployed or subsistence beneficiaries, or between the dominant culture and a so-called 'culture of poverty'). Normative inclusion refers to the concordance between these standards and behavioural patterns (does the 'management culture' of training initiatives exist just for the public eye or do trainers behave according to these standards?). How deep are common symbols embedded in society and groups and how widely are they accepted is what communicative inclusion is about? The degree of reciprocal dependence is the subject of functional integration: does the labour market need vocational training initiatives and is this the case for all types of vocational training? These forms of exclusion will underlie a number of discussions in this paper, particularly those in chapters 3.4, 3.5 and 3.6.

1.2 The labour market

1.2.1 Problems of specific target groups

The list of population groups affected by social exclusion is long, very long indeed. It includes larger or smaller sections of the elderly, the disabled, the illiterate, most of the homeless, people living in institutions (psychiatric wards, prisons), people living in ghetto-like neighbourhoods, asylum seekers, most of the long-term unemployed or low-skilled, and the poor in general. Their exclusion is the result of insufficient economic, social or cultural capital in one or more of the important societal domains: housing, health, social networks, income, and – last but not least – education and work. Being excluded from any of those fields generates problems, the more so if it is about exclusion from education or work. Overcoming any form of social exclusion nearly always implies external help, be it social work, special housing programmes, special training programmes or the creation of jobs adapted to the particular skills and handicaps of the persons concerned.

Target groups with respect to the labour market refer to persons who have a considerably smaller chance of finding a job; if they succeed in doing so, the jobs they access are usually marginal ones. Their marginal character refers to characteristics such as employment insecurity, low pay, bad working conditions, low degree of social protection, very high flexibility or low degree of unionisation; in short, characteristics of the secondary labour market. Target groups thus are 'groups at risk' and have been identified on the basis of numerous analyses of statistical, administrative and other databases. It is not our intention to reproduce these results in detail; we suffice with a general picture. We will, however, elaborate on some of their specific problems.

The usual criteria for defining risk groups regarding the labour market are: gender, age, educational level (or level of qualification in general), household status, nationality, occupation, and economic sector. The groups at risk then are younger or older employees, women, the unemployed in general and the long-term unemployed in particular, the low-skilled, early school-leavers, sick or disabled persons, people on means-tested benefits, political refugees or asylum seekers and ethnic minorities in general; they may also be combinations of these subgroups. The 'poor', for example, are disadvantaged in many respects.

Although these people form a heterogeneous group, most of them have one common char-
acteristic: low educational and skill level. This common characteristic, however, presents itself in many forms. Let us mention an inadequate knowledge of the native language (migrants, asylum-seekers), obsolete vocational skills (older workers, the long-term unemployed), lack of work experience (the young and, again, the long-term unemployed), and loss of appropriate work attitudes. The loss of appropriate work attitudes constitutes a particular handicap that is often underestimated. Indeed, it usually takes a rather long period to familiarise the target groups with things such as sticking to time schedules, meeting strict requirements, integrating into a team, accepting authority, and concentrating on one task for a longer time.

Next to these handicaps regarding job requirements, a series of other deprivations outside the work situation permanently threatens their work capacities. Bad housing conditions, bad health and insufficient health care, family problems, household responsibilities (for women), and (ethnic) discrimination are just some of the many factors that could be mentioned in this context.

Only a few Member States retain women as a target group for training measures (Joint Employment Report, 1997). In Luxembourg, several training programmes which focus on women (including women returnees) have been created. In the context of the European year on lifelong learning, a special project for (young) women was established. In Ireland, 'back-to-work skills' are provided for women who have been out of the labour force for a long period of time. The integration of women returnees is also a priority in Austria, where more than 7,000 women found a job through career guidance courses, skill training opportunities and employment projects.

Of course, not all of the socially excluded are target groups for vocational training, although most of them would benefit from some form of training. Later on, we will discuss target groups for training that are expected to reintegrate into the labour market, either the dominant one or some alternative labour market ('social economy').

1.2.2 ‘Social economy’

When can a certain activity be labelled as ‘social economy’? The classical definition of the social economy is that it ‘brings together the economic activities generated by co-operatives, mutual insurance organisations and associations with the following ethical principles:

- service to the members or the community rather than profit;
- autonomous management;
- democratic structure;
- priority of labour and people over capital in the sharing of profits’ (Defourny, 1997: 51).

The definition of newer forms of social economy, as they have manifested themselves over the past few decades, is a combination of criteria from the above classical definition and of new elements. The latter can largely be inferred from historical developments, and more particularly from the renewed interest in the 1970s.

First of all it could be stated that the initiatives in the ‘new social economy’ should reasonably not belong to the ‘established’ social economy. In addition, the organisations are to be involved in an economic activity and should neither belong to the public nor to the private sector. This positioning of the social economy vis-à-vis the private profit maximising market sector, on the one hand, and the public sector, on the other, remains one of the most important identifications of the third sector. In contrast to what happened in the 19th century, the social economy of today does not want to take the place of the capitalist system, but would like to function in a complementary manner (Monzon Campos, 1992: 25).

Beside their economic objectives, these organisations wish to accomplish social objectives. These objectives are related to the problems generated by classical economic models that apparently cannot be solved by the public sector. The issue here is a shift in sectors where new needs have arisen. The ‘old sectors’ where the social economy attempted to meet needs
were as follows: savings and credit; social housing; consumer goods; social and medical care; culture, information and press; mutual and co-operative insurance; and employment. The needs of today, however, are to be found in different sectors: ethical savings and investments; renovation; recycling; new care needs; and employment. Present initiatives undoubtedly focus most of their attention on the unemployment problem by creating employment and taking special care of people in high-risk groups. In the industrialised countries a rising number of co-operatives and associations are being established with the aim of social integration through labour. This employment creation is also often linked to environmental objectives by the pursuit of environmentally friendly production processes, products, and integrated environmental protection. This is how the new social economic sector of nature conservation, recycling, and renovation came about. Depending on the problem that needs to be solved, the nature of the social-economic organisation varies, although certain problems can be tackled simultaneously. In this way, the social economy has absorbed a number of functions from the public sector, which is increasingly withdrawing from certain areas of social life.

A second characteristic that has clearly been placed to the fore is the local nature of the activities, although this feature is not really new. In spite of increasing economic internationalisation, the third sector remains primarily rooted in local or regional initiatives. This is a response to the call for local identity and solidarity as a result of that globalisation. Through their ties with new or old social movements, initiatives are chiefly started from the base. This also results from the need for influence on the production process and the need for transparency, which led to the foundation of numerous consumer organisations. The relationship with consumers is also given special attention by the newer forms of social economy.

In addition, the new social economy has kept a number of criteria of the classical definition. First of all, service to the members or the community is still taking precedence over profit making, and there is a related priority of labour over capital. The pursuit of a democratic structure is considered equally important. Because most of the organisations are created from the base, it can also be assumed that the principle of management autonomy is preserved, even though it will appear that contemporary forms of social economy often do not match this criterion. According to international discourse on the subject, the legal form of the initiative is of lesser importance in the contemporary forms of social economy than in the classical forms (Westerdahl, 1998: 197), even though the organisations concerned have a strong tendency to assume certain forms of legal incorporation.

On the basis of the above definitions a number of questions can be formulated, which should allow us to distinguish social economic organisations from other organisations. Is the organisation concerned engaged in economic activity? Is this activity situated between that of the private sector on the one hand and that of the public sector on the other? Is this activity linked to social objectives? These objectives can be related to a number of factors: (un)employment; social integration of the socially excluded and the poor; ecological objectives; the provision of services that respond to a pressing individual or collective need, neglected by the public sector; durability of production quality; or a combination of these objectives. Does the realisation of these objectives take priority over making a profit and does labour take priority over capital? Is there management autonomy? Is there an endeavour to establish a democratic structure? Is any attention paid to transparency and the quality of relationships? Was the organisation founded bottom up? Does the organisation assume a legal form typical for the social economy (cooperative society, mutual insurance organisation, non-profit organisation, registered charity)? And finally, in order to be able to distinguish the classical from the new social economy: Does the initiative belong to the 'non-established' (or new) social economy?

Depending on the number of positive answers to these questions, an initiative will be further from or closer to the ideal type and thus to the core of social economy. Social economic organi-
sations are therefore ‘different’ from the other two sectors in relative and not in absolute terms (Seibel and Anheier, 1990: 12). Also, the criteria were more or less formulated in order of importance. It should be clear that an initiative that does not match the first criterion, does not belong to the ‘third sector’ at all.

1.3 Training for the labour market: a typology of relevant training measures

As discussed in the introduction, we are focusing on training of a vocational nature provided by external training organisations to persons who are out of work. Training at the workplace is taken into account insofar as it is linked to external training courses. Initial vocational training thus is not considered in this contribution for two reasons. It would widen our target population too much. Indeed, although youngsters on initial vocational training possess a number of characteristics that are typical of risk groups, they still have the capacity to prevent their exclusion from the labour market. Moreover, the introduction of initial vocational training would increase the institutional and programmatic array of our field of research to such an extent that it would become unmanageable. We prefer to focus on more acute situations of exclusion.

External training courses for excluded people are usually designed and managed by organisations that do not offer permanent jobs themselves; that is, except for social economy initiatives. Given the type of training that is needed, the provider then acts as an independent training centre. At best, the training initiative focuses on a certain sector but mostly, there is no direct relation with a specific enterprise. This does not prevent training being organised within a particular enterprise of the sector that is targeted by the training, such as hospitals or related institutions in a programme to train ‘logistic health assistants’ for example. In many cases, the accumulation of problems in the target group requires training in many respects: work attitudes; vocational training; work experience; and sometimes even literacy training. This means the planning of a ‘trajectory’ or ‘pathway’ with successive periods of training, coaching, teaching or practical experience, of using the tools of work, either at the training centre or in the work situation. (European Commission, 1997: 85)

Training in a work situation is less relevant for excluded people, except for social economy programmes. It means that training is organised in an environment that largely resembles the likely place of work of the future; this environment may even be simulated. Training in a work situation possesses a number of specific features. It often includes practical experience using appropriate tools. Often, it is very specific to the future work of the trainee. Its primary purpose should be the development or improvement of skills. In the case of a ‘social economy enterprise’, however, it also contributes to the enterprise’s output. In this case, however, the enterprise itself can be considered to be a ‘learning experience’. Because social economy initiatives provide us with a stimulating context for vocational training initiatives, we will pay specific attention to them.

1.4 Exclusion from the labour market and from training programmes

Unemployment and exclusion from the labour market has been a major social issue in European welfare states for the past two decades. A first explanation lies in the fact that we have come to regard unemployment in a different light. In the 1980s, policy-makers tended to reduce the unemployment issue to a question of market trends. And even if unemployment was referred to as a structural problem, it was in terms of a mismatch in the labour market to which the appropriate schooling and training policies could formulate an answer.

Unemployment rates have always been unevenly distributed among different population groups. Crucial factors in determining the unemployment risk are gender, age, health situation, educational level, and ethnicity. These lead to an overrepresentation of women, elderly, disabled, lower educated and migrants in unemployment statistics. It was not until the late 1980’s, however, that policymakers came to fully recognise the structural
nature of unemployment and more in particular of the rather permanent exclusion of certain population groups from the labour market. That period was characterised by the phenomenon of jobless, and even job loss, growth. Besides of the recognition of unemployment as a structural and qualitative problem, a consensus grew about new fault lines and high-risk groups. It became clear that the poorly qualified were finding it the most difficult to keep their jobs, let alone to re-enter the labour market.

This large gap between high skilled and low skilled and the question of how to bridge this gap, is often called the ‘new social issue’ (Rosanvallon, 1995). Usually, the term is narrowed down to the question of how the growing group of poorly qualified and/or long-term unemployed people and individuals who are totally dependent upon income support can be re-involved or more closely involved in society, through the (labour) market or otherwise. Thus, the problem is restricted to the structural gap between predominantly highly skilled insiders and a (growing) group of mostly unskilled outsiders. Training, in this respect, is seen as the ultimate instrument to bridge this gap.

### 1.4.1 The recruitment behaviour of firms as a factor in selection processes

Reasons for this uneven distribution of labour market exclusion have been looked for at both the supply and demand side of the labour market. On the demand side, recruitment behaviour of firms has been the subject of much research. Main conclusions have become part of the theoretical framework of labour (market) sociology. A useful framework to understand the relative importance of these factors and their interrelations, is that of the segmented labour market, such as the typology developed by Mok (1994). Selection processes that lead to social exclusion will take place mainly within both the internal and external secondary labour market segments; the firms’ recruitment behaviour will be different according to whether the internal or external segment is involved. This is so because the type of jobs, and thus the type of workers the firms are looking for, are different in both segments. The secondary internal segment is made up of lower skilled operational staff whose knowledge is largely based on workplace experience. This segment is very sensitive to technological developments. These have resulted in a decreasing demand for specialised workers. Since the supply remains high, employers possess a high degree of choice. The secondary external market is populated with an even weaker set of population groups: marginal workers who lack specialised vocational skills and who have been stigmatised by social or physical handicaps.

Phenomena such as ‘statistical discrimination’ and ‘crowding’ are frequently used as mechanisms for selecting workers in both segments. Statistical discrimination refers to the fact that employers do not employ certain categories of workers because they suppose that they are less productive or do not show the behaviour pattern that is expected, because of their ethnic characteristics or gender. These characteristics thus become stereotyped and are used as arguments for not employing migrant or women workers, irrespective of their individual capacities.

Crowding (or vertical segregation) is rather typical of recruitment behaviour regarding women. It is based on certain stereotypes regarding women (emotionality, lack of dominance, manual dexterity, moral behaviour) and leads to a negative selection, directing women to less qualified jobs and obstructing their access to more desirable jobs.

Labour market research also has illustrated a third mechanism; that employers prefer workers that already have a similar job over unemployed workers. This has been compared to a train in movement: it is easier to move from one compartment to the other than to jump on the train. The long-term unemployed are particular victims of this mechanism and are the more so, the longer they remain unemployed.

A more general factor is that of ‘social closure’, which is operated not only by employers but also by workers and their organisations that are already ‘in’. Access is limited by defining
conditions of entrance that are not related to
the job capacities that are required. These
conditions can be formal (diploma, age, uni-
ionisation) or informal ones. The latter relate
to personality or attitudes.

Substitution effects are another important
element. With the recent return to higher and
sustained growth figures, the related im-
provement of the labour market and policies
that are supportive of the reintegration of low
skilled workers into the labour market (acti-
vation, reduction of the labour costs of lower
paid employees), however, these effects seem
to become less important. These developments
have had an impact on both the substitution
of the lower skilled in their jobs by higher
skilled personnel, and the replacement of the
lower skilled through machines.

From this brief review of the recruitment be-
avour of firms, it should become clear that
it is not sufficient to increase or to amelio-
rate the human capital of persons excluded
from the labour market. More structural and
institutional barriers are at stake in overcom-
ing the gap between ‘out’ and ‘in’ in the la-
bour market.

1.4.2 Trapped between unemployment
trap and training trap

Traditionally, poverty policies have discussed
how to avoid the ‘poverty trap’, which prohib-
ited escape from poverty because of the at-
tractiveness of subsistence income and related
poverty schemes compared to the alternative.
Lately, the focus has shifted to a comparable
‘unemployment trap’. In general, the unem-
ployment trap refers to the fact that an unem-
ployed person is not significantly better off
when he takes up a job, and sometimes is even
worse off. The factors that account for are,
firstly, the relationship between wage and
unemployment benefit or subsistence income.
Sometimes, the worker also loses related ben-
efits such as higher family allowances or lower
tax impositions. Finally, additional costs, such
as travel or child care, often reduce the im-
provement in income obtained by the shift in
status or even offset it totally. The question
remains whether the non-financial dimen-
sions of a job, as listed in Jahoda’s ‘latent dep-
rivation model’ (Jahoda, 1982), are enough to
compensate for the absence, or low level, of a
financial stimulus. Specifically, this refers to
the labelling the unemployed as compared to
the status of having a job, in combination with
socio-psychological impacts of unemployment,
the obsolescence of skills and the disappear-
ance of work experience and work attitudes.
If the total advantage is insufficient to stimu-
late the transition from unemployment to em-
ployment, unemployment beneficiaries are
trapped in their unemployment. This unem-
ployment trap may imply a poverty trap when
both unemployment benefits and wages are
insufficient to guarantee a subsistence in-
come. This is supposedly the case at the lower
end of the US labour market, where even a
double income sometimes does not suffice to
obtain a decent level of living.

A similar effect has been found when target
group individuals taking up training courses
are worse off, at least financially, than when
on benefits. We could call this the ‘training
trap’. When benefit is supplemented with earn-
ings from informal or black work, training can
lead to a substantial income loss. In short,
sometimes a financial stimulus to take up
training is absent and the person on a mini-
um income scheme or on unemployment ben-
efits is trapped in his/her jobless situation.

Even if training allowances are provided, how-
ever, other financial constraints remain. Par-
ticipation in training programmes could be
considered a ‘risky investment’. Indeed, train-
ing implies an investment because partici-
pants have to meet a number of expenses
(such as transport, childcare, learning mate-
rials) and are at the same time expected to
postpone job-seeking activities. Moreover, a
‘deferred gratification pattern’ is usually not
one of their characteristics. At the same time,
training carries a risk because the outcome
is far from certain. This is particularly so in
periods of low economic activity and high un-
employment.

On the other hand, remuneration while in
training can not be too high. In that case, the
inflow into training programmes would be
very much stimulated but outflow from train-
ing to a job would be obstructed. This perverse
effect is usually avoided by the fact that training schemes are limited in duration and accessibility. However, both considerations imply that an adequate remuneration while in training means that both the ‘unemployment trap’ and the ‘training trap’

2. Labour market policies and training policies need coordination

Why is coordination so important in this matter? Society has become more differentiated and therefore more complex; vocational training and labour market policies are embedded in these developments. The structural nature of long-term unemployment, the gap between skills and schooling, new forms of social exclusion, the number of actors involved and the shifting balance of power between them, the development of new policy instruments, the definition of new policy objectives, the call for ‘inclusive’ policies and for integrated ‘trajectories’ or ‘pathways’ for the target groups are but some of the relevant developments. All in all, it is possible to identify four types of this increasing complexity (differentiation) and of the resulting need for (more) coordination. They are the result of the combining of two dimensions. The first refers to the axis vertical/horizontal, the second to the axis actors/fields. The table provides an illustration of the four types.

In the end, these aspects can be subsumed under two types of coordination: ‘inclusive policies’ and ‘governance’. The former is in the coordination between sectors, especially between the so-called ‘soft’ (training) and ‘hard’ (employment) sectors. In Belgium this has led to a debate about the need for ‘inclusive’ policies. ‘Governance’ is mainly about the coordination between agencies, institutions, and programmes in the administration of policies. Coordination is particularly considered a problem in the field of social policies because of the many institutions and agencies that are active in the field. The number of relevant decision-making levels (European, national, regional, and local) particularly increases the need for crossovers between policies.

Let us first discuss the vertical dimension of coordination and continue with the horizontal dimension. Policies often are strongly top-down in character. Recently, new programmes have given more autonomy to local authorities. Ideally, central government should develop the general policy framework and define objectives; this policy should then be implemented and realised at the local level, through partnership with private agencies and by choosing means adapted to the local situation to achieve the identified objectives. Results then should be evaluated by central government.

NGOs (non-governmental organisations) are important providers of different kinds of vocational training. They are largely financed from national, regional or local public authorities and they often are obliged to act in accordance with the regulations of these authorities, especially regarding labour exchange, unemployment provisions and other labour market regulations.

In a recent comparative research report, Frade and Darmon conclude that, with regard to the organisations providing training, a considerable shift in the status of these organisations has taken place: from the public to the private and/or voluntary sector. Furthermore they notice the increasing introduction of competition in the sector, in the form not of a proper training market, but of quasi or pseudo markets differently defined according to the rules for tendering (Frade and Darmon, 1998: 1).

---

1 This means that three traps have been identified: the benefits/training trap, the training/job trap, and the benefits/job trap that is more than just the sum of both former traps.

of higher targets with fewer and stricter controlled means that cannot be used as flexibly as is needed, given the target groups' characteristics and needs. Some experiences suggest that NGOs must often take on the responsibilities of (local) public authorities that are often more concerned with obtaining their full share of available funds and then spending it, not on new projects, but on their regular activities.

Sometimes, actors from civil society oppose the public authorities' idea of what vocational training policies should and could be. This can be explained by the fact that they possess the professional capacity and do most of the work, whereas the other side gets the money. NGOs however, at least not the ones that are active in training, do not control the levers of power. Some do, such as pillarised organisations. The plurality of these welfare organisations and their different organisational interests adds complexity to coherent planning and coordination and common initiatives.

Decentralisation is primarily a vertical process, influencing the way in which policies are formulated: from the top down or from the bottom up. However, it has an important horizontal dimension: it necessitates (better and more) coordination between authorities, public services, social partners and NGOs at the local level. This coordination is complicated by a large variety of institutions and agencies operating at an intermediate level; these are public, semi-public and non-governmental organisations. Do local authorities have the powers for this? Does the central (regional) government offer new possibilities to local authorities so as to develop more autonomous policies, or are local authorities rather used as an instrument to get more grip on the heterogeneous and incoherent field of initiatives?

What is the position, the role of the 'regular' (subsidised) private welfare sector in these programmes? With concepts such as 'policy networks' and 'inclusive policies', some participants try to structure the new framework that has emerged from the recent changes in institutional relationships and the socio-economic conditions.

The crucial question is how the different actors co-operate in order to achieve a coherent policy with common objectives, a coherent set of measures and a smooth partnership between the different actors.

Two levels can be distinguished: the policy level and the service level. For each level we have to define the coordination objective separately:

Approaching vocational training policies from the point of view of coordination (between different fields, between different levels) helps us to identify several crucial problems. We mention the most important ones:

2.1 Coordination or 'creaming off'

One of the problems is that the success rate of policies and projects is often influenced by the fact that the long-term unemployed and other disadvantaged groups are not only marginalised in the labour market. They also are at a disadvantage in selection for re-integration programmes, and thus further excluded from the labour market and society as a whole (Nicaise et al., 1995: 70-82; O'Connel, 1997: 122, 135).

A bottom-up approach that focuses on the most marginalised groups (people on means-tested benefits) should enable us to find examples of good and bad practice. These refer to measures that have been taken in order to promote access for these groups to the different programmes, or to examples of why this access is not successful in employment measures that should be accessible to people on means-tested benefits.

2.2 Coordination or a lack of continuity

The majority of the people receiving means-tested benefits have been excluded from the
Selection, social exclusion and training offers for target groups

(primary) labour market for a long time. They were excluded because of their lack of skills and during the – sometimes extended – period of exclusion, they added a number of other deprivations. They have lost their self-confidence, family problems have arisen, often resulting in psychological problems. Strategies that were developed for coping were perhaps very effective for non-labour market issues, but constitute a problem for getting a job. Thus, diverse inputs are necessary to redevelop their employability and reintegrate them into the labour market, such as work ethic and work attitudes, vocational training, on-the-job training, work experience. A crucial question concerning coordination, therefore, is whether these different activation measures can be integrated into a coherent pathway or trajectory for the participants. Are the different measures meant for promoting re-entry to the labour market sufficiently complementary in time and content? Are perverse effects identified and taken into account? Important perverse effects are the ‘unemployment trap’ and the lesser-known but even more important ‘training trap’. A bad trajectory from labour market exclusion to labour market inclusion gives participants the impression that they are turning around in circles or ‘invites’ them to step out of the process and return to their former state.

An important problem for many participants in vocational training is the lack of perspective: training or some work experience is offered for a certain period (a number of weeks, months, and sometimes one or two years). During this programme, or at its end, a number of participants find their way (with or without guidance) towards the labour market. Another group of participants, however, is not able to bridge this gap or is unable to remain in the labour market. Their only perspective seems to offer a return to unemployment schemes or means-tested benefits.

### 2.3 Coordination or perverse effects (unemployment and training traps)

Coordination between the different benefit schemes and employment and training programmes is crucial to avoid or reduce unem-
ployment and training traps. These traps should not be restricted to their direct financial impact; they also include the indirect financial consequences of taking up a job and the social and socio-psychological facets of this change in status (see above). We are referring to the status of the job offered, the work satisfaction, the trade-off between care for children or parents and the income and status that accompany a job. These non-financial dimensions do not always aggravate the gap, they sometimes compensate for an insufficient income gain or even for an income loss.

2.4 Coordination with other services

Employment services traditionally care for the unemployed, social services for people on means-tested benefits. The reason for this distinction is that people on means-tested benefits usually are not considered to be fit for the labour market. Moreover, employment services often are linked – directly or indirectly – to a logic of contributions, whereas other social services are financed from general revenues (taxes).

Recently, social services have become increasingly involved in employment programmes. Coordination between these two government services is crucial. Furthermore training and employment programmes are often realised in cooperation with NGOs. In this case coordination becomes even more important.

2.5 Coordination at the local level

The local level often is described as the only one at which coordination is realised in a more substantial way rather than just formally. The reason is that the local level is the meeting point for concrete actions by different actors (clients and providers) and programmes; it is the level that relates directly to the level of practices. This means that the results of efforts to coordinate immediately become visible.

In many European countries this level has become more important in the fight against poverty and also in the development of local employment policies. Another aspect is that the NGOs have become more prominent because of recent welfare state developments. These provided them with the means to keep, and to increase their hold on, numerous aspects of the citizen's life. Government subsidies and private initiative go side by side in a number of fields. This means that a relatively autonomous field of 'training and employment programmes' has developed from private initiative but it survives thanks to support from public authorities. Private initiative and public subsidy often form a particular relationship. Formal policy objectives are often adapted under practical pressure and power relationships. Recently, many initiatives, agencies, and projects have developed outside the traditional structures or are only loosely related to them.

This often creates coordination problems on two different levels: between the policies of the central or regional government and the local authorities, and between local authorities and other local actors (NGOs). To start with the latter, the training initiatives we are discussing here were often initiated by small NGOs. Once they became successful – partly due to the structural character of high unemployment, partly to the innovative ways that training was organised and inserted into local social and economic networks – local authorities tried to recover these initiatives. They have a number of levers to assist this aim, such as control over the input of clients (unemployed, social assistance beneficiaries).

Public authorities at higher institutional levels want to maximise the input of funds, at the same time exercising a degree of control over local training initiatives. They promote new institutional arrangements and partnerships. One strategy is the promotion of institutional coordination. Other strategies include the redefining of the institutional and legal framework, the introduction of new incentives (such as output ratios) or the creation of new institutions that act as 'gatekeepers' in the local network. Special funds intended to combat poverty and social exclusion at the local level – such as the 'social impulse fund' in Flanders or the 'big cities’ programme in the Netherlands – can bring about a new relationship between the central and local levels. At the
national and regional levels, new forms of co-
ordina­tion has been established. Initiatives of
this type imply some kind of contract between
the different levels. The existing legal and in-
stitutional framework, the hierarchical and
bureaucratic structures of the public sector and
rooted traditions, however, can create barri-
ers to institutional cooperation.

In order to achieve good collaboration, certain
conditions need to be fulfilled. The different
measures offered or proposed, the obligations
they imply, and their interrelationships
should be clearly defined. From the point of
view of the clients, it should be known if these
measures are coherent, and that the differ-
ent actors and/or organisations involved are
not using opposing logic.

Several aspects are relevant to evaluation of
training measures from this point of view. We
mention:

a) the financial consequences of participation
(or non-participation) for the beneficiary,
including access to or loss of secondary
rights;

b) prospects or perspectives for the future
after participation; access to other pro-
grammes, measures or jobs, including the
degree of personal choice in participation;

c) the impact on forms of ‘social inclusion’
including the reduction of psychological
consequences of isolation, the development
or strengthening of social networks, the
adaptation of the (working) environment
to the specific problems and characteris-
tics of the target groups.

Coordination then should be seen as a condi-
tion for successful initiatives linking voca-
tional training to employment, and from the
point of view of the beneficiary or participant.

This includes:

a) coordination at the policy level;

b) and coordination at the service level;

c) in order to guarantee to the participants;
d) a coherent supply of vocational training ini-
tiatives;

e) which improves their situation (financial,
social, personal, employability);

f) and provides a real prospect of integration;
g) in collaboration with all other relevant ac-
tors and institutions.

In other words, neither the existence of dif-
ferent coordination initiatives, nor the ques-
tion of the identity of the service-provider, is
in itself relevant; the results are, certainly
from the point of view of the beneficiary. Only
if the result is a coherent and well coordinated
set of measures for the clients does the or-
ganisational setting offer an example of good
practice. If the result is not coherent from the
point of view of the participant, whether or
not coordination initiatives have been taken,
the measures will be considered as examples
of bad (or insufficient) practice.

A last but important point is the question of
whether coordination was a policy objective
in setting up the programme or organisation,
or whether local or other actors took on that
responsibility on their own, in order to meet
an existing need. We are interested to know
if, in the programme or the organisation,
someone is made responsible for the coordi-
nation aspects and why (not).

3. Exclusion from training
programmes

Participation and non-participation in train-
ing schemes is influenced by the same set of
variables that, in the same way, determine
exclusion from the labour market in general;
gender, educational level, age, ethnicity,
health situation. The following groups are
underrepresented in training programmes;
women, the lower educated, the older unem-
ployed, the migrants, and the disabled. In
short, certain groups of unemployed to be
more excluded than others.

4 This chapter will mainly be based on Darmon and
Frade, 1998, pp.69 en; Nicaise et al., 1995, pp. 146.
Exclusion from training offers for target groups and its causes can be studied from different perspectives: an institutional, an economic, a psychological, a socio-cultural and a policy perspective (see Nicaise and Bollens, 1998: 121-153). The institutional point of view explains how people are excluded by not complying with administrative selection criteria; being officially registered as unemployed, the minimum duration of unemployment and additional criteria. The need for economic efficiency obviously constitutes the most important single factor of exclusion from training programmes. Stricter funding frameworks seem to result in processes of creaming-off the target group. From a psychological point of view it is the non-correspondence of training provisions to the needs and motivations of the unemployed that mainly cause exclusion. These psychological factors – needs and motivations – will be illustrated by different typologies of the unemployed with regard to their motivational level (see paragraph 3.4).

The cultural factor has been somewhat underestimated in these processes of exclusion and inclusion with respect to (selection for) training offers. Indeed, the process (sequence) of 'input-throughput-output' of target groups in training initiatives carries an important but underestimated component of cultural confrontation. This can be subsumed under the question: how do training initiatives succeed in overcoming the confrontation between the target group's 'culture' and that of the dominant labour market (we are not referring to 'social economy' initiatives'), if, indeed, they aim to bridge that gap. In this part, exclusion through cultural clashes between the dominant culture of the training staff and the subculture of the unemployed, will be discussed.

In the last paragraph the effects of general (labour market) policy with respect to exclusion from training programmes will be discussed. From this policy point of view, attention will be paid to the recent trends in policy. Among them are budgetary constraints, activation in labour market policy, decentralisation, the emphasis put on a preventive policy by the European countries and the 'hot topic' of the unemployment trap.

3.1 Exclusion through selection procedures (institutional)

3.1.1 Who is entitled to participate?

Administrative criteria

Eligibility for training programmes not only depends on a person's position in the labour market but also on more general characteristics, as is shown by training for immigrants, drug addicts, disabled people, social welfare recipients, ethnic minorities, or gypsies. With respect to labour market position, three main categories can be identified: persons employed in the regular labour market, persons employed in the black labour market and the unemployed. There are, however, important subdivisions within each category. A first type within the first category is the employed who work full-time in the formal or regular labour market, which is supposed to be the ideal labour market situation. In a lesser position within this category of the regularly employed are those who work part-time. Those who are engaged in temporary employment, seasonal employment, homework, or other kinds of atypical work constitute the third category of the employed in the formal labour market. These forms of atypical work are not necessarily informal jobs or illegal/black market activities. Jobs within this informal or 'black' labour market are not regulated or protected by work legislation or other forms of social security and suffer from poor working conditions. On the other hand there are the unemployed, with one group that are registered as such and another who are not. The registered unemployed, in turn, can be entitled to a benefit or not. Schematically the following labour market positions can be discerned:

- full-time employed in the formal labour market;
- half-time employed in the formal labour market;
- employed in the informal labour market;
- registered unemployed entitled to a benefit;
- registered unemployed not entitled to a benefit;
- unregistered unemployed.
3.1.2 Officially registered unemployed

In most European countries only one of these six categories is able to participate in a training programme: the registered unemployed entitled to a benefit. Although there seems to be a recent trend to open up training initiatives for social assistance beneficiaries in some countries, most of the training programmes focus on the officially registered unemployed only. This is a consequence of the way in which labour market programmes are often closely linked to the social benefit system. Only when an individual is allowed to claim an unemployment benefit can she or he gain access to training programmes with the aim of reintegrating them into the labour market. As a consequence the most vulnerable groups – those employed in the informal labour market, the registered unemployed not entitled to benefit, and the unregistered unemployed – are excluded from the programmes.

In addition, this group of unregistered unemployed seems to grow every year, causing most European countries feel the need to brighten up their unemployment statistics regularly. This is less the case for countries that have a limited duration for entitlement to unemployment benefits, because most individuals are no longer registered as unemployed after the termination of their period of entitlement. In other countries, the official unemployment count has been subject to all manner of artificial intervention in order to avoid further inflation of the unemployment rate. This means that a number of people who would, under other definitions, belong to the category of registered unemployed receiving benefit are referred to other categories that are ineligible for programmes designed to combat exclusion from employment. Single parents in the UK, the ‘disabled’ in the Netherlands and the older unemployed are examples of groups that are considered as being out of the labour market (Nicaise et al., 1995). Their total number is regarded as ‘global underemployment’, which can be estimated in Belgium, for example, at about double the number of the officially registered unemployed.

In addition to this, vulnerable people can also be found in the category of those already engaged in paid labour (Beweging ATD-Vierde Wereld, Lutte Solidarité Travail, 1998). The intensification of international competition has led to a growing need for labour market flexibility. Flexibility of the organisation of production seems necessary in the face of technological change. Flexibility of workers is expressed in terms of multi-skilling or mobility from task to task; flexibility of jobs, in terms of ease of hiring and firing or of changing working hours and the upward and downward flexibility of wages (Delsen, 1995). This flexibilisation trend results in an increase of atypical employment relationships. These differ from the traditional model of employment relationship, which was characterised by the fact that the worker had only one employer, worked full time on the employer's premises and was expected to continue doing so indefinitely. Part-time work, labour-on-call contracts, fixed-term contracts, seasonal work, agency work, home-based work, telework, freelancers, self-employment and informal work all are forms of employment that deviate from full time open-ended wage employment. Many of those who engage in these forms of flexible labour do not have a secure status within the work force but occupy only a marginal position: they are lowly paid and do not enjoy legal rights or social status arising from their employment (Alcock, 1997: 259). These individuals are unable to take advantage of most labour market programmes because they are considered as 'employed' although the employment is inadequate because it is marginal. It can be expected that this group will keep on expanding in the near future because of the growing need for flexibility.

---

5 For those working in the formal labour market (other types of) training programmes are also accessible but they are less relevant with respect to the theme of social exclusion and therefore they will not be discussed in this contribution. This contribution will focus on those training programmes that strive for full-time employment in the formal labour market for their trainees, a position which is already being achieved by the category of full time working people in the formal labour market.
3.1.3 Minimum duration of unemployment

Except for being officially registered as unemployed, a candidate has to comply with a number of other administrative criteria before he or she is able to participate in a programme. In particular, all those who are funded by public authorities (local, regional, national or European) have to comply with a minimum period of unemployment. Two opposite goals are at stake here. On the one hand, the longer the required minimum duration of unemployment, the lower the threshold for weaker groups since they do not have to compete with better trained groups. If the minimum duration of unemployment is put at one year, it is very likely that a training provider will prefer someone with the minimum period of unemployment to someone who has been unemployed for over two years. As a consequence the (unequal) competition for those unemployed for two years is reduced when the minimum period of unemployment is fixed at two years. So, the longer the minimum period of unemployment, the less those with the longest period of unemployment (the most vulnerable) are excluded. On the other hand, these face the risk of being labelled since they become more visible through their participation in specific programmes.

The answer to this dilemma seems to be to offer training for all after a short period of unemployment, as for example proposed by the Commission. Early intervention could prevent the occurrence or increase of a number of problems, such as loss of work experience, interiorisation of a negative self-image, reduction of network, and loss of capacity. Problems here are the dead-weight effects, since the probability for a short-term unemployed to become a long-term unemployed cannot be predicted, so that limited resources could have been spent on persons who would anyhow have reintegrated the labour market before the end of the training programme.

If access to training programmes is linked to the time a person has been registered as a beneficiary (to unemployment benefits), other problems arise. If the period referred to is a period of uninterrupted unemployment, then each interruption starts a new period of unemployment. A person with short spells of employment between longer and frequent periods of unemployment will never reach the threshold. He is, in a way, handicapped by his eagerness to find a job and by his success in doing so. This concept of taking into account not only the last period of unemployment but the (un)employment career over a longer period is very important. Empirical data do exist (in longitudinal surveys such as the ECHP) but have not yet been properly analysed. This becomes all the more problematic with respect to marginal workers who perform temporary or seasonal work.

In short, the mechanisms and criteria of labour market training programmes are related to the very foundations of our social protection systems: the meritocratic rules of access to continental social security are implicitly transposed into the reintegration programme. These criteria are tailored to the needs of the median (unemployed) worker: the full time, registered, healthy, insured unemployed (thus, the previously full-time, stable, healthy worker) (Nicaise et al., 1995).

3.1.4 Different selection criteria acting as a filter

Despite the maintenance of large public or quasi-public training institutions for the unemployed, training activities are increasingly provided by voluntary, private and non-profit (or ‘social profit’) organisations. They are funded by a mixture of public authorities; local, regional, national or European (see paragraph 3.2), which all put forward their own selection criteria. These criteria have to be met by the organisation in order to receive the payments of a given funding body. It is, however, often the case that the selection criteria of the different funding bodies are not concurrent or are even in opposition to each other. In this way, a double/triple/quadruple filter is being created, depending on the number of sets of criteria put forward by the different funding authorities. As a conse-

Selection, social exclusion and training offers for target groups

The manager of a Flemish training provider organisation, studied within the CASEL project (Darmon, Frade et al., 1998) describes this problem very clearly:

‘(I: Are there different criteria imposed by different organisations?) R: These criteria vary according to the organisation that imposes them. But in the case of input criteria they are very different. Every organisation sets up its own requirements and you have to comply with all of them. As a consequence you have to create a lot of filters with respect to the participants. This means that you sometimes have to reject people whose ideas may fit perfectly within the organisation, but whose duration of unemployment is three days too short or too long or because they don’t fit in the right pigeon-hole. So, if you depend on three different financing institutions then it is as if you put three different sieves above each other and in the end nobody gets through them anymore.’

Selection criteria, imposed by who pays for the training – be it local, regional, national or European authorities – can be regarded as one (institutional) explanation for exclusion from training programmes.

3.2 Exclusion through the need for (economic) efficiency

Because of the general decrease in the funding available from public sources and the tightening up of the access to it, training providers are forced to organise training programmes in a cost-efficient way. Employment services in European countries are increasingly aimed at maximising the ‘penetration rate’ of the unemployed into labour market training programmes. The training programmes’ funding requirements and monitoring procedures are more and more based on targets, output-driven indicators of performance, stringent conditions of payment and other controlling devices. The evidence gathered as regards (un)employment and training policies in Europe, clearly shows that the greater the emphasis public employment officers place on the efficiency of the schemes they run, the more the people targeted – especially the most vulnerable – tend to be excluded from the schemes.

**Public versus private training schemes**

With respect to constraints coming from the funding structure, a distinction has to be made between public (governmental) institutions on the one hand and private (voluntary, local, non-profit, social profit) organisations on the other hand. The first – also chronologically – type of training programmes, provided by the public institutions, suited national and public policy to combat unemployment. They were aimed at teaching the job seeker skills and qualifications required by the labour market. The main objective was to combat unemployment as efficiently as possible by meeting an explicit demand for workers in a specific sector. Public organisations were getting paid by public authorities, who controlled and managed the budgetary means and financial resources to achieve this. As a result of this labour market orientation, the most vulnerable were often excluded.

Private, voluntary organisations were consequently created to compensate for the selection procedures applied in the public sector, by focusing on the most disadvantaged. Unlike public training projects, financial support from public authorities for private organisations is given in the form of a grant and comes from different administrations (local, regional, national, European) sometimes supplemented by alternative resources. Instead of a labour market orientation, the private organisations showed a job seeker orientation

In recent times, two important developments occurred. First of all there has been a shift from public to private or voluntary status (Darmon, Frade et al., 1998). Organisations have recently been created as voluntary or private bodies, whereas those with a longer existence sometimes have lost their status as public or ‘quasi-public’ institutions. Despite the maintenance of large public or quasi-public training institutions for the unemployed, training activities are increasingly provided by voluntary, private and non-profit (or ‘so-
cial profit) organisations. Developments in this private sector have been enormous in recent years and seriously undermined the previous monopoly position of the public-training providers. Secondly, those organisations which previously had a remit towards the most vulnerable – private organisations – have increasingly tended to direct themselves towards the better off, as a result of the increasing orientation of funding requirements towards output/performance criteria. The harsher the funding requirements, the more the most vulnerable are excluded from training programmes.

3.3 Funding requirements and the need for efficiency

In assessing the harshness of the funding framework (and thus the possibility that exclusion occurs in a given training programme) a number of crucial factors can be discerned. The extent to which these factors are present in a given funding structure will determine the harshness, and thus the effects on training provider organisations, with respect to exclusion from training programmes. In the following paragraphs, we focus on the development of an analytical framework that needs to be applied to a complete and comparable data set. The impression indeed arises from reading case studies that the situation differs internally in each country, according to the type of initiative, and that these differences are sometimes more relevant than the ones between countries.

3.3.1 Targets and creaming off

The most important factor in this respect is whether or not the funding is target-based. In target based training programmes, subsidies are directly linked to the number of trainees that find a job (and/or the number of people that engage in further education) after finishing a training programme. The organisations have to show results before they are paid. As a logic result of this criterion, training provider organisations do not have the urge to pick unemployed people who are the most disadvantaged or who have been out of work for the longest period of time. Instead, they will select those candidates that have the greatest chance of achieving the targets put forward by the funding bodies. The more the emphasis is placed on reaching targets, and the higher the targets, the tighter the funding framework. Compulsion from funding bodies is less strong, on the other hand, when a training provider organisation is subsidised on another basis, for example on the basis of past results, on the basis of the number of trainees participating in the training, or of the kind of training provided. This variation should first be analysed at the national level.

If the short-term return-to-work rate is used as a funding criterion, training providers will almost inevitably resort to a selection procedure oriented to the labour market, that is, focused on employability, on how job-ready the unemployed are. By so doing, providers expect to increase their success figures, above all the percentage of jobs obtained by the unemployed, which is the key for them to survive in a training market shaped by the funding frameworks. These strong selection procedures and a creaming off the target group to restrain only the most employable, can be seen as a natural reaction to the need for efficiency, enforced by the funding institutions. Creaming off can take extreme forms, such as subjecting potential trainees to medical, psychological and technical tests and by using assessment scales, whereby the way of selecting only the best people is further being improved.

The problem of rigid targets can be remedied through the use of differential targets. This means that when placement results are used to assess the effectiveness of an employment initiative, this has to be done on not in absolute but in relative terms. The number of people who have benefited from the programme should therefore be put in relation to those who did not benefit but who have the same characteristics as those who have.

3.3.2 Tendering and competition in the training market

Another factor that has an impact on the tightness of funding mechanisms is whether or not the funding is based on tendering and contracts. The establishment of new forms of pub-
lic expenditure, based on cost-efficiency, seems to prefer competitive tendering as a way of allocating public funds. On the other hand, the funding framework is less controlling when payments are made on the basis of an agreement between the training provider organisation and the funding institution. One-to-one agreements between public or private funding bodies (such as sectoral funds in Belgium) and training providing organisations also remain an important basis for funding. However, there seems to be a general trend towards public tendering processes which means that the training providing organisations are increasingly competing for public funds.

Whether funding is directly linked to the achievement of targets or not, all organisations, because they have to compete in the training market, are forced into marketing through placement rates. Indeed, even though targets may not be put forward by the financing bodies, private training provider organisations will try to increase the percentage of trainees that find a job after finishing the scheme. The trend away from public providers and towards the generalisation of public tendering processes inevitably increases the competition between training organisations to obtain 'scarce' public money. When subsidising bodies have to choose which training project to finance, this percentage is regarded as one of the most important – if not the most essential – indicator. To use this short-term return to work rate as a success criterion will lead training organisations and public services responsible for intake to use strong selection processes and creaming-off practices (Nicaise et al., 1995). Because of this competition for public funds among training providers, a training market has been created. This has resulted in the introduction of the need for efficiency and the assertion of a 'competitive advantage' in those organisations that were previously oriented towards the most disadvantaged. The involvement of the private sector in this search to secure funds has also resulted in increased competition and market strategies directed to employers. If the employers' view of the training organisation is positive the organisation can even take over the function of selecting and hiring possible employees.

3.3.3 Funding insecurity and short term solutions

Besides the impact of result-oriented funding, the period for which subsidies are given and the way in which subsidies are paid are important variables. In general, support from government is given in the form of a grant to be negotiated and renewed each year. Insecure and irregular funding, resulting from precarious contracts with public authorities, seems as problematic as the lack of sufficient funding for training organisations. This short-term funding very much reduces an organisation's capacity to work on the basis of a long-term plan. It also hampers its ability to react quickly to a changing labour market situation, be it on the part of the supply side (the job seekers) or on the part of the demand side (the employers). If training organisations are not allowed to build up reserves, they are totally dependent on what they receive from the funding bodies. As a result, delays with money transfers to local projects can have dramatic consequences for the organisation.

Financial insecurity linked to short-term subsidies also renders it very difficult for the organisation to find highly qualified staff. Contracts offered to the staff are only for short periods of time and their salary is much less than they can earn in other sectors of the labour market. The quality and qualifications of the staff, in turn, influence training programme results. Underpaid staff, or those with a precarious status, do not ensure professionalism and continuity. In addition, staff have to spend a lot of time and energy meeting all of the necessary requirements of funding bodies, looking for supplementary sources of funding and trying to gain control over their organisation's expenditure.

Short-term based funding has implications not only for the staff but also for the trainees. Funding only covers the training itself and is often inadequate to finance additional services that can be necessary to lead the trainee to the labour market. Because of the lack of money, organisations are sometimes unable to guide the unemployed socially or to develop and apply a trajectory. Follow-up care also has to be dropped in this case. If this results in
continued unemployment after successful completion of the scheme, the trainee is sometimes worse off than before the training. Consequently, for the unemployed, too, training can be a short-term solution.

3.3.4 Possibility of selection and ‘double bind tension’

The possibility of selection implies room for manoeuvre for the training provider and thus compensates for the tensions arising from a target-based funding framework. If this possibility does not exist, providers are expected to take on any person referred to them. When this lack of selection possibility is combined with the requirement to achieve certain targets, it can lead to a ‘double bind tension’. Indeed, training providers in such funding structures are bound in two ways: on the one hand they have to accept all those referred to them – including the least employable – and on the other hand they have to meet certain placement results. As a consequence organisations sometimes face a dilemma: either losing the funding (by not reaching the targets) and thus seriously putting at risk the survival of the organisation or reaching the targets and thus putting the unemployed at risk. The decision is often made at the expense of the unemployed, by prioritising the achievement of placement results. The problem with ‘double bind tension’ is not so much the creaming-off effect excluding the most vulnerable, as is the case when there is a selection possibility. It is the quality of jobs the trainees take up after finishing their training programme. A case study of a London training provider organisation within the framework of the CASEL study is a clear example of this kind of tension faced by the provider. Pushed by tight funding conditions they were paying trainees between GBP 100 and GBP 180 if they accepted a job, no matter how precarious this job might have been (Darmon and Frade, 1998).

In the end, it is important to identify the degree and kind of the ‘double bind’ character of funding frameworks. Is there a correlation between the type of selection, the type of training chosen and the forms and degree of social exclusion/inclusion? Indeed, the fact that every unemployed person has to be accepted can be a positive feature, but this is not the case at all when it is combined with rigid targets.

3.3.5 Range and kind of activities

In situations where there is a lack of funds and training initiatives are populated by volunteers, there is much more room for engaging in specific societal and political projects. Once the main yardstick in assessing the success of a training scheme is the rate of job placement, the training landscape changes drastically. Targets, combined with competition for funds in a very competitive market, encourages suspension of certain activities simply because the expected placement results cannot be met, even though these activities might have been crucial for the reintegration of certain groups of unemployed. Contract renewal is increasingly based on the previous years’ results and projects with ‘easier’ targets will be preferred. As a result, training projects are accepted if they fit with the organisation’s survival needs rather than if they are the most promising answer to the unemployed’s training needs.

Another result of this drive for efficiency is called, in managerial terms, product differentiation. This refers to a number of activities provided by the training organisation that are sufficiently differentiated. The trend is definitely towards larger organisations that cover a wide range of activities. They usually organise several or even all of following activities; basic education, training for job search, teaching basic work habits, vocational training leading to certified qualifications, advice and guidance, ‘social employment’ (protected employment, either temporary or permanent) and even constancy. The presence of an array of opportunities can mean that the selection threshold is kept lower, because alternatives are present within the organisation. Different training programmes are offered according to the degree of employability, differing in their effectiveness as to job placement. The distance between the unemployed and the labour market (employability) and between the training and the labour market seem to go together. In this way, the most
employable candidates can be directed to the programmes with the strictest targets, most directly linked to the labour market. Less employable candidates can be led to less directly work-oriented programmes (or even ‘social employment’) where target-based pressure is not that high.

3.3.6 Managerialism

Under the pressure of more and more stringent funding regimes, there has been a shift towards managerialism. Managerialism refers to the adaptation of training activities to stringent output-related monitoring, targets and indicators (such as ‘placement rates’). It is concerned with compliance with external procedures imposed by funding frameworks, with promoting the organisation in the training market and competing for funds. In a managerialist mode of organisation, the role of training managers is particularly difficult since they are responsible for making their project sustainable and they can be held responsible for that. The renewal of staff employment contracts is usually directly linked to the renewal of the contract by the funding bodies, and thus is very precarious.

The problem, then, becomes to combine the goal of ‘efficiency’ with more social considerations. The economic goal and the social goal are often regarded as opposites: the more a certain initiative attains its first objective of economic viability, the less it achieves the second one of reintegrating the unemployed, especially the most needy, into the labour market. The problem of unemployment is defined in managerial terms. It is about matching employers and potential employees, for whom the path to employment is strewn with all kinds of barriers. The unemployed and companies are considered as two ‘customers’ between whom no tension should exist since the goal of the training initiative it to match the needs of the one partner with those of the other. In that way, those who participate in training are seen as ‘products’ that can be delivered at the request of the employers. Are the unemployed to become – preferably good – ‘products’ that have to be delivered to the companies where jobs are available? If, however, these training organisations have to satisfy firstly their efficiency criteria, is not the social concern then threatened and consequently the position (selection) of marginalised groups/persons?

3.4 Motivation and (non-) participation (psychological)

In the selection of possible candidates it is not only the administrative criteria imposed by public authorities that play an important role. Most of the organisations have freedom to apply their own selection criteria. ‘Motivation’, in the meaning of the will to improve one’s situation, is the criterion that seems to be paramount importance for the training provider in selecting trainees. It is also a subject of discussion, for example, when complaints are made by training organisations for not being able to fill the vacancies in their training programmes. Are the unemployed not motivated anymore and do they not want to participate? How can non-participation in training be explained? And how can participation be fostered?

3.4.1 Typologies of motivation

With respect to the motivation levels of the unemployed, different attempts have been made to distinguish different groups of unemployed and thus to develop a typology of motivations. An attempt to develop a typology of the unemployed has been carried out by De Witte (1992). The author distinguishes five types of unemployed. The first group is called the ‘moderate optimists’ because their concern for work is only moderate, although most of them would like to work in the near future. Their expectations of finding a job are favourable and they do not have problems with respect to their situation of unemployment. They show a positive attitude towards labour market programmes, though they seem only willing to participate when it fits within their plan for the future. Their expectations of finding a job are favourable and they do not have problems with respect to their situation of unemployment. They show a positive attitude towards labour market programmes, though they seem only willing to participate when it fits within their plan for the future. The ‘desperate seekers’, the second type of unemployed, are very much concerned with work, actively look for a job and experience unemployment as very negative. They feel frustrated in their search for a job and are clearly aware of the barriers that hamper their entrance into the labour market. Because of this, willingness
to make sacrifices to find a job and their need for guiding and counselling are considerable. The 'discouraged' also have a positive attitude towards work, although they only search for it in a moderate way. Their experience of unemployment, however, is less problematic than in the group of the desperate seekers. The most obvious characteristic of this group is their pessimistic view of the future. They also ask the institutions to guide them in their search for a job in the area of work mediation because they have given up hope of realising this on their own. The attitude of the 'adjusted' towards work is positive but they have given up searching for it. They differ from the discouraged with respect to the experience of unemployment because they seem to be adjusted to the situation of being jobless. The combination of this unproblematic unemployment experience with a negative view of their chances in the labour market explains their lack of interest in training programmes. The interest in work of the last group, that of the 'withdrawers', is quasi non-existent, just like their search behaviour. In addition they experience unemployment as unproblematic and are the least willing to make sacrifices to find a job, nor do they ask social or employment services for help. On the contrary, they would rather 'get them off their back'.

Another study on AIF (Actions d'insertion et de formation) in France reveals four types of trainees with different motivations towards training (Verdié and Sibille, 1992). The first group does not regard training as an investment but as a way of spending their time. They are well aware of their unfavourable position in the labour market (because of a handicap, health problems, or age). Their attitude towards the labour market is fatalistic: they don't see any chance of finding a job at all. The second group are those who would like to work immediately but engage in training to improve their employment chances. The third group accept training as a last resort. They have been unemployed for a long time and, because of repeated failure, do not expect to find a job. Their attitude to training and the labour market can be regarded as very negative. The last group sees training as a way of coping with uncertainty related to unemployment.

In a study done by Kroft et al. (1989) a typology was drawn up of six different 'groups of unemployed'; conformists, ritualists, withdrawers, enterprising, calculating, and autonomous. They differ in the way they handle the three main problems associated with unemployment: work (and the search for it); time (and how to pass it); and consumption. The different types of unemployed place a different emphasis on these three values and experience them differently. With regard to the attitude towards 'work' and 'consumption' and their view of the labour market and society as a whole, the authors have derived the following typology:

First of all, the 'conformists' show a positive attitude towards work and consumption and try to achieve both but only by accepted legal means. The 'ritualists' seem to be indifferent to work and consumption because they have given up hope of ever achieving it. If they want to improve their work situation of and consumption, they use only accepted means. The 'withdrawers' attitude towards work is one of withdrawal (they see no further chance for them in the labour market) and their attitude towards consumption is one of resignation. If they want to improve their situation, only accepted means are used. The attitude of the 'enterprising' towards work is instrumental. Because they show a positive attitude to consumption, they regard work as an instrument to achieve a higher level of consumption. To realise this, informal and/or illegal means are also used. The attitude of the 'calculating' towards work is conditional, which means that it is considered positive on the condition that it increases the level of consumption. For them, consumption is more important than work and all means are used to achieve this. Rejection of both work and consumption is the attitude of the last type of unemployed, the 'autonomous'. Their rebellious – even revolutionary – attitude of rejection of both values, imply no use of informal means.

The type of unemployed an individual belongs to strongly influences the willingness to make sacrifices in order to find a job. This can be the case with regard to the income level, the contents of the job, the duration of the contract (limited or unlimited duration), dura-
tion of employment (full time, part time), the necessity to move or to commute. Because of the great value attached to work by the conformists and the ritualists they are willing to make many sacrifices. They are willing, for example, to accept hard and rather dangerous forms of jobs, they are ready to move somewhere else or to travel long hours in order to find a job. Even their demands concerning income are quite small. Compared to the ritualists and conformists, the willingness to make sacrifices is a lot smaller in the individualist unemployed. The exercise of a job is conditional and instrumental for the enterprising and the calculating: only when their high demands concerning contents and type of jobs and level of income are guaranteed are they ready to take the job. Trainees also belonging to the fatalist category, place great demands on a job, but for reasons other than the enterprising and the calculating. Their low willingness to make sacrifices can be explained by the existence of a defence mechanism. They make such high demands to defend themselves against the reproaches of their social environment for their continuing failure in the labour market. By placing relatively high requirements on work, they justify failures to the outside world in a dignified way. The autonomous, finally, are only prepared to make minor concessions, because they are not interested in any kind of job. These requirements are formulated in such a way that their current situation prevails over a formal work situation.

3.4.2 Motivation and (non) participation in training programmes

This perspective of the unemployed on work (work ethics, work attitudes) and their (un)willingness to make sacrifices to achieve this, has a direct impact on whether or not they participate in training and, equally, on the reasons they have for actually taking part. Trainees who belong to conformist, ritualistic, enterprising and calculating types are more likely to engage in training, whereas the withdrawers and the autonomous are less likely to participate (with the fatalists showing the lowest rate of willingness to participate). When they actually do take part, the motives are diverse. They can be pushed by their social environment to engage in training or they can see training as a means to earn money, as the only way to a job and thus as a means to access a higher consumption level. They can be obliged by social or employment services or they can see training as a means for self-development.

This can be considered important because the motivations and aspirations of the trainee will determine whether the training results in success or failure for the trainees. As a consequence, they have to be treated differently by the trainers and to be handled according to their background. For example, withdrawers have withdrawn themselves from the labour market because of the many rejections they experienced from employers. As a consequence, their self-esteem and self-confidence are very low. Therefore, it can be useful for them to participate in training to enhance their ability and their confidence. For the autonomous, on the other hand, it is important that trainers take into account their alternative labour ethics. Conformists, in turn, easily become withdrawers as the duration of their unemployment goes on: they experience continuing failure in the labour market, high social costs with regard to their search behaviour and their social bonds are gradually destroyed. They slowly arrive at a situation of resignation and dependence on social services. Individual guiding of the trainees into a regular job could be helpful in slowing down, halting or even reversing this process.

3.4.3 Correspondence of provisions and needs

Obviously, there seems to be a close relation between the type of unemployed and his or her needs and motivations. This relationship should be taken into account when offering particular services to the unemployed. Few long term unemployed or persons on minimum benefits require only vocational training; most of them also need work experience and even basic education. Consequently, training should be considered as a trajectory that, step-by-step matches the needs of the labour market with the needs of the job seekers. In short, a training programme not adjusted to the needs and motivations of the
Jan Vranken, Mieke Frans

unemployed can explain a great deal of the non-participation in training programmes. When training courses are not tailored to the needs of the individual, the individual is not motivated to participate. Therefore it seems to be important to take into account – along with the needs of the demand side of labour (the employers) – the needs of the supply side of labour.

These typologies do not take into account a number of ‘contextual’ factors, such as the family context of the unemployed. It is clear that the motivation to participate in training or to search for a job also depends on whether a family member – spouse – is employed or not. If this variable is not taken into account, aspects of social exclusion may be biased.

### 3.5 Exclusion through cultural clashes (socio-cultural aspects)

A somewhat underestimated factor in these processes of exclusion and inclusion with respect to (selection for) training offers has been the socio-cultural aspect, though it can explain a great deal of the exclusionary practices in labour market programmes. This socio-cultural perspective concentrates on training organisations as actors in an acculturation process. The interplay between the unemployed and the training providers and staff takes the form of an acculturation process, that is an interaction between a dominant culture and a subordinate one. This process can take different forms ranging from assimilation – which leaves no room for differentiation – through to inclusion – an incorporation which demands some form of adaptation but accepts the permanence of differentiation – and, in between those two extremes, different levels of inter-penetration. This is a relevant perspective, given that it has become quite clear that many initiatives have failed – as programmes and in assisting the target groups – not because of their educational, practical or organisational failures but because they did not take into account this ‘hidden agenda’.

#### 3.5.1 Socialisation and acculturation patterns

The specific question then becomes: does the organisation providing training choose for the target groups’ ‘culture’, for the labour market’s culture or does it successfully bridge the gap (if any) by integrating both cultures into a proper ‘organisational culture’? And how do they handle the contradiction between the mainstream cultures’ dominant value of work and the reality of lack of work? To find an answer to this question, nine training schemes were investigated and thus nine case studies were carried out in four countries within the CASEL-project. In the comparative interpretation of these nine case studies, diversity in the interaction between the most important actors – the staff and the trainees – could be observed: four different patterns of socialisation-acculturation occurred.

These four socialisation-acculturation patterns (SAP) are in turn specific and complex constellations of relational characteristics. These characteristics are the underlying ethos of the training provider organisation, the kind of training and the approach of the trainees, and the trainees’ relationship to and reaction to those aspects.

The SAP of ‘identification’ (or extreme assimilation) overrides the difference represented by the individual trainees and ultimately seeks to transform their personalities into that of the ‘ideal employee’. This type of SAP occurs in organisations which have a management ethos; this means that the dominant characteristics of these organisations are efficiency, management, and precarious working conditions for the staff. The motivational approach of the trainees, that accompanies identification, is underpinned by a sort of ‘idealisation’ of the labour market, as the unquestioned reference. In this kind of organisation the lack of jobs is totally denied. Consequently, the emphasis is put on behaviour and attitudes rather than skills and qualifications. The reaction of the trainees in the pattern of

---

7 This paragraph will mainly be based on a research carried out by the CASEL-consortium (1998), of whom CASUM has been a member, about the socio-cultural aspects of labour market (re)integration.
identification is one of polarisation in attitudes, which corresponds to the categorisation of the unemployed by the staff. One group of unemployed were very enthusiastic and identified themselves very strongly with the staff. The other group rather showed passive and sometimes even critical accommodation.

The pattern of assimilation seeks to fashion the trainees’ attitudes and conduct according to a predefined model of attitudes and conduct required by the labour market (autonomy, motivation, and self-confidence). There is no recognition of differences between the trainers and the trainees, and no attempt to override it either. This type of socialisation-acculturation is also the result of a managerial ethos and a motivational approach and a strong polarisation between assimilating and passively accommodating trainees.

Inclusion, the third SAP, seeks to teach already employable trainees techniques and ‘tricks’ to facilitate access to the labour market, but allows for mutual differences. Crucial factors in this pattern are the ‘elitist ethos’, which promotes individual autonomy of the trainees. Because they have ‘room for manoeuvre’, these organisations show the urge to select only the most employable and thus are ‘elitist’ in a certain way. Their view of the labour market is more realistic: the lack of job is acknowledged but access to the labour market still seems possible for them because the most job-ready are selected. In this instrumental approach trainees do not have to identify with the rules, which consequently leaves room for mutual differentiation. The trainees actively adapt in order to learn the game, to learn the tricks.

In a pattern of adaptation-accommodation the aim is to make the best possible match between adaptation to the labour market and accommodation to the individual trainees. The training schemes where such a pattern was found are based on a ‘service ethos’. This means that they have a special remit towards the most marginalised. In addition their aim is not mere labour market integration but integration in society as a whole: a global approach to the trainees. Training is, therefore only one of the possible means for realising the social as well as the professional integration of the trainee. This SAP comprises an easy relationship between actively adapting and more passively accommodating trainees.

3.5.2 Implications of this approach towards the unemployed

The main causal factors for the occurrence of different types of socialisation-acculturation are undoubtedly those stemming from the policy and funding framework and its consequence of competition in the training market. The existence of this link between the different patterns and the policy and funding framework is very strongly suggested in the case studies. If the funding framework is considered according to its degree of harshness (see paragraph 3.2.2) it could be said that, the tighter the funding framework, the more likely that a pattern of identification or extreme assimilation occurs in a given training (provider organisation). Thus the funding framework explains variation between the ethos of the training organisation, the type of approach of the trainees, and the trainees’ reaction, constituting the specific socialisation-acculturation pattern.

The most important implication of this socio-cultural approach is that the three crucial elements, constituting a specific kind of pattern – the ethos of the training organisation, the approach of the trainees, and the trainees’ reaction to both – are regarded as a relational property. They are not understood as much as an attribute of a particular actor, whether the training staff or the unemployed. In current policy, however, trainees’ attitudes and reactions are often seen as a result of their specific characteristics: they are seen as lacking crucial work attitudes, for which they must be punished or of which they must be cured by different kinds of training programmes. Instead of underpinning this ‘individual deficiency model’, the attitudes of trainees should be treated as a relational factor. This means that they reflect the position of those actors in the midst of a network whose main domains are the policy framework and the market. It should be taken into account that the motivations and attitudes of the unemployed should not only be understood on a
psychological/attributional basis but all the more on a relational/socio-cultural basis.

3.6 The social and policy context

From a policy perspective, different developments can be discerned that have an impact on training provisions and exclusion from it. In the first place, in a number of European member states national budgets are under great pressure, which indirectly affects social and employment policy. The trend of active labour market policies also has a direct impact on provision of training programmes. Perverse effects become all the more obvious when activation policies inhibit disciplinary characteristics, especially when the availability and quality of jobs, which training should lead to, is taken into account. The emphasis put on a preventive policy by European countries and the 'hot topic' of the unemployment trap, in addition, influences the occurrence of exclusionary practices.

3.6.1 Budgetary constraints

High unemployment is a burden on social security budgets. This became especially problematic in the 1990s, when most member states of the European Union were implementing strict budget controls with a view to attaining the so-called '3 per cent norm' as laid down in the Maastricht Treaty; this norm prescribes that a member state's budget deficit should not exceed 3 per cent of GDP if this state is to participate in the European single currency. Assigning an unemployment benefit to each and every unemployed person turned out to be very costly. Unemployment benefits and thus passive labour market policies are under ever-increasing pressure. Policy measures eagerly try to reduce the pool of unemployed in order to brighten up their unemployment statistics and to ensure the financial sustainability of the system of unemployment insurance. The development of active labour market policies should also be seen as potential saving of expenses in the unemployment insurance system. In consequence, the breaking up of a passive system goes hand-in-hand with the development of active policies, for they serve the same purpose of budgetary savings.

Cutting budgets also has had a direct impact on training policy in the sense that one tries to achieve the greatest results with the least possible means. This principle of efficiency, applied within the domain of training, resulted in a tightening of funding requirements and monitoring procedures. As mentioned in paragraph 3.2 these are increasingly based on targets, tendering, stringent conditions of payment, and other controlling devices, with all their consequences for the targeted unemployed.

The impact is different according to the specific funding mix in a particular country. State regulations and programmes, social-partner regulations, individual financial contributions, enterprise funding (joint or individual), tax incentives, and vouchers all play a part. Although 'comprehensive, systematic and longitudinal empirical data are in short supply', Kath (1999: 42) endeavours a 'tentative evaluation' on the basis of an analysis of the situation in Germany, the U.K., France, and Denmark. He asks the question whether the use of inappropriate instruments of funding is responsible or whether it is, as often claimed, an expression of conceptual and organisational weaknesses in the system of vocational training. His answer is negative 'since it reflects a much too narrow viewpoint, inadmissibly instrumentalising vocational education and training policies with their different funding regulations as deciding factors in solutions. Actually they can only help offset existing imbalances within the framework of a comprehensive labour market policy' (Kath, 1999: 42). This framework is perhaps provided by 'active labour market policies'?

3.6.2 Active labour market policies

Parallel with the pressure upon the passive system of benefits, the activation discourse has, in a relatively short space of time, become fashionable amongst all those involved with policies concerning benefit recipients and the unemployed. Public budgets spent on active labour market measures keep on growing year after year. There is a growing attention towards activation not only in the policy world but also in the academic world, as part of the debate on the future of the welfare state.
and the 'new social question'. More generally, one speaks of the activation of social security or of the welfare state: income support policy, welfare policy and unemployment policy. Usually, the term is narrowed down to the question of how the growing group of poorly qualified and/or long-term unemployed people and individuals who are totally dependent upon income support, can be re-integrated in society, through the (labour) market or otherwise. Thus, the problem is restricted to the structural gap between predominantly highly skilled insiders and a (growing) group of mostly unskilled outsiders.

Within the scope of the more narrow approach of this so-called 'new social question', policy-makers and social scientists in various European counties have, in a relatively short period of time, adopted the notion of social activation into their own vocabulary. Today, they take activation measures or they underpin the activation discourse. Generally speaking, this concerns policies aimed at the speedy reintegration into society of people who are excluded from the labour market and are living off an allowance. This reintegration can and must, according to most programmes, happen exclusively via the labour market (Geldof, 1999).

3.6.3 Training as an active labour market policy

Activation in employment policy can take different forms, ranging from training and schooling to counselling, work experience and employment (in the normal labour market or in the alternative sector also called the 'social economy'). However, it always aims at increasing labour market participation by job seekers and thus stimulating labour supply. Instruments for active labour market policy have rapidly gained popularity in European countries, especially the instrument of training. Since it became clear that the poorly qualified were finding it increasingly difficult to cope in the labour market, more and more emphasis is placed on training. This was clearly shown at the Extraordinary European Council Meeting on Employment, held in Luxembourg on 20 and 21 November 1997. In the conclusions of the presidency, we read the following:

'Transition from passive measures to active measures.

Benefit and training systems (where that proves necessary) must be reviewed and adapted to ensure that they actively support employability and provide real incentives for the unemployed to seek and take up work or training opportunities. Each Member State will endeavour to increase significantly the number of persons benefiting from active measures to improve their employability. In order to increase the numbers of unemployed who are offered training or any similar measure, it will in particular fix a target, in the light of its starting situation, of gradually achieving the average of the three most successful Member States, and at least 20%.'

(Conclusions of the presidency, Luxembourg 20/21 November 1997, 53-54)

Putting forward this percentage, as a result of which most countries have to push up their efforts substantially, implies that the number of unemployed who will be able to participate will also increase considerably. This evolution exhibits positive features for the most disadvantaged because the chance of participation will increase, but a number of dangers are lurking with regard to compulsion in activation and the contradiction of activation with the lack of jobs.

3.6.4 Compulsory features in active labour market policies

The range of measures in activation policies is very broad, but it always concerns combinations of employment and benefits, even in the case of training. Workfare in the strict sense, where one is forced to work in order to maintain the benefit, is still, for the time being, rather exceptional in Europe (certainly compared to the American situation). However, workfare in the broader sense is increasingly common. In the broad sense it means that welfare recipients are expected to make efforts for re-employment and reintegration (Andries, 1997). European countries, however, are moving more and more in the direction of learnfare: the beneficiary can be obliged to follow training in order to receive benefits.
The improvement of opportunity in the labour market (via training) can be accompanied by the threat of a sanction: diminishing or ending unemployment benefit. Thus, increasing pressure is exerted on the (long-term) unemployed and there has been a shift in the meaning of the concept: besides the emancipatory angle, it now also includes a disciplinary element.

Compulsion to participate in training schemes has created much controversy, however, because it can be used as a means of testing the willingness to work, and thus a means of suspension from benefits. The mandatory nature of recent programmes carries with it the danger of generating additional risks of exclusion for those who do not follow the rules of the game properly. In addition, studies have shown from the literature that mandatory schemes are often ineffective. The fact that the supply of clients is guaranteed for training providers and thus that there are less incentives to improve the quality of training, can be one explanation. Secondly, compulsion can lead to stigmatisation of the trainees in the eyes of the employers and thirdly, the mere fact of obligatory attendance can demotivate the trainees, especially when the programme is not suited to their needs. Consequently, an equilibrium should be established between the duties (to engage in training) and the rights (the freedom of choice) of the unemployed.

3.6.5 Activation and the availability and quality of jobs

The stimulation of labour supply by active measures, however, is very much in contrast with the actual lack of jobs and high unemployment rates. Indeed, unemployment is basically a situation of excess supply and/or depressed demand in labour markets. The low-skilled sector of – where the most of the trainees will end up – is already characterised by a situation of excess supply. So, on the one hand, training can be the answer to the new social question by bridging the gap between low-skilled and highly skilled workers but, on the other hand, this can only be done efficiently when jobs are actually available.

So, does the Centre for Social Policy at the University of Antwerp (UFSIA) believe that activation towards the labour market is the answer to the ‘new social question’?

‘This new social question requires a truly new approach. We must move towards a policy of activation; a policy that is targeted at all individuals with poor qualifications, including poorly qualified housewives, and not just those who are officially unemployed. A policy of activation is also necessary for reason that marginalisation of the poorly-qualified is not merely – not even primarily – a question of poverty. The aspect of poverty has, in fact, been adequately addressed. It is now primarily a matter of social integration and socio-cultural cohesion. If a further economic and political polarisation is to be avoided and the ideal of the welfare state safeguarded, then a radical choice for jobs for the poorly qualified is indispensable’ (Cantillon and Marx, 1995).

Cantillon and Marx’s plea for activation indicates that there is an essential distinction to be made in activation policy. The word jobs in the final sentence of the quote is important: it signifies a much broader concept of activation than is evident in many current activation measures, which are almost exclusively aimed at the activation of benefit recipients. If one takes the option for jobs seriously, then this firstly implies an activation of the labour market rather than – or even contrary to – activation of benefit recipients.

Not taking into account the current situation of high unemployment rates eventually leads to a further marginalisation of the already disadvantaged, for the trainees may be forced to accept any jobs, no matter how precarious they may be in terms of working conditions and wages. The pressure to accept lower-standard jobs, manifested itself in a very extreme way in the London organisation already mentioned, where under the ‘British job start schemes’, the long-term unemployed were offered allowances should they accept a job within three months.

The quality of employment is not only brought into question in general job-search training, that does not train for a particular types of
work. Questions can also be asked in the case of training programmes with a specific professional outcome: 'For what kind of jobs is the training a preparation? For a pool of unspecified (very) precarious jobs? Or for specific jobs?' In this wide field, a relatively recent trend exists towards training for 'new' occupations. One reason for this development is that changes in the structure of publicly accepted needs requires new services and therefore new jobs and qualifications to carry them out. These new jobs can result from the splitting up of the job description of an existing profession into a more qualified and a less qualified component, or from the combining of several such job parts. These are mostly 'intermediate' jobs, which require a combination of general and technical skills ('logistic assistant' in Flanders, auxiliaires de vie or 'mediators' between neighbours in peripheral estates in France). The question is whether this new labour market that is developing and that is accessible to people without necessarily high skills (women returnees, young people) will integrate the segment of the secondary labour market?

With regard to jobs in the so-called third labour market circuit, those created for the unemployed who are not considered able to move into a normal job ever again, the status of the jobs can be questioned too. These projects are very much dependent on subsidies because self-sufficiency is hard to achieve. Therefore, they are not always able to do any more than propose temporary, subsidised and informal work of a marginal type. In addition, the transition from this third labour market to the regular one seems almost impossible and no effort is made to try to realise this transition. Unless the status of the jobs provided in this segment of the labour market is changed into stable, normally-remunerated jobs fully covered by social security, (full-time) employment in the formal labour market must still be the aim for every individual unemployed.

3.6.6 Reasons for increasing popularity

Training has become a most important part of the 'activation' of employment policies and is therefore geared to reintegration into the labour market in the most cost-effective way. Budgets spent on active policies are growing rapidly, whereas those on passive policies are decreasing. This evolution is not very surprising given the current policy context of budget savings and the fact that this kind of policy is very visible. Policy makers can actually show that they are doing something about the problems, and even quantify their effort.

This approach is characterised by an individual deficiency model. According to this model unemployment – especially of certain disadvantaged groups – is the result of individual events or the lack of individual qualities, such as an appropriate attitude towards work and the working environment. There has thus been a shift in responsibility from the policymakers to the unemployed individual; The responsibility of the authorities lies only in the provision of training opportunities and the person who, despite those efforts, remains unemployed is suspected of not being willing to work.

3.6.7 European guideline for a preventive policy

The statement 'You can't bail out a leaking boat without plugging the hole' of Allan Larsson, Director-General of DG 'Social Affairs and Employment' of the European Commission clearly illustrates the European idea of a preventive policy. The idea is that the longer the duration of unemployment, the more difficult it will be for the unemployed to get out of it. Intervening at an earlier stage of unemployment should prevent this. The 'plugging of the hole' therefore should happen by means of offering every young person a new start before they reach their sixth month of unemployment and every unemployed adult before reaching twelve months of unemployment (guidelines 1 and 2). This policy trend, again, is contrary to a policy targeted to the (long-term) most disadvantaged unemployed or who show the highest risk profile: a curative policy.

The problem with a preventive policy, when it is translated into early intervention, is that chances are high that dead weight will occur. Dead weight relates to the fact that benefici-
aries of a programme, who would have found a job without following the training too, fill the jobs. As a result of the much larger target group, in which the most employable are over-represented, the threshold for the long-term unemployed will be much higher because they have to compete with more job-ready unemployed (see paragraph 3.1.1). The long-term unemployed will be neglected in a preventive policy. The group of unemployed will be filtered and those who remain in unemployment will be the hard core unemployed. Early intervention can only be justified when the unemployed are screened on risk characteristics: those characteristics that result in a higher chance of drifting into long-term unemployment. However, these risk categories are difficult to measure.

4. Conclusions

Both participation in the labour market and participation in training programmes are unevenly distributed among different population groups: women, elderly, disabled, lower educated and migrants are underrepresented. Gender, age, health situation, ethnicity and educational level are thus of crucial importance in explaining non-participation in the labour market and in training schemes. Accumulation of these factors increases the risk of becoming unemployed and decreases the chance of participating in training. In this way, a hard core of unemployed and untrained is been created.

The crucial factors that generate this unequal distribution are institutional, economic, psychological, and cultural. Persons who are most likely to be excluded from training programmes do not comply with the administrative criteria (from an institutional point of view). Moreover, they have fewer chances of finding a job after finishing the training and thereby contribute to lower placement rates (from an economic point of view), they are less motivated (from a psychological point of view), and they identify less with the labour market (from a socio-cultural point of view). As a consequence the most vulnerable of the unemployed – who share these characteristics – are being excluded from training initiatives. Therefore, continuing efforts should be made to re-integrate these ‘hard core’ unemployed and untrained. This is not an easy task, at least if we take the definition of ‘social exclusion’ seriously. Social exclusion, indeed, is not only about unequal access but mainly about ‘fault lines’ between these groups and the rest of the population, between their behavioural patterns and the dominant ones, between them and the institutional and cultural framework of society. Social exclusion often does not present itself in one domain. It is not about employment or training, but about employment and training. Moreover, both training and employment are often embedded in a larger network of exclusions that encompasses other fields of the individual and social life of the target groups of this contribution: housing, health, associational life. This reality implies that research, policies and social action have to take account of many initial factors in order to understand and remedy exclusion from training initiatives. Moreover, the opposite of social exclusion – the process of social inclusion – is not just ‘the way back’. Additional obstacles can be expected, such as the restoration of the former roles or of the different forms of inclusion (cultural, normative, communicative and functional).

In spite of the strong interrelation between the implications for research, policy-making and social action, we intend to specify our conclusions and proposals according to these three dimensions.

4.1 Conclusions for further research

What is lacking, is a more profound understanding of the structures of daily life in the target groups. We are referring to their social networks, their interpretation of the direct and indirect societal environment, and their coping strategies. This kind of knowledge cannot be obtained through traditional surveys. A more qualitative approach is needed here, based on in-depth interviews and analysed with the help of specific methods (network analysis, grounded theory, structural analyses).

Another focal point for further analysis is the institutional framework of training. We refer
to the different 'management styles' that are being used by training initiatives. Some of them are more appropriate to helping the target groups bridge the gap between their deprived situation and typical behavioural patterns, and the training initiatives and/or the labour market than others. An adapted version of the Bourdieu & Passeron concept of 'cultural deficit' could be productive in this context, referring to the difference between the culture of the training initiative and the trainers and that of the trainees.

4.2 Conclusions for policy makers

Of the many important points in this respect, we would like to stress the need for coordination of legislation, of initiatives. There is an urgent need for a governance approach to vocational training initiatives, integrating the different stages leading from social exclusion to social inclusion, the different levels of decision-making (from the European to the local level) and the multiple actors (public and private) engaged in this venture.

Integration into the labour market alone should not be the sole objective of VET. The ultimate goal is integration into society. We acknowledge the importance of work, of a job in this respect – Jahoda's 'latent deprivation model' has to be used as a frame of reference. There are, however, parallel routes in this respect and the organisation of a social economy sector is an important one. Social economy should no longer be seen as a temporary solution, to be developed in times of economic crisis and high unemployment. Its logic should no longer remain the 'lower productivity' of a growing part of the 'active population'. It should become, instead, the mix of the different goals discussed.

What about 'active policies' or 'activation', policy objectives that have become very fashionable today? The most important point in this debate concerns the interrelation between the client, the vocational training initiative and the labour market: the need to increase the emancipation dimension of vocational training and the potential for the trainee to have a job at the end of her/his trajectory. This implies not only adaptation at the actor dimension (training the trainers), but, even more so, adaptation in the cultural and institutional training framework and larger societal context.

4.3 Conclusions for people responsible for training organisations

What kind of vocational training model is to be developed, so that accessibility for risk groups and their successful participation increases? Méhaut presents us with one possible answer: the integrated training model. It refers to training that is more integrated into the working situation, through its relations with 'the organisation (and content) of work, job mobility and pay conditions' (Méhaut, 1999). The problem with this model is that it only refers to the relation with the (potential) work situation, whereas it has become clear that social inclusion of the target groups usually implies taking account of multiple exclusions. The holistic model of Ott provides us with an alternative. 'Holistic vocational training is not just oriented towards the acquisition of technical competences. It seeks to actively encourage the self-determination of individuals, their social co-responsibility and democratic co-determination of the worlds of life and work' (Ott, 1999). This model, however, is too much focused on the individual dimension; it does not sufficiently take account of the institutional, cultural and larger societal requirements that are needed to organise successful vocational training initiatives for our risk groups. The approach that is needed here has been discussed in terms of 'inclusiveness' 'governance' or 'mainstreaming'. At the level of specific organisations, this approach is to be translated into the development of coherent trajectories, that take account of the multiple and specific problems encountered by long-term unemployed and subsistence income beneficiaries. It also means that these trajectories should not only take account of personal strengths and weaknesses of their clientele. The behaviour of the actors that organise these trajectories (managers, trainers) and the institutional settings also have to adapt to the specificities of situations of social exclusion.

Training and employment perspectives for lower qualified people

Jittie Brandsma

Abstract
Learning and a qualified labour force become increasingly important in our societies. At the same time, European countries are still confronted with relatively high unemployment which in particular affects the least qualified or low-skilled workers. The combination of a weak labour market position and low education achievement levels, might further marginalise these groups of low-skilled workers in the future if learning becomes a necessary precondition for gainful employment. Appropriate training models for developing the skills of these workers remain lacking.

This paper addresses the labour market position of low-skilled workers and factors in the functioning of the labour market that might further weaken their position. It goes on to discuss the issue of training the least qualified, drawing upon European research in the area of the effectiveness of training for the unemployed and exemplary models developed in different European Member States.

1. Introduction

Learning becomes ever more important in our society. Policy documents from both the European Commission and the Organisation for Economic Cooperation and Development, stress the importance of a well, if not highly, qualified labour force for the competitiveness of national economies (EU, 1996; OECD, 1996). At the same time various European countries are still confronted with relatively high unemployment levels, which in particular affects the least qualified or low-skilled workers. The combination of a weak labour market position and low education achievement levels, might further marginalise these groups of low-skilled workers in the future if learning becomes a necessary precondition for gainful employment. Appropriate training models for developing the skills of these workers remain lacking.

This chapter first addresses the labour market position of low-skilled workers and the factors in the functioning of the labour market that might further weaken their position. Next, the issue of training of the least qualified is addressed, drawing upon European research in the area of the effectiveness of training for the unemployed and exemplary models developed in different European Member States.

2. The low-skilled in a changing and dynamic labour market

2.1 Low-skilled: possible definitions

Before launching into an analysis of the changes in the labour market, and the implications these might have for the least qualified, it is necessary to provide a definition of the least qualified or the low-skilled. The terminology of the 'least qualified' underlines that education and training, or the level of educational attainment, is, to a certain extent, a 'positional good', in the sense that the link between a certain level of education and a certain job level can vary over time, and what, at a certain moment, is considered, for instance, as being a middle-skilled level depends on the qualification demands in the labour market vis-à-vis the supply of workers with lower or higher levels of educational attainment (Brandsma 1993).

'Least qualified' or 'low-skilled' elicits, certainly nowadays, a connotation of being 'at risk' of unemployment, social exclusion or at least being referred to those parts of the labour market with relatively little job stability, low paid and low-skilled jobs (cf. Hannan et al. 1998). What is considered to be low-skilled also depends, partly, on policy targets and on national systems. In the Netherlands, for instance, the 'common sense' connotation of being low-skilled would refer to those who dropped out of lower secondary education (or even earlier) without having obtained any diploma or formal certificate. Or to those employed in jobs which, at face-value, do not require much general education or job specific training. At the same time, educational policy defined the 'at risk' group as being all those that did not succeed in obtaining a certificate from any upper secondary programme, with upper secondary education encompassing the apprenticeship system, school-based secondary vocational education and the last two or three years of general secondary education. This establishes a rather heterogeneous group, encompassing (cf. Bock and Hövels 1991):

- the real early leavers from lower secondary education;
- those leaving the education system after having obtained a certificate from lower secondary education;
- those leaving the education system after having spent some time in upper secondary education (including vocational education);
- those leaving the education system after having failed the final examination in upper secondary education (again including vocational education).

Defining the 'at risk' group in this way, the policy target is set such that every school leaver should enter the labour market with a
so-called ‘starting qualification’. This is defined as being the equivalent of a two-year vocational (apprenticeship) programme, which is considered to be the minimum level necessary in order to have an adequate chance of obtaining a job in the labour market. It will, however, be clear that there are major differences within this target group. Those who achieved some years of upper secondary education (the latter two categories), have a different starting position in the labour market from those who did not. Those in vocational education, for instance, sometimes drop out during the period that they receive practical training within an enterprise, because the employer offers them a job (cf. Brandsma 1999), while those who have received some years of general upper secondary education appear to have more chance on finding a job in which continuing training is provided and, with that, opportunities to build a career through the internal labour market (Meesters 1992).

In attempting to define ‘low-skilled’, various methods could be applied ranging from the use of formal level of educational attainment within the national education system to more direct measurements of actual skills (like numeracy, literacy or computer literacy skills). Hannan et al. (1998) underline the differences and difficulties, as outlined with regard to the Dutch example, in their comparative analysis of ‘early leavers’ in France, Scotland, Ireland and the Netherlands, and indicate that terms like ‘at risk groups’, ‘early leavers’, ‘unqualified leavers’ or ‘persons inadequately prepared for labour market entry’ are problematic and value-laden. They also point out the heterogeneity of the at-risk group labelled in this way. What is considered to be at risk depends on the policy targets and on supply and recruitment behaviour, which tend to change over time. Hannan et al. (1998) propose – in the context of their research project – the following definition of what they call ‘lower level leavers’:

‘Those who leave initial full-time education without reaching the first point of (or first opportunity for) certification within the upper second-level system’.

With this they deliberately take on board the earlier mentioned heterogeneity of this group. They discard the International Standard Classification on Education (ISCED) level categories, which they consider as being too broad and too imprecise to capture the full meaning of ‘lower level leavers’. Their definition, therefore, also captures those that passed lower secondary examinations or passing grades and those that left upper secondary education before the final examinations at this level.

In their work for the Newskills project, Murray and Steedman (1998), McIntosh (1998) and Leuven, Oosterbeek and van Ophem (1998) took various approaches in order to define where the cutting-off point for the definition of low-skilled should be set. On the basis of this work, they conclude that, though using recognised qualifications obtained as a proxy for the skill levels of people is less accurate than actual measurement of such skill levels, application of the ISCED levels can be considered an acceptable solution. Apart from the fact that data on ISCED-level attainment are collected on a regular basis, thus providing up-to-date information on the proportions of national population for each level of attainment, ISCED does take into account the differences between educational systems in different countries (cf. Newskills 1999). Using the ISCED levels, the cut-off point for the definition of the low-skilled group in Europe was set at having obtained an educational attainment level of ISCED 2 or less, which equals to lower secondary education or less (with level 1 equaling primary education and level 0 less than primary education). A possible counter argument against this cut-off point could be that specific forms of training, like short continuing vocational training courses or less structured, or formalised, forms of training like attending seminars or on-the-job training, are difficult to classify. Even though such forms of training often are not officially certified, they might be recognised as adding up to the formal skill level of workers, certainly within the company specific labour market. Given that such training is difficult to capture within ISCED, applying ISCED levels might result in a slight over-estimation of the number of low-skilled workers (cf. Brandsma 1999).
The two different 'solutions' for this problem indicate the problematic character of demarcating the research (and policy) area of the low-skilled/least qualified. With this, is implied the sensitivity of this area for changing labour market and training policies as well as changing policy priorities. It does not seem to be a wild speculation to suppose that whether the upper or lower boundary of the 'at risk' group – as defined in the Dutch example – will attract most attention and benefit most from labour market measures, partly depends on the overall economic and labour market situation. To be more precise, in situations of high unemployment and a restricted absorption capacity of the labour market, it is likely that labour market measures will – be it intended or not – have a bias towards the upper boundary of the at-risk group, while in situations of a low or rapidly declining unemployment with difficult to fill vacancies, all attention goes to the lower boundary of the at-risk group (cf. Brandsma 1993). The present labour market situation in the Netherlands, for instance, shows these shifts in attention. There the debate presently focuses on the possibility of activating the real 'hardcore' of the long-term unemployed as well as the possibility of offering work to refugees not yet certain of their final status. Notwithstanding these possible shifts in attention, depending on the general economic and labour market situation, there appears to be a growing consensus that, at least, completion of upper secondary education (ISCED level 3) is needed for a good starting point in the labour market, as is reflected by the various 'safety net' programmes established in various countries for young people that do not continue their studies after lower secondary education (e.g.: social guarantee programmes in Spain, individual training programmes in Denmark and Sweden, assistant training programmes in the Netherlands, 'qualification contracts' in France and NVQ/SVQ level 1 programmes in the UK).

2.2 Labour market perspectives for the low-skilled

Even though the economic upswing in many European countries might, to a certain extent, also bring relief for the weak labour market position of the low-skilled and/or long-term unemployed, overall this position is rather vulnerable. Based on IALS-data, the OECD (1998) comes to the conclusion that low skills (defined as ISCED level 2 or less) have a strong correlation with inadequate foundation or literacy skills. This does not only concern the whole labour force aged between 16 and 65 years, but also the younger age cohorts of 16 to 25 years old. Poor literacy skills among young people increase the chance of becoming unemployed. Even if these young people with poor literacy skills find employment, their chance of ending up in unstable and poorly paid jobs is substantially higher than young people with adequate foundation skills.

In their comparative study across four countries, Hannan et al. (1998) show that lower level leavers are more likely to be unemployed or in apprenticeship or labour market schemes than being employed. Here it is necessary to recall their definition of lower level leavers, which states that it concerns those who leave full-time education without reaching the first point of certification within the upper second level, that is full-time education system. Therefore, their conclusion also encompasses apprenticeship, which by definition means that entrants have left school and which is perceived by Hannan et al. (1998) as an alternative post-school vocational training and as an early labour market outcome. However, in countries where apprenticeship training has a strong tradition and is highly institutionalised (like Germany, Austria and also the Netherlands) apprenticeship training is considered an integral part of the upper secondary education system and those who enrol in apprenticeship training are certainly not perceived as lower level leavers.

In countries with high unemployment rates in the youth labour market, those with a higher educational level have significantly

---

1 Though there are differences between countries in the sense that in some countries adequate literacy skills have been obtained even if young people did not conclude upper secondary education.
better chances of staying out of unemployment than lower level leavers. At the same time, it appears that the quality of jobs held by lower level leavers is less than the quality of jobs (in terms of stability, income and utilisation of what has been learned) available for higher level leavers. Lower level leavers appear to be more often employed part-time in manual occupations, though on a steady basis. Lower level leavers are also less actively engaged in the search for another job. The findings of Hannan et al. (1998) indicate that unemployment appears to be handed down from one generation to the next. In addition to the relation between parental unemployment and the unemployment of the present generation, it appears that the chance of 'early leaving' (or low level leaving) is related to such background variables as gender, ethnicity\(^2\), and socio-economic background. Young men are more likely to become lower level leavers, as are young people from lower socio-economic backgrounds. At the same time young women have a higher chance of being unemployed or in labour market schemes (including apprenticeship) than young men.

These findings, and, in particular, the one regarding the influence of socio-economic background, lead Hannan et al. (1998) to the conclusion that the educational casualties will be concentrated amongst those from the most deprived families. Even though there are differences between countries, this conclusion holds for each of the four countries included in the study.

The previous section mainly addressed the labour market position and perspectives of low-skilled school leavers in a period of increasing average levels of educational attainment. What is the labour market situation of the low-skilled (ISCED 0-2) in general, including the other generations? In their work for the Newskills project\(^3\), Murray and Steedman (1998) show that, overall, the proportion of the low-skilled (according to their earlier definition) in the labour force is dropping, with the younger age cohorts (16-28 years old) being substantially better educated than the older cohorts. Again there are differences between countries with regard to both the proportion of low-skilled in the labour force and the speed with which this proportion is dropping. In some countries with a relatively high proportion of low-skilled (ISCED level 2 or less) in the labour force (like the UK) this proportion drops faster than in countries with a relatively smaller proportion of low-skilled (e.g. the Netherlands), but, given the initial higher proportion of the former countries, it will take more time for the proportion to drop to a 10% level than in the latter countries (Murray and Steedman 1998).

Analysing data covering a period from 1985 to 1997, Kirsch (1999) concludes that the labour market position of the low-skilled (ISCED 0-2) is not a prosperous one and has deteriorated during that period (with the exception of Portugal). The likelihood of both unemployment and inactivity are considerably higher for the low-skilled than for the total labour force. Even though in all countries included in the Newskills project the proportion of the low-skilled has decreased, the likelihood of being either unemployed or inactive has increased during the period between 1985 and 1997. This suggests that the low-skilled have faced a further marginalisation during those years (Kirsch 1999).

2.3 Labour market mechanisms; implications for the low-skilled

2.3.1 Upskilling, deskilling and substitution

2.3.1.1 Changing labour market structures

The previous section outlined the relative weakness of the position of low-skilled workers in the labour market as well as the deterioration of this position. The question is whether this can be explained given that, at the same time, the proportion of low-skilled in the total labour force has dropped. It appears that there are several, more or less rival, explanations referring to (among others) economic restructuring, upskilling, substitu-

\(^2\) Ethnicity has only been included as variable in the Dutch data set.

\(^3\) This project encompassed France, Germany, the Netherlands, Portugal, Sweden, and the UK.
tion and segmentation. These possible explanations will be discussed in this and the next section.

Looking at the changes in employment structure during the 1980s and the early 1990s, it becomes clear that there has been a significant redistribution between sectors with regard to employment. Traditional sectors like agriculture, manufacturing and utilities have strongly declined while the service sector has boomed (Robinson 1997). In his analysis for the Newskills project, Kirsch (1999) indicates that employment for the low-skilled (ISCED 0-2) has a rather segmented nature. Irrespective of country specific differences, there is a group of sectors where employment for the low-skilled appears to be concentrated, while other sectors have little or no employment for low-skilled workers. The former group appears to consist of sectors like agriculture, manufacturing sectors like clothing and extractive and process industries, transport and hotels, catering, retailing and small repairs. Apart from the last four service sectors, these are mainly sectors in decline, which, as indicated earlier, can (partly) explain the worsened labour market position of the least qualified.

At the same time, these traditional sectors have been the major providers of employment for the low-skilled. The decline of these traditional sectors appears not to be compensated for by the growth of the service sector, at least not in terms of the employment of the low-skilled. As in other sectors, employment growth in the service sector is mainly accounted for by the increasing number of managerial and administrative functions, proximity services and personal services. It appears that, especially in those non-manual functions, skill demands have been raised as well, both in terms of formal educational attainment requirements and in terms of training time needed to fully master the job (Gallie 1991).

2.3.1.2 The skill-biased technology hypothesis versus the trade shift hypothesis

Wage inequality literature offers two rival hypotheses to explain the rise in skill demands. One the one hand, skill demands have risen as a consequence of skill-biased technology. On the other hand, skill demands have risen due to shifts in the location of production of low-skilled manufactured goods; this is an argument that could be related to what has been indicated with regard to decline of employment in specific sectors (Newskills 1999). Both hypotheses assume that an increased wage inequality indicates a drop in both the wages of and the demand for low-skilled workers. The skill-biased technology change hypothesis mainly focuses on the relationship between technological change (often equated with increased use of computers) and the increasing demand for highly skilled workers (as expressed in increasing wage inequality). Overall, the literature suggests that there is a relationship between computer usage and the increased demand for high skilled labour, if an increasing wage inequality is taken as an adequate indicator for this. However, much of the research undertaken focuses on ‘computer-usage’ and on subjective judgements of either employers or employees, or both, without taking into account other explanatory factors (like the hierarchy or flatness of work organisations, worker independence in taking decisions, etc.) nor trying to find more objective indicators for actual differences in skill demand levels. As will be argued later on, there is some evidence for contrary developments as well.

The trade hypothesis focuses on the effects of the shift of mass production of low-skilled goods from highly industrialised countries to developing countries. This shift reduces the price of those goods and, in consequence, causes deterioration of the competitive position of such manufacturing industries in highly industrialised economies, since these are confronted with much higher labour costs than developing countries. The evidence to support this hypothesis shows that only a small proportion of the falling demand for low-skilled labour (or the increasing wage inequality) can be explained by this (Newskills 1999). Nevertheless, there are various examples of sectors, or parts of sectors, which completely relocated production to the so-called ‘low wage countries’ to the detriment of (low-skilled) employment in Western European countries.
The textile industry is a very impressive example in this respect, but it is also the case that various enterprises in consumer electronics replaced part of their production (of half fabricates) to the low wage countries.

The wage inequality approach focuses on wage inequalities as an indicator of, or proxy for, the changes in skill demands, but does not measure the actual (changes in) the demand. Other studies, like the earlier mentioned study of Gallie (1991) indicate that there has at least been a rise in the demand for formal educational attainment level. This work also indicates that this is the particular case for jobs in which automated and computer equipment is used, while this is much less the case for jobs in which such equipment is not used. Similar findings with regard to the increasing levels of educational requirements and periods of additional training needed are indicated by Green et al. (1998) and Hasan and Tuijnman (1997). Again, it should be stressed that this work draws to a large context on 'subjective' judgement of the change in skill demands.

2.3.1.3 Upskilling versus deskilling; the role of technology

However, there is also evidence which seems to contest such findings. Some studies show that there is complementarity between skills (or skill levels) and organisational change, indicating that organisational change stops when there is a relative shortage of highly skilled workers (cf. Caroli and Van Reenen 1999; Newskills 1999). The question is whether it is the availability of highly skilled labour that drives organisational change, or whether organisational change elicits an increase in demand for highly skilled labour. Currently, evidence seems to support both assumptions without (yet) giving decisive support for either one of them.

Various authors have underlined that technological change does not automatically lead to higher skill demands, but that the effect of technological innovation on skill requirements is mediated by the organisational structure of labour organisations (Carnevale 1991; Brandsma 1993; Keep 1997; Stern and Benson 1991; Tuijnman 1993). These authors argue that the fact that technological innovation has not led to the expected increase in productivity and economic growth could be caused by a less optimal, if not, inflexible and inefficient use of such technologies. Efficient and flexible use of the production factor technology might require flatter and more flexible organisations and additional training of the employees working with those technologies (Tuijnman 1993). Whether or not introduction of new technologies will result in increased productivity and/or increased skill demands, partly depends on the way in which new technologies are employed. Available skills or skills to be developed, design of work processes and the effects of the implementation of new technologies are very much intertwined, as is shown in Figure 1.

In line with this, various authors have argued that whether or not upskilling takes place, will depend on the particular management strategy employed. Technology can be used for further rationalisation as well as for innovation in the organisation, providing workers with greater responsibilities. In this context, Brown and Keep (1998) indicate that it sometimes seems that the new forms of work organisation, which are alleged to be necessary if enterprises want to survive, are primarily advocated by academics and management gurus, but do not (or only partly) reflect practices in business and industry. In less knowledge-intensive sectors in the UK, like the retail sector and insurance companies, there appears to be a tendency to increase scale and rationalise work processes in order to reduce costs and optimise profits. In this

---

4 Above all it focuses on wage inequality as an indicator of productivity. Concerning the latter, there is substantial evidence that productivity is relatively low for low-skilled workers if compared with more highly educated workers, though the relative level of productivity of low-skilled workers appears to be influence by the overall level of educational achievement of the total labour force as well (with higher levels of overall educational achievement increasing productivity among low-skilled workers) (Nickell 1998). There are indications that increasing levels of skill demand are related to, or stem from, increasing demands with regard to productivity.
Training and employment perspectives for lower qualified people

Figure 1: Relations between the three primary production factors and education and training of the labour force

context, Brown and Keep (1998) come to the conclusion that Fordism certainly is not dead yet. Similar tendencies are observed for Germany. In sectors where knowledge or competence is a less crucial factor, enterprises try to rationalise their production and work processes in order to increase profits, with the consequence of reducing employment. For workers being made redundant due to these rationalisations, the consequence is often a further marginalisation of their labour market position (cf. Tessaring 1998).

Of course, this might concern specific enterprises or sectors and does not necessarily apply to the whole economy or the macro-level, though there appear to be country specific tendencies in this respect. Some studies indicate that, for instance, British managers appear to require significantly lower levels of skills and qualifications than the EU-average and perceive a skilled workforce less as a source of competitive advantage than their French or German colleagues (Coopers and Lybrand 1995; European Foundation for the Improvement of Living and Working Conditions, 1998). Nevertheless, if the drop in demand for low-skilled workers (which occurs in all OECD-countries) is taken as an indicator, at least at a macro-level there appears a shift in employment structures towards a high-skill, high-performance mode of working (cf. Brown and Keep 1998).

Labour organisations can thus choose management strategies and market profiles that might actually result in deskillng or in a form of polarisation between different groups of employees. An exemplary development with regard to the latter, is the slowly emerging development in some labour organisations that distinguishes between 'core workers' on steady contracts and so-called flex-workers, that are only employed temporarily. Keep and Mayhew (1998) further indicate that there are various alternative strategies to allow enterprises to cope with this competition — alternatives (e.g. like growth through takeover or new forms of Fordism) that are not based on upskilling and higher quality. The strong belief that increasing levels of knowledge and skills are the core factors in increasing and improving performance of enterprises, does not take into account that there are other factors playing a role in this process as well. As Keep (1997) states:
'The other pieces include human resource management systems and policies (...), product market strategies, work organisation, job design, investment in R&D and plant and equipment, supplier policies and the external infrastructure (...). Each element needs to be finely meshed with the other in order to produce the high performance organisation'.

2.3.1.4 Substitution processes

Next to the issue of upskilling or deskillling, there is another phenomenon that could explain the not-so-prosperous labour market situation of the low-skilled. As Hannan and Werquin (1999) indicate various studies show a rapid growth in the supply of workers with higher educational levels across most EU-countries but without an accompanying and similar rapid growth in occupations that require such higher levels of education. Most of the educational change in terms of an upward shift in average educational attainment appears not to be due to an upward change in skill or qualification demand, but to changes in the supply of more highly educated labour (cf. Béduwé et al. 1998; Robinson and Manacorda 1997; Hannan and Werquin 1999; Robinson 1997). Hannan and Werquin therefore conclude that the research in this area does not support the demand-driven technological change hypothesis and that there is also some evidence from the same studies for the credentialist hypothesis (see also Büchel's contribution to this report on the debate on overqualification).

Whereas the demand-driven technological change hypothesis stipulates that increased demand for higher skill levels due to technological innovation has led to increased average educational attainment, the credentialist hypothesis refers to the role educational attainment or diplomas have in the recruitment and selection processes in the labour market. In this instance, education is seen in terms of achieved level of diplomas and certificates are perceived as 'earned credentials' that indicate, for instance, learning capabilities, trainability and perseverance of the candidate. Certainly in situations where employers can choose what they like, such as high (overall) unemployment and/or an oversupply of highly educated labour – and especially the combination of the two – they will opt for the highest credentials. The consequence of this is that the higher educated (or overeducated) substitute those with lower qualification levels by competing with them for jobs formerly taken by less qualified workers, thus pushing the least qualified (or otherwise less attractive workers) out of the labour market. There is substantial evidence that such substitution processes have occurred and most probably still occur in periods of economic recession (Brandsma 1993). At the same time, as Hannan and Werquin indicate, there is quite some evidence that the highly educated may enter the labour market in lower status jobs, but appear to become upwardly mobile after some years in the labour market, moving up to jobs that match their qualification level (cf. Hannan et al. 1998). Similar evidence has been found in various Dutch labour market studies (Brandsma 1993; Hövels and Van den Berg 1992; Hövels and Van Dijk 1989).

2.3.1.5 Segmentation of the labour market

As indicated earlier, Kirsch (1999) states that employment for the low-skilled has a rather segmented character, being concentrated in specific sectors of economic activity. His analysis points at a particular phenomenon in the functioning of labour markets, which can provide an additional explanation for the weak or weakened position of the low-skilled in the labour market. It concerns the segmentation of the labour market into different (sub)segments with differential access.

The labour market has never been homogeneous. In the debates on the match between vocational education and the labour market during the 1980s, critics of so-called planning approaches pointed out the neglect of the segmentation of the labour market as one of the weaknesses of these models. It was stressed that, on the one hand, graduates from a particular vocational programme could end up in completely different jobs (even in occupational areas for which they had not been trained), while within particular occupations or jobs one could have varying educational backgrounds. On the other hand, it was indicated that the extent to which graduates
Training and employment perspectives for lower qualified people would have access to that part of the labour market that provides relatively skilled and secure jobs depends on the valuation of their particular training by the labour market as well as other attributes like gender, age and ethnicity (Brandsma 1993). This segmentation of the labour market was considered to be one of the complicating, if not distorting, mechanisms in the match between education and the labour market.

Probably the best known distinction between different segments is the one between the primary and secondary segment (cf. Doeringer and Piore 1971), with the primary segment (or economic sector) encompassing competitive and profitable sectors and enterprises with good prospects, that are able to offer stable jobs, good wages and career perspectives. The secondary segment (or economic sector) encompasses the marginalised sectors and enterprises that have to struggle to survive and mainly offer rather unstable, poorly paid, unskilled and monotonous jobs with little career perspective.

The distinction between primary and secondary segments is slightly confusing in the sense that it actually mixes sectors of economic activity with the distinction between internal and external labour markets. Referring to the latter, Lutz and Sengenberger (1974) assume that labour market segmentation is primarily based on the recruitment, allocation and utilisation of qualifications. In their perception, enterprises have two options for solving problems in filling their qualification demands:

a) recruiting and hiring qualified staff in the external labour market;

b) training their own staff up to the level required.

Based on this, they distinguish three segments: the internal enterprise-based labour market (with internal training as the drive for this segment); the external vocation-based labour market (with the availability of external qualified labour as assumption); and the residual market or the market for Jedermensqualifikationen.

Of course, this is not the only typology of labour market segmentation. Althauser and Kallenberg (1981) for instance, indicated that the internal enterprise-based market and the external vocation-based market can be further subdivided into a general external and an internal enterprise-based market, with the latter being characterised by vertical job-chains or career ladders that are only accessible by a limited number of entries at the bottom.

Labour market segmentation has not disappeared and is still an issue, though less pronounced than one or two decades ago when it was strongly highlighted in the context of the match between education and the labour market. What, however, appears to need more attention in this theoretical area, is, on the one hand, the inevitable changes in labour market structures and, on the other hand, the implications for access to (continuing) training and lifelong learning. With regard to the former, Hövels (1999) distinguishes two dimensions for classifying the present labour market into sub-markets. The first dimension refers to the complexity of the jobs or the complexity (or level) of the technical-instrumental qualification requirements. The second dimension is the bond to the company or the firm-specificity of the qualifications. One can argue that the first dimension is too simple and restricted, actually returning to one of the alleged mistakes of previous planning methods by referring only to technical-instrumental qualifications and neglecting the non-technical and non-instrumental qualifications that have become more and more important over the last decade (Brandsma 1993). However, the dimensions as such, can be relevant for identification of emerging sub-market or labour market segments. Applying the two dimensions, Hövels (1999) distinguishes four submarkets (Figure 2).

The professional, company-specific, and residual sub-market are the same as, respectively, the external vocation-based, the internal enterprise-based, and the residual labour market as distinguished by Lutz and Sengenberger (1974). The complex sub-market is a new labour market segment, characterised by Hövels as the labour market where specific

combinations of professional qualifications and company-specific qualifications are required (Høvels 1990, 1993). As examples he mentions teachers, medical specialists and mechanical engineers, working in changing labour-markets, requiring more and more company-specific skills.

An occupational identity might be relevant for the complex and the professional sub-market, but in a company specific sub-market one could better speak of a corporate identity, while neither of the two concepts seems applicable for the residual market.

A tendency which cannot be fully captured by Høvels’ classification of sub-markets, is the differentiation between employees that some authors presume will become more and more important in the near future (cf. Kessels 1996). It concerns the distinction between ‘core workers’ and ‘flex workers’. ‘Core workers’ are employees with a strong bond to the enterprise where they work, and with steady and gainful labour contracts. ‘Flex workers’ are employees that either are hired on the basis of a temporary contract or through temp agencies. Though one could argue whether this development is really in existence and affecting all economic sectors to the same extent, or only partly exists on the desk of academics, there are indications that support this distinction. Out-sourcing and retreat of enterprises to their core activities is a development which has been signalled already for a couple of years, though to different degrees between sectors of economic activity. In the areas of the complex sub-markets and professional sub-markets there appears to be a particular tendency for part of the ‘non-core’ employees to be highly educated workers employed on a temporary basis. Such workers set the present trend of so-called ‘job-hopping’, moving from one project to another with different employers, accumulating a wealth of experience of applying their knowledge and skills in different settings, and thus accumulating their human capital.

The implications of this development for the labour market position of flex workers, needs further elaboration. The tendency towards flexibilisation of the labour relations does not, by definition, mean a weakening of the labour market position of all flex workers. It is necessary to distinguish between relatively...
highly qualified flex workers and low-skilled flex workers. The former will often have no difficulty in finding new jobs for which, given their qualifications and experience, they can demand good labour conditions. Though employed on temporary contracts, these 'job hoppers' have a relatively good labour market position with sufficient opportunities to develop their career as well as their skills and competencies. There is evidence that temp agencies have great interest in these 'job hoppers', providing new market niches for the temp agencies while meeting the demands of the high skilled flex-workers for flexibility and alteration.

The implication of the distinction between core workers and flex workers for less or low-skilled workers, might be less promising. For them, the flexibilisation of the labour market might mean that they will be faced with periods of unemployment in-between periods of temporary work. Given the learning potential of the type of jobs they will take on, and the temporary nature of their employment, neither these flex workers themselves nor the enterprises that hire them will be much inclined to invest in training and learning. For temp agencies too it does not appear profitable to invest in the training of these workers. What the implications of the flexibilisation of the labour market might be in the long run for these low-skilled flex workers, is difficult to say. Nevertheless, developments in the labour market as outlined here, show that the labour market becomes ever more complex and differentiated. This will have implications for lifelong learning.

2.3.2 Summarising conclusions

Summarising the previous, one can say that the deterioration of the labour market position of the low-skilled appears to be caused by a combination of factors. Sectors of economic activity which traditionally employed relatively large proportions of the low-skilled have economically declined or moved to developing countries with lower labour costs, while other (and newer) sectors have not compensated for this, since educational requirements are higher and have increased over the last decades. This segmentation of the labour market, with low-skilled workers being allocated to certain, declining sectors of economic activity and/or jobs that are characterised by instability and little career and learning potential, is another factor in the deterioration of the labour market situation of the least qualified. Tendencies like the distinction between 'core workers' and 'flex-workers' might even worsen their situation in the (near) future.

Economic recessions – the most recent during the early 1990s – have further aggravated the weak labour market position of the low-skilled. Average levels of educational attainment have increased rapidly in most countries of the EU, while job openings matching this increase in educational level, have not kept up with that shift and labour markets have provided insufficient possibilities for the absorption of all the highly qualified labour market entrants. This leads to the (possible and plausible) consequence of substitution. Technological innovation does play a role in this, but not such a straightforward one as is sometimes assumed. Depending on organisational and managerial decisions, and the way in which work and production processes are designed, new technologies can lead to upskilling, but also to deskilling, at least for some of the employees.

3. The increasing importance of training

3.1 Introduction

Concepts like learning organisations, learning societies, learning regions and learning economies appear to have rapidly gained popularity among policy makers as well as researchers. Though some would argue that these concepts are already on their decline, being overtaken by newer 'management' concepts like knowledge management, competence management and competence development (cf. Mulder 1999), this only seems to be a question of 'labelling'.

Though the issues of continuing training and lifelong learning per se are not new, they seem to have settled in the centre of (political and
public) attention more strongly than ever before. Publications like the European Commission's white paper 'Teaching and learning; towards a learning society' and the Organisation for Economic Cooperation and Development's report 'Lifelong learning for all' (both published in 1996) reinforce this impression. These are not the only examples. Debates on arrangements and incentives to increase the investment in training are on many a political agenda and in various countries national committees or national action programmes been established during recent years, with the aim of enhancing lifelong learning if not actually establishing a 'system' for lifelong learning (examples are: the UK, Norway, Iceland, Finland, Sweden the Netherlands and recently also France). In the terms of the European Commission's white paper, the aim is to establish a 'learning society'.

The common arguments underpinning the various training and management concepts, refers to the necessity of a continuous development of knowledge, skills and competencies of the labour force in order to sustain and enhance the competitiveness of European economies and individual enterprises. With reference to developments such as the ageing labour force, globalisation of economies and societies, increasingly wide-spread use of ICT and flexibilisation of labour and the labour market, it is stated that lifelong learning is inevitable (European Commission 1996; OECD 1996). In order to be able to maintain the competitive position of European enterprises, it is considered a necessity that these enterprises are both innovative and knowledge-intensive. It is presumed that Western European economies should focus on knowledge-based industry, products and services and discard more routine mass production. The market demands tailored goods and services and the areas of (financial and business) services, and information and communication technology are the most promising sectors for the next decade. The ability to innovate is perceived as a precondition for enterprises to meet new and increasingly differentiated demands.

The implications these developments might have for enterprises and their workers are emphasised in a report from KPMG (1998) on a scenario for lifelong learning:

'... lifelong learning has meanwhile become a necessary precondition for further economic success. Labour organisations of the near future have definitively said goodbye to the organisational principles of Taylor and Ford. A customer-oriented way of working and permanent innovation are the most important credos of enterprises that are robust enough to face the future. Continuous innovation is not only necessary for satisfying customers, but also for staying ahead of competitors. The goods many knowledge companies produce are, moreover, often unique and only produced once, which makes innovation an integrated part of the production process. Customer-oriented production and permanent innovation require flat organisations with independent, responsible and competent workers, capable of working in varying teams.'

Whether or not this quote reflects the practices in all enterprises or only an elite group of learning organisations – which presently still seems to exist of mainly a relatively small group of large(r) enterprises (Tjepkema 1998) – is difficult to say. At the same time it is not clear yet to what extent developments implied in the quote will permeate all economic sectors and all enterprises, irrespective of their size, profitability or locality. However, it cannot be denied that the increasing emphasis on flexibility, adaptability and continuous learning of the labour force, directly affects the least qualified or low-skilled workers (whether employed or unemployed). Overall, the least qualified have a relatively weak position in the labour market and are more often confronted with (long-term) unemployment, with the risk of social exclusion in the long run.

3.2 Barriers to (lifelong) learning

The necessity for lifelong learning seems to be less homogeneous than often assumed on the basis of the dominant economic perspective on lifelong learning. At the same time, this dominant perspective seems to be based
Training and employment perspectives for lower qualified people

on an implicit starting point that might not simply be inadequate, but actually ignores important barriers to investment in learning and training. The implicit starting point is that all enterprise and individuals are confronted with a similar necessity for learning and, moreover, that all individuals are equally stimulated to learn, just as all enterprises are equally stimulated to invest in training. It is assumed that increased learning, and increased investment in learning, is good and that we all equally want to learn. With this position, important barriers to participation in training and lifelong learning are denied, which can result in the development of inadequate strategies to implement and enhance lifelong learning.

On an individual level, important barriers to learning are related to motivation to learn, aptitude to learn and assessment of the possible benefits of learning. Individuals that are not motivated to learn, or do not see the value added of learning, will not easily take their own initiatives to start learning. The work environment and the specific job in which one is working can be an important determinant of the motivation to learn. A work environment that does not stimulate people to learn and is characterised by routine jobs will not motivate people to learn. Certainly, if employees have been working for a longer period in such a work environment, they will often have 'dislearned' to learn and need targeted support to pass (psychological) thresholds to start learning again. Often restoring the aptitude to learn and increasing the motivation to learn will take time.

At the same time, the motivation to learn can also be reduced and suppressed by a lack of clarity in the possible benefits of learning. This might be caused by a lack of opportunity to apply what has been learned or by unclear, or even contradictory, expectations from managers and supervisors. In addition to this, it is very difficult for individuals to foresee and quantify the benefits of their private investments. Considering that, individuals cannot, like large(r) firms, spread financial risks, and that it is nearly impossible for them to identify the optimum level of investment – the Pareto-optimum after which costs will exceed benefits – investment in training is an even more risky undertaking for them than for enterprises (Brandsma 1994; Ritzen and Stern 1991).

Lack of motivating work and clarity with regard to the benefits of learning are not the only barriers to participation in learning, though the importance of the motivational factor cannot be underestimated and the work (or living) environment plays an important role in this. There are indications that the unemployed are more ready to enrol in labour market training if there is a guarantee that it will result in gainful employment once the course in finished (Brandsma et al. 1999; Anderson et al. 1993).

Other barriers to participation in training can be the lack of a training offer that matches the interests and capacities of people, the locality where the training is provided (places difficult to reach by public transport, less safe areas, etc.), the lack of practical assistance such as child care facilities or lack of time or energy (Brandsma 1994). Concerning the last of these, Keep (1997) indicates that long-term unemployed or the most excluded, suffering from pure poverty, might not even be able to participate in any learning or training, given that they need all their time and energy just to survive. In a cynical way, some point out that even this is a form of (lifelong) learning (cf. Bolhuis 1999).

3.3 The effectiveness of labour market oriented training

The present emphasis on the importance of training and learning raises the issue whether this can contribute to the improvement of the labour market and the work situation of the low-skilled, and especially the (long-term) unemployed. Nicaise and Bollens (1998) report that, at an individual level, participation in training can have an important effect in terms of obtaining a job, but that, at a macro

---

5 This section is based on the final report of the TSER-funded project on effectiveness of labour market oriented training for the long-term unemployed (Brandsma et al. 1999).
level, the effects can be offset by dead weight losses and substitution. At the same time, they point at the 'black box issue'. Although there appears to be a substantial body of work on long-term unemployment and training of (long-term) unemployed, theoretical or empirical work concerning the relative contribution of the programmes’ organisational, curricular and instructional characteristics and the interdependencies between these characteristics is much less developed (cf. Nicaise and Bollens 1998).

In general, it is known that, on the one hand, the background characteristics of trainees are related to the effectiveness of training programmes (cf. Lee 1990; West 1996), and that, on the other hand, the selection procedures and criteria, used by employers in hiring personnel, influence the extent to which the former long-term unemployed will be able to find a job, once they have finished their training (cf. Van Beek 1993). Various research projects (in the Netherlands, but in other countries as well, cf. Nicaise and Bollens 1998) have shown that in training courses with a mixed population (short- and long-term unemployed, women re-entering the labour market, and those who participate on behalf of retraining), the long-term unemployed have the least chance of finishing the course successfully, while women re-entering the labour market and those participating in retraining are the most successful. These differences in success rates are partially explained by the relatively lower level of prior educational attainment of the long-term unemployed (cf. Den Boer 1995).

Ethnicity and the length of the unemployment period, prior to enrolment in the training course, also appear to have an influence, certainly on the outcome. The longer the period of unemployment prior to enrolment, the smaller the chance of finding a job once training is concluded (De Koning and Van Nes 1990). Ethnic minorities have a lower chance of finding a job after training has been finished; it might be that in this case ‘discriminatory creaming’ plays a role (Bavinck and Van der Burgh 1994; De Koning and Van Nes 1990; De Koning, et al. 1988; De Koning et al. 1993). In addition to this, results from other evaluation studies indicate that training programmes become less effective with the increasing size of these programmes and with the increasing heterogeneity of the participants (OECD 1998). This indicates that targeted training programmes are needed, tailored towards the specific capacities, interests and needs of specific groups of participants.

There is also evidence of differences between training programmes in their efficiency and effectiveness (e.g. from studies from the Netherlands, Denmark and Norway), which cannot simply be explained by sectoral or regional differences in the labour market situation. But the extent to which process characteristics are taken into account is rather limited (Nicaise and Bollens 1998). The question, therefore, is what causes these differences? If the training (process) as such, is interpreted as a black box, this question could be rephrased in terms of, 'what makes the difference inside the black box?'

### 3.3.1 A comparative European study into the effectiveness of training for the unemployed

One of the research projects funded under the Targeted Socio-Economic Research programme within the fourth framework programme of the European Commission, specifically focused on the issue of differences in the effectiveness of labour market training for the (long-term) unemployed caused by differences in the training process and organisation. Seven countries participated in this project (Belgium, Denmark, Greece, Ireland, the Netherlands, the UK and Norway). The project was established as a comparative research project aimed at developing a (multi-level) effectiveness model of labour market oriented training for the long-term unemployed. The study was structured in three stages, encompassing an inventory of the major characteristics of the various labour market schemes in the participating countries, comparative case studies to further develop the conceptual model and a survey among training providers and former trainees that followed a labour market-oriented training course within those training organisations. The last stage was specifically in-
tended to test the model and to test which process characteristics of the training provided influenced the effectiveness of the training. With regard to the ‘effects’ of the training, a distinction was made in the preliminary model, drafted on the basis of a literature review, between ‘output’ and ‘outcome’, which were defined as:

a) output: finalising the course;

b) outcomes: finding a (stable) job related to the course and/or continuing in education or vocational training.

The process indicators included in the study concerned, among others, the availability and offer of guidance and counselling, the inclusion of practical training within an enterprise (and the form of this practical training), the duration and practical orientation of the course, the enrolment procedures and criteria, and the organisation and flexibility of the course.

One of the major difficulties within the project concerned the substantial differences in labour market training programmes run in different countries. Differences were, of course, expected beforehand, as were the problems with undertaking comparative research in the area of education and training, given the differences in the systems. However, in dealing with formalised education and training systems (certainly primary and general secondary education), ISCED provides a certain reference framework for comparability, even though many problems still remain to be solved (Brandsma and Sherman, forthcoming). Where labour market related education and training comes into question, the variety (for instance in specialisations) becomes increasingly more complicated, which is further aggravated if programmes cannot be easily classified within ISCED (which at least gives an indication with regard to the comparability of level). In addition to this, it appeared that there were major differences between countries with regard to the extent to which training schemes were centralised or stand-

ardised (according to content) and the extent to which work experience or work placement was included. Concerning the first of these, it appeared that an overall distinction had to be made between:

- national programmes encompassing courses which are provided on a national level (that is: courses which are similar, or more or less comparable, irrespective of the region or place where they are provided);

- national framework programmes, within which actual course decisions and provision are more or less decentralised (or devolved to a lower administrative level, like regional committees), and where courses are not, by definition, comparable between regions;

- decentralised provision of training, characterised by a variety of local initiatives.

With regard to the extent of inclusion of work experience periods, a distinction could be made between:

- school-based courses, with only a small percentage of total curricular time spent on practical training (either within the training centre or within an enterprise);

- mixed type courses, in which a more substantial part of the total curricular time is spent on practical training in enterprises, or in which school-based and work-based training are alternated;

- mainly work-based courses, where the majority of the curricular time is spent on practical ‘on-the-job’ training;

- fully work-based training or work placements.

This variety made a comparative study particular complicated. This was particularly so since, in some of the participating countries, a rather wide range of different training initiatives existed (e.g. Denmark) aimed at different target groups, while, in other countries, only a few major schemes were run (e.g. Greece, Ireland), though sometimes with sub-

6 This particularly holds for the revised ISCED 97.
substantial regional variation according to the actual courses provided. The Training and Enterprise Council (TEC)-led system in the UK in particular posed a problem, since variations between regions could be very large without having at the same time a national overview of what was being provided in different regions. This made a comparative research project a particularly difficult undertaking. Though attempts were made to sample training programmes or courses in such a way that comparability on basic issues was ensured (attainment level at the end of the training, main sector of economic activity for which was trained), it was necessary to accept the differences in the labour market training systems between countries.

3.3.2 Major results of the study

Differences and similarities between training programmes

Notwithstanding the problems encountered in actually undertaking the research, the study yielded some interesting results. As expected, the training programmes included in the study differed substantially according to organisation, content and process, though differences were less great than expected (only the duration of the course, the flexibility of curricular organisation and the extent to which the training organisation attempted to keep track of former trainees appeared to be significant).

In addition to this, there were some striking and not-expected similarities between the different training programmes studied in the seven countries. These similarities concerned:

- design characteristics of the training courses and, in particular, the extent to which courses were modularised (which held for about two-thirds of the courses). However, it should be taken into account that the concept of modularisation can be confusing. Some understand it as ‘cutting’ the curriculum into blocks or periods, while others perceive it as a didactical principle as well, where modules constitute relatively independent curricular units encompassing, presentation, practice and evaluation, increasing the flexibility of proceeding through the programme and the trainee’s influence on his/her own learning process;
- inclusion of job search training, often paying attention to job search training throughout the whole course;
- provision of guidance and counselling to trainees, again often throughout the whole course. Financial and economic support is one of the lesser support systems and, if it is provided, this is mainly done by specialised staff (counsellors or specific trainers) or the employment service. In addition to this, guidance and counselling during the transition stage, i.e. during the transition from the training into the labour market (or other further training), is rarely provided.

Former trainees

Former trainees were interviewed on behalf of the study. It appeared that the majority that responded had been unemployed for one year or less (with over a quarter of the total response group having been unemployed for less than six months), were relatively ‘well’ educated, with less than a fifth not having followed any education after lower secondary education and that the number of respondents that left the course was remarkably small (only 12% of all the respondents). At the same time, it appeared that two thirds of those interviewed had found a job once the training was concluded, the majority of which stated that it was a steady job, which they still held at the time of questioning. Those that had lost their job in the mean time, had mostly managed to find another job.

---

7 Pure work placement schemes, where training is not included by regulation, have been left out. However, the (then running) Community employment scheme in Ireland has been included, given that it does by definition include training and was during the study, one of the major schemes. The focus of the study was on training for the least qualified (ISCED level 2 or less), but this appeared not to be feasible in Greece, since the major schemes there focus on the large group of young unemployed that has mostly finished upper secondary education, but not gained access to university education.
Given these characteristics, and especially the labour market situation of the trainees after the course and the fact that relatively little drop-out occurred, the possibility that the trainee data are somewhat biased cannot be excluded. It could be that those who dropped out of the course were less willing to cooperate either for reasons of not wanting to admit that they left the course prematurely or for reasons that they did not want to be reminded of the course (which might also have been the reason for drop-out). There is also the possibility that those who did not obtain a job after finishing the course were less willing to cooperate. Therefore, there might be a bias towards the relatively more successful trainees. This means that the results of the study have to be interpreted with a certain caution, certainly where generalisations are concerned.

A key problem in finding clear relationships between process characteristics, was the fact that the variance in the 'output' and 'outcome' measure was relatively small, given that the number of trainees that left the course before finishing it was very small (both absolute numbers and proportional) and that a relatively large group of former trainees found a job. Nevertheless, it became clear that the background characteristics of the former trainees were not related to either finishing the course nor finding a job. Age, motivation and the duration of previous unemployment made no difference. Nor did there appear to be a significant difference between those that finished the course and those that did not with respect to finding a job.

**Programme characteristics influencing drop-out**

Five course characteristics appeared to influence drop-out (that is leaving the training early):

1. the design of the practical training; this influenced drop-out slightly according to its approximation of work practice. The closer practical training was to real work practice, the higher the chance that a trainee would not finish the course, a finding which appears to be in line with the assumption concerning the 'pull impact' of providing practical training within an enterprise (Section 3.1). It also appeared to be in line with the fact that finding a job was the major reason for leaving the course before its conclusion. Whether, in the long run, the jobs found will be steady, full-time jobs, or temporary insecure jobs, could not be investigated. For this a longitudinal design running over a longer period is needed;

2. the flexibility of the curriculum; a distinction was made between flexible and non-flexible modularisation, the former providing trainees with optional modules and the opportunity of setting their own learning pace and sequence. The likelihood of drop-out appeared to increase with an increase in the flexibility of the curriculum. At first sight this seems to be at odds with newly-advocated instructional principles, where trainees' own responsibility for their own learning process is emphasised. However, several scholars have indicated that adults' motivation for learning is essentially 'situated' in the sense that social contacts and learning in a group are important for them (Boshier and Collins 1985). This 'motivation', is lost in highly individualised learning environments. It has also been stated that individualised learning, e.g. by means of modularization, requires 'learning capacities' in terms of being able to plan and steer one's own learning process. These capacities might not have been developed or have been lost by those having acquired little previous education or those having left the education system at an early stage (Brandsma 1994). From research into modularisation it is known that too much flexibility – in terms of individual planning and pace – might have adverse effects on learning achievements (Harms 1995);

3. the way in which job search training was provided; there appeared to be a significant relationship between dropout and the provision of job search training. However, this relation was difficult to interpret. In general, it seemed that the provision, or lack of, job search training will influence drop-out (the likelihood of drop-out increasing with the provision of job search training), but the relationship was less clear in
terms of the stage at which this training was provided. It seemed that job search training towards the end of the course increased the chance that the course was not concluded;

4. the ‘selectivity’ of the training organisation at enrolment; this also had an influence on drop-out, though the relationship is weak (modest significance). The less selective a training organisation, the bigger the likelihood of drop-out. This would indicate that it could be ‘profitable’ for training organisations to ‘cream’;

5. the provision of guidance and counselling; an adverse, and unexpected, relationship appeared, with the chance of dropout seeming to increase if guidance and counselling (in general) was provided. This rather surprising result could indicate that guidance and counselling does not only help trainees to finish the course, but might also contribute to an (early) acknowledgement that the course a specific trainee enrolled in, was not the most suitable for that particular trainee. However, looking at the particular stage in which guidance and counselling was provided it appeared, on the one hand, that if less guidance and counselling was provided during the enrolment stage, the likelihood of dropout increased. On the other hand, the likelihood of drop-out also increased with an increase in guidance and counselling provided during transition to the labour market. Guidance and counselling during the enrolment stage seems to corroborate the ‘early acknowledgement’ assumption. Guidance and counselling provided during the transition stage does not seem to fit with this. However, it is quite possible that those who reached that stage of the training are, to a certain extent, ‘pushed’ out of the training, in the sense that they obtain help in finding a job and that the fact that a job is found is the reason that they leave the training.

Process characteristics influencing the outcomes

In line with expectations, it appeared that the more selective the training organisation was in enrolling trainees, the more successful it was in terms of the number of former trainees finding a job. This was certainly so if, in addition to the general eligibility criteria, additional criteria and an entry test were being applied.

Questions were asked with regard to the type of guidance and counselling provided and the stage at which guidance and counselling is provided. Whether guidance and counselling was provided did not make a difference. However, how guidance and counselling was provided, at which stage and on what topics, did appear to have impact. It appeared that guidance and counselling during the enrolment stage has an influence on the chance of finding a job, but not a linear one. The same holds for guidance and counselling during the course and during the transition stage. There appeared to be an optimum level between little guidance and counselling and too much guidance and counselling, though it was difficult to state exactly where the optimum lies. Providing little guidance and counselling seemed to decrease the chances of finding a job, while ‘too much’ guidance and counselling seemed to have the same effect. However, increased guidance and counselling during practical training (within an enterprise) improved the chances of getting a job.

It also appeared that whether or not guidance and counselling on personal (welfare) issues is provided has an impact. If provided, it seems to increase the chances of finding a job, especially if provided by specialised staff (that is, counsellors employed by the training organisation or trainers specifically assigned to this task). In addition to this, providing guidance with regard to other or further training enhanced finding a job as well, though the particular direction of the relationship between the two variables is not fully clear. Focussing guidance during the practical training period or work placement, on either solving particular problems (e.g. problems with colleagues or problems of fitting in) and/or technical advice on work related tasks and problems, also enhanced the chances of finding a job.

Where flexibility of training had an impact on drop-out, the relationship with the chances
of finding a job was more complicated. Modularisation per se does not influence the chances of finding a job; whether the modular structure of the training is flexible or non-flexible made no difference. However, it appeared that the extent of individualisation of the training – in terms of whether the duration is fixed or dependent on the trainees’ capacities and learning pace – did make a difference. Participating in a training course of fixed duration seems to enhance the chances of finding a job. It also appeared that drafting individual training plans at the start of the course did not have an impact either, but here it is necessary to indicate that developing individualised training plans at the start of the course (or before) did not occur much (mainly in the UK and Ireland, though it has been stated that some individual agreements occur in Greece as well, though these are not formalised).

Does practical training prove to be a vehicle for getting into a job? It was presumed that practical training provided within an enterprise might help trainees into a job. At the same time, the ‘practical nearness’ of the training appeared to ‘pull’ trainees out of the training. As expected, it was not as much the issue whether or not practical training is provided that made a difference, but the way in which it was delivered. The closer to the reality of the work practice, the greater the chances of finding a job. In this respect, providing trainees with a practical training period or work placement in an enterprise provides them with more opportunities to find a job, but with the paradoxical effect that it also increases the likelihood of drop-out.

Whether or not job search or job search training is included appeared to make a difference as well. It became clear that job search training provided towards the end of the course increases the chances of finding a job, while job search training provided throughout the course actually seemed to decrease the chances of finding a job.

What final conclusions can be drawn from these results? Among the trainees that responded to the survey, there is a low percentage of drop-out. Also, the number of trainees that found a (steady) job is high, ‘staying on’ at the employer where the practical training took place, being the most important channel for getting a job. There are, however, differences between countries in this respect, which seem to relate to the extent of formalisation of the labour market, especially the role of the employment service. In countries with a strong and institutionalised employment service (e.g. Norway), the agent has a more important role in getting former trainees into work than in countries where the employment service is not so strong (e.g. the UK). Both in terms of output and outcome, training courses seem to be successful. The question, of course, is what and how did these courses contribute to the labour market position of individual trainees.

If one looks at the extent to which former trainees think that the course was necessary for getting the job they obtained, it appears that nearly half of the trainees think that this is not the case, while slightly fewer are convinced that the course was necessary. Slightly over a quarter of the trainees are convinced that the job is (absolutely) not what they have been trained for (judged on level and content). On the other hand, if one looks at the course characteristics that seem to contribute to either output or outcome, there are process characteristics that do make a difference. The roles of practical training and job search training are particularly interesting. The closer practical training is to the reality of working life and the more job search training is situated at the end of the course, the greater the chances of finding a job. There is a potentially cynical interpretation of these results, in the sense that these two process variables also influenced drop-out. However, there is a (high) probability that the drop-out reported in the survey are those that left the course towards the end and not the early ones (more or less corroborated by the indications from former trainees on the time spent in the training course). In this respect the conclusion concern drop-out during the transition stage. Whether or not this should lead to the conclusion that training as makes no difference to dropping out or staying in is, however, questionable. Apart from the role of practical training and job search training, there is also the influence
of the amount of flexibility and the guidance and counselling. In consequence it would be interesting to gain more understanding of what might cause early drop-out.

### 3.3.3 Possible implications of the findings

Effectiveness research into vocational training, as performed here, is still rather underdeveloped. In addition to their recommendation of further research into the causes of disadvantage in the labour market, with special reference to the accessibility of labour market programmes for particular target groups, Nicaise and Bollens (1998) point out that the question 'why' something is effective has been little addressed and needs specific attention. From a policy point of view this is an important question, if not the most important question. At the same time it is often one of the more difficult questions to answer. On the one hand, experience of effectiveness research in initial vocational education and training in the Netherlands has shown that it is quite difficult to find specific process characteristics that influence the effectiveness of this type of vocational training and that what does seem to matter varies substantially between specific vocational programmes (cf. Van Batenburg 1995; Brandsma 1999). This might indicate the need for more differentiated effectiveness models that can capture the specific differences between programmes. On the other hand, there are indications, both from effectiveness research in primary education (Doolaard 1998) and some (Norwegian) studies concerning labour market schemes, that effectiveness can change over time (decline, increase) and that changes in effectiveness are not necessarily caused by changes in effectiveness-enhancing process characteristics. To state it more bluntly: once effective does not mean always effective.

Brandsma et al. (1999) state, on the basis of Norwegian evaluation studies, that, in the short run, participants in labour market training have a higher potential for employment than non-participants and that labour market training is more effective than work placement only, with the combination of training and work being the most effective. However, they also conclude that there are major differences in effects, not only between programmes, but also for one given programme if measured at different points in time. Moreover, studies with regard to long-term effects of labour market programmes are inconclusive and sometimes contradictory.

Cynics might conclude that this indicates that it is not very useful to try to detect what causes the difference in effectiveness between training programmes. This is supplemented by the findings of Pedersen and Møller which seem to indicate that the effectiveness of labour market oriented training might be more dependent on the general unemployment situation, than on the process characteristics (or the 'quality') of training. While this is probably true, it does not imply that any additional contribution from the training process itself should therefore be discarded.

It cannot be denied that the 'sample' of former trainees of labour market training schemes is somewhat biased, given that most found a job and a relatively small number dropped out. There are, however, other traits of the trainee sample that pose more fundamental questions; first, the accessibility of training provisions for long-term unemployed and, second, whether or not, and to what extent, the "real long-term unemployed" are reached by labour market oriented training measures. From the study it became clear that training organisations do 'cream'; that is, they try to assess informally the chances of a trainee finishing the course (or even finding a job afterwards). This tendency is all the more strong if the funding for the training programme or the training provider is based on output-related funding (cf. Felstead 1998).

In addition to this, it was clear that, in most cases, eligibility criteria were at stake, not only setting conditions in terms of previous unemployment duration, but also with regard to the actual unemployment situation or labour market status. With some exceptions, training was made available mainly for those registered as unemployed or for the remunerated unemployed. There are some (though relatively weak) indications that motivational...
issues might have led to self-selection processes, which excluded certain groups of unemployed. Motivation is an important factor in distinguishing between participation and non-participation. Investment in training is risky, given the uncertainty of the returns participation may yield (cf. Brandsma 1997, 1998). Though one can argue that, in many cases, participation in training for the unemployed does not require a monetary investment from participants, since most costs are born by public funding, time devoted to training can be perceived as lost time in terms of finding a job. This is certainly true if the unemployed have the impression that participation in training does not lead anywhere or can even have adverse effects (as has been proven in some studies; cf. Anderson et al. 1993).

Moreover, training often is not the first priority for the long-term unemployed. In the short term, they may perceive direct employment as the best strategy for getting back into the labour process, training being only a postponement of gainful employment or even a barrier to it. Other, psychological barriers, such as fear of failure, a negative self-image or fatalism, may also demotivate unemployed people in relation to training. If the unemployed have already participated in training without realising their (high) expectations, there is a chance that they will perceive this as a personal failure or as a reinforcement of the belief that training does not pay, reducing their motivation to participate in further training. Though it is difficult to say to what extent motivational issues and self-selection have affected enrolment in training programmes and courses included in this study, it became clear that one of the ‘learning effects’ frequently mentioned (though perhaps not explicitly intended by the courses) is growth in self-esteem and self-confidence. On the other hand, trainee motivation was an important, if not the most important, criterion in the recruitment and selection processes prior to enrolment.

What became clear from the study is that some sort of enrolment selection, of a more or less rigorous form, takes place and that the expected success of candidates, in terms of finishing the course or finding a job or both, plays a role in this selection process (sometimes by means of various tests to ‘measure’ the learning capabilities of candidates, but more by ‘subjective assessment’ of those deciding on enrolment). Some training organisations are very explicit and open on this issue, referring to the need to be selective given the output-related funding regime they are subject to or the specific relationships with (local) employers, which does not allow for ‘failure’ (or in other words, forces them to maximise their credit-worthiness; cf. Nicaise and Bollens 1998). In this sense, too strong an emphasis on effectiveness in terms of realising set, quantitative targets, could, in the long-term, prove to be counter productive. As has been argued before, it is difficult to decide whether selection in order to optimise the match between trainees and their motivation, capacities and preferences and course content and level, should be judged as wrong per se. Mismatches at this level might lead to a reduction in motivation, early drop-out and discouragement or even reinforcement of disbelief in the benefits of training. However, if selection does result in systematically pushing out the least advantaged, the question is whether this is not an undesirable societal effect (certainly in the long run). Nicaise and Bollens (1998) state in this respect:

‘Some state that we simply have to learn to live with the trade-off between effectiveness and equity, arguing that it makes no sense to operate an adverse selection system and only provide training to the poorer candidates.’

This might be considered a rather cynical conclusion, certainly if alternatives tailored to, and really reaching, the bottom end of the labour market are lacking. Even though cynical, this statement does raise the issue of effectiveness of training in terms of reaching the intended target groups and getting them back into work. But it also raises the more general issue of whether training does pay off. At the individual level, one can, to a certain extent, answer this question affirmatively. Looking at the results of this particular study, it appears that a large percentage of the former trainees have found a job, with well
over three thirds still holding the job at the time they were questioned. However, less than half of the former trainees are convinced that training was necessary in order to obtain the particular job, and, according to trainee opinion, there is a certain mismatch between the training received and the job obtained.

Does training pay off at a more aggregated level, that is the level of society? It is much less easy to answer this affirmatively. First of all, we have to acknowledge that little is known about the macro-economic effects of investment in training for the (long-term) unemployed. But the macro-economic effects were not the focus of this study either. There are, however, indications that the macro-economic effects of labour market measures for the unemployed are less convincing than the micro-effects mentioned earlier (dead weight and substitution).

If training cannot create jobs, what are the possible policy consequences? The economic upswing in various European countries during the first half of this decade has resulted in the reduction of unemployment even among those considered long-term unemployed. But what if economic growth does not keep its present pace or even turns into a recession? Will this mean that those who have returned to employment after training are the first to be hit by unemployment again? This will depend on various factors such as whether the first job obtained was a steady job or not, whether those former trainees who lost their first job, obtained another job and the characteristics of this job. There are more general factors such as the stability of both the economic sector and the enterprise in which former trainees are employed, as well as the overall vulnerability of the national economy to global economic cycles.

It appears that two basic lines of reasoning can be distinguished in this matter. On the one hand, various (economic) scholars state that, due to the demographic development of ageing of the work force, it will be necessary to get unemployed and ‘inactive’ labour back into employment – preferably after sufficient training – in order to meet the demand for labour. If this demand is not met, economic decline will occur, not so much as a result of economic downswings, but due to the fact that the labour market cannot match supply and demand. On the other hand, there are (economic) researchers who foresee that those with the most vulnerable labour market position (the least qualified, older workers and workers with an unstable working career) are the first to be hit by increasing unemployment rates. Some of the most cynical among them point out that, due to the lack of quality of the training that has been provided to the former long-term unemployed, these persons tend to end up in the vicious recycling of qualifications (cf. Thijssen 1997). With this (and with the quality of training) they mean that the training provided is too much focussed on getting people back into employment as quickly as possible, without taking into account the long-term employment perspectives of the training provided. In their opinion, the level of training is too low and the scope of the training is too narrow, often focussed too much (or ‘customised’ too much) towards specific vacancies that exist within certain enterprises or that are expected too arise in the short-term.

In principle, both lines of reasoning once more underline the dilemma to be faced in designing labour market measures for the long-term unemployed, though in the case of demographic arguments it will depend on the particular demand for labour to be met. If labour market measures intend to promote the reentry of the long-term unemployed, and especially the least qualified among them, in gainful employment with the prospect of employment in the long run, and even the prospect of continuing training in the context of employment, the initial investment needed for training these unemployed should be substantial. At the same time, as is seen in various literature sources, the least qualified long-term unemployed often are confronted with multiple problems and do not (necessarily) give priority to training.

Notwithstanding the potential power of training as a labour market measure and the great attention training for the unemployed receives in various European countries, Hasan and Tuijnman (1997) conclude that:
Training and employment perspectives for lower qualified people

'The learning opportunities open to the unemployed and the disadvantaged groups in the society are far limited in scope and quality than those available to the employed group.'

3.4 Training of low-skilled workers

3.4.1 Who receives training?

Work is an important source for learning in the sense that it is often an important – if not major – stimulus for the motivation to participate in training, and also a major financial source. Hasan and Tuijnman (1997) stipulate that, overall, the role of the government in participation in adult education is relatively small and that 40-60% of adult training is financially supported by enterprises. At the same time, a large percentage of adult training (estimated to be 70 to 90% of the training undertaken by men) is work-related. However, the likelihood of receiving training is not equally distributed among workers and the inequality between workers in this respect appears to be a very persistent phenomenon (Brandsma et al 1995; European Commission 1999; Hasan and Tuijnman 1997; Houtkoop 1985; Newskills 1999; Tuijnman 1989).

Results from the Newskills project (1999) indicate that there is relatively little difference between men and women with regard to the question of who receives additional training within the enterprise. However, given that the labour participation rate among men is higher than among women, the majority of training concerns men. Furthermore, it appears that younger workers receive more training than older workers, better-educated workers have a greater chance of receiving training and full-time employees receive more training than part-time employees – findings which are corroborated by various other studies. The results of the first European Continuing Training Survey, for instance, reveal that those employed as craft and trade workers, operatives or in elementary occupations, participate less in training courses than those employed in higher level occupations. This, however, only concerns formal training courses and not less formal types of training, like training on the job or quality circles. Differences between men and women appear to be small (European Commission 1999).

IALS data reveal, however, that there still is a gender bias in the participation in training. Women are less likely to participate in job-related training and are also more likely to experience lower training intensities than men (Leuven 1997). If the focus is taken away from job-related training only, participation rates of men and women appear to be quite similar, but pattern, type and conditions of participation show a considerable gap between the genders, with women having to overcome more difficulties than men (Valdivielso Gomez 1997). At the same time, data from the IALS data base strongly indicate that the chance on participation in training sharply declines for older workers (over 55 years of age) (Van der Kamp and Scheeren 1997).

Overall, participation in training, be it work-related or other training, shows the following pattern:

- workers in small enterprises have significantly less training opportunities than workers in large enterprises;
- older workers have less chance of participation in training than younger workers (with training opportunities diminishing after the age of 45);
- training opportunities and participation in training increase with the prior level of educational attainment (with the low-skilled, defined as ISCED 0-2, having the least chance of participation);
- workers with a less stable labour relationship with an employer (part-time workers, homeworkers) have less chance of participation in training.

3.4.2 New training models

If the aim of learning, in particular lifelong learning, is the inclusion of the least qualified, or low- and unskilled, into gainful employment and into the learning economy, this has consequences for education and training.
policies as well as for vocational education and training systems. VET policies should take into account that the low-skilled might need considerable guidance and support in order to start learning. Rigid divisions between unemployment benefit, training and working are not supportive in this respect. The unemployed often only want one thing and that is a job. Creating opportunities through which unemployed can combine work with motivating training and learning processes, or alternate periods of work with training and learning, might be more helpful than obligatory incentives (like withholding their unemployment benefit) to get them back into work (e.g. the USA). There are various examples of wage subsidy or work placement schemes, but these seem to focus on low-skilled jobs with little or no learning possibilities, often leading to the vicious circle of being employed for a time and returning back to unemployment afterwards.

The training-system as such, should not only provide the basis for lifelong learning for all, but also contribute to the development of the competences of that part of the workforce which presently is perceived as being unskilled. Current training-structures and institutions have to open up and become more flexible, not only in terms of structure and content of curricula and didactical approaches, but also in terms of increasing their own innovative capacity, taking on board innovations such as portfolios and assessment of prior acquired competencies.

Assessment of prior acquired competences (in the UK known as assessment of prior learning) might be a helpful tool for stimulating the learning among the low-skilled. The basic rationale behind assessment of prior acquired competences is that the assessment is independent from the way in which something is learned and that it also takes into account what is learned informally (cf. Klarus 1998). Definitions of ‘low-skilled’ are mostly based on official educational attainment (like the one given earlier), not being able to take into account what might have been learned outside the classroom (or outside a CVT course). Also, when hiring staff most employers often base their decisions on educational attainment and/or work experience. These are only global indicators, but time and resources are mostly unavailable for assessment of the competences of potential workers in more detail (except in the case of potential staff for highly qualified jobs).

Providing opportunities for assessment of prior acquired competences has various advantages both from an employer’s and from an employee’s perspective. For employees, it can define and show the competences acquired, whether through formal learning or informal learning. The results of the assessment can, for instance, be included in a personal portfolio, which can be used during applications, in addition to an application letter or interview. For employers, assessment of prior acquired competences can be one of the tools for competence management, identifying available competences and competence gaps. Assessment of previously acquired competences can contribute to individual learning motivation by showing what has already been learned (indirectly boosting self-esteem) as well as indicating potentially powerful directions for further learning on the basis of what has already been obtained.

A possible disadvantage, however, could be that employed (low-skilled) workers fear that the results of such an assessment might get to their employer as well, providing a basis for a judgement of the worker. Experiences with the French ‘Bilan de Competence’ show that this is not a theoretical disadvantage, but a real drawback. In this respect it is necessary to install sufficient rules and procedures to protect confidentiality (Brandsma 1998). In addition to this, it appears that employers object to assessment of prior acquired competences if it results in recognition of these competencies with wage consequences. Effective implementation of this tool therefore requires that both employers and employees gain from its application (Thomas and Frietman 1998).

Another possible tool is the so-called job rotation scheme. Such schemes as presently implemented in Denmark and some parts of Germany (on an experimental basis) are based on the principle that a worker going off on training, is replaced by an unemployed
worker, who, if necessary, receives training in order to be able to perform the work. These schemes provide the possibility of combining training and work, which appear to be more motivational than pure training without a clear perspective of obtaining work afterwards. If the training of the employed worker aims at, and results in, upward mobility within the enterprise, this might provide a job-opening for the unemployed worker. However, there are also disadvantages. If the trained worker returns to his or her job after training has been concluded, this will most likely mean that the unemployed replacer returns to unemployment if no other job-openings are available inside or outside the enterprise. The extent to which the unemployed worker will be able to find another job, is partly dependent on the training received in the context of the replacement scheme. There are examples from the Danish job rotation scheme which show that the unemployed person received only relatively short training that did not fully match the needs of the enterprise. This makes some employers reluctant to continue participation in such schemes. At the same time, providing more job specific training might be more appropriate from the perspective of the enterprise, but not from the perspective of the unemployed. If training is too job specific, this might be of little help for the unemployed replacing worker at the moment that he or she has to search for another job once the temporary contract has been terminated. In this respect there is a dilemma between providing training sufficiently relevant for a particular job and training sufficiently broad to strengthen the labour market position of the unemployed (Brandsma 1998).

4. Concluding remarks and discussion

The labour market position of the low-skilled is relatively weak and it seems that increasing their skill levels might be the only way to strengthen this position. At the same time it is clear that the low-skilled have a substantially lesser chance of participating in training, at least in work-based or job-related training. With the latter becoming increasingly important, this poses particular challenges for designing training policies to overcome the deadlock.

Various European countries have attempted to develop policies aimed at enhancing lifelong learning. Debates on arrangements and incentives to increase the investment in training are on many a political agenda and various countries have seen national committees or national action programmes established during recent years, with the aim of enhancing lifelong learning, if not actually establishing a ‘system’ for lifelong learning (examples are: the UK, Norway, Iceland, Finland, Sweden the Netherlands and recently also France). In the terms of the European Commission’s white paper, the aim is to establish a ‘learning society’. In these attempts a strong emphasis is given to increasing the employability of individual workers. What sometimes makes the potential effectiveness of such strategies (slightly) doubtful, is the fact that core concepts are not clearly defined. Employability, for example, is often equated with employment in the sense that it is assumed that employability will result in employment. However, this will depend on the strategy used to enhance employability and with that employment. Basically two strategies can be distinguished (Thijssen 1996):

a) enhancing job search and job acquisition skills, focussing on the process of getting a job;

b) enhancing work or occupational skills, focussing on the skills needed for performing a job well.

In a cynical way it could be said that the first strategy aims at learning a ‘trick’, while the second strategy aims at qualifying people in order to get an adequate and more or less secure start in the labour market. In terms of the learning needed or provided, both strategies have profoundly different implications as well.

---

8 The training provided is AMU-courses from the standard offer of the AMU-centres. It concerns publicly funded training that is not tailored towards specific enterprise needs.
Learning, in the context of lifelong learning, means a permanent process of learning and of ‘learning to learn’. Both ‘learning’ and ‘learning to learn’ can have different meanings (Thijssen, 1997):

- learning (to learn) in the sense of acquiring a set of meta-cognitive skills (e.g. problem solving, applying knowledge and skills in new situation, information processing, etc.);
- learning (to learn) in the sense of acquiring a positive attitude towards learning and continuing to learn;
- learning (to learn) in the sense of acquiring a broad set of occupational skills and competencies applicable in a broad occupational domain (as contrasted to job-specific skills);
- learning (to learn) in the sense of acquiring ‘coping skills’ or ‘life skills’ as defined within a new OECD project, focussing on the type of skills people need, in order to cope with the modern (information) society (including basic ‘computeracy’ skills).

It is clear that the last of these seems more closely related to the job search/find strategy of employability, while the third meaning of learning (to learn) is more closely related to the qualifying strategy of employability, with the first and second meanings being more or less preconditions for lifelong learning in the sense of a continuous process of personal development. What makes it all the more important to be crystal clear about which learning is intended, is the expectation that independent and self-directed learning will get greater emphasis (Hasan and Tuijnman 1997). Benefiting from more independent and self-directed learning will require ‘learning skills’ and the capacity to learn in ways other than traditional classroom teaching. What is presently considered as being effective learning (in the context of learning organisations) is characterised by (cf. Brown 1997; Brown and Keep 1998):

- reflection: the need for a culture inside organisations that values learning and development can be supported by an emphasis on reflection;
- development of thinking skills: the importance of developing learning to learn skills, thinking skills to manage and process information and problem-solving skills is presumed to be crucial;
- development of learner independence: this refers, in relation to the previous, to the need to make learners more aware of their learning processes, as well as making them the controllers of their own learning processes and owner of their own skills, competencies and knowledge;
- teamwork and collaborative learning: if responsibilities are increasingly delegated to workers, this will require better cooperation between workers, which puts new demands on the interpersonal skills of workers and also on their ability to learn collaboratively;
- learning and assessment processes have to be linked: there should be a synergy between the way in which learning takes place and the way in which the outcomes are assessed; too detailed assessment standards, that encourage students as well as assessors to focus on meeting these standards and not on the (de)construction of the learning process behind this, would be counter-productive;
- developing a substantive knowledge base: learners should have the opportunity to develop a substantive knowledge base in order to be able to achieve broad occupational competence (with the latter meaning that learners should really acquire occupational competence applicable in various situations, instead of learning ‘tricks’ that will get them into a job, but leave them with ‘empty hands’ once this job disappears).

Learning as presently perceived will be less formalised and rely to a greater extent on self-supported and self-steered learning. In this sense there is a shift away from more traditional school- or classroom based training...
Training and employment perspectives for lower qualified people

(courses) towards informal learning. For individuals to fully benefit from the learning opportunities, this requires a particular learning attitude, which previously has not been incorporated in traditional education and training. In addition, it requires a particular social and cultural capital, that often has not been acquired through education, but through other channels (e.g. family, peer groups). Low-skilled workers in the working age are in a disadvantaged situation. Often they have left education, because the means to continue education were lacking, but also because learning was not attractive for them. In order to provide them with opportunities to benefit from the learning options offered, it will be necessary to develop the learning attitude and cultural capital needed.

The fact that work-based training is becoming increasingly important as well, might have (negative) implications for the low-skilled. On the one hand, work-based learning has long been considered as one of the best ways of delivering vocational training. However, the effectiveness of work-based learning has been scrutinised over recent years. Though work-based learning, or on-the-job training, is still considered important model within vocational education and training, it is more and more acknowledged that not all workplaces are effective learning places and effective work-based learning needs to build upon well-designed learning and instructional models (Raizen 1994). It is in this context that concepts like ‘cognitive apprenticeships’, ‘complex learning situations’, ‘communities of practice’ and ‘learner independence’ have been developed as alternatives to the more traditional models of either school-based or work-based learning (cf. Attwell and Brown 1998). At the same time, the currently evolving learning society and learning economy is highly work-based. Unskilled, simple jobs have neither high learning potential nor do they stimulate learning outside the workplace. In order to prevent low-skilled workers (whether employed or unemployed) being faced with ‘learning exclusion’ (on top of social exclusion for those that have become marginalised in the labour market), VET-policies should focus on strategies and tools that can enhance the learning of the low-skilled.

Thus far, the focus of this chapter has been on the options for increasing the skill level of low-skilled workers in order to strengthen and improve their labour market situation. However, Freeman and Gottschalk (1998) indicate that such ‘supply-side’ policies might (in the short run) be less effective than hoped and, at the same time, quite costly. They argue that it might take a very large investment in skills and skill increase over a long period, to restore the loss in wage American low-skilled workers have experienced due to their low level of skills (and productivity) (cf. Nickell 1998). Their plea is to reconsider ‘demand-side’ policies, focusing on the increase of demand for less skilled workers, as an alternative for supply-side policies. The studies presented in their book show that such demand-side policies (like: lowering the costs of employing low-skilled workers, creating public jobs, changing pay modes and changing employment regulations) can increase employment opportunities for the low-skilled, but only rather modestly contribute to the increase of wage and skill levels of the low-skilled covered by these policies. Freeman and Gottschalk therefore conclude that such demand-side policies as implemented in the past, do not offer magic solutions for the problems low-skilled workers (in the US) are facing. However, they also state:

‘... several policies that singly contribute only marginally to raising employment or earnings of the low-paid can have a larger effect in combination’.

Improving the labour market position and employment perspectives of the low-skilled is necessary if European countries want to maintain their economic competitiveness and prevent marginalisation and exclusion of a still substantial proportion of their labour force. Taking the conclusion of Freeman and Gottschalk to heart, it seems that policies aimed at increasing the skill level of the least qualified as well as their employment prospects, should not put all the eggs in one basket. Achieving such aims appears to require carefully designed measures, combining the advantages of both supply-side and demand-side policies and geared towards the particular situation of different target groups.

Part six:

VET research activities outside the European Union
Research on vocational education and training at the
crossroads of transition in Central and Eastern Europe

Olga Strietska-Iilina

Abstract
The following analysis provides an overview of state of affairs in vocational education and
training research in eleven countries of Central and Eastern Europe. The report attempts to
analyse the responsiveness of the VET research to the major socio-economic challenges occurring
in the process of transition. The objective of the study is to identify main research gaps and to
bring about better transparency on VET research, its achievements and failures in these
countries. The report is a first attempt to map the existing research results in the field of VET
in the region, and therefore has an illuminative rather than evaluative character.

The author argues that the VET research in CEE has found itself in the middle of a double
reform process, where transition from a state planned to a market economy has been multi-
plied by the global changes. The VET research has successfully reacted to major challenges of
the transformation period. It is, however, argued that there have been certain drawbacks, where
national research was not in place to justify the transfer of foreign models and had a somewhat
passive role in the reform process in the initial stage of the transition. Nevertheless, the recent
years demonstrated the growing maturity of the national research and its increasing import-
ance in the support of the reform process. Although there is still a lack of comprehensive
conceptual strategies that embrace different aspects of initial and continuing vocational edu-
cation and training in the perspective of lifelong learning, the shift from highly fragmented
research has been noticed.

The report demonstrates systemic inefficiencies (organisational, institutional, financial) that
create obstacles to research development. The hardship of the transition period caused many
challenges for the research community, the brain drain not being the least. The paper comes
with the set of recommendations for the support of comprehensive multidisciplinary VET re-
search in the priority fields, as well as suggests organisational measures to make the research
process more efficient.

1. Introduction

1.1 Approach and definition of the scope of the study

This part of Cedefop’s research report is a comparative analytical overview of research in Central and Eastern Europe (CEE) in the field of *vocational education and training* (VET). The study covers a wide geographical area of eleven countries: Albania, Bulgaria, Czech Republic, Estonia, Hungary, Latvia, Lithuania, Poland, Romania, Slovakia and Slovenia. The countries were chosen on the principle of the geopolitical ‘commonality’ of the region of CEE. All countries in question share a socialist past and are undergoing the reform process from a state-owned to a market oriented economy. All countries, apart from Albania, are candidates for membership in the European Union. All countries are covered by the European Community’s Phare assistance programme, and therefore, in this text will be referred to terminologically as Phare countries or partner countries. In spite of the certain degree of similarity, the countries of the CEE region differ greatly, and do so from their very point of departure in the pre-reform period, at which time Slovenia belonged to Yugoslavia, (the most democratic and open of all socialist countries), the Baltic republics were part of the Soviet Union, Albania remained in almost complete isolation, and all other countries also differed greatly in terms of their socialist “pathways”. The countries undertook different approaches to economic reform, and the reform progress that has thus far been achieved also varies to a great extent.

From a cultural perspective, the region enjoys vast diversity, which has implications for all aspects of society. For this reason, generalisations about the region and the typologies used in the study represent general trends rather than judgements on each particular country, and certain reservations must be considered when looking at different countries.

The paper provides an overview of state of art of VET research against the background of vocational education and training in the context of socio-economic development in the partner countries. The cultural diversity presents a semantic challenge for understanding not only of what vocational education and training is, but also for what research into VET means. In this view, VET is understood in its broader sense, which embraces not only initial education but also continuing vocational training (CVT). The overview analyses research that has been produced so far on the problems, challenges and developments in the relationships between VET, the labour market, and the economic and social aspects of the reform process in the countries undergoing transformation. Therefore, the study also looks at contextual research, primarily dealing with the labour market.

There have been several attempts to give a definition of research into VET (e.g. Sellin and Grollman’s (1999)), but it is difficult to find an exhaustive one. Therefore, we will adopt the following definition of *education research and development* (the ‘Frascati Manual’): ‘Educational R&D is the systematic, original investigation or inquiry and associated developmental activities concerning: the social, cultural, economic and political context within which education systems operate; the purpose of education; the process of teaching, learning and personnel development; the work of educators; the resources and organisational arrangements to support educational work; the policies and strategies to achieve educational objectives; and the social cultural, political and economic outcomes of education’.

Without attempting to give an exhaustive definition of VET research, for the purpose of this paper and with a certain amount of oversimplification, we understand research into VET as those analytical studies that base

---

1) Sellin and Grollman use a too rigid definition of VET research in the view of the *scientifity of criteria* and methodology. Through this strictness perhaps we will not be able to take count of analytical studies produced in the framework of development projects and even some applied research. The definition also overlooks the labour environment and the world of work as such, looking instead at psychological and behavioural aspects in the socio-economic context (see more Sellin and Grollman 1999).
themselves on accurate methodology and focus on one of two aspects: the requirements, and the process and the outcomes of VET.

The first aspect involves not only research into VET as such, but also and above all contextual research aimed at the identification of social and economic change (both macro and micro), labour market requirements, the development of new technology, the changing nature of work, the shifts in job profiles and qualification systems, the identification of vocational standards and the approximation of curriculum development to meet the needs of employment, key skills and competency-based qualifications, financial incentives to support training provision and access to training, problems of the transition from schooling into the labour market and so on.

The second aspect involves research on teaching and learning methods, mechanisms of quality assurance, evaluation of study results, certification, curriculum innovation, modular training, etc. Although the traditional division between fundamental (or basic) research, applied research and development projects is used hereon in the text, the division is somewhat artificial and must be considered with some limitations. It is rather difficult, or almost impossible, to distinguish pure examples of each type, as most projects contain some elements of another type. Moreover, to draw a strict line between applied research and development projects might in some cases be not only artificial but also misleading. Pure theoretical research is very rare and one may even question the significance of such research without thorough empirical support. Thus, the aforementioned typology is used in very general terms.

1.2 Objectives and hypotheses

The objective of the study is to provide an analysis of current research in the field of initial and continuing VET in CEE with reference to its theoretical and methodological foundations, its research results and its research “efficiency” in policy making and practice. The overview of VET research seeks to identify the structures and “products” of research in VET, irrespective of whether the research has been produced in or outside the region. Therefore, the study covers research at the international level, the national level, and when available also at the regional or local level. Although an analysis of the institutional framework of VET research is not a primary task of the study, the paper does make an effort to identify deficiencies in the research systems of the countries. The paper does not attempt to assess either the institutes involved in VET research or the studies and analyses produced by them. This is not our objective.

The major objective of the study is to identify the main research gaps in the field of VET (areas of research, which are insufficiently covered) and systemic drawbacks that create obstacles for further research progress. Furthermore, the overview of VET research in CEE attempts to bring about the transparency of analyses in the field of VET produced in the region and to give examples of good practice in VET research where possible.

Thus the study is composed in the following way: first, it looks at the main challenges for VET research in socio-economic context; second, it examines the institutional and financial environment of VET research; then it looks at types of research and topics which are tackled by VET research in CEE, and its basic findings in thematic clusters (research into systems and contextual research) and finally, the paper defines the problem areas in CEE VET, which are not covered by research – the research ‘gaps’. The concluding part of the study offers a set of recommendations for policy makers, researchers and practitioners at both the national and international levels.

The paper hypothetically suggests that identified priorities for research into VET will often coincide among the countries of CEE. The nature of the transitional period in CEE along with the process of globalisation and change has placed special importance on socio-economic contextual research as far as VET is concerned. Therefore, priorities will concentrate on the requirement aspects of research (see above). The future priorities of research are not necessarily gaps, i.e. neglected or
abandoned areas of research, and in many cases will be dictated by the challenges of recent developments, introducing either new areas of research or rather new challenges in areas explored. The problems and priorities of VET research in CEE are, hypothetically speaking, not unique to the region, and in the majority of cases they will be similar to ones seen in the EU member states. However, the degree of specificity of the regions and the milestones of recent socio-political and economic change will to some extent render the future needs and objectives of research also specific in nature. Hypothetically we may suggest that VET research has a higher level of production and maturity in the countries where VET itself enjoys a long-term tradition and prestige.

1.3 Methods and sources

The study was commissioned by Cedefop and was supported by the European Training Foundation (ETF) for the preparation of additional short overviews produced either by the National VET Observatories or by experts in the CEE countries nominated by them. The Czech National Observatory of Vocational Training and the Labour Market at the National Training Fund coordinated the work of the ten sub-contractors. National Observatories are small institutions established under the initiative of the ETF in the partner countries to provide accurate and up-to-date information on VET and the labour market. Different types of institutions host the National Observatories, varying between the governmental and the non-governmental sector, research institutes, academic centres, development agencies, independent non-profit foundations and private establishments.

Due to the wide scope of our overview on the state of affairs of VET research in CEE, in most cases only the recent studies and papers were considered, i.e. not extending beyond the period of the last two years, and only in few cases we looked at earlier analyses. The paper is based on four types of sources: National Observatories were sub-contracted

1. for preparation of a short overview on the basis of the standard Terms of Reference, with a commonly identifiable structure; and

2. for delivery of publications and other materials that represent research results in their countries (theoretical studies, surveys, reports, evaluations, etc.

3. The ETF commissions thematic analytical projects mostly with the help and direct participation of the National Observatories, but sometimes with the assistance of other national experts and institutes. On the basis of these thematic reports, cross-country, comparative reviews are produced by international experts or the ETF themselves. The transnational reports and sometimes the country thematic reports served as another important source of information for the present paper.

4. Additionally, studies commissioned by other international institutions as well as international statistics were used (OECD, World Bank, European Commission, Cedefop, ETF, Unesco, etc.).

In respect to the latter, it is important to note that not all, international studies are produced with the direct or indirect participation of national experts. Therefore, the paper might not always provide an adequate impression of state of art of research within the countries of CEE. This is especially true in the case of some of the less developed countries, where research has not been a priority in recent years, national analytical works have been largely abandoned and consequently foreign expertise has represented the foremost analytical operation there.

The summary of preliminary findings was presented first at a National Observatories' meeting in Tampere, Finland in November.
1999, and later at the conference Shaping social innovation and VET – the contribution of Leonardo surveys and analyses projects in December 1999, where main priorities of VET research in CEE were presented. Comments from the audience were taken into account as well as commentary on the draft version of the paper, which was distributed to National Observatories and selected experts. The author is extremely grateful to all those who did their best in collecting information and commentary on the paper in the given limited time frame. Despite the numerous contributors to the preparation of the paper, the author takes complete responsibility for statements expressed herein.

The author had to rely mainly on the information provided by the National Observatories, although a great deal of additional publications, expert judgements and comments were used. Given the limited time frame and the broad scope of the study, the analysis could only provide a general overview of the state of art of VET research in the region. The author had to take into account the natural limitations of the study. In some countries more materials were available in English than in others. The country background papers differed in terms of the quality and the scope of information and reference materials provided. For instance, there was very limited access to studies and other research materials produced in Hungary, and the country overview on research provided rather vague information. Another important limitation must be mentioned with regard to Albania, where most statistical data is not available, which made the inclusion of the country in the analysis very difficult.

Therefore, the analysis is not completely balanced and some countries are more comprehensively presented than others. Areas of research might also be presented with a certain imbalance, as it highly depends on the specialisation of the institutes or experts involved in the preparation of the paper. In the identification of country-specific research gaps, the author also had to rely on reporting from the countries, where in many cases, however, this was prepared from the perspective of one institute without a consensus necessarily being reached on a national level. Therefore, the so-called research gaps in the countries may have a different meaning, varying from neglected research areas to topics that have received considerable attention from researchers but need further elaboration. Taking into account all aforementioned shortcomings, we must still point out that this paper is the first attempt to analyse the research situation in CEE in the field of VET and could act as a useful tool for discussion. A more in-depth analysis may be useful in the future, commissioned in a series of papers on specific topics of VET research, in order to avoid rendering the scope of analysis too broad and to a certain extent fusing the task as a result.

2. Context and challenges of transition for vocational education and training in CEE

2.1 Research and democracy

For half a century, scholarly discourse in CEE was dominated by writing in the spirit of official political rhetoric. At the same time one should not ignore the tremendous role the research community and intellectual forums did play in supporting democratic ideas under the previous regime and the role of re-
VET research in CEE countries

search in the advancement of new ideas immediately after the break-up of the socialist system. Resourceful thinking and an intellectual debate appeared to be the main driving force of change at the end of the 1980s. The new polity introduced new chances for the research but also new challenges.

Of all political arrangements, it is democracy that is the political context most fertile for science, 'because it encourages and strengthens the scientific ethos' (Kazancigil and Makinson 1999 p.261). Approached from the opposite direction, 'democracy requires an interested, competent, knowledgeable, educated public' (Ibid, p. 262). It requires an elaboration of the reform rational by researchers, and researchers seek for recognition and public consensus on the value of this rational. Democratic polity demands a scientific background for political decisions and thus creates a favourable environment for research.

The new universal democratic values in science have introduced the principle of diversity into scientific thoughts and traditions, cultural pluralism, academic autonomy, and scientific freedom. Research in CEE could not remain in isolation, and in the environment of the global internationalisation of the research community, the CEE countries have gained the most from benchmarking comparisons with contemporary international scientific achievements. In the field of VET, the modern Western theories and concepts of the systems and content of education served as a point of reference for an elaboration of the national concept of VET reform. The initial 'stocktaking' phase of the reform has expired in most countries of CEE, and a turning point has now been reached when the scientific community is to elaborate its own national concepts and approaches. Innovation in the field of VET on the basis of foreign know-how turns to original national innovative abilities in research and exchange with the international community on the basis of equal partnership.

This is an important challenge for the CEE research community which is undergoing a transformation itself. In the past, not only political rhetoric dominated the research but in addition the forms of research were influenced by the regime. Applied research had not been sufficiently employed, as the regime did not require support for political arguments with empirical data, or if it did, it often turned to falsification and scientific discourse. VET research, to the same extent as VET itself, served the political power and was fully dominated by it, not being an equal partner of the decision-maker but rather an instrument, serving the needs of the centrally planned economy with the precise provision of the workforce.

At present the research community in CEE is pursuing global developments in science: internationalisation, universal principles and culturally-centred concepts, multidisciplinarity of research, inter-institutional cooperation, diversification of the institutional base of research (incorporation of civil society and the private sector), cooperation in decision-making and in the world of employment, putting results into practice. The transitional context, however, is not always favourable and imposes certain implications on the development of research in CEE at the present time. For instance, the current interests of research are largely defined by their financial needs, and so turn to applied research, while theoretical elaborations are largely abandoned. For many researchers this presents the dilemma of the choice between 'paid' research or other work and private scientific interests. In the following sections we shall see what the main socio-economic and political challenges for VET research are. Further we shall also look at what the shortcomings of the institutional, organisational and financial contexts of VET research are, and where the VET research in CEE has or has not been successfully addressing the challenges of transition.

2.2 Recent socio-economic developments

All eleven countries in question had a four-decade history of socialism before 1989, following either the Soviet pattern or their own socialist path (Albania, Yugoslavia). During socialist rule, the region maintained member-
ship in CMEA, which involved a division of labour between the countries, with specialisation in the production of certain goods. Therefore, after the years of cooperation within CMEA, the countries suffered from overspecialisation in particular industries and agricultural products. Vocational training, being closely linked to enterprises, and education in general, and provided in accordance with a meticulously calculated manpower supply for the state planned economy, repeated the pattern of overspecialisation of the economy itself, with narrow branches of specialisation at the top. Training was often directed towards lifetime jobs (ETF 1999a). The nature of the centrally planned economy was reflected in an under-representation of market-oriented branches, for instance in the services sector. Poor technological development in the economy was reflected in poor equipment for education. The school system and as well as the content of education were defined by the state and its structures, neglecting modern innovative methods of curriculum development, teaching and learning. Passive learning and encyclopaedic knowledge (Parkes et al. 1999) along with an old-fashioned mechanical mediation of the knowledge defining teaching methods, were features of schooling prior to 1989.

The process of democratic and economic reform began in CEE countries between 1989 and 1991. The political transition commenced in most countries in 1989 (with the exception of the Baltic states and Slovenia which gained independence in 1991), but substantial market reforms were not initiated before 1991 (with the exception of Hungary and Poland, where reforms started before 1990).

Since the beginning of the process of economic restructuring, the progress achieved in transforming economies into competitive and dynamic markets has differed to a significant extent. The early 1990s were characterised by a collapse in output and a decrease in labour productivity throughout the entire region. GDP in terms of output volume fell by at least 20% in all countries at the beginning of transition, and only in Poland, Slovenia and Slovakia had the GDP by 1998 re-gained its pre-transition level (in Poland it was some 17% higher than in 1989)(European Commission 1999, p. 52). Productivity growth has been a feature of the majority of countries in the region in recent years, although output per person employed in the Czech Republic is still at the pre-transition level. In Bulgaria, Romania (European Commission 1999) and Albania, both output per person and GDP are well below the pre-transition level. These countries have yet to rationalise their economy, making it more efficient, and reducing the excess in manpower in industry and agriculture.

At the beginning of the economic transition from a planned to a market economy, in most CEE countries there was an immense drop in employment in the state-sector industry, which was then followed by a steady decline. Whilst there has been a net creation of jobs in the private sector, it could not absorb the entire labour shift from the state sector. This resulted in continually increasing unemployment. Even in the countries that initiated intensive economic reform in the early 1990s and where growth in employment has been stable over the last four years, this increase in employment was still unable to compensate for job losses in comparison with the situation in 1989. In 1998, the average employment rate in CEE countries (with the exception of Albania, where comparable data are missing) was around 63%, slightly above the EU average of 61%, with the highest employment rates, at around 70%, registered in Romania, Estonia and the Czech Republic (68%), and the lowest, at around 55%, in Hungary (European Commission 1999). In all three countries with a high rate of employment, however, employment declined in 1998. In the Czech Republic and Romania, the deterioration of the employment situation could also be explained by economic decline (GDP fell by 2.5% and 7% respectively in 1998, see table 1), and above all by the delayed imple-

---

4) Council for Mutual Economic Assistance was established in 1959 and included Albania (only until 1962 when the country stopped any cooperation within CMEA after the break-up of relations with the USSR), Bulgaria, GDR, Hungary, Poland, Romania, USSR, Czechoslovakia. Yugoslavia had a status of associated partner in CMEA, underlying its independency in the socialist path. The latter was a member of the Non-Aligned Countries.

**Notes:** ¹) estimation; ²) year 1996; ³) year 1997

The implementation of a number of economic reforms (European Commission 1999). The employment situation improved in Poland and Hungary in 1998 (European Commission 1999), the countries that started intensive economic reforms in the early 1990s. A slight improvement in employment situation has also been recorded in Latvia.

As in the EU Member States, unemployment has fallen in most CEE countries in recent years. The exceptions are Slovakia, Romania, Slovenia, and especially Bulgaria and the Czech Republic, where the unemployment rate increased significantly (see table 2, annex 1). The Czech Republic and Romania have still enjoyed the lowest unemployment rates⁵, at about 6.5% in 1998, though the tendency toward unemployment is strongly increasing in the Czech Republic. The unemployment rate in Hungary and Slovenia was below 8% in 1998, and in all other countries close to 10% (Estonia, Poland, Slovakia) or above 13% (Bulgaria, Latvia, Lithuania) (European Commission 1999).

In all transition countries unemployment and income decline caused the spreading of poverty and demographic crisis. The demographic situation has been characterized by the sharp fall of natality rates, the rise in mortality in a few CEE countries and the large flows of international migration, particularly from more deprived countries and regions (Ellman 1997). Furthermore, the ageing of the society brings many implications on social policies and the burden on the public budget.

The structure of unemployment has been changing in all countries, manifesting increasingly higher proportion of young people, fresh graduates, people with low or no qualifica-

Notes: 1) ILO Methodology; 2) year 1997; 3) year 1995; 4) year 1996; 5) year 1996, 2nd Quarter

Youth unemployment increased during the transition period in all countries, and the situation has only started to slowly improve in Bulgaria, Romania and the Baltic States. Youth unemployment as a percentage of the unemployed varied in 1998 from about 22% in Latvia and Lithuania to 43% in Romania (European Commission 1999, pp.146-149, see also table 2). In all countries, with the exception of Romania and Slovenia, job losses brought about the withdrawal of a substantial number of people from the labour force, which led to a significant rise in early retirements and the subsequent fall in the employment rates of those aged 50 and over (European Commission 1999, p.60).

The two age groups mentioned above—the young and the elderly—already suffer from a lower level of participation in the labour market, and when this is multiplied by low or inadequate qualifications, they may find themselves as being at a high risk for marginalisation and social exclusion. This challenge has been reported by many CEE experts. Lithuania represents a peculiar example of an even more dramatic situation due to economic disorder experienced in the early transition period, as a large portion of the of youth population (reportedly almost two entire age cohorts) do not possess any vocational qualifications recognised by the state (Gurskienė 1999). Thus if the state will not conceive special training programmes which could help these people to obtain a vocation, they will constantly be found knocking at the doors of the labour exchange office (Dienys and Pusvaskis 1998). The same holds true for the older part of the population, which has an even higher risk of marginalisation in that they face greater difficulties in adapting to the new conditions than do the youth, and also in that they are somewhat disadvantaged in re-training provisions during times of economic hardship, when training authorities often need to prioritise their subsidies for training courses.
In all countries of the region, a certain proportion of the respective age group leaves the general and vocational education system prematurely and without qualifications. It is estimated that this proportion can be up to 20% of the age group in vocational types of education in some countries (ETF 1999b). The factors behind this lack of achievement are essentially not very different from those in EU member states, but obviously, the specificity of the transition period add to their particular dimensions (ETF 1999b).

Although activity rates decreased in all CEE counties in the transition period, employment among women aged 25 to 49 was still higher than in the EU average throughout the entire region (European Commission 1999). Nevertheless, the employment rate among women decreased in at least two countries of the region, Hungary and the Czech Republic, where with the decline in the absorption capacity of the labour market females often withdrew from employment and opted to stay at home. This temporary withdrawal may turn into lifetime exclusion if there are no special supportive measures assisting women in their return to the labour market (including re-integration into the labour market after maternity leave).

The opening up of the economy and the subsequent pressure from competitive markets has pushed the transition process into adjusting to global changes. Although the basic pattern of the employment shift and the restructuring of output and trade was the same in CEE as in the EU and global markets, the excess of manpower in industry and, in some countries, agriculture on the one hand, and the underdevelopment of the services sector on the other, have demanded an even higher rate of adjustment. The characteristics of employment have changed dramatically since 1989, when in majority of countries there was a big shift from the primary and secondary to the tertiary sector.

At least in several CEE countries the issue of unemployment and especially hidden unemployment is closely related to agriculture. A decline in employment in the agricultural sector was registered in the majority of countries, and only in Bulgaria and Romania has employment in agriculture slightly increased (European Commission 1999), absorbing part of the job loss from the industrial sector. Agricultural sector had been overstaffed in the whole region under previous regime, and although substantial shifts in employment from agricultural sector have been marked, still far too many people work in agriculture. In all countries the proportion of employment in the agricultural sector is above the EU average (about 5%), especially in Romania (about 40%), Poland (about 20%) the Baltic States (see more table 2), and Albania. In the situation of reforming economies it is not a facile exercise to provide sufficient amount of jobs in alternative sectors. Therefore, two aspects are important in this view. First, development of infrastructure and agriculture-related jobs in rural areas such as food processing and distribution, banking and other services (Bialecki et al. 1996), agrotourism and other innovative semi-rural activities, which introduce ever-new challenges to traditional skills. In this respect widely available vocational guidance services and re-training courses are crucial. This cannot be implemented without a thorough analysis of regional development and labour market needs. Second, in order to make agriculture more efficient and competitive as compared to a highly subsidized EU agriculture, adaptation of education and training to the new demanding requirements is necessary.

Despite the extensive job losses in industry, the proportion of employment in this sector was still above EU average (about 30%) in the majority of the countries, exceeding 40% in the Czech Republic and Slovenia (table 2). The opening up of CEE markets also introduced an important qualitative shift in the industrial sector, featuring a move from heavy industry and labour intensive production to sophisticated manufacturing and technology and knowledge intensive production. This shift has brought about quickly changing skill requirements in the industrial sector.

Employment in the services sector has risen throughout the entire region since early 1990, although in 1998 it was still far below the EU average (European Commission 1999, for

</table>

1997 data see table 2). Thus the absorption capacity of the services sector still maintains the potential to compensate for job losses in industry and agriculture. Taking into account the underdevelopment of the sector and the negligence in the vocational preparation for it during the pre-transition period, the shift in labour towards the services sector often occurred without any specific vocational preparation and large scale re-training activities (this is especially true for less demanding occupations). In order to cope with the competition in open markets in terms of providing client-oriented quality services, the need to pay particular attention to the provision of training in this sector speaks for itself.

The shift in employment from large to small and medium-sized enterprises followed the pattern of EU countries, but saw a greater rate of change due to the restructuring of large state industrial enterprises. In spite of the significant employment shift towards SMEs, the proportion of those employed in large industries in CEE still remains larger than in the EU. Given that the tendency will continue, it is important to take into account the special skill requirements of SMEs, where highly adaptable manpower with multiple qualifications and the ability to learn during their employment life signifies focal challenges for VET. The latter change is closely related to changes in work organisation with flexible job definitions, greater responsibility and independence of employees, more emphasis on team working and adaptability to quickly changing new technologies with ability to 'undertake a variety of tasks at the shop floor' (ILO 1998, p. 42).

In addition to the specific problems of transition economies, the CEE countries face the same challenges as EU member states, such as facing demands involved with the globalisation of the economy, technological change, and the rise of the information society. These challenges impose a special role on VET, which is to produce a highly qualified, flexible and employable labour force. The figures in all countries show that the higher the level of education attained, the lower the risk of unemployment (table 3).

The consequences of globalisation have an ambiguous impact on education and training. On the one hand, the increasing importance of knowledge-intensive industries, cumulating new technologies and ICT in the production process, the employment shift to the services sector and SMEs, increase the demand for upskilling and multiskilling. On the other hand, globalisation trends cause a more severe competition, which, under the conditions
of the turmoil of transition economies, increases the danger of troublesome access to training, especially after the completion of the initial training. These challenges impose a demand in the elaboration of national policies and the introduction of special incentives for companies to support training provision. The initial education needs to enhance access and capacities at higher levels of education and provide a broad basis as a primary incentive for lifelong learning.

2.3 Initial setting and future challenges

Virtually all CEE countries had an advanced system of education that had developed in pre-socialist times and during the socialist period. Under the communist regime, elementary and lower secondary education was provided on a compulsory basis by state-run schools. Upper secondary education (ages 14-18) was provided in the three main streams of general, technical and vocational education. General education was provided mostly for a small cohort of potential enrolments into higher education, the capacity and selection of which was rather limited. The republics of the former Soviet Union, in particular Estonia and Lithuania, represented an exception, where VET had very low prestige, general education enjoyed higher participation rates and access to higher education was somewhat better. The vocational education and training available was traditionally broad, enjoying high participation rates and relatively high prestige in many CEE countries. VET had primarily narrow specialisation schemes, often attached to state-run enterprises. VET had to fulfil its basic function of producing semi-skilled and skilled workers to meet the occupational needs of state industry and agriculture, based on the rigid, central manpower-planning framework. The process of democratisation had serious implications for VET in CEE countries. The lack of flexibility in training, too narrow specialisation, overproduction of semi-skilled and skilled workers and underproduction of highly qualified labour force were features of the VET systems in CEE at the beginning of the 1990s, at which time VET began to find itself increasingly irrelevant to the quickly changing demands of the reforming economy.

The weakening of state-based enterprises and the process of restructuring the economy worked to fracture the links between enterprises and vocational schools, and as a result the danger of vocational knowledge and skills remaining irrelevant to labour market requirements has increased. Companies, concerned with their own survival on the market have ceased to operate on-site schools and have lost interest in making contracts with vocational schools for the practical training of apprentices. This has led to a situation in which the VET system in CEE countries is predominantly school-based (the case of the Baltic republics, Romania, Bulgaria). In some countries, elements of partial, enterprise-based apprentice training have been preserved, but the extent of this continues to diminish (Czech Republic, Slovakia, Poland), and only in two countries (Hungary and Slovenia) was the dual system of apprenticeship training either preserved or re-introduced. Hungary is virtually the only country where the attempt to keep enterprises interested in participating in the provision of VET, has been relatively successful as compared to other countries. This is largely due to the early establishment of a system of financing through a national levy fund for vocational training and of tripartite bodies at the national and county levels. Economic hardship in enterprises as well as their shortsightedness have also depreciated training and development in human resources, and participation in CVT in many countries has been decreasing over the past decade.

The communist legacy has had an impact on trends in the participation rates in education even up until the present. The analysis of the Key Indicators (ETF 1998) shows that most of the countries with traditionally high participation in vocational education (ISCED 3) as compared to general education (Bulgaria, Czech Republic, Hungary, Poland, Romania and Slovenia) still have substantially higher enrolments in VET. A shift away from VET towards general education is evident in Bulgaria and Hungary. In all CEE countries there has been an increase in enrolments in general education providing preparation for entry into higher education. Lithuania and Estonia that have traditionally seen higher
participation in general education than in VET, experienced an increase in enrolments in VET between 1993 and 1996, but also a further increase in enrolments in general education. Latvia, the only Baltic country that had somewhat higher participation in VET but still very low prestige of it, has experienced a significant increase in enrolments in general education, and a decrease in enrolments in VET during the same period, which has almost levelled proportions enrolled in the two types of upper secondary education. Another country with substantially higher participation in general education as compared to VET is Albania, which suffered an overall drop in enrolments at the upper secondary level in recent years, especially in VET, although there was a slight increase in enrolments in general education in 1996. Additionally, in all countries (except Latvia and Poland) the proportion of enrolments in VET culminating in final examinations (Matura) has also increased. This demonstrates the increasing demand for higher qualification levels among students and on the market. The limited capacities at general secondary and higher education levels in a vast majority of CEE countries do not correspond to the demand of the economy and the society, and support 'creaming' of small proportions of age cohorts on the one hand and the underskilling of early school-leavers and the low qualified on the other hand.

The process of democratisation and the transition to a market economy presented the VET system with challenges, and instigated the need for substantial reform. The reform process in VET in CEE featured a high rate of diversification in available education, the introduction of private education, an improvement in access to complete upper-secondary education programmes, especially in general education, and subsequently in higher education. The reform encouraged innovations in teaching methods, standards and curricula, promoting the efficiency of VET, putting an emphasis on core skills and on the relevance of skills/capabilities to the labour market. The reform process has not been completed in any CEE countries yet and is considered rather as an on-going process with a long term orientation. In all CEE countries, reform has been supported by Phare and other international donor support programmes.

Preparation towards EU accession introduced new challenges for the VET systems in the CEE countries. The countries stress an objective of focusing on the development of the human capital, prepared to compete at global markets. The competitiveness, based on low labour costs, clearly is not a solution in a longer run. The CEE countries need to concentrate on investment into human resources, the provision of diversification of the training offer, an increase in the suitability of given qualifications to the new competitive requirements and ensuring equality of opportunity in access to education and training for all. The EU policy guidelines increase the demand for the employability of the work force, which must be tackled by reforming the content of education as well as teaching and learning practices. The goals and contents of education need to integrate education for democracy, the European dimension and multicultural aspects in education. The shift from input quality control to output control of education, and the elaboration of vocational and qualification standards shall be enhanced in close collaboration with social partners. The EU accession prospects will introduce greater labour mobility across Europe; under these circumstances a highly qualified labour force is the key to success. In the context of labour mobility it is also important to ensure transparency and recognition of qualifications, provided in the CEE countries and beyond.

Preparation for the EU accession also involves activation of the process of institution building, improvement of systems of social partnership and enhancement of the principle of subsidiarity in decision making. The latter point is especially important in the context of the initiated regional reform in most CEE countries. The specificity of the region is still large hidden unemployment in rural areas and high redundancy in state enterprises that cause significant differences in unemployment rates between regions. The unemployment is especially high in rural areas and in the regions with heavy industries (coal mining and metallurgy). In the disadvantaged areas further shrinkage of employment in ag-
VET research in CEE countries

diverse and heavy industries is expected. An elaborate policy, including education and training measures, to promote social cohesion in such regions is important. The process of institution building at a regional level needs to go hand in hand with expert capacity building of institutions and individuals at regional and local levels. The regions need effective collaboration in partnerships, inter-institutional cooperation, exchange of information for analysis and definition of priorities for regional development. The lack of expertise and capacity at a regional level in defining problems and suggesting solutions in a broader perspective ("think globally, act locally"), may become an obstacle in further development. The next stage of the VET reform process needs a great deal of strategic thinking and conceptualisation in order to utilise the human potential in the CEE countries at all levels.

2.4 Conclusions

In all countries of the region, vital changes have occurred since 1990, the lasting importance of which should not be underestimated. Nevertheless, the progress made by the countries during the period of transition varies markedly throughout the region. The countries that have advanced economically are already experiencing some growth in economic output and employment. However, the excess of manpower in the industrial and agricultural sectors is still an issue in most parts of the region, and a further shift towards the services sector could be expected in the coming years. Job losses and a decrease in employment in the early years of transition, though partly compensated for by the expanding private sector, especially in successful transition economies, still affects large portions of the population. Disadvantaged groups on the labour market have suffered from the increasing rates of unemployment in the region, putting young people and the elderly, especially with low or no qualifications, people with different forms of physical and mental disabilities, and national minorities at a high risk for social exclusion. The nature of the issue of social exclusion and an analysis of the causes and effects of the situation become especially important under these circumstances. The countries have tackled the problem through specific employment and training measures, the effectiveness of which has been measured in some countries (see further), providing a useful benchmarking perspective for the others.

The crucial challenge faced by the counties of the region is to complete the transition to a competitive market economy while at the same time creating sufficient jobs to avoid excessive rates of unemployment or inactivity (European Commission 1999), especially among the risk groups. The analysis of the socio-economic context has provided evidence of a double transformation in CEE, in which the countries of the region experience not only the single transition from a state to a market economy, but also undergo (and to no less an extent) a global transformation. The latter involves shifts in employment towards SMEs, deindustrialisation, changes in the world of work with the stress being placed on information technology and knowledge-intensive industries.

The opening up of economies to the highly competitive global markets introduces a dilemma of there being a need for ever higher standards of skills and competences (up-skilling) and at the same time a lack of training provision by enterprises as a result of severe competition on the market. The latter point is not unique to CEE, but its severity is certainly exacerbated by the transition period, when many firms are faced with the question of survival. In this respect, the provision of initial and continuing vocational education and training becomes increasingly more important, and for the CEE countries the role of VET in preventing and combating the negative consequences of transformation has additional accountability. The role of the state in providing initial VET and re-training for adults under the aforementioned conditions becomes indispensable, but even more so is its role in the systemic re-organisation of training provision in such a way as to allow for alternative methods and sources of financing the system, better access to training among all age cohorts, and increasing the relevance of education to the needs of the labour market. The VET systems are undergoing tre-
mendous changes, trying to meet the challenges of “both” transformations, and finding themselves in... the middle of the reform process. In the surroundings of such profound and fundamental change the role of research speaks for itself. Research into VET and the labour market must be of sufficient aptitude to analyse the change that has occurred against the background of global trends and suggest further evolutionary steps. But is there a conceptual framework that can allow for this type of thorough analysis? Does research itself in the turbulent times of transformation have the adequate capacity to tackle this challenging task?

3. A conceptual framework for the analysis of change in regard to education and training

Indeed, the change that had to occur after 1989 was almost taken for granted, without any particular specification of what needed to change and how. In the conditions of global change (see above) the challenge is even to find the point of departure, as well as the one of intention.

A great deal of literature has been written on change and even on the management of change, most of both concentrating on social and political theory and social psychology. The conceptual framework for change from the perspective of transition and with a strong reference to education aspects is missing, especially as far as research in CEE is concerned. Mestenhauser (1998), a scholar of Czech origin residing in the US, sought the answer to this problem in comparative thinking and in the key concept of “culture”. He turned to cultural anthropology, using literature (Kluckhol and Strodbeck 1961) as a reference point, and on this built up the concept of system diagnosis and knowledge recovery by the means of cross-cultural comparison. Indeed, the remarkable post-socialist change appears not to be merely a change within the same system, but rather an unprecedented transformation from one major system to another, which is not a simple linear change (Mestenhauser 1998) but a qualitative shift from one cultural perspective to another. Thus, the cross-cultural analytical perspective is a multi-dimensional variable where each research environment represents certain cultural values not only in a spatial dimension but also in a temporal perspective. Different cultural perspectives have different values of education, work, motivation, achievements, etc. The change in the period of transition, therefore, is an ongoing (non-static) change from one culture to another with the aid of an adaptation of values inherent to other cultures. The latter point is crucial.

The transition period, especially its early phase, was characterised by a high volume of research and development projects, produced with the help of foreign expertise, in which the mechanical transferral of their knowledge and skills could not be directly applied to the environment of CEE countries. While not intending to undervalue the contribution of foreign consultants to the revival of the region, it is difficult to deny that their intervention was not always efficient and workable. There is a great deal of evidence in social and political theory that the mechanical application of replicas of Western conceptual models in societies with different history and traditions may lead to scientific and existential discontinuity. However, complaints about this matter by the Eastern scholars were not accompanied by any elaboration of a local conceptual framework for development, often for the simple reason of a lack of thorough knowledge on strategic development. Dramatic change and profound societal developments require a massive infusion of ideas everywhere. It is, however, a dilemma to find a balance between universal and unique values. This balance is difficult to determine from the outside. The answer is certainly to be found not only in

---

6) This part is predominantly based on Mestenhauser's essay (1998) on Cross-cultural perspectives of change. The author, however, addressed the essay as a point of reference for conceptual framework, and the following text does not directly repeat Mestenhauser's statements.
VET research in CEE countries

Figure 1: Scheme of changes influencing vocational training policy and the supporting research

The mere collaboration of scholars across borders and cultures, but also in effective dialogue, value sharing and a joint search for balance from both sides. This cannot be achieved without a massive “knowledge recovery” programme aimed at assisting Eastern scholars in acquiring intellectual knowledge, critical and comparative thinking and an elaboration of their own insight regarding future evolutionary needs. This will bridge the gap between “external” and “internal” cultural influences (Mestenhauser 1998).

The Lithuanian scientist Lauzackas (1998) pointed out that ‘the focus of continuous vocational training change is the preparation of the participants and their predisposition to change themselves and the surrounding environment. Hence, only systematic knowledge of vocational training and anticipated problems can guarantee a well-grounded, strategic vocational training policy’ (p.6). Lauzackas attempted to develop a complete, systematic, theoretical model of constantly changing vocational training, meeting educational needs of an individual and preparing him for the world of work’ (p.6). The change of VET was tackled as ‘an all-rounded development, determined by ever-changing relationships between a person and the surrounding economical social environment, as well as personal actions of vocational training participants’ (p.11). Therefore ‘the main quality of vocational training is the ability to change together with the changes in the surrounding environment so as to confirm to the most general principles of democracy and humanism’ (p.21). Thus, provision of general qualifications, lifelong learning and the ability to learn, VET as a continuing process of human development, are crucial principles of contemporary VET (Lauzackas 1998). ‘Having described vocational training change presumptions and principles, the object of vocational Education science is defined as the object of interdisciplinary science’ (p.21). Therefore, ‘labour market research, research of vocations, qualification research and vocational training research’ are integral parts of the single system of research objectives.
A comprehensive understanding of the entire system and the dynamics of change is therefore an important aspect. What has been demonstrated in VET research in general and especially in the research in CEE is an examination of the autonomous parts of the system without an attempt to analyse it as one whole consisting of interacting and mutually shaping parts. Indeed, reductionism to one particular field (e.g. provision of initial vocational education at the upper secondary level) in the high dynamics of change and subsequent induction analysis does not allow for an account to be taken of all aspects of systemic change and mutual interference. Deduction from the complexity of system dynamics to the dynamics of its integral parts is an alternative conceptual approach, thus far not sufficiently exploited. This is subsequently reflected in the separation of institutional structures, researching bits and pieces of the system, with a lack of awareness of the achievements, information, knowledge and appraisal of the others. What is even more peculiar and novel for CEE, with the introduction of competitive relationships, the separate institutional structures within one country and one field of VET, including analytical structures, started to act as rival entities, just as though they were not parts of one and the same system. This phenomenon, although not necessarily typical for all countries, was evident in a few, not only in the private sector, where such behaviour could be explained by their market-oriented nature, but also among public or state institutions.

4. Institutional framework, organisation and development of VET research in CEE

4.1 Institutional framework of VET research

The following section is mainly prepared on the basis of a discussion paper written by M. Csako Identifying and assessing VET research institutions in the Phare and Tacis countries (1998) and the country overviews of VET research. As the former was commissioned by ETF with the specific purpose of analysing the situation in research institutes and the feasibility of establishing a network of research institutes in partners countries, the country overviews for the purpose of our study did not pursue the objective of assessing the situations of and in the research institutes. Furthermore, this is not an objective of our analysis. Logistical and financial arrangements are considered only in terms of the constraints or advantages they induce in research. Therefore, information from Csako’s paper (drawn from the analysis of two questionnaires distributed among experts in partner countries) was used above all, and only additionally compared with the information supplied by the National Observatories and their experts.

The patterns of institutional organisation for the purpose of the analysis of VET differ somewhat throughout the region. An attempt at typology in the later section of the paper provides only a general framework and is not intended to take into account the entire complex of arrangements of structures involved into VET research, which are at any rate in a continual process of change. Institutional arrangements for the provision of research in partner countries are still suffering from the consequences of the socialist past. 'VET research shared the fate of VET in general amidst the turbulent changes of the transition: many institutions have not survived, others have been reorganised, split into parts or re-emerged into new organisational structures. VET research has no uniform institutional structure throughout CEECs and the CIS. Central VET institutes seem however serving as foci of crystallisation of research efforts where they exist' (Csako 1998, p. 4).

Here it is important to emphasize one methodological remark about what actually Csako looked at in his paper. In the CEE region, he noted that only two countries established an institution called research institute in the field of VET: communist Czechoslovakia (in 1950) and Lithuania (a research centre of Vytautas Magnus University in Kaunas established in 1993). Other countries have governmental institutions developing and supervising VET, or methodological or academic centres. No matter what the institution was called, our
analysis demonstrated that there is no strict difference between them, and while research institutes deal with theoretical research as well as (and even predominantly) with development projects and applied research, this fact also applies in reverse. Even in countries where there is no institute in the field of VET with a major research capacity (Estonia and Latvia, Jogi 1999; Ramina 1999), other institutions have emerged as substitute structures (other sectoral institutes, universities, and National Observatories that under the circumstances seem to serve as focal points for VET research in these countries). Irrespective of whether the institutions involved in VET research are or are not research institutes, in CEE they have a far better capacity to carry out applied research (e.g. labour market analyses, school to work transition, sectoral studies) or development projects (e.g. curriculum development, elaboration of standards, evaluation of outcomes of education, etc.) and less ready to analyse the relationship between VET and labour market and even less fit to do theoretical research of larger socio-economic context of VET (Csako 1998).

'Research in VET can be distinctively [highlighting by OSI] split into two main parts: research in vocational education, (under the Ministry of Education and Sciences) and research in vocational training, (under the Ministry of Labour and Social Affairs or other ministries). The first part is relatively broader than the second one, having qualitative advantages also'.

Mustafai A., 1999, *VET research in Albania*

These facts in no way question the aptitude of the research personnel: researchers are of high quality in terms of level of scientific degree, volume of publications, involvement in international projects, etc. A lack of analytical capacity in the countries to cover the multidisciplinary of the analysis of links between VET and the labour market reveals the traditional, old-fashioned, inductive approach of VET research, also heavily mirrored in institutional specialisation. For instance, institutes of labour and social affairs would mostly deal with research on labour and social issues, VET institutes would concentrate on the curriculum of initial education, pedagogical institutes would deal with didactics, etc. In the countries where there is no special research institute in the field of VET, VET research is sometimes located at institutes of education research. This arrangement also reveals an outdated privileged link of VET to education, along with its separation from the economy (Csako 1998, p.15). This problem is not a specific concern of the CEE region: it is rather a general issue on the European research agenda. Furthermore, in each one of the studied CEE countries there is evidence (mostly recent) of the positive practice of intersectoral, suprainstitutional and multidisciplinary studies, even though it is still rather exceptional. The idea of National Observatories as institutions that work in an intersectoral network of experts and institutions in their countries hopefully contributes to this positive development.

As has already been mentioned, another weakness revealed by Csako (1998) and confirmed by country papers on VET research (1999) is a lack of thorough theoretical works on the larger socioeconomic context of VET. Why this is so could not be straightforwardly explained on the basis of information provided by national experts. Perhaps the financial constraints of the transition period and the consequent prioritisation of projects that can evidently provide immediate results (i.e. ideally applied research and development projects) offer at least a partial explanation. In each country there are again fortunate exceptions, where attempts to undertake comprehensive theoretical research in a broad socioeconomic perspective have been undertaken (more so observed in Poland, Lithuania and the Czech Republic).

In general, the VET research community in Albania is limited, in terms of quality and quantity. Only during the last years, close cooperation of Albanian and foreign VET experts has influenced the improvement of their expertise.

Mustafai A., 1999, *VET research in Albania*

The actual research and development work is often hindered because of a lack of researchers. There are only few people who could be called VET researchers and they are either of retirement
age or close to it, while there is no young generation emergin. There are also no schemes at present available or planned for initial training, continuous or retraining the researchers.

Jogi K., 1999, VET research in Estonia

Although in general the high quality of expertise of the researchers in CEE is not questioned, there are certain limitations to expertise and deficiencies observed and reported by the countries (e.g. Bulgaria, Albania, and Estonia). It is interesting to note that it is for the most part (although not only) in the link itself between VET and the labour market, the world of work, and social partnership and VET, that a lack of expertise is pointed out. The problem is again derived from the same sources: the old-fashioned separation of the research function in education and the employment field. One peculiar complaint is found in the Estonian paper, (Jogi 1999) concerning the lack of training provision for researchers. The intellectual potential in the society actually emerges out of higher education, in which Estonia is not exactly an example of the “creaming” of small intellectual cohorts. According to data, this country enjoys the second highest rate of educational attainment in ISCED 5-7 (tertiary level) among all age groups, although somewhat decreasing among the young (here table 4). The only suggestion is that this is an indication of a lack of preparation at the university and postgraduate level in the field of VET and its macro-context.

There are certainly other reasons for expertise shortages than the lack of appropriate knowledge in the field: the limited number of experts in small countries (the majority of them in CEE) on the one hand, and numerous projects on the other hand, create a deficit among analysts; in some countries also the issue of the brain drain is not of little significance (the latter will be approached further on). Nevertheless, a programme of massive knowledge recovery seems to be a healthy and appropriate measure in all CEE countries, not merely by attracting foreign expertise (this will be further explored later on), but rather by sending existing and future experts for training and temporary work placements abroad (here more Mestenhauser 1998). Joint research projects are another invaluable tool for knowledge recovery and a strong stabilising factor in science: the analysis of data collected in one comparative survey (Bobeva 1997) shows that the higher the participation in joint research projects in the country (e.g. Hungary, CR, Slovenia), the lower the outflow of researchers from science.

‘There is no one single central institution dealing with research in the field of VET. In 1990 the Institute of Vocational Education and Training, the only agency in the education sector that dealt with research in this field, was closed. During almost ten years since the institute had been closed, a gap emerged, which has not been really fulfilled’. It is also worth adding that at the beginning of the 1990s other sectoral institutes, that operated in such important fields, as education programmes, teachers training and research of youth, were also closed. The reason for abolition of these institutes was low effectiveness and inconsistency with the new conditions of the state functioning. The rational behind these decisions was assurance, that higher education and science will undertake research in this field, but in practice it did not bring about the expected results.’ [Translation by OSI].

Drogsz-Zablocka et al., 1999, VET research in Poland

‘It is estimated that actual inclusion of faculties is importantly connected with the interests of their researchers. It has to be mentioned that the most important research projects which led to the introduction of new vocational education and training system were carried out within the research activities at university. Out of three research projects from the field of vocational education and training, currently carried out within the National research programme, two are carried out within university research activities. Research projects dealing with the relation between vocational education and the labour market are also mainly carried out by the researchers at independent research institutes and university research institutes.’

Ivancic et al. 1999 VET research in Slovenia

The analysis of background country reports has demonstrated that in most countries the institutional arrangement is still suffering from the consequences of the socialist period,
when research was separated from universities and placed mainly within the structure of national Academies of Sciences, or was transferred to state ministerial research structures. Pedagogical faculties were often closed under the communist regime, and were re-opened only after 1989. Research at pedagogical faculties, however, mostly tends to cover general and academic education and deals little with VET. Pedagogical research (didactics, educational psychology, etc.) also takes place primarily in the pedagogical faculties of universities.

Exceptional cases are Lithuania, Slovenia and to some extent Romania and Poland, where university VET research is quite well developed. In Slovenia, a great deal of applied research is undertaken at Slovene universities which also actively participate in the development projects of national interest. Vytautas Magnus University in Lithuania is a central VET research point where substantial applied and basic research has been carried out. In Poland, schools of higher education are active in research into agricultural training, and in the field of management and human resource development, done mostly by economic schools. A high share of profit from the research activities of Polish institutions of higher education (Drogosz-Zabolocka et al. 1999) is an indicator of the activity of research function there, although the data refer to research in general without particular reference to VET.

In Romania, approx. 15% of the state budget for universities is allocated to research (Balica et al. 1999). The orientation of university research toward the field of VET came to be a component of Romanian reform. VET research constitutes a considerable share of the university research in this country. Universities in Romania mostly focus on fundamental scientific research, analysis of programme contents with reference to labour market requirements, regional development and other aspects (Balica et al. 1999). In the Czech Republic, although the Institute of Educational Research and Development at the Pedagogical Faculty of Charles University does not study VET as its primary topic, it has played substantial role in strategic studies and the formulation of policy documents working with experts from other institutions.

At present, the research function of universities throughout the entire region is undergoing revival. Although VET research at universities is fairly active in some countries (e.g. Lithuania, Romania, Poland, Slovenia), it still remains inactive in the majority of countries in the region.

The cooperation of universities with industry and the business sector in general is very exceptional even in countries where university research into VET is well developed (e.g. Lithuania). Only Romania and Slovenia reported somewhat better cooperation. In Romania, cooperation between universities and the business sector concentrates on human resource development requirements and makes up approximately 30% of university research financed by business (Balica et al. 1999). In Slovenia, universities are involved in developmental and advisory projects for the needs of companies in the field of human resource development (HRD), education provision, career planning, etc. The extent of this cooperation, however, has decreased during the years of transition due to financial constraints in companies (Ivancic et al. 1999). It seems that businesses prefer to work either with private sector consulting firms (applied research and consultancy) or with management development advisors from the MBA type of higher education. Unlike the other countries, cooperation between the university and VET schools is lively in Lithuania, where the results of master theses are often used by VET schools (Gurskiene 1999).

Social partner organisations are involved in VET research still only to a limited extent. During the period of transition, the institute of social partnership had to be re-instituted in the countries of CEE. From rigid, highly politicised and largely discredited structures, social partner organisations had to transform into active organisations representing the interests of the employer and employees at all levels of societal development. This process has been very challenging, and the role of social partner organisations in VET as such is rather limited in all countries (only Hun-
Olga Strietska-Iлина

Gary and Estonia seem to be more successful in this transformation. Cooperation between research institutes as well as universities with social partners is also very weak. The role of social partners undertaking research into VET is negligible. Slightly more active are employers' organisations, which conduct analyses of enterprise training and qualification needs and their HRD policy (e.g. Czech Confederation of Industry and Transport, Latvian Confederation of Employers, Latvian Chamber of Commerce and Industry). There is no evidence of the active involvement of trade unions in VET research in CEE.

The role of private, for-profit companies in VET research within CEE is extremely limited. The process by which VET experts working in state institutions go private is only starting. So far a process of accumulation of VET knowledge from the perspective of international achievements and management skills has occurred. Harsh competition in the consultancy market comprised of leading European firms has also not been a supportive factor for entrepreneurship in the field of VET expertise by national specialists. This situation has started to change slowly and we can find a few studies produced by private firms in all countries. They mostly concentrate on applied research, surveying the training needs of companies, supply and demand in education, CVT offer (DHV Prague), assessing competences in the telecommunication sector (Telekomunikacja Polskiej S.A.), elaboration of the system of qualification standards in the banking sector (Polish Foundation of Banking Education and Research), assessing the graduates in enterprises and company skill requirements (AMD and Universitas in the Czech Republic), conducting regional (GAREP – Czech Republic) or subsectoral analyses (Gradua in the CR, AS PW Partners in Estonia). Sometimes private firms combine analytical work with training courses (mostly trainers training) and publishing activities (CIVET in Albania).

Studying human resource management, human resource development in companies, management training needs and management development are other fields where private firms are relatively active. Often national surveys are done by the national branches of international consulting firms, which are already well established and have national experts working with them (e.g. PriceWaterhouseCoopers 1999). Access to the results of such surveys is often hindered either by client-related policy (delivered only to a client, otherwise confidential) or by a strong, for-profit orientation, meaning that the price of the final product is extravagant. It is important, however, to note that private consultants often participate in open tenders announced either by public/state institutions or by agencies with international funds in both the narrowly defined applied research and in comprehensive strategic studies (e.g. Euro-In Consulting in Romania, Deloitte & Touche in the Czech Republic, EMOR Ltd in Estonia).

7) The company survey was conducted in 1998 by the Czech Confederation of Industry and Transport, examining inter alia human resources development and skills needs in enterprises.

8) LSE has conducted two company surveys: Specialities and qualifications requested in the labour market - in 1996-1997, and Links between the labour market and the vocational education system in Latvia - in 1997 (Ramina 1999).

9) Latvian Chamber of Commerce and Industry organised a questionnaire survey among employers on the quality of qualification provided in existing vocational schools in textiles sector (1997) (Ramina 1999).

10) Euro-In Consulting coordinated the Study on labour market and related implications on the manpower provision by the vocational education and training system within the framework of Phare Project No. RO9405 carried out in 1998 (Balica et al. 1999).

11) Deloitte & Touche produced A study of needs, demand and supply of management training in the banking and financial sector of the Czech Republic in 1996 on the basis of a contract with the national Training Fund, Phare HRD programme.

12) Emor Ltd. Conducted qualitative research among SMEs in three focus groups in Tallinn and Rakvere. The study Training of skilled workers and personnel management of companies (Tamm 1997) was initiated by Estonian National Observatory. Similar studies were undertaken in 1998: Using skilled labour in enterprises (Tamm 1998a) and Survey on vocational schools (Tamm 1998b).
The recent strengthening of the private sector of VET expertise (research and consultancy) is evident in all CEE countries, although the extent varies. It depends not only on the level of advancement of the country in terms of the economic transformation, but also on the state tax policy, market competition (both private and public) and the employment environment in public sector research. The private status has its own advantages in VET analysis, as it presupposes independence from state structures, and therefore, provides a good incentive for objectivity and equality in cooperating with all public bodies. However, it may impede the implementation of findings and recommendations insofar as state decision making is concerned. Some of the National Observatories or their host institutions have had or have even recently attained a private non-profit status (Bulgarian Human Resource Development Fund, Czech National Training Fund) or the status of a non-governmental organisation (Estonian Foundation for Vocational Education and Training Reform, Albanian National Observatory, Latvian Academic Information Centre, Polish BKKK-Cooperation Fund). This positive development is also a big challenge, not only for these organisations, but also to the reciprocity of society.

Civil society sector research is still rather inactive in the field of VET (unlike the social sciences in general where quite a few studies have been conducted by non-governmental organisations (NGOs). This is connected with the insufficient development of civil society institutions and the still rather 'centralised' (state oriented) mentality of the public. Nevertheless, it seems that where funds are available (often allocated from international assistance programmes), NGOs are more active. Apart from non-governmental foundations with partial foreign funding, very few significant research projects undertaken by NGOs are reported.  

4.2 Financial aspects and coordination of VET research

The financial constraints of the transition period affected all sides of research life in CEE. Some institutions have been closed down (e.g. Poland) or were never created after the introduction of state independence (e.g. Estonia, Latvia, Slovakia14). All research structures have reduced the number of staff in an effort to make research more efficient. Large research institutes were replaced by smaller, but more flexible and autonomous research units as a logical reaction to a common problem of all post-socialist countries – overstaffing and the too narrow specialisation of research structures (Bobeva 1997). The other side of the coin is that with poor economic conditions and tight budgets in the early transition period, research often failed in the category of least priority areas. Reliable data on the number of staff engaged in VET research are not available, as numerous institutions and individual researchers are involved. We assume that VET research is experiencing the same trends as research in the CEE countries in general. Aspects of financing VET research are also difficult to analyse, as information on this point is very scarce. Therefore, general data on research and development have been used for the purpose of our analysis.

'...institutions are vastly underfunded and lack a wide range of well-qualified personnel to adequately respond to the complex needs of the VET subsector'

Mustafai A. 1999, 
VET research in Albania

Comparing the number of scientists and engineers in research and development (R&D)  

14) Slovakia and the Czech Republic are a classical example of the consequences of disintegration. Following dissolution of the federal state in 1992, there is are number of sister institutions in Prague and Bratislava, where only Prague's central VET institute (Research Institute of Technical and Vocational Education) maintains its predominantly research identity, and Bratislava enjoys a higher capacity Institute of Labour, Social Affairs and Family than its sister institution in Prague.
per million people, we can see that the CEE-10 average (data for Albania are not available) is about 93% of the EU average (calculated on the basis of World development indicators 1998). The Czech Republic, Hungary, Latvia, Lithuania, Poland and Romania fail in the category of being understaffed. However, the number of scientific staff in Bulgaria is about twice the EU average, in Estonia – about 1.5 times, and slightly above average in Slovenia. The latter two cases are specific examples of very small countries where the reported numbers represent almost the total of the small research community there, while Bulgarian science is clearly overstaffed. At the same time, expenditure on R&D as a percentage of gross national product (GNP) in Estonia (0.6%) and Romania (0.7%) are far lower, not only than the EU average (1.8%), but also than the CEE average (slightly over 1%). In the more stabilised economies, after a sharp reduction of the number of staff at research institutions and the number of institutions themselves during 1990-1997, the number of scientific personnel has started to grow slightly since 1998 (CSO, 1999), building on the rational of development and the consequent necessity of increasing investment into R&D. Indeed, although the number of staff in research had been decreasing in all countries up until recent years, in their efforts to rationalise and make the research field more effective, investment into research increased, at least in some of the CEE countries. Nevertheless, the expenditure of partner countries on R&D still lags behind the expenditure of EU member states, approximately to the same degree as the latter lag behind US spending (2.8%).

15) It is important to mention the relativity of the above statistics as the GNP absolute numbers between CEE and the EU member states differ to a great extent, which is only an additional confirmation of the poor financial conditions of science in CEE.
Thus, in spite of personnel reduction, which occurred in all countries, research is still over-staffed in a few of them, although in several CEE countries the redundancy policy was exaggerated and scientific establishments there suffer from understaffing. In most CEE countries, the academies of sciences and state research institutes were mainly affected by the reduction of personnel, while staff at universities did not experience personnel redundancy to the same extent (Bobeva 1997). The number of staff / expenditures ratio still signals that, in CEE, researchers are poorly paid, and work under poor conditions with very limited funds for undertaking research. Indeed, salaries in the science sector in most countries are low and even lower than the national average salary (Poland, Bulgaria, Romania, Slovakia, Estonia, Latvia), varying from the highest paid research personnel in the region – in Slovenia, followed by the Czech Republic, and the least paid in Lithuania (Bobeva 1997)

Working conditions showed the greatest variety, as revealed by Csako’s survey (1998): ‘Financial shortages and in some countries organisational limitations also hinder access to modern communication’. Access to modern technology, software, the Internet, the results of international research, etc., directly influences the mode of work undertaken by researchers in CEE (see table 5 on the rate of Internet usage in CEE). The financial constraints of the transition period imposed particular difficulties on the development of research and often prevented the initiation of innovative research projects. In many cases, financial constraints on research activities, low salaries and poor working conditions led to an outflow of experts from the research field and for the most part into the private sector. The big difference between the number of employed researchers and those working on research projects, discovered by Csako (1998), ‘supports the assumption that in transitory conditions, with restructuring institutional system, there are far too many factors to keep even prominent VET researchers outside VET research institutions’ (p. 16). The situation is so complex that even directors and senior researchers can be seen undertaking private activities at the same time (Csako, 1998). They are mostly involved in research or development projects, conducted by other agencies, and financed either by national sources and granting schemes or, even more frequently, by international ones. This issue is not obvious, and the consequences are rather ambiguous. Indeed, on the one hand, involvement in work of other institutions and especially international projects increases the mutual awareness of ongoing projects and interinstitutional co-operation. On the other hand, it leads to a de-concentration in the work of researchers and the atomisation of the scientific aspirations of research institutions.

The wage gap between the East and the West, as well as the other factors mentioned above, also creates a high incentive for emigration. Research on a problem of the brain drain and brain waste in the period of transition has been largely neglected. The only exception was Poland, where the massive emigration of scientists had been an issue even before initiation of the reform process. In 1997, the European Commission – DGXII supported a collaborative survey carried out in ten CEE countries within the framework of the COST programme (Bobeva 1997). The main findings showed that the highest volume of emigrating scientists out of the overall outflow from science between 1989 and 1995 occurred in Poland (15%), Estonia (14%), Bulgaria and Slovakia (above 11% in each). It is worthy to note that all four countries also belong to the group where scientists’ salaries are below the national average. Most of those who emigrated were young (mainly between 30 and 40), with a high professional profile, and prevailing in possession of doctoral degrees. The analysis of the situation in Albania showed an even more dramatic situation: nearly 15% of the entire population, the most active and qualified, emigrated to neighbouring countries (Mustafai 1999).

The report revealed, however, that internal migration of scientists was a far more signifi-

16) The data used by Bobeva (1997) are outdated (1993) but wage statistics show that the trend remained the same. Data for Albania are missing.
cant problem for the countries than external migration. The internal outflow (internal brain drain) mostly occurred in the direction of the private sector and self-employment, but also into other research institutes, government administration, or unemployment. Unfortunately a large part of the outflow from science proved to be not only a real loss for science, but also a brain waste. Part of the internal brain waste was an outflow into types of work with lower qualifications in the private sector and into entrepreneurship for the sake of higher income. Moreover, the mass outflow of scientists could not be fully absorbed by the labour market, and a considerable proportion of the outflow from research is reported as being unemployed: in Bulgaria – 28% of the outflow, Latvia – 9%, Slovakia 8%, Estonia 4.5%, and Romania 3%. The brain drain primarily affected the natural and technical sciences, but also, though to a lesser extent, social and economic sciences (Bobeva 1997).

Although the outflow of scientists from the sector is declining as a result of stabilising factors, the problem remains significant. At the same time, the opening of borders and the intensification of research cooperation has changed profile of migration of researchers: the number of scientists employed abroad is increasing (especially in Poland, Hungary and the Czech Republic), where short-term employment or involvement in research projects abroad are especially widespread (Bobeva 1997).

Coordination mechanisms of VET research at a national level vary among the countries. Whatever the mode of research organisation and its coordination at the decision-making level is, coordination was reported as either insufficient or entirely missing in all CEE countries. The problem of research decentralisation was understood by national experts in two distinctive ways: the first tackled general institutional and administrative decentralisation of the state as an integral part of the reform process (positive connotation); the second associated decentralisation with the highly scattered VET research function and very poor coordination of projects among numerous institutions involved (negative connotation). The first meaning was referred to by all CEE countries as virtually non-existent or negligible, while many countries reported the second one as a serious obstacle to greater transparency and cooperation between the institutes. It is peculiar to see that in the countries where VET research is in fact highly centralised and very close to the state sector, a lack of coordination (even under one and the same ministry!) and cooperation between different institutions was reported (Mustafai 1999). The reform process has imposed certain improvements in inter-institutional cooperation, noticed in recent years (Drogosz-Zablocka et al. 1999).

"In Poland state budget resources for R&D activities form above 60% of all R&D expenditures, and this is far more than in European Union member states. For comparison in EU member states state budget funds for R&D reach about 40%, and in OECD countries – about 33%." [Translation by OSI].

Drogosz-Zablocka et al., 1999, VET research in Poland

Research into VET in CEE countries is predominantly funded by the state budget and concentrated around the main VET (research) institute or several institutes (e.g. institute of pedagogical studies, adult education centre, etc.), mostly financed by the Ministry of Education. Research into the labour market is mostly organised around the institute, studying issues on the labour market and social aspects, and financed through the Ministry of Labour. This arrangement leads to the fragmentation of research, lack of intersectoral collaboration and a lack of contextual perspective in narrowly defined (as determined by sectoral bodies) research topics.

Research in general is normally regulated by the law on research (Estonia 1995, Czech Republic 1992 with amendment in 1995, Slovenia 1991, Lithuania 1991), although not all countries have reported so. The laws define the status of executive, administrative and advisory structures in the field of research and development, and main financing principles and methods (including granting procedures where available). The state usually provides seed funding for research institutes,
financing its current expenditures and the salaries (fully or partially) of the personnel. Financing is channelled through relevant sectoral ministries, and therefore in the case of VET it is mostly the ministries of education which finance and request for research. Project funding comes from national grant system, state research orders (e.g. ministerial), and significantly from international assistance programmes. Universities as independent entities receive financing for their teaching and research activities as part of their budget (allocated through the ministries of education), but can also apply through the national grant system or participate in tenders for the announced research project. Institutes of academies of science receive separate funding allocated for this purposes out of the state budget.

As the ministries of education are the main funding source for research in education, some countries have an executive body which runs grant procedure under or within the ministry (e.g. Estonian Science Foundation, Grant Agency at the Czech Ministry of Education, Polish Ministry of National Education, the Romanian National Agency for Employment and Vocational Training): announcing calls for tender, allocating competitive research grants on the basis of peer reviews, monitoring projects and in some countries also identifying the research priorities of the subsector in the coming period. Similar executive bodies operate under other ministries. Their linkage to state level advisory or another type of body (e.g. Governmental Council on Research and Development in the Czech Republic, Estonian Research and Development Council, Polish Committee of Scientific Research, Romanian National Agency for Science, Technology and Innovation, Lithuanian Council of Science, Slovak Council for Research and Technology) is to provide coordination at a national level, avoid duplicity in project funding and ensure transparency on research projects already available. Even in countries that have such arrangements it does not seem very efficient, as coordination has been noted as being weak in all countries. The mere existence of research coordination structures at the national level, however, does not mean that they allocate funding or announce research projects in VET (e.g. Poland) and sadly enough they almost never have any reference to VET research.

The crucial question remains as to how these bodies can be made functional and integrate VET issues. Perhaps these structures with a complex hierarchy have become too bureaucratic to be efficient, or VET research has not been a priority. Moreover, coordination of research in the ministerial domain is not beneficial enough for such a multidisciplinary field as is VET. It would seem that the nomination of one of the existing VET research institutes, or even the establishment of an intersectoral group of VET experts and the subsequent nomination of them for the task of coordination, could be helpful, in this way separating the coordination function from the bureaucratic machine. This has been partially achieved in Lithuania where no coordination specifically for VET research is foreseen at the state level. The Centre for Vocational Education and Research (Vytautas Magnus University) is coordinating research in the field of VET, while other leading institutions in the field of VET are responsible for VET policy formulation VET (Lithuanian White Paper 1998). The establishment of coordination structures or the improvement of the existing coordination framework is especially important for Latvia and Estonia, where no major VET institute which could be a focus for all major VET activities in the country exists.

Information provision on the existing or completed research projects is achieved by constantly updating databases, mostly operated by the same (executive or advisory) coordination structures (e.g. Poland, Czech Republic). Without questioning the value of such information systems, we would however stress the importance of broad information provision for the public. This can facilitate not only the mutual awareness of institutions about the research work in the country, but also may help to identify potential partner institutions and individual researchers for future projects, and consequently facilitate cooperation. Some institutions have been publishing for these purposes periodicals with information about ongoing projects and their outcomes. These
periodicals mostly remain based around a single institution and a central scientific magazine in the field of VET research is rarely available (the exception is Lithuania where the journal *Vocational education: research and reality* covers the entire VET research field in the country (Gurskiene 1999)).

The declaration of national priorities for research in general is rather common for the whole region, but the definition of priorities in VET research is systematised only in a few countries (in the Czech Republic, Slovenia, Latvia, Romania and recently partly in Poland), though mostly done at the ministerial level without the involvement of other interested parties. Slovenia, for instance, has a National Research Programme, enacted by the parliament, which defines public service in research activity with a definition of the aims and extent of particular disciplines (VET is part of social science research in the programme and deserves about 8% of the budget earmarked for research activity) (Ivancic et al. 1999). In Estonia, identification of research priorities is done in a more ‘informal’ way through discussion among VET actors in the Estonian Education Forum and subsequent statements on future priorities for research. The latter approach is acceptable as it brings about at least a certain level of consensus, while the mere declaration of research priorities at the political (decision-making) level does not mean that there had been any identification process with the involvement of different experts and other actors in VET. In Lithuania, future research priorities were defined in the White Paper EU Phare 1998, which also presupposes a prior discussion process.

The research institutions and universities in Poland that conduct research projects from their own main budget turn to their founders with the request to define research priorities, but in the end they usually define them themselves. This all leads to the fragmentation of research topics and demonstrates a lack of policy in the field (Drogosz-Zablocka et al., 1999)

National ‘granting’ procedures seem to be rather rigid, whereby the majority of research is done either on the basis of an addressed order to a particular institute or on the basis of terms of reference with a tender procedure. There are very few cases in which the state defines only broad research fields (priorities) and announces open calls for proposals. This is the case of Slovenia and the Czech Republic. The former runs such granting procedures for broad intersectoral topics, the latter may change the system due to low transparency and poor practical outcomes of such ‘ground-generated’ projects. Both of the countries attempt to promote inter-institutional cooperation, taking into account the intersectoral nature of VET research. A balance must be found between assigning the research tasks and allowing the institutes to generate the project according to their understanding of the current needs in research fields broadly defined by the state.

In Albania as in other CEE countries, ministries are the main clients that determine studies at research institutes, but there is no system of national granting procedures for undertaking research in VET (Mustafai 1999). In general, the role of national actors in VET research in Albania was reported as very limited for two main reasons: financial constraints and the absence of the habit of analysing the situation before making a political decision (Mustafai 1999). ‘Scientific’ culture in political action and rhetoric is still rather low in CEE, and in Albania in particular.

4.3 Role of international activities

As we have seen, the issue of the outflow of researchers from science is directly connected to the level of salaries among researchers, and also to the volume of investment in research. In a period of economic hardship, assistance to research and development by international donor organisations has become indispensable. D.Bobeva (1997) in her synthesis report comes to the conclusion that while the long-term migration of researchers is mainly in the direction of the USA, the exchange of research contacts and cooperation in general ('brain exchange') is more intensive with EU countries. This tendency is reflected in the volume of financing research within the framework
of support programmes by the EU and the US. In all CEE countries, financial support from the EU has been far more substantial than from the USA.

Financial support from international donors has often been a major source of sustainability for research institutions and researchers themselves. We would have suggested that this has especially been the case in those countries where national resources have been very limited, but the available data do not actually confirm this. Only some donor organisations have clearly identified priority regions, based on the principle of aid intervention in areas with worse economic conditions (e.g. USAID was one of the major donors in early transition years in Central Europe but with an improved economic situation and a pre-accession status of these countries, USAID moved its priorities further to the East). As the EU Phare assistance programme has been the major source of financing in the majority of the countries, and because its assistance has been largely aimed at preparing the CEE countries for the entry and harmonisation of their systems with the EU, Phare did not have a preferential funding policy for more deprived countries. The share of the interviewed scientists in the aforementioned brain-drain survey (Bobeva 1997) involved in a joint research project with Western institutions was also the highest in Hungary, Slovenia and the Czech Republic (table 3).

This shows that the farther along the country is in the process of EU integration, the higher the volume of joint research projects. This is also influenced to a great extent by eligibility for the EU programmes (not only Phare but also Tempus, Leonardo da Vinci, Socrates, Youth for Europe, etc.), and especially by the momentum brought about by the enactment of full membership. There has been a certain level of spontaneous coordination at the international level. Where Phare funds were not a major source of support for VET reform, the World Bank or another donor

(ILO, UN, Soros foundation, etc.) took the lead (e.g. the case of Albania). In some countries also the World Bank loan funds were supplemented with Phare funds to run a more comprehensive national reform of VET (e.g. Poland). Research cooperation is dependent on access to international programmes, but also on information availability and efficiency, the preparedness of the institutional and legal system to incorporate and market international programmes, and to some extent on the traditional openness of the research community to such cooperation.

The role of international donor organisations in research in general and in VET research in particular has been highly appreciated by all countries (Country overviews of VET research see list of background reports 1999 on first page; Bobeva 1997; National Observatory country reports 1998). The issue of coordination and transparency is less positively referred to, with frequent criticism of the duplication of funding, the lack of information, and especially in the case of bilateral projects, the lack of coordination with national priorities.

All countries, with the only exception of Albania, reported the Phare VET reform programme as the major reform source and often a driving force of change and innovation. Reforms of vocational education and training systems, which took place between 1990-1998 and were supported by Phare, served as a catalyst in curriculum development primarily in the area of initial VET, in the training of school staff, the upgrading of learning equipment, the involvement of social partners in policy and needs formulation, the evaluation of programme results and the drafting of policy papers on further reform steps. The Phare supported reform in VET made an attempt to initiate systemic reform through the development of a new curriculum reform model in a limited number of pilot schools. ‘The model was imported from EU countries and, though ideologically attractive, paid little attention to the specific transition conditions of each individual country’ (Parkes et al., 1999, p. 30).

The extent to which the research component was present in the reform process varied from one country to another. All programmes started up from some sort of prior analysis, in which the Western consultants normally participated directly or which they mainly carried out and involved the participation of national experts. The analyses were aimed at an assessment of the national VET systems, the institutional and socioeconomic conditions in the countries, as well as at a comparison of existing systems and arrangements in the EU.
member states as far as their appropriateness and feasibility for implementation in partner countries was concerned. ‘One of the main drawbacks of the first phase of vocational education and training reforms in some of the Central and Eastern European countries is the fact that reform programmes were generally launched with little labour market information’ (ETF 1999a, p.15). Indeed, although all reform programmes started from an elaboration of the conception and analysis of the labour market and general socioeconomic and demographic developments, information on trends in employment and prospective information on the labour market was very limited. Indeed earlier Phare VET programmes possessed a thorough concept of the reform, derived from the long-standing needs of education and from a pro-Western model of development. But the analysis of the transitional nature of socioeconomic developments, employment prospects and the changing nature of employment were not sufficiently considered. Sometimes this was taken into account during the following phase of the programme, when a series of feasibility studies and system assessments (e.g. UPET programme in Poland in 1992) and subsequent needs analysis (MOVE in Poland in 1993) were conducted (Dlugokecka et al., 1996).

‘The fact that the Strategic Study was prepared by foreign experts in close collaboration with Czech (and Slovak) professionals contributed to the high quality of the Study and at the same time the broad professional public was made aware of the modern approaches to the issues at hand applied in developed countries as well as of the knowledge and experience in these countries’ (Grootings and Kalous et al. 1997, p.179)

Both Czech and Slovak reforms emerged out of the Strategic study of vocational education and training, developed jointly by foreign (Birks Sinclair and Associates Ltd., 1993) and national experts, which ‘presented the first comprehensive view of the issues of VET after the political turnover of 1989’ (Grootings and Kalous et al. 1997, p.178). The analysis of the advantages and disadvantages of the then existing VET system was performed against the background of social, economic and political conditions. The study remains one of the most respected pieces of analytical work in the countries up until now, and one of the strong aspects of its methodology – collaborative research between foreign and national experts – has been noted many times as its convincing advantage. The study naturally lacked a thorough analysis of current and upcoming employment trends, as these data has been largely missing in both countries.

Later Phare VET reform programmes paid more direct attention to the analysis of employment trends, maintaining labour market analysis as a component of the programme (e.g. Romania, and recently FYROM). For instance, the Romanian Study on labour market and related implications on the manpower provision by the VET system (CNA Veneto Euro-In Consulting 1998) attempted to substitute the lacking prospective data on labour market trends with specific field surveys, measuring a) the occupational supply of vocational school graduates, and b) labour demand by occupations in stock and flows.

The aforementioned study and others like it attempted to outline the main systemic drawbacks and suggest reform steps leading to a more flexible VET systems and curricula through implementation in a decentralised manner via selected pilot schools. At the end of the programme period, each country conducted an evaluation in which the main results and findings were assessed with respect to European developments in the field of VET. This programme component involved a great deal of research and was very important from the point of view of subsequent political development, outlining the future steps for national implementation.

The pilot character of the reform, though attempting to address systemic problems, has had certain limitations. Without trying to depreciate the added value of the reform programme, it has certainly been difficult to mainstream the specific achievements after the programme’s completion. The countries that succeeded to actively involve decision making and a broad spectrum of social partners at an early stage in the programme, and that managed to reach a consensus on the future of reform, have been doing better in im-
plicating the results nation-wide. Indeed, the innovation of curriculum being run in some 20-40 pilot schools in a flexible decentralised manner certainly brings about an added value, but if the approach is not disseminated at a national level, then the value of the project runs out. Paradoxically the problems of mainstreaming the achievements of Phare (and other) reform projects could be at least partially connected with the direct reproduction and testing of the foreign experience in a sample of schools, where the reform could be seen as something not developed nationally but copied from abroad. The reform models paid insufficient attention to the specific transition conditions of each individual country (Parkes 1999). The eventual success of the implementation of achievements at the national level not only involves the recognition of findings and the consensus regarding the issue, but also involves the question of existing institutional frameworks (and consequently often a need in institution building), reform of other integral parts of education system, mentality of all actors involved, and allocation (or the very existence) of financial resources.

‘VET development projects funded by international donors are normally anticipated by a preliminary research phase to clarify the objectives of the projects and to appropriately define the activities, partners, time schedule, budgeting etc. In the majority of cases there are foreign specialists that lead this process, cooperating with Albanian specialists or local experts that normally have a second hand role (as a source of information). In some cases, this phase is neglected or underestimated and has resulted in not realistic project documents and weak results on the application of it. One of the main weaknesses experienced during the conception and application of bilateral and international VET projects in Albania is not taking sufficiently into account all the aspects of the Albanian context.'

Mustafai A. 1999, VET research in Albania

In spite of the few drawbacks of the Phare supported VET reform programmes in CEE, the latter are seen as success stories in all countries, and the role of Phare as the main or sometimes even the only VET reform ini-
tiative is widely acknowledged. A peculiar case is Albania, where Phare VET reform in comparison with other international assistance projects, has played a very limited role (presumably due to the fact that Albania does not belong to the pre-accession group of partner countries). The Phare VET reform programme was postponed for several years and was finally rushed through in 1998, making it impossible to fully accomplish the objectives that had been started in this country rather late (Mustafai 1999). The research component of the project was vague, particularly represented by an attempt to introduce a new approach for market analysis. However, in a later Phare project, which aimed at piloting a modular curriculum system in Albania (ALBAVET), research played a more substantial role (Mustafai 1999). The adaptation of the Scottish model for the development of vocational qualifications, registration, accreditation and certification, and in conformity with the Albanian context, has demanded research (still ongoing), in which the national institutions are fully involved (Mustafai 1999). Although the Albanian background study is far more critical towards the way foreign assistance reform programmes have been organized and coordinated than are reports from other countries, generally it is admitted that VET research in Albania is almost entirely financed by foreign donors. The limited national funding is used to cover the salaries of state research institutions, and foreign assistance is used for research activities, allowing for normal operations (Mustafai 1999).

Another major, international, expert contribution has been the involvement of some of the CEE countries in the OECD analyses. During the last six years, several countries were engaged in Reviews of national policies on education, labour market analysis, analyses of aspects of transition from school to working life and of the financing of life long learning. All these studies have been done on the basis of background reports produced by national teams with a subsequent analytical reflection (reviews, country notes, comparative reports) of the OECD experts. It is important to note that OECD does not finance projects, and the primary value of its involvement is precisely the expertise, collaboration
of national and OECD teams, the exchange of knowledge and ideas, recommendations, discussions with national decision making bodies, and the professional follow up on the implementation of proposals. The OECD analyses are among the most comprehensive studies that were produced in the region at the beginning of transition, viewing the VET system as a part of the entire system of education and life long learning in the context of changing labour market conditions. Many of the recommendations produced in 1995-1996 remain acute and significant until even now. This certainly is true of the majority of recommendations produced within the context of the reviews of national policies of education (OECD 1996a, Bialecki ed. 1996), especially in the case of the Czech Republic. Many recommendations have been closely linked to the need for institution building in the field of VET (Czech Republic), which requires substantial financial resources or a radical reorganisation of existing institutional structures. Therefore, the implementation of these recommendations is hindered by the lack of consensus at a national level as well as the lack of financing required for the implementation of such demanding reforms. In 1998-99, Slovenia (OECD 1998), Latvia, Estonia and Lithuania benefited from participation in the OECD education policy reviews (in the latter cases the drafts are not officially available yet). OECD also produced many comparative studies, either examining only a few countries of the region within a bigger, international group (OECD 1999, Green A. et al. 1998), or examining the CEE region with the involvement of all countries (OECD1996b). The comparison with other CEE countries and advanced democracies has been a very useful benchmarking attribute of OECD studies.

The World Bank has also contributed to the comprehensive analysis of VET and the labour market in CEE: it started with a comparative analysis of the systems in the region (The World Bank 1995); its loan programmes have substantially contributed to an up-grading of VET systems in some countries (e.g. Hungary); it has been a major reform driving force and implementation tool in the countries, where Phare funds were limited (e.g. Albania).

Another principal contributor to transparency and a greater comparability of CEE vocational education and training systems and matters is the European Training Foundation. It has been operating actively since 1995 in close cooperation with national experts. The creation of a National Observatories network in 1996 brought about a standard comparative perspective in studying major VET issues, a comprehensive understanding of the VET system in the wider context of the labour market, and continuity by following main trends and indicators in VET and the labour market on an annual basis. ETF projects attempted to narrow the gaps in VET analysis in CEE. During recent years its projects concentrated on studying the role of social partners in VET within the CEE countries, systems of continuing vocational education, standards, employment policies, teachers and trainers training, tertiary professional education, VET in the context of regional development in the partner countries, etc. ETF has contributed to the coordination of donor activities in some countries by organising donor workshops (e.g. Albania 1997). It has supported preparatory activities for the initiation of the Leonardo da Vinci programme and directly participated in the implementation of the Phare VET reform programmes in CEE countries.

Despite the indisputable great value of the ETF activities in CEE, there have been certain drawbacks, often noted by national contributors. The ETF became operational rather late and the changes in partner countries that occurred between the decision to establish the ETF (1990) and its actual operational start up (1995) were already enormous. In this situation the ETF had to define its role in the development process when transition was already well under way and many structures and concepts were already in place. At the same time, the initial transition period in most CEE countries was largely undertaken on the basis of bottom up initiatives, spontaneous developments and often intuitive thinking in the situation of the lacking conceptual vision of the education and training reform at the central level. This shortcoming was tackled by the ETF through the introduction of analyses and recommendations within the many dimensions of VET. The main reason
behind the occasional criticism of these efforts seems to be the ETF’s endeavour to run many projects with relatively limited funds and very short time frames. This approach resulted in a certain fragmentation of projects and tasks. The projects aimed to tackle the most urgent areas for reform and were expected to have immediate results, i.e. recommendations for future reform steps. The latter approach has been rather typical for the internal mechanisms of support of the CEE research at the national level as well. This sometimes led to a lack of support for thorough theoretical research per se in CEE, which would be necessary in the future, but lies beyond the scope of the Foundation’s activities. Early announcement of the planned studies and projects and subsequent agreement at a national level (sort of OECD model) may facilitate not only a consensus and, consequently, the success of project implementation, but also co-funding from the national sources.

As the ETF is not directed at supporting research projects and infrastructures, the studies produced under its auspices have been of a mainly developmental and applied nature. Therefore, as it has been mentioned above, there has not been support for basic research in the field of VET in CEE. In 1998, the ETF initiated assessment of research institutes in CEE (Csako 1998) with the view to establish a network of such institutes in CEE and the CIS. Support for research agencies was limited to a marginal contribution for the initial sustainability of the CEE Club for VET Research Institutes (exists since 1995) and (co-)financing of meetings of researchers. However, the very establishment of National Observatories in the countries where research institutions had been missing contributed to the revival of VET research there. The ETF also supported the present overview of VET research in CEE, and in general intends to assist in strengthening the research function of National Observatories, an initiative received very positively by NOs themselves. A wider involvement of the research community and support for research projects, including fundamental research, would be desirable.

CEDEFOP maintains long-standing cooperation, albeit still limited, with research institutes and independent researchers in CEE. Between the two EU decentralised agencies that deal with VET in synergy but with a different mandate and scope of activities, it is CEDEFOP which is the more research oriented and has well established links with the leading EU research structures. The CEE countries would certainly welcome more extensive cooperation with CEDEFOP and its partners in the research field, while further cooperation with the ETF in applied analyses and development projects would be necessary also beyond the point of EU accession.

A big step forward in knowledge and methodology sharing between member states and partner countries has been the gradual opening of the possibility to join EU programmes for CEE countries (Socrates, Leonardo da Vinci, Youth for Europe, Research Framework programmes). Of special importance for VET research has been the Leonardo da Vinci programme, with its Surveys and Analyses (S&A) strand, opened to partner countries during 1998-199917. Unfortunately so far there has been only one call for proposals in this period, which allowed for applications under the S&A strand. The data on recent calls is very scarce and does not allow for a comparison of the share of S&A projects out of the entire number of approved projects in member states and in CEEC under the same call. The most recent project compendium refers to the 1997 call, in which CEE countries still held primarily the roles of associate (‘silent’) partners and could not promote the projects. Thorough information on the 1998 Call is not yet available.

As a result, we could only compare the results of the 1997 Call for member states and the 1998 Call for partner countries18. The share of S&A projects within the total number of

17) Although Pilot Projects – another type of the Leonardo da Vinci projects – also often contain a research component, their primary objectives are innovation and development, and analysis often present there is only a tool (assessment, comparison, etc.) for application.

18) Information on the 1998 Call - S&A successful projects was collected with the help of the Czech national Resource Centre for Guidance through National Coordination Units.
projects is traditionally low in all European countries, which is possibly due to the relative complexity of the application requirements in the S&A strand. In 1997, this share was 7% in all participating countries, which corresponded to approximately two to four S&A projects per country with population of 10 to 20 million people (Compendium 1997). In CEE we could identify only two S&A in the whole region: one in Romania and one in the Czech Republic. In the latter case, this corresponds to an approximately 1% share of S&A projects out of the total number of approved projects in the country under the 1998 Call. It is worth noting that both institutions that generated and submitted the successful S&A project bids possess considerable previous experience in international cooperation and presumably a capacity for project generation and management skills. Needless to say, the excessive complexity of procedures in project administration and financial management often hampers participation of institutions in such programmes. Project management capacity and foreign language skills are insufficiently developed in research (and other) institutions in CEE, and deserve special attention at all levels so that it will be possible to benefit in the future from the EU programmes.

Participation in such programmes is invaluable as it supports the ‘brain exchange’ (one should not omit mentioning the special importance of the TEMPUS programme in this respect), the sharing of scientific knowledge and research tools, and a from the ground up initiative in project generation. If the national decision-making bodies succeed in defining the priorities for international programmes in accordance with national priorities, such participation also turns into a direct contribution to the reform process at a national level, and makes available funds that are otherwise limited. The definition of national priorities is especially important in the case of EU programmes, as governments allocate financial means for the programme each year.

Among the reporting CEE countries, it seems that Romania has paid significant attention to the development of a strategy for identifying national priorities for the Leonardo da Vinci II programme. This country initiated the Study on national training priorities, which is being elaborated by the Romanian National Observatory with an extensive inter-institutional team (Balica et al. 1999). By means of a survey, case studies and an analysis of available data and national legislation, the team intends to examine the needs of the labour market in terms of qualifications and competences, the mismatch between demand and supply, and training needs for specific disadvantaged groups on the labour market. Such a systematic approach to the identification of national training priorities could be used well beyond the preparation process for Leonardo II. It seems that the country, being in the situation where World Bank funds have ceased, has also made a substantial effort to introduce the coordination and transparency of various funding sources in VET by creating the National Centre for the Development of Vocational and Technical Education (Balica et al. 1999). Romania is a good example of the utilisation of the main conclusions from the evaluations of Leonardo I (Birzea et al. 1999) and Phare VET programmes for the formulation of future strategy and priorities.

‘So far, in Romania there is no strategy meant to utilise the recommendations and conclusions of international research programs. We notice an insufficient correlation between the studies and analyses resulting from the implementation of international grants and programs, on the one hand, and the research activity carried out in specialised research centres and institutions, on the other hand. In some cases, substantiating new projects does not benefit from the conclusions of the external efficiency of some finalised projects or the conclusions of fundamental research in the field.

With reference to the activities for continuing the programs, evaluations have highlighted the fact that some projects often have a reduced capacity of adjustment to situations undergoing change, in the sense that they tend to be carried out according to the logic of the initial context that generated them. The mode of administrating the projects is often centralised and continuation of the projects is extended in the immediate proximity of co-ordinating institutions, without involving other interested partners and institutions’.

Balica M. et al. (1999), VET research in Romania
Assessing the general impact of international assistance in the field of VET, with a specific reference to research, it must be said that the overall outcomes are invaluable. However, certain steps could be taken to improve the efficiency of international assistance and matching it to better meet with the national needs. It is necessary to concentrate on the support of development follow up projects, aimed at the implementation of research findings and recommendations. However, it is also important to strengthen the research component of development projects. The early involvement of the local/national experts and institutions at all steps of programme implementation, including the planning stage, strategy elaboration, analysis and research components, is crucial, as it is the key to reaching consensus at a national level, with the direct involvement of all actors, and consequently also the key to effective implementation. At a national level, there must be mechanisms for coordination in order to increase the transparency of research projects already undertaken with international assistance, to avoid duplicity, and to ensure that the national priorities are taken up.

Since 1990, the CEE countries have undergone several phases of transformation, and in each of them the role of international assistance was different. The initial phase was largely defined by enthusiasm after the collapse of the totalitarian regime, and was characterised by spontaneous developments, decentralisation and ground up initiatives. Deep confidence in the legitimacy and the universal value of the Western democratic approaches and traditions in education on the one hand, and a high degree of interest and goodwill among international donor organisations and experts on the other, drove foreign experts into CEE en masse. The majority of comprehensive analytical works during this period were undertaken by or with the help of international experts. In the second half of the 1990s, and especially during recent years, the countries began to formulate national strategies and priorities in a more systematic way. The reform process had been more regulated with from the top down approaches more clearly articulated. The international assistance and research engendered in its framework during this period mostly appeared to be a joint product of international experts and national teams.

At present, the countries are experiencing the reinstatement of their own traditions and values in education with a more cautious attitude towards foreign advice. The contemporary challenge is the elaboration of clearly defined and comprehensive national priorities and strategies. The latter development appears 'as yet another logical step in the overall evolution of research of this topic – i.e. a step away from individual pieces of research of partial issues undertaken by national professionals, possibly in collaboration with foreign experts, or its comprehensive examination undertaken exclusively by foreign experts' (Grootings and Kalous et al. 1997, p. 183).

5. Systems, concepts, requirements, arrangements: what does VET research in CEE enquire into?

In this section we shall look at the range of topics encompassed by the CEE researchers in the field of VET in recent years in two broad areas: research into VET and contextual research. The overview given herein is far from being exhaustive. Instead of giving a detailed inventory of the research projects in CEE we try rather to see what sort and range of questions are asked by the researchers there, to what extent they tackle the CEE reform dimension and how they cope with the global changes. This approach would assist understanding whether the CEE research has actually supported the national reform process, and whether it manages to follow the scientific argument in other countries. Nevertheless, the line we have embarked upon is illuminative rather than informative or evaluative.

5.1 Research into systems in the lifelong learning perspective

It was not the end of the communist regime that suddenly made people realising the need
for the reform of education and training. In the 1980s in many countries of CEE there was a lively debate about the need to reform the system. It was also realised that such reform was especially needed in VET, the social esteem of which was very low. Too narrow specialisation, poor training facilities, inadequate teaching quality, were all seen as features that hampered the provision of skills adequate to the economic objectives and development of new technologies. At the beginning of the reform process the countries faced the challenge of the new, market oriented, economic objectives and the need to reform the VET provision to trigger off the overall reform process. There was no deliberate planning on the government side though, and the VET experts simply looked at VET systems in the advanced countries in order to obtain a benchmarking perspective.

Comparative analysis of VET systems, therefore, has become the most frequent topic in CEE as well as among international organisations analysing the CEE systems throughout the 1990s, ranging from a comparison of system organisation, administration and legal provision to financial arrangements, the system of social partnership, curriculum policy, and segments of education and training (e.g. CVT, tertiary education). It is important to note in this context that the CEE research has been rather concentrated on comparison of the systems of the advanced European countries aspiring toward future reform steps, while the international research analysed mostly the progress made by the CEE countries, and thus compared them to each other. The latter appeared as being a form of the reform progress assessment. The former type of comparison has somewhat neglected the debate about advantages and deficiencies of systems, taking place in the EU member states on the research arena; pros and cons of each of the systems were considered at first glance without concentrating on the in-depth analysis of the suitability of the system to the country and without following a multifaceted scientific argument taking place in the West.

The National Observatories of the Baltic countries with the support of the ETF and in the light of the Common education space agreement between the three Baltic Countries, carried out comparative study on the VET systems, legislation and regulated professions between the countries. The report has been the first attempt of the Baltic National Observatories to compare VET related issues.

Comparative analysis of VET systems and regulated professions in Baltic states.

The initial VET is provided in two basic types of schools: the secondary technical/professional schools, providing qualifications of technicians and white-collar workers (four to five years of studies), and vocational schools leading to the skills level of blue-collar workers (one to three years of studying) (see annex 2). One of the common features of the process of restructuring of VET systems in CEE was elimination of the strict division between the two types of VET, introducing the combined programmes, diversifying the range of choice among educational programmes, and providing vocational types of programmes leading to complete upper secondary education (matura). The general positive trend has been an increase in enrolments in the programmes that provide higher qualifications.

These positive systemic developments, however, occurred against the background of changing economic conditions of the VET system, where former ties between schools and enterprises were impaired and a former semi-apprenticeship system was damaged or completely abandoned. The former system of (semi-)apprenticeship itself, though it provided necessary work experience and linked trainees to their potential workplace, had a dubious character. The central point was not the learner, and therefore the form of apprenticeship was not intended to ease youth transition into working life but to provide the state enterprise structure with a workforce (Grootings 1998).

With the collapse of the state enterprise structure, the CEE VET systems found themselves almost exclusively school-based (Baltic countries, Albania, and Bulgaria) or enjoyed only very limited enterprise participation in the
model (Czech Republic, Slovakia, Poland). This has increased the danger of skills provision at schools being irrelevant to the labour market needs. Only two countries – Hungary and Slovenia – managed to re-introduce elements of the old (pre-Soviet) tradition of the dual system.

Yet in the CEE research, unlike that in the West, the discussion about alternatives of integration of work and learning into the VET system has not been adequately addressed. Indeed, the different analyses of responsiveness of CEE systems to the new economic objectives and requirements of the labour market demonstrate the need for higher proportions of vocational theory subjects in the content of education on the one hand, but on the other hand the necessity to provide adequate practical training and work-based learning. The latter can and is provided in a variety of forms (enterprise training, enterprise-based workshops, school based workshops, creation of intermediary labour markets, etc.) but there is no assessment of such practices, especially in the private sector (Romania).

The theoretical background of the project was based on the assumption that schools must develop a new identity by which school 'is no longer seen as the only institution and location for work-relevant learning', and where the humanistic paradigm of education as ‘learning through theoretical understanding’ is obsolete (Grootings 1998, 2.3, Buck 1997). The ‘increased blurring of education and work’ (Grootings 1998, 2.7) introduces a different theoretical perspective to various aspects of VET development, such as systemic arrangements and enhancement of social partners’ involvement, contents of education, skills and competences, and teaching and learning methods. This is recognised in the advanced western democracies and in CEE, although it is not at the top of the priority list when compared to the still more acute problems in the immediate CEE reform process. Taking into account that the CEE countries are gradually leaving the phase of curing the diseases inherited from the previous regime and entering into a new phase of transformation in which these countries must harmonize conceptually with the developments in Western Europe, adequate theoretical perspectives for the research need to be introduced. Thus what range of questions to be involved in research in CEE appears crucial: for the time being, equilibrium must be found between the acute issues and the issues of a global concern. This would correspond to the challenges of the double transformation mentioned earlier.

The international research and rhetoric in the field of the changing role of the school – from being a mediator of knowledge to becoming a mediator of knowing how to apply the knowledge – and the changing role of the workplace – from an end in itself for knowledge application per se to the learning organisation – has not influenced the research debates in the CEE countries. A certain improvement was stimulated by preparation and then first phase of implementation of the project Integration of work and learning in the two countries.

Integration of work and learning is a three-year development project, initiated by ETF and implemented through the national teams in Hungary and Slovenia. The project will be completed in 2000. The project seeks to support and supplement innovative VET actions in the field of the integration of work and learning; to improve the conditions for further integration of work and learning for both individuals and educational and work organisations; and to establish the co-operation and exchange of experiences between organisations that are most advanced in the implementation of integration of work and learning in and between the countries concerned. There are four organisations involved in the project in Slovenia (two school centres, two companies) and four organisations in Hungary (three school centres, one company) (Ivancic et al. 1999).

Knitting the two worlds – education and employment – must eventually bring about knotting the two systems and its structures in order to provide a flexible and adaptable lifetime studying workforce. The CEE wider research suggests actually two key notions: ‘flexibility’ and ‘partnership’. Taking into account that ‘the paradigm of learning society implies weakening the barriers between the persons learning life and working life’ (Tempus CME-
researchers in CEE advocate support for flexible learning strategies at all levels. Diversification of education systems by introduction of alternative pathways and integrated programmes at a secondary level, and non-academic type of tertiary vocational education, was one, systemic step forward in adaptability to the new circumstances. From the conceptual point of view, however, it is not sufficient, as in the new environment we must think from a perspective of the lifelong learning concept, where the initial education is only a starting point of learning for one’s whole life. The functions of continuing vocational training (CVT) and professional development must be advanced in secondary VET schools, universities and higher vocational education establishments to make them flexible units of learning for various target groups (Tempus CME-97-3007 1999, Kofronova et al. 1999). The attempts to integrate the various segments of VET (youth, adult and retraining) under one roof is evidenced in the EU member states (Parkes (ed.) 1999), while in the CEE such innovative examples are not yet systematic.

From the perspective of the lifelong learning concept it is especially important from which angle researchers approach VET and how they include different education and training segments in their analyses. The experience of the study of the emerged sector of post-secondary and tertiary professional education in CEE, for example, demonstrated the complexity and variety of the systems appearing in CEE in recent years (Hennessey, M.A. et al. 1998). In a number of cases the complexity came into view, given by the ad hoc development of the system, when the necessity of such reform was recognized by the educators and asked for by the society. The general up-skilling trend and the changing nature of the world of work in the direction of knowledge-based performance was displayed in the shift of enrolment trends towards higher and more general qualifications at a secondary level, providing for the possibility to enter higher education. The increased importance of the higher level of qualifications ‘as a determinant of labour market status and earnings potential has encouraged students to prolong their education and to continue on to university’ (Laporte and Ringold 1997, p.33). The restructuring of higher education has therefore become important, especially in the countries with insufficient participation at this level (Czech Republic, Slovakia, Hungary, Poland, Slovenia, Romania). Moreover, for the countries where higher education enjoyed high participation rates (Bulgaria and the Baltic states) but enrolments in VET were comparably lower (ETF 1999c), the restructuring of higher education was a means by which to diversify the provision of vocational qualification at a higher level.

No ready-made unique model of a non-university professional education system was at hand (Hennessey, M.A. et al. 1998). The countries had to build the system upon the existing VET and higher education provisions. Other countries introduced tertiary/post-secondary professional education in its remarkable complexity at least partly in a deliberate manner, in which the complexity of the system is meant to correspond to the complexity of the world of employment and social choice. As a result post-secondary/tertiary professional education in the CEE countries differs in the length of the programmes (from two up to four-five years), in the level of qualification provided, entry requirements, institutional provision, etc. The system often overlaps with university-type higher education on the one hand, and with secondary vocational education on the other hand. The demarcation between post-secondary and tertiary as two levels of professional education is also not very explicit in the CEE countries (with the exception of the Baltic countries) (Hennessey, M.A. et al. 1998). The complexity of the system is in line with the context of lifelong learning, where all sub-categories of education and training system become interrelated, overlap and interact.

Higher levels of participation at the tertiary level, driven strongly by demands reflecting the diverse interests of students, employers and society at large, have created challenges which must be met. In 1995, the OECD’s Education Committee launched a multi-country ‘thematic review’ of the first years of tertiary education. Redefining tertiary education, a comparative report of its findings and conclusions was published by the OECD.
in the first half of 1998 (http://www.oecd.org). The CEE countries were not covered by the thematic review but they benefited from the study *Tertiary professional and vocational education in central and eastern Europe*, co-produced by the ETF and the Council of Europe in 1997 and published in 1998 (Hennessey, M.A. et al. 1998). The latter analysis covered sixteen countries of CEE and the CIS.

The above study (Hennessey, M.A. et al. 1998) 'provided evidence that many phenomena of this range of education programmes and qualifications and of related institutions tend to be overlooked if one focuses solely on higher education or solely on vocational education and training' (p.45). Therefore, the system must be comprehended in its full variety. Inclusive research must be encouraged; fragmentation in analyses and in practices (the major drawback of the reform process in CEE) must be avoided. It is, unfortunately so far a prevailing mode, and initial VET is studied separately from CVT and the rest of the system, as well as often without a particular reference to the labour market and socio-economic context. Moreover, each segment is often put under the responsibility of a different institution, which further exacerbates the intersectoral and interdisciplinary approach.

There are, however, positive attempts to comprehend the system in its entirety within CEE. For instance, the last two years featured the generation of a number of research outputs such, as the synthesis report *Initial VET in the framework of lifelong learning* (Kofroňová 1998), report *The role of employment policy and employment services in the state education policy* (VÚPSV 1999), Estonian *Education scenarios 2015*, study *The model of integrated career guidance in Poland* (Trzeciak, Drogosz-Zablocka (eds.) 1999), *Restructuring alternatives for Albania's vocational/technical education and training subsector* (Lamoureux et al. 1999), *National strategy for human resources development* (Birzea et al. 1999), *Human resources in the Czech Republic* (Hendrichová (ed.) 1999), *Czech Education and Europe* (Čerych et al. 1999), OECD education policy reviews, and others. A number of projects of comparable comprehension are under preparation.

### 5.1.1 Research on financing of VET

Recent years have also featured analyses of the financing of initial education and training (though still very limited), its mechanisms and trends in the CEE countries, where one of the recent OECD projects analysed alternative methods in financing lifelong learning. The study analysed various aspects of the role of financing in promoting access, participation and quality assurance of lifelong learning. Only two CEE countries could benefit from participation in the study, even though with certain restrictions given by the lack of data. The latter is a characteristic common to the CEE countries in this field: data on financing by employers, private sources, and data on CVT participation in general are very scarce. The OECD study also revealed that the mere understanding of the concept of lifelong learning differs between the OECD countries to a great extent. The CEE countries lack a thorough elaboration and common understanding of the concept and further research in this field is desirable.

The OECD report on *Alternative approaches to financing lifelong learning* (Green et al. 1998) aimed at analysis of emerging strategies for mobilising investment for implementation of lifelong learning for all, and for improving its returns and reducing its costs (p.2). The study is based on background reports submitted by ten OECD countries, including Hungary and the Czech Republic.

The CEE countries equally lack thorough comparative research on systems of financing lifelong learning in these countries, where the above-mentioned lack of data is certainly a drawback. Nevertheless, such research is badly needed, it may actually by itself instigate *inter alia* the data collection. The CEE countries, which enjoyed a steady increase in public expenditure on education as a percentage of GDP between 1990 and 1994, have suffered from a decrease or stagnation in spend-
ing on education since 1995 (with the exception of Estonia, Lithuania, Poland and Romania), ranging in 1997 between about 3% (Bulgaria) and 7% (Estonia) of GDP spent on education (Laporte and Ringold 1997, ETF 1999c).

The difficulties in public budget allocation in the transition period were multiplied by inefficiency of resource allocation, where the bulk of funding was spent on personnel (though the teachers salaries being protected still are far too low to maintain or to gain prestige for the profession) and capital expenditures remaining extremely low. The latter has been a crucial issue over years, as the education facilities become outdated and become an obstacle to implementing modern education programmes, including ICT education. The research on Efficiency in Bulgaria's schools suggests to increase efficiency in using classrooms without jeopardising learning objectives, by e.g. consolidating several grades in a multiple grade system in rural areas where classes are small (Bogetic and Chattophadyay 1995).

There is, however, the question as to how this instrument would affect the quality of education provision. Further research on different means of making the system more efficient is necessary. The CEE countries particularly need to introduce a system of incentives for individuals and employers to participate in education and training, including tax incentives, a system of benefits and indirect ‘qualitative’, systemic incentives to encourage participation in education and training. The system thus far of financing in the CEE countries is somewhat inflexible, with the per capita or per-unit financing prevailing as a nucleus system with certain variations (e.g. elements of output-based funding in combination with per capita funding in the Czech Republic), low involvement of enterprises in financing due to severe economic conditions, and a low, though steadily increasing, private component (ETF 1999c).

The low financial involvement of enterprises in training increases the danger of the irrelevance of the practical skills and competences, provided by education and training. Therefore, finding the instruments for encouraging employers to participate financially in VET or to directly provide training for their current and future employees becomes crucial. Hungary is an example of a CEE country which has provided certain financial incentives, namely tax allowances for non-profit making organisations engaged in educational services (Green et al. 1998) and through a levy fund paid by employers or alternatively direct contribution to VET schools or on-the-site workshops (20% of total VET secondary schools expenditures are paid through the levy fund (ETF 1999a)). Such a system, however, presupposes a high level of participation of social partners in VET, which is still rather weak in the CEE countries. In any case a thorough analysis of the Hungarian system, its evaluation and comparison with other similar systems of incentives in CEE (Poland, Lithuania, in the latter a contribution from employees is also levied, (ETF 1998a)) and in the EU member states (the Netherlands, Finland, Spain, etc.) as well as a feasibility analysis of its applicability in different CEE countries is highly desirable. The CEE countries should concentrate on the analysis of whether it is preferable to tackle the issue of financing by merely increasing resources allocated to training or by setting up training funds (ETF 1999a).

5.1.2 Continuing vocational training and human resource development

Continuing vocational training has been tackled by research very sporadically. The concept itself is not very elaborate and all research exercises in the area of CVT experience difficulties with the exact definition of which types of training to include. Numerous definitions of CVT created perhaps more confusion than clarity, and eventually arrived at a very vague definition of ‘learning that improves employability of adults who have left the compulsory education system’ (ETF 1999d). Some definitions involve employment or keeping/improving the employment position as a virtual objective of CVT, by this means setting up CVT in opposition to training as a leisure pursuit (Palan 1997). It is, however, questionable as to where the line can be drawn between the
two, and what kind of ‘leisure’ training may eventually bring about better employability and employment.

Nevertheless, the crystallisation of certain types of training of adults under CVT has naturally occurred, involving (from the viewpoint of participants):

- CVT as an instrument of active labour market policy for unemployed, young graduates and those at risk of unemployment,

- CVT as a part of human resource development policies of companies for those with employment, and

- CVT as an individual initiative.

From the perspective of lifelong learning CVT has attained a new importance: it is no more a mere second chance, retraining or further training, but a regular lifelong educational path for everybody (ETF 1999d, p.4). At the same time ‘CVT has received a little attention so far, apart from labour market retraining measures’ (ETF 1999d, p.9).

The ETF report on Continuing vocational training was prepared in 1999 and used the information from the country reports, written by National Observatories in CEE in 1998. The reports appeared to be an invaluable mapping source, where all major surveys and studies existing at the time were recorded and the results were evaluated. This has been a first step in appallingly demanded research in the field of CVT, which should be tackled, however, in a wider perspective of lifelong learning.

The evidence of participation in CVT is inadequate, but the one available evinces higher participation among people with higher qualifications in all CEE countries. This is evidence of people’s individual commitment and initiative, and perhaps also of greater capability to get access to CVT (where not only money matters but also, and even more so, access to barely available information). The system of CVT (if one can speak about a system in this context at all) suffers from a lack of transparency and lack of information on the offer and quality of training. The system of monitoring and evaluating CVT (as well as initial VET) is insufficiently developed. Conceptually this must be tackled by research in both segments (initial and continuing). While the initial VET is relatively well monitored in all countries, CVT suffers from a lack of data and particular indicators that can provide evidence of the sub-sector development. Furthermore, interlinking the initial and continuing VET involves the issue ‘of educational and occupational standards and their related certification and qualification’ (ETF 1999d, p. 13).

The debate so far has taken place in the field of initial VET although some CEE countries have decided to introduce a unified system of national competence-based qualifications and the corresponding system of standards and certification for both initial and continuing VET (e.g. Estonia, to some extent Hungary). This appears to be an optimal solution from the perspective of lifelong learning. It must, however, go beyond the point and involve assessment of prior learning and recognition of informal learning – issues that are actively debated in the EU research arena but so far almost totally neglected in the CEE research (Slovenia prepares to introduce such a system).

The research on quality assurance and linked to the certification and accreditation in CVT is equally scarce in the CEE countries. There are very few examples of research, one of them being the feasibility study initiated by the National Training Fund in the Czech Republic in the area of quality assessment and quality assurance of management training (Zaludová et al. 1997). It set up principles and drew up procedures for quality assessment at the level of training organisation (both self-assessment and a third-party certification), but also in a company training department. The study provided pilot field testing and suggested the steps for implementing a standardised model of quality assurance according to the ISO 9000 series as a first step to total quality management. The study also sug-

---

20) Research in the field of retraining will be dealt with later in the chapter.
suggested measures and recommendations for the implementation of a system to assure and improve the quality of management training at a national level (Zaludová et al. 1997, p.100). Such research in the area of CVT provision beyond management training is needed, especially if the national system of qualifications with the credit system, unique for VET and CVT, is not in place. There are other positive examples of research into quality assurance in education (e.g. Hungarian project Comenius 2000) which could be disseminated.

The CEE research materials provide very poor evidence of CVT or human resource development (HRD) in enterprises. Several international company surveys will perhaps shed light on the problem in the near future, namely the Second CVT survey by Eurostat, which included several CEE countries this year, and the Cranfield project on European human resource management, which was conducted the last time in 1998 and would announce the comparable longitudinal results in the near future. The surveys will give the information on training provision, participation, financing, HRD policy at a company level, recruitment problems, flexible forms of employment, etc. The results would present an invaluable primary source for further research in the field of CVT and HRD. The preliminary results thus far show that the CEE countries have somewhat lower participation in CVT than the advanced EU member states, the systematic HRD policy elaboration is not a rule for the majority of companies yet, companies spend on education and training less than their EU counterparts. The bigger companies enjoy higher participation and expenditure on CVT. The research on methods of support for CVT and HRD among SMEs is another area where analyses and suggestions of innovative solutions could be especially welcomed.

The benchmarking survey Key indicators for HRD appeared to be one of very few existing sources in this field. The companies which participate in the survey are interested in obtaining a benchmarking perspective which helps them to grasp where the company stands. The survey revealed that in all CEE countries middle management had the most training days, the highest frequency numbers being found in professional (technical) training. Leadership training, ICT and languages training are also in demand. The survey also demonstrated that it was not HRD, HRM or education and training that kept the HR departments busy but personnel and payroll administration – the activities that take up the most time of the HR departments in the CEE companies (PriceWaterhouseCoopers 1999).

The Second International Adult Literacy Survey (SIALS), supported by OECD, UNESCO and Eurostat, was conducted in 1996-1999. The survey was a second wave of IALS, conducted in 1994. The two surveys included inter alia several CEE countries, namely Poland (IALS), and Czech Republic, Hungary and Slovenia (SIALS). The survey, based on a representative sample, analysed functional literacy (prose, document and quantitative literacy) among the adult population at five levels. The comparative results for SIALS will be published in mid 2000.

The Second International Adult Literacy Survey (SIALS) analysed the outcomes of education among the adult population. The preliminary results of the SIALS unfortunately do not yet make it possible to compare the results cross-country, and to see where participating CEE countries stand. It is possible, however, on the basis of the preliminary results of the Czech Republic as compared to the first wave (IALS), to conclude that the Czech respondents demonstrated the incapability of working actively with information given in a particular context, but demonstrated excellent functional numeric skills and formal document literacy. Poland showed very poor overall results in the survey, but also performed the worst in the active usage of information (Matějů 2000). These results derive from the mode of education provided in CEE schools, which provides encyclopa-
dic knowledge rather than an ability to work with information actively, to use the knowledge and be innovative (‘to know’ vs. ‘to know how’).

The survey also gave evidence that people with higher educational attainment perform with better results, but different levels of education demonstrate different efficiency, as compared to the performance of respondents with the same level of education. Those Czech people with full secondary education and with vocational training qualification performed, when compared with the same level in other countries, much better than the higher education graduates as compared to their counterparts in other countries (Matějů 2000). The analysis of intergenerational mobility revealed at the same time that higher education is characterised by the lack of openness and eliteness (Matějů 2000). Taking into account the insufficient capacity of higher education in the Czech Republic and the poor performance of its graduates when compared internationally, the results are rather striking. The restructuring of higher education and its better integration into the system of lifelong learning needs to be enhanced. The role of CVT in this process is indisputable as well. At this point we come back to the conclusion that the whole system must experience better integration of its different, and so far rather fragmented, segments.

5.1.3 Teaching and learning: a one-off task or a lifelong perspective?

The perspective of an individual learner in the educational process and outcome has been somewhat neglected in the CEE research. At the same time individual development is a crucial democratic value. The education must provide an individual with the best possible chances for life success. What kind of education can provide this?

A re-thinking of the two paradigms – education and employment – and their role in the life of the individual brings us to a new appraisal of initial education and a re-assessment of the roles of different actors in the education process. The school must provide a basis of knowledge broad enough to create incentives for further learning. Two aspects are important in this respect: what is learned and how it is learned.

It is important to perceive the content of education from the point of view of the eventual outcome for the individual, be it employment, further learning, entrepreneurship or self-development. Therefore the system should presuppose a flexible form of learning and a flexible award system of qualifications. Under new conditions the CEE countries are trying to find different approaches and concentrate on combining the two basic ones: an orientation toward curriculum input (a more traditional one) and the output control, based on output occupational standards and the national system of occupational classification and vocational qualifications.

In curriculum innovation the countries try to develop flexible competence-based systems. There is little research, however, on competence-based training and especially on the methods and tools for implementing such approach. The research is needed to suggest how to modify the traditional way of teaching, which is divided between theoretical and practical teaching, and turn it into an integrated competence-based approach. The research is needed to suggest how to modify the traditional way of teaching, which is divided between theoretical and practical teaching, and turn it into an integrated competence-based approach. The research is needed to suggest how to modify the traditional way of teaching, which is divided between theoretical and practical teaching, and turn it into an integrated competence-based approach. The research is needed to suggest how to modify the traditional way of teaching, which is divided between theoretical and practical teaching, and turn it into an integrated competence-based approach.

A cross country analysis of curricular reform in VET in CEE (Parkes (ed.) 1999) was a report commissioned by the ETF and was drawn on the basis of ten CEE country case studies. The report evaluated the reform experience of the countries and outlined the key issues for the future actions.

The experience of pilot schools under the Phare VET reform programme resulted in the proc-
VET research in CEE countries

cess of the implementation of competence-based curricula, where competences are understood at different levels – professional performance related and designed for unstructured work situations. Some countries have set up the national system of qualifications linked to occupational classifications (e.g. Hungary, initiated in Estonia, Slovenia, Lithuania and the Czech Republic). The system is however at the moment very time consuming, as occupational profiles have become outdated, and this is an ongoing process. It therefore requires the ongoing involvement and commitment of social partners. Additional research on methods for the efficient construction of occupational profiles as a living process would be useful. Some countries make an emphasis on general subjects in vocational preparation (e.g. Latvia). The latter corresponds to the objectives of lifelong learning but has certain drawbacks in its linkages to the requirements of the labour market (Parkes ed., 1999). The Czech Republic has introduced a two stage curriculum, allowing for the input control at a state level and leaving room for the innovation and for adjustment to local labour market needs at a school level.

In the framework of the introduction of flexible forms of learning and as a result of the pilot Phare reform, a debate on modular training has become very popular in the CEE countries. Modules are conceptualised in their linkage to occupational tasks. Most countries try to gradually introduce a flexible and adaptable system of modular training, which embrace both initial and continuing VET, allowing for transparency, recognition of qualifications and mobility. The most flexible systems are based on credits allowing for mobility and flexibility inside the system (e.g. Estonia under implementation, Slovenia in planning, in Hungary implemented at a post-secondary level). Such a system corresponds best to the needs of learners, as it presupposes open pathways and is a step forward toward recognition of informal learning. The latter is in the direct interest of an individual as well as of the society. The issue of assessment of prior learning and informal learning, widely discussed in the West, has not yet appeared on the agenda in CEE, nor has how it may be linked to CVT.

Two points are especially important as far as the VET research is concerned. First, in spite of obvious advantages of the modular system, thorough research is needed to analyse the possible impacts of a modular system in the context of the CEE countries. The experience of the pilot schools is invaluable but the countries should be aware of the current debate in the EU member states on the shortcomings of the modular system, as well as analyse its impact as applied to the CEE context. Second, due to the decentralisation of the school system and the greater independence of schools research on different types and methods of evaluations and assessments is important as a part of the quality assurance system. The research on standardisation of output assessment, though it has been developing in recent years, requires further research and concentration on alternative methods (examination, portfolios, etc.) more appropriate in the context of lifelong learning.

No matter how perfect the VET system is, and how good the content of education and school facilities, the crucial task of the reform for the CEE countries, and so far largely unsolved, remains that of the quality of teaching. The new flexible forms of learning assume innovative, informal forms of teaching and the existence of necessary teaching and learning materials. But again, no matter how wonderful the teaching materials and tools are, the teacher remains a cornerstone of mediation in the learning process. The task cannot be narrowed down to the reform of the preparation of teachers and trainers. It involves the much deeper problem of redefining the roles of individual partners in the educational process, where the mentality of all actors must be changed. The teacher is no more an intermediary of knowledge but a student partner. The methods shall become more informal, pro-active, and integrative. Research on innovative methods of teaching (e.g. project, team work, etc.) must complement the research on the preparation of teachers and trainers recently widely implemented at a national level by many countries and at the international level.

The question of the reform of training for teachers and trainers, which still suffers from many drawbacks of the old system, shall be tackled
in the wider perspective of the integration of work and learning. The preparation of teachers and trainers, its transparency, standardisation, upgrading, and other aspects should be considered along with such aspects as the integration of the teaching function with employment, the changing role of agents in the teaching and learning processes, the new flexible methods of learning, school openness to the external environment, its integration with the employment environment, and in the comprehensive context of the lifelong learning system.

The ETF report *Innovative practice in teacher and trainer training in VET* (Oldroyd D., 1999) was prepared on the basis of the survey conducted among the members of the ETF Advisory Forum Subgroup D. The report collected information about innovative practices of teacher preparation and expert opinion on problems and priorities in the CEE countries in this area.

A cross country review *Reshaping the focus of vocational teacher and trainer training* (Nielsen et al. 1999) was commissioned by the ETF and prepared on the basis of country reports submitted by National Observatories. The report scrutinises the existing situation and arrives at proposals and recommendations.

The project major *Trends and actors of education policies and reforms in Central Europe* was implemented with the support of Soros Foundation and include Czech Republic, Hungary, Poland and Slovakia. The project has contributed also to a better understanding of recent developments of teacher training in CEE (Nagy 1998).

*Reshaping the focus and structure of VET teaching personnel training in Latvia and Lithuania* is a project (1999-2000), supported by ETF and the governments of Denmark and Finland. The project has a common frame and objectives for both Latvia and Lithuania. It seeks to open the VET schools to the world of work, introduce organisational development within schools, promote training of teachers, modernisation of teaching and learning methods.

### 5.1.4 Social partnership

It must be remembered that earlier in this chapter we stated that the challenge of blurring the worlds of education and work and the concept of lifelong learning involve two key notions – flexibility and partnerships, being indeed present in all the rhetoric on each segment of VET. We have tackled the point on flexibility and we shall come back to this later on; we shall now look at how the system of social partnership has been researched. Analyses of the role of social partnership in VET appeared in CEE very recently as a part of an on-going pilot project on the role of social partners in VET, launched by the ETF in 1997. The study examined the state of the art in this area and came up with recommendations for the future, which were verified during workshops and public discussions. As the overall exercise involved social partners’ representatives from the early stage, the project itself has contributed to improvement of the situation. The ETF continues to work with partner countries in this field, and the project will eventually attain a development character.

*Enhancing the role of social partner organisations in the area of VET in the candidate countries of CEE* (ETF 1998a) was prepared in the framework of an identically named project, launched by ETF in 1997. The report was prepared on the basis of country reports submitted by National Observatories. The reports analysed social partners involvement in financing of VET, elaboration of vocational standards and systems of qualifications, quality assurance, and VET planning. The analysis was produced in close collaboration with social partners' representatives and their close involvement in the follow-up discussion at a national level and at the international conference organised by the ETF.

Although the project is not purely of the research type, the analysis has contributed greatly to mapping out the current situation. It showed that in spite of the general immaturity of the system of social partnership in CEE, the countries have reached quite different levels of development in this field, and have also undertaken rather different patterns of development. The common obstacles to the higher involvement of social partners in VET are the above mentioned lack of incentives for employers, lack of commitment from their side, and the lack of resources.
Some countries still lack the legal framework or suffer from insufficient institutional development. Nevertheless, it is possible to state that the countries that have managed to set up a system of financing with the participation of employers through a fund mechanism enjoy greater involvement of social partners in VET in general (e.g. Hungary).

Similarly those that started developing the system of national vocational qualifications (e.g. Hungary, Lithuania, Estonia) and worked with social partners on development of vocational and occupational standards (e.g. Slovenia, Estonia and Lithuania – in selected sectors) were more successful in developing systemic ties with social partners. Their involvement in the development of vocational standards is relatively low in all CEE countries, as is their involvement in quality assurance or identification of future labour market needs.

The Phare VET reforms have pushed forward significant progress in the area of a systematic consultation process with social partners, covering, though, only a limited number of pilot schools. Some countries have been more successful in involving social partners at a regional level within the framework of the overall regional administration reform (e.g. Poland), and many countries have succeeded in securing social partners’ involvement at a community or school level (ETF 1998a). The latter is a peculiar point, which showed a great potential of flexibility at a very local level. The weak social partnership system in CEE is a part of the overall weakness of civil society and the instruments for its provision. The issue of finding mechanisms for the rehabilitation of the institutions of civil society, NGOs, public and professional associations, trade unions, the whole third sector, after the compromising of ‘public’ organisations under the previous regime, could perhaps be tackled in research from a wider sociological perspective.

5.2 Contextual research

Contextual research is a provisional expression for research which, although it does not deal with VET exclusively, looks at the contextual aspects of VET that define e.g. qualification requirements of the labour market, skill requirements in companies, and various social aspects as far as education and employment are concerned. The ‘contextual’ research in CEE, although concentrating on the same range of topics as in the EU countries, sometimes actually analyses somewhat different models and processes, when it comes to employment, unemployment, social exclusion, poverty, transition from school to working life, etc. Needless to say most of the mentioned notions are also new or have a new meaning for countries in transition: under the state planned economy unemployment, poverty, and social exclusion purportedly did not exist. Therefore these are also new research subjects in the countries of transition.

5.2.1 Employment and unemployment: factors of transition

All reporting countries enjoy better analytical and statistical coverage of unemployment than in the area of employment. Unemployment appeared as a new notion in CEE countries in 1990s as compared to the imaginary ‘full’ employment during the communist regime. In this situation the state had to generate social policy, a system of benefits, and employment measures on a principally new basis. Information from official registers of the unemployed was quickly generated for subsequent analyses and evaluation of national policies to fight unemployment. Comparable data with the standard ILO definitions appeared, however, in the CEE region only with the commencement of the national Labour Force Surveys (LFS) from the first half of 1990s.

Labour Force Sample Survey (LFS) was commenced in CEE countries between 1991-1995 with the exception of Slovenia where LFS has been in place since 1989. LFS applies standard ILO definitions of employment, unemployment, activity, and others, and therefore, appeared to be the major source of comparable data at the international level. Although LFS itself is not a study, the majority of reporting countries mentioned the importance of the survey for the research. Through LFS data, collected through a representative sample of households, the coun-
tries have acquired an alternative to the official registry picture of the unemployment situation, and additional data not only on the unemployed but also otherwise largely missing employment data. LFS therefore being a major stocktaking source contributed to the research development.

As far as unemployment data are concerned, there are marked differences among the countries in the relationship between registered and LFS (ILO definition) unemployment, reflecting the efficiency of employment services and the level of unemployment benefits in CEE. For instance in the Baltic States, the number of registered unemployed is very small (between one half and two-thirds) as compared to the LFS data (European Commission 1999). The trend is similar in Bulgaria (Beleva et al. 1999). This shows that there are very limited incentives for people to register due to the low level of unemployment benefits and the underdeveloped nature of public employment services (European Commission 1999). This was confirmed by Background studies on labour market and employment (e.g. Eamets et al. 1999; Beleva et al. 1999). The situation is the opposite in Hungary, Slovakia and Slovenia, where the number of registered was 40-60% higher than recorded by LFS, which reflects that those registered as unemployed did not comply with the ILO criteria (e.g. were not available for work or were not actively seeking a job). This may mean that they were involved in very short-term temporary work, or may indicate fairly high unemployment benefits and effective public employment services in these countries. This however may also imply that a relatively large proportion of the population is still involved in the grey economy (European Commission 1999).

Educational planning, structural adaptation of the system, curriculum development, career guidance, all need to be based on sound labour market analysis, derived from the monitoring of actual labour market developments, and identifying the current and forecasting the future qualification requirements (ETF 1999a). The studies in the field of monitoring the actual situation in the labour market could be found in all researched countries. As labour market instruments and policies were introduced by states in the early 1990s, naturally the states have mostly financed studies evaluating the effectiveness and efficiency of active and passive measures. This sort of study is available in most CEE countries. However, the impact measurement in these studies has been rather weak and analyses mostly display insufficient attention paid to measurement of (re)-employment after participation in active labour market measures as a major indicator of policy success. The available studies mostly measure the efficiency of the programme by calculating the cost per unit, and accessibility of programmes by participation rates. There are some attempts in alternative measurement and its analysis (e.g. Světlík (ed.) 1992; Pert 1998) which can serve as a good foundation for future research. Generally speaking, although the studies stress the usefulness of programmes for particular disadvantaged groups in the labour market, they also note relatively small proportions of participants and insufficient spending on the active measures. The latter features certainly vary from country to country to a great extent; nevertheless, they are a common characteristic in the region.

Background studies on labour market and employment were conducted in all countries in Bulgaria, Czech Republic, Estonia, Latvia, Lithuania, Hungary, Poland, Romania, Slovakia and Slovenia in 1999. The studies were initiated by the European Commission, DGV, and the European Training Foundation for preparation of the background analysis for the labour market and employment policy assessment in ten pre-accession countries (see Beleva et al., Munich et al, Eamets et al, Horvath et al, Trapenciere et al, Gruzevskis et al, Szthanderska et al, Lubyová et al, Ciobanu et al, Pirher et al, 1999).

Unemployment, inactivity of the population as well as employment have their specific characteristics in CEE, stemming from the huge shift from the state-owned to private sector economy and between agriculture, industry and services (see more 2.1). Hidden employment and hidden unemployment, early retirement and women's withdrawal from the labour force, structural unemployment in 'mono-industrial' regions (especially mining and metallurgy) and rural areas, which in-
VET research in CEE countries

Figure 5: Unemployment rates by educational attainment among 25-59 year olds, 1997 (%)

creases long term unemployment, are some of the employment characteristics typical for the different countries in the CEE region, each to a different extent. There is no strong correlation between gender and unemployment in the region (it varies from country to country but it seems that female withdrawal from the labour market has obscured unemployment among them at least partly). Unemployment is highest among the young, poorly educated, and older age groups. The level of educational attainment proved to be a crucial success factor in the labour market. Background studies on labour market and employment as well as other studies in the field of the labour market (Allison and Ringold 1996; Guegnard and Cvetkova et al. 1998; Martuzans et al. 1998; Rutkowski 1998; ETF 1999c; OECD 1998; Vecernik and Mateju et al. 1999) proved that the higher the qualification level, the higher the level of employment. They also demonstrated high proportions of people with low or no qualifications among the unemployed and especially the long-term unemployed. The latter trend has been confirmed by the annual collection of key indicators on VET and the labour market (ETF 1999c), where the vast majority of the CEE countries have demonstrated an appalling correlation between low skills level and unemployment.

'Key indicators' is the annual statistical publication on VET and the labour market in the CEE countries, compiled by the European Training Foundation through the network of National Observatories. The data are provided by national statistical services and the ministries of education. For the purposes of comparability the publication also includes EU data for selected indicators, provided by Eurostat.

Rather few analyses have focused on the relation between unemployment and employment as two specific paradigms and stimulating factors of transition. One of such studies (Jackman and Pauna 1997) attempted to build the analysis on the examination of the reallocation of employment between sectors (public and private sectors, and sectors of growth and decline). The analysis questioned the fact that unemployment in the particular circumstances of the transition was an inevitable factor in facilitating of the move-
ment of workers to growth sectors. The authors justified their views through two pieces of evidence: first that private firms appeared to recruit almost exclusively from those with jobs in the state sector or new entrants to the labour force rather than from the unemployed; second the example of the Czech Republic with the highest rate of new job creation in the growth sectors (trade and finance) had the lowest unemployment rate in Europe. Jackman and Pauna, therefore, questioned 'the rationale of policies directed at speeding up the shake-out of labour from the excess employment sectors' (p.386). The analysis proved that unemployment in the transition economies was 'neither necessary nor efficient from the perspective of labour market restructuring' (p. 387).

It is, however, a dubious conclusion, taking into account later developments: the so called Czech miracle is no longer the case; economic recession and the fast growing unemployment rate are largely explained by the delayed restructuring of the state sector there; in the countries that started the economic reform earlier and intensively restructured the state sector, the initially high unemployment has already started to decline. A further analysis of unemployment and the effects of employment policies as factors in the transition process would be useful as a comparison of the development in the last decade in all CEE countries.

5.2.2 Human capital and social exclusion: the prize and price of transition?

Background studies on labour market and employment demonstrated that the process of differentiation of income, which increases with the advancement of the process of transition to a market economy, is remarkably linked to the relation between wage growth and the level of educational attainment. The previous regime put certain social groups in the ill-fated circumstances of the egalitarian society, hampering their life success and income growth, a fact which namely concerned specialists with higher education and people with entrepreneurial inclinations. After the change of regime the social stratification started to modify, and this has been reflected in the change of values.

One of the greatest among such changes has become the association of education as a crucial characteristic of life success. Although the CEE countries still tend to undervalue education as a crucial factor in life success as compared to the advanced democracies in Western Europe, the rate of importance given to the education factor increases along with the advancement in the process of transition. The higher the level of educational attainment, the more value is conferred on education as a factor of life success. The transition period in CEE countries has been characterised by the gradual formation of the value of human capital, the rehabilitation of career rising, and a steady transformation of stability values into mobility values as factors of employment success.

The trends are partly evidenced in the International Social Survey Programme (ISSP), in particular in the Social inequality survey (1992, 1999) and the Work orientations survey (1997). The longitudinal study Returns to human capital under the communist wage grid and during the transition to a market economy (Munich et al. 1999) demonstrated through the example of the Czech Republic that while during the decades of communism an extremely low rate of return on education was maintained, it increased dramatically after the change of regime, and that the inter-industry wage structure varied substantially after the economy switched from central planning to market orientation. Human capital embraces not only the attained education but also initial skills, competences, talents, motivation and commitment to further develop and use the skills and competences. Human capital represents a very important capacity of the workforce, which can eventually activate economic capital (Matějů 2000).

The International Social Survey Programme is a continuing annual programme of cross-national collaboration on surveys covering topics important for social science research. It brings together pre-existing social science projects and coordinates research goals, thereby adding a cross-national, cross-cultural perspective to the indi-
VET research in CEE countries

Thirty-four countries are members of the ISSP, including Bulgaria, Czech Republic, Hungary, Poland, Latvia, Slovakia, and Slovenia (http://www.issp.org).

The reverse side of the healthy differentiation processes, increasing returns on education and formation of the human capital value were, however, raising inequalities: the greater the life success of the educated, the fewer the chances received by those without qualifications. The overall income decline and rising differentiation in the CEE societies have become major pitfalls of transition and put the disadvantaged groups at the high risk of social exclusion. 'In this respect, it is necessary for human resources policies to combine social policies for the human capital protection... with policies for human capital development' (Romanian national HRD strategy, p.4). Some analyses show the growing inequality in access to education in the CEE countries (e.g. Matéjfi 2000) and predict its further deepening. The growing importance of education for life success on the one hand, high intergenerational reproduction of educational qualification on the other hand, and finally insufficient participation in higher education in a number of CEE countries will contribute to rising social inequalities.

Social exclusion is a young topic on the research agenda in CEE, as is the problem itself, and very little research can be found in this field. Under the communist regime the existence of social exclusion as well as poverty was not admitted; marginalisation was perceived as a social choice. Therefore these phenomena were not scientifically and empirically addressed. In the early transition period, with the rapid growth in poverty, the countries and international society focused on studying poverty, though with a certain reduction of the concept of poverty to measuring income and consumption based definitions of poverty, and insufficiently focusing on the educational and occupational aspects of poverty (also criticised by Szalai 1999). UNDP focused on studying poverty in transition economies in 1997, where limitations of the income-based perspective were realised and the Human Poverty Index was introduced, which includes indicators of different dimensions of deprivation, including lack of education (United Nations Development Programme UNDP 1997). The latter report revealed the enormous social cost of transition, which in most CEE countries, particularly in the early transition period, led to a decline in income, the highest ever growth in income inequality, crime growth, loss of social protection, decrease in life expectancy and a sharp decline of the birth rate.

Atal (1999) noted that ‘careful sociological investigation is needed to understand the phenomenon of poverty in these countries. Is it a new form of poverty that is emerging, or is it suppressed poverty that is resurfacing?’ (p.6). His work (Atal 1999) was a subsequent attempt to summarise different approaches to poverty definition and measurement in the selected CEE and CIS countries. This has been a first step, which certainly demands further elaboration, and especially analysis of marginalisation and social exclusion from the perspective of education and training.

The latest UNDP report (1999) revealed that in the process of globalisation and the rising importance of the development of information and communication technology, as well as biotechnology, the race to lay claim to knowledge becomes inevitable. The lack of access to knowledge (PC skills, language skills) and to information tools (the Internet), widens the gap between ‘knows and know-nots’, not only between “conventional” ‘haves and have-nots’ (UNDP 1999). Therefore the topic of social exclusion, so far insufficiently considered, deserves more attention on the CEE VET research arena.

Every year since 1990, the United Nations Development Programme has commissioned the Human Development Report to explore major issues of global concern. The UNDP reports look beyond per capita income as a measure of human progress by also assessing it against such factors as average life expectancy, literacy and overall well-being. This year's Report focuses on the positive and negative aspects of globalisation. (http://www.undp.org)

So far the scarce research in this field has mostly been tackled from a sociological or eco-
nomic perspectives (e.g. Svetlik (ed.) 1996; Vecernik 1991; Sirovatka 1997). Only recently the research started to focus on issues of the role of VET in the promotion of social cohesion, as a tool of 'systemic inclusion of the generation of youngsters in the vocational education and training, and in all forms of education and training of adults – those related to jobs and those not directly related' (Trbanc 1999). The question therefore should be tackled from the point of view of access to education, flexibility and permeability of the systems, financial incentives to promote participation in education, especially among disadvantaged groups, and finally the content of education to promote participation, achievement of qualifications and the relevance of educational output to the needs of the labour market. Trace studies and analysis on drop outs from education and training, as well as on the causes and effects of low participation rates in education may shed the light on how to reform the system to promote access to education and life long learning. These studies are so far missing, which has been noted by most of the countries, especially the ones where drop out rates are high – above 10% (Hungary, Slovenia, and the Baltic states).

The ETF initiated extensive studies on VET against social exclusion in the CEE countries. The project is in its starting phase, and the first results shall be available in mid 2000. The very preliminary results demonstrated that social exclusion has several tendencies common to CEE countries: it occurs in the case of an accumulation of a number of disadvantage characteristics (e.g. low skills, long-term unemployed, belongingness to/membership in a national minority); there is a spatial accumulation of risk factors (deprived regions); it has a reproductive intergenerational tendency. This makes research from the spatial and social accumulation and reproduction perspectives crucial for finding mechanisms to fight the social traps.
Studies on VET against social exclusion, commissioned by ETF at the end of 1999, and currently under preparation by the National Observatories, shall tackle the problem from the starting point of identification of groups under the risk of social exclusion, collection of factual information about the situation of these groups in education and training and on the labour market, analysis of policies, actions and best practices to promote the social cohesion in the countries. The studies shall come up with the set of preventive and reactive recommendations for targeted policy measures and projects to support the disadvantaged groups and promote social cohesion.

5.2.3 Transition from school to working life: transition in transitory societies

The growth of youth unemployment in CEE facilitated relatively frequent trace analyses of school leavers’ integration to the labour market and research in the field of transition from school to employment.

Roberts (1998) looked at the school-to-work transition in CEE from the perspective of an analysis of basic categories of the transition process, examining the relevance of the Western models. He argues that although the basic categories of transition such as employment, self-employment and unemployment are the same, their meaning and impact may be quite different. Indeed, he demonstrates that variations inside the employment status of young school leavers in CEE are much wider than the ones in the West. With the emergence of the private sector and especially ‘westernised’ types of employment (local offices of Western firms) employment conditions vary a great deal, often providing wages well above the national average. Employment in unstable jobs in the private or public sector, and especially in the redundancy sectors, or self-employment often mean low or vulnerable income and insecurity regarding the future. The young people in CEE appeared more likely to work on their own accounts, being self-employed, than their Western counterparts.

K. Roberts’ analysis is based on the enquiries undertaken in Poland, Hungary, Slovakia, Bulgaria, Ukraine, Georgia and Armenia, based on the methodology which allows for broad comparisons within the group of countries and with experiences of young people on the labour market in the West, developed by the Anglo-German foundation in the early 1990s.

Similarly the unemployment status among the youth in CEE appeared to have a different connotation as compared to the West. Tra-
ditionally much closer intergenerational family ties in CEE affected deprivation as a direct consequence of joblessness, where the unemployed young people often relied rather on the assistance of their parents than on the employment services, managing to maintain the reasonable standards of living and leisure patterns, unlike their Western unemployed counterparts. A relatively high rate of withdrawal from the labour market, especially among young women, was found characteristic for the CEE youth (see also OECD 1998, p.28 for Bulgarian case). Unemployment often actually meant employment in the grey economy, casual labour practices or part-time studies. The young people in CEE also often demonstrated being more likely to be involved in the growth sectors, private SMEs with foreign capital, or successful entrepreneurship than the older population, diminishing by these means the age income inequalities. Thus although the categories of transition to the labour market are the same in the West and in the East, their connotation differs substantially. Roberts, therefore, defines ‘westernised’ employment, public sector, self-employment, partial employment, and unemployment as more appropriate categories to address in research on the school-to-work transition (Roberts 1998, p.236). He proposes, therefore, to research career routes rather than labour market statuses.

The thematic review of the transition from initial education to working life was conducted by OECD between 1997 and 1999. The review covered fourteen nations, including two CEE countries – the Czech Republic and Hungary. The review was built upon Background Reports (NTF 1997, OECD 1998a), prepared by all involved countries, and Country Notes (OECD 1997, OECD 1999a), prepared by expert reviewers. The final comparative report focused on the analysis within the lifelong learning framework of how transition has been changing during the 1990s, and what policies are the most effective (OECD 1999).

The OECD thematic review of the transition from initial education to working life (1999) tackles the topic primarily from the point of view of the flexibility of educational pathways and also of the effectiveness of systems and policies. It was remarkable that both the Czech and the Hungarian post-compulsory schooling pathways were found selective, and the system of partnership to promote effectiveness of education pathways leading to integration to the labour market, insufficient. Moreover, the general trend of the growing length of the transition process in both CEE countries was partly connected with inadequate capacities of tertiary level education, making therefore the overall system of lifelong learning even more selective. The study puts a particular emphasis on the lifelong learning perspective, where high drop-out rates from secondary education in Hungary should be tackled in elementary schooling, and higher levels of qualifications should be achieved by offering a broad basis of both general and vocational qualifications at an upper secondary level and by restructuring higher education in both countries (OECD 1997, 1999a). The role of CVT in improving the employability of young people on the labour market is especially important in this respect (ETF 1999d), as it provides a quick solution by supporting employability of the young before the systemic changes come into being.

The sociological survey School leavers in the Czech Republic conducted in the framework of the OECD project Transition from school to working life (Kuchař 1999) was carried out among population of 20-29 years old who are graduates of standard full time education of all types or are without education, who are employed, unemployed or inactive. The survey analysed educational paths and their length, professional paths, (mis)match of the first job after graduation and the obtained vocational qualification, evaluation of quality of the school education from the employment perspective, and intergenerational mobility.

Both research perspectives – analysis of the educational pathways and career routes – have been combined in a sociological survey, carried out in the framework of the OECD project Transition from school to working life in the Czech Republic (Kuchař 1999). The survey confirmed that the key reason for prolongation of the educational paths was unsuccessful attempts to enter into higher education. The survey also demonstrated linear
school pathways, an early start in professional pathways (combined studies and employment), most frequently out of self-employment, relative instability of professional pathways for people with vocational type qualifications, given by a high concentration of these qualifications in restructuring industries. The survey revealed that particular problems in the transition process were experienced by people with no qualifications, and that the higher the level of education, the stronger the tendency toward social reproduction in the educational and professional mobility (Kuchař 1999). The trace studies on school graduates were also undertaken in other countries (CNA Veneto Euro-In Consulting 1998, and Jigau et al. 1998 in Romania; Study of graduates of VET schools in Estonia, 1998; Pavelson 1999 in Estonia and others). An absolute majority of the trace studies confirm that the higher the level of educational attained, the less the likelihood of unemployment, and the smoother the transition process. They also mostly agree on the need to provide broad-based qualifications with substantial general knowledge and social skills. They confirm that the majority of both the current students and those already in the labour market seek to enhance their knowledge and obtain a higher qualification.

All countries report the lack of a regular system for tracing school leavers' success and failure on the labour market. The above-mentioned surveys are irregular (most of them are one-off surveys financed on an accidental basis), and they lack a consistent methodology. Several countries tried to elaborate a mechanism for the regular measurement of youth integration in the labour market by using the standard available statistics (e.g. Horáčková and Ryška 1998, 1999 used unemployment registry, Vojtěch 1998 employed LFS data, Markausa 1997), but the analysis is circumscribed by the data sources and often happen to be somewhat mechanical, unable to follow the whole complexity of categories and factors of the school-to-work transition. Moreover, not all countries witness research in this field, but all of them report the school-to-work transition as one of the under-researched fields. Finally, our overview of the research on transition revealed that perhaps it is some-what reduced to the school-to-work perspective, neglecting other transitional aspects, such as transition from unemployment to employment, from one type of employment to another, inter-occupational transition, transition from the labour-intensive type of employment to the knowledge- and technology-intensive type of employment, transition between employment in large enterprises and SMEs and so on. Analysis of these notions from the perspective of the role of lifelong learning in lessening the transitional encumbrance may bring the analysts to useful recommendations.

5.2.4 Labour market requirements and skills mismatch

The research on school leavers in the labour market is closely connected to the research on labour market requirements. Indeed, while the trace studies on school leavers in the labour market try to understand the reasons for success and failure in integration into employment, measuring the failure by type, level and branch of education, there are a number of studies that attempt to undertake a preventive approach. They survey the employers' needs in terms of the qualifications and skills of the new labour force, and draw up conclusions on the implications for education and training. It should be admitted that this type of study is not very widespread in CEE yet, and the main reason behind the limited analysis in this area is the costs connected to such types of research. The system of social partnership is still very weak in these countries, and it is rather difficult to persuade branch associations and employers to take interest in and to take charge of generating this type of data and information.

The lack of employers' commitment to cooperate with educators in defining qualification standards is partly compensated by the surveys on employer's needs, mostly paid and organised by the state, the non-governmental sector or foreign donors. The surveys, which have been reported by CEE countries, either take the form of questionnaire surveys among employers or embrace a wider scope of the pro-active operation, involving social partners in the discussion and verification of
the survey results and statistics otherwise available. The latter approach is particularly important as in the long run it may help to activate the role of the social partners in the development and adjustment of VET provision in their branches.

The questionnaire survey *Graduates on the labour market: what do employers expect?*, conducted in the framework of the OECD project INES, was designed to measure employers' demands in terms of skills and competences. It was carried out among 820 Czech companies that employed more than five employees, at least one of them being a school graduate recruited within last two years (Šťastnová et al. 1998).

The survey *Graduates on the labour market: what do employers expect?* (Šťastnová et al. 1998) revealed that Czech companies expect first of all to recruit young candidates with a comprehension of quality and entrepreneurship, a propensity to learn in order to deepen their knowledge or obtain a new qualification, and who are flexible and adaptable to new environments. The schools are assumed to be primarily in charge of providing broad general knowledge, developing verbal and writing skills, and learning aspirations. The companies declared their preparedness to train young people in vocational subjects, health and safety at work, and develop their entrepreneurial skills; they, however, expect schools to take charge of the provision of foreign language proficiency, managerial skills, quality comprehension and customer-oriented skills, self-confidence, motivation, and initiative. Therefore, employers primarily lack social or core skills among school graduates rather than professional competences, and moreover, the employers assume their readiness for providing necessary vocational training leading to excellence in qualifications.

The objective of the *sectoral study in the wood processing and furniture industry in Estonia* (1999) was to assess the importance of the factors influencing its development, clarify the current situation and workforce requirements, including future training needs. The questionnaire survey and indepth interviews covered 165 SMEs (PW Partners Ltd. 1999).

Most of studies on employers' requirements are organised either at a sectoral or at a regional level. Estonia organised a sectoral study in the wood and furniture industry (Jogi 1999) with an attempt to employ a more proactive approach, actively involving employers' representatives in debates on the results of the survey. The survey demonstrated that companies experience skills shortages among qualified labour, not in terms of the numbers among the prepared workforce but rather in terms of skills and competences. On the top of the lack of entrepreneurial skills, a sense of responsibility, commitment and other social skills, as well as thorough theoretical knowledge, the companies see a lack in practical skills, insufficiently provided at schools. The peculiarity of the perception of small enterprises was demonstrated in their appeal for a staff with multiple skills, capable of fulfilling the entire cycle of the production process.

Transition economies have been characterised by a situation in which the job profiles were changing more rapidly than the system of occupational standards. Many jobs are new on the list of occupations or their content has changed so much that the skills required do not correspond to vocational qualifications formally requested for job performance. Therefore the mere measurement of shortage and surplus occupations or enquiries into recruitment problems are insufficient. The added value of the research into particular skills and competences is therefore unquestionable. Another aspect of possible research is the reconstruction of actual job profiles as a tool to upgrade vocational standards. Job analysis (the nature of tasks performed, work environment, responsibilities and perceived skills required) was undertaken in the survey on needs in management training in the banking and financial sector (Deloitte & Touche, 1996). The latter survey also scrutinised customer attitudes in order to enrich the skills perspective.

*VET in the context of regional development* was a project initiated by the ETF in four pre-accession countries (Czech Republic, Hungary, Poland and Slovenia) and implemented by National Observatories in 1998. The studies analysed the
education and training provision, labour market and institutional development in selected regions of the four countries. The Czech Republic conducted a company survey to help to measure qualification supply and demand mismatch in the coming two years in the Ostrava region. Although the project did not involve other CEE countries, some of them took their own initiative and conducted research at a regional or local level, displaying a particular need in such studies.

A number of studies on labour market requirements were undertaken at a regional or county level, varying from a quantified measurement of the present shortage and surplus occupations (Rittau et al. 1998 in Poland) and the training needs analyses (Podravje region 1997-1999, including SMEs needs analysis in 1998, in Slovenia) to rather complex studies on VET in the context of regional development (Versa 1998 in Slovenia, Kidyba and Kozak 1998 in Poland), including the supply/demand analysis (PMU/OBS/IC003, 1998 in Bulgaria, Czesana and Strietska-Illina et al. 1999 in the Czech Republic, and Cvetkova et al. 1999 in Latvia). Regional development is a process still in its starting phase in the CEE countries. Some of them have established regions and basic structures and responsibilities (Poland, Hungary), others have just undergone the legislative process or are still engaged in debates over the regional reform. In this context the regional perspective of socioeconomic development, labour market requirements, and education and training offers becomes very important. Matching supply and demand may best be addressed at the local level and support the establishment of regional and local ties among key institutions. In the context of preparation for EU accession and entering into pre-structural funding, including the European Social Fund, the regional research perspectives are rendered ever more important.

5.2.5 Prognostic research and strategies

Zecchini (1997) rightly noted that existing statistical services in CEE are not prepared to measure facts which are not directly observable in all their detail. He further noted that ‘the tradition of precisely and meticulously quantifying facts related to the implementation of the central plan was suited to an era in which the economy was dominated by few large firms over which the government held strong control...’ (p.4). Indeed, in the past most CEE countries had an elaborate mechanism and infrastructure for manpower planning as an integral part of the overall economic planning. With the end of the communist regime the old practices were abandoned and institutions dissolved. The word ‘planning’ acquired very negative connotation and attempts to conduct prognoses had little recognition in the societies.

The situation has recently changed and in a few countries future oriented studies have been conducted. The research that deals with the needs and requirements of future labour force training, which we provisionally call ‘prognostic’ research, may occur in very different forms. The research also may have a different time span for prediction or planning strategy. Short-term forecasting is much better developed and more widespread than mid- and especially long-term oriented prognostic research. At the same time the need for a longer term anticipation of qualifications and skills requirements, which can go beyond the educational cycle, has started to be recognised.

Prognostic research varies from the relatively simple collective brainstorming of experts and social partners with an attempt to verify existing statistics and to produce an outlook for future development, to quite complex attempts at quantified forecasting models, and to a rather complex mixture of qualitative and quantitative methodologies for elaborating scenarios and strategies for future policies. In CEE prognostic research uses methods
available and at some point applied in the EU member states, where most quantified forecasting models are based on retrospective data and extrapolation of the past trends on the future. In the West, the traditional forecasting models were abandoned by some countries (e.g. France) after the oil shock of the 1970s when the method proved its inability to produce a reliable forecast in exceptional conditions.

Unlike traditional forecasting, scenarios present alternative images (van Wieringen and Dekker 1999), and proved functional in a changing environment. In the case of CEE countries the latter point is especially important, as the reliable retrospective data comparable over a longer time period and the sectoral employment forecasts supplied by macro-economic models, necessary for manpower requirements models, are often not available (NO of VET and Labour Market 1999).

Scenarios certainly cannot fully substitute the presence of data, moreover, the approach itself requires sound statistical data for the initial context analysis. The scenarios method is not meant to ‘de-legitimise the work of those who try to improve the statistical and labour market information base. It is just meant to lay stress on the question of whether there are additional, alternative, faster, and simpler ways of taking decisions about the development of education and training’ (Baumgartl et al. 1999, pp. 186-187). Examining the scenarios method as such is not an objective in our study and we shall simply concentrate on examples of projects using the scenarios approach which either occurred in the countries in question or involved their participation (see more on examples of projects based on the method of scenarios elaboration in van Wieringen and Dekker 1999).

In CEE countries the scenarios approach started to be discussed and subsequently developed in 1997, at which time Estonian researchers were in the forefront. Estonian ‘Education scenarios 2015’ were developed with the objective of initiating discussion in society about the future of education and receiving public support and contribution for the development of strategy in education policies. The idea emerged and started to develop among the members of the Education Forum Committee along with those involved in the elaboration of the nationwide planning Estonia 2010 at the Estonian Institute of Future Studies (Jogi 1999). Thus, the elaboration of education policy scenarios took place hand in hand with the planning process at a macro level. The major assumption for scenarios elaboration was that the future of education cannot be observed separately from the future of the society. Two key factors, which determine the nature of the Estonian society, were chosen as a result of brainstorming meetings and a wider public discussion: cohesion and innovativeness of the society. In the light of these factors four models of the future Estonian society and corresponding education scenarios were drawn: a) Estonia of public schools (nation-centred Estonia), b) Estonia of permanent education reforms (corporate Estonia), c) Estonia of market education and elite schools (Estonia of the rich and the poor), d) learning Estonia (interactive) (Jogi 1999, Baumgartl et al. 1999). The idea of drawing up possible paths of development also implied that the core expert group, civil servants and decision makers would also draw a certain plan of achievement of the most positive scenario, and, even more importantly, would reach a certain level of consensus on how to achieve that.

Scenarios and strategies for VET in Europe is a project initiated by Cedefop, supported by ETF and coordinated by Max Goote Expert Centre at the University of Amsterdam. The project eventually involved five CEE countries (Estonia, Czech Republic, Hungary, Poland and Slovenia) along with five EU member states. The project ‘aims to develop a tool to improve the understanding of VET systems in their economic-technological, employment-labour and training-knowledge environment’ (van Wieringen and Dekker 1999, pp.3).

Another, most recent example of scenarios elaboration was the international project Scenarios and strategies for VET in Europe. The study is based on the Delphi method – the structured consultation of selected experts through questionnaires. The project intends to identify not only scenarios and strategies...
for VET in the involved countries, but also to define the most suitable scenarios and strategies for VET in Europe. As only the first phase of the project has been completed, it is impossible to speak about specific results yet.

It is, however, noteworthy that even on the basis of preliminary results CEE countries often have a sound distinctiveness in defining trends, strategies, key actors and scenarios as compared to the EU member states. The distinctiveness is not necessarily indicated as a difference but rather as giving more or less importance to the same factors. For instance, in scoring the responsible actors for the strategy both the CEE countries and the EU member states assign the same importance to the nation state. However, the EU member states assign a bigger role to the EU agencies than the CEE countries, while the latter undervalue the role of the trade unions as a responsible actor. Furthermore, on average the respondents from the EU countries assign larger responsibility to the individual than respondents from CEE (van Wieringen and Dekker 1999, pp.102). This is given to a large extent by the shared past experiences of the CEE region, its egalitarianism on the one hand, and aversion towards certain types of institutions and partnerships that in some way connote the ‘officialdom’ of the past regime.

The CEE countries also remarkably differed from the EU member states in weighing the relevance of the strategies and scenarios provisionally developed in the project in a number of cases. In terms of importance for CEE in the context of economy and technology, the key issues seem to be those of providing incentives for the private sector and social partners to encourage their engagement in training, developing learning organisation and knowledge management, and forecasting specific needs. In the employment and labour market context a strategy based on the modern flexible workforce (flexible, part-time, employable, entrepreneurial) was rated by all participating in the project CEE countries as highly relevant, whereas scenario dimensions ‘changing in the workplace’ (the organisation becomes multicultural; ICT, knowledge management and social skills become more important whereas hierarchies become less important) and ‘mobility of labour’ (trends towards mobility of labour in flexibilisation, new combinations of work and training, but also higher migration) were not largely shared by the CEE countries, and Slovenia was the only country that supported both scenario dimensions.

The certain contradiction in weighing scenarios and strategies in the context of the employment and labour market is given by the fact that scenarios are built by exploring certain developments, measuring responses on how the selected 23 trends are important and likely for the given country. In other words this means that although the strategy based on the modern flexible workforce may be highly relevant for CEE countries, scenarios based on the ‘modernisation’ of the workplace and the increase in the flexibility and mobility of labour may not yet be feasible.

In the context of training, skills and knowledge, the CEE countries lay stress on reforming the VET system as a whole (decentralisation, flexibility, expansion) rather than changing the role of VET providers and flexibility in training programmes. The CEE countries are at the top of the list for relevance of the strategy based on a transparent qualification structure and mobility, and on individuals investing in their own training (van Wieringen and Dekker 1999, pp.134). Although CEE countries generally support European scenarios and strategies, the above-mentioned preferences show that the systemic reform process in CEE has not been completed yet, whereas other European countries concentrate on scenarios and strategies based on more targeted measures.

As we have already mentioned the above results are only preliminary and may be verified by further analysis. The involvement of the CEE countries in the project on scenarios and strategies in VET in Europe has been no doubt very beneficial, albeit the methodology itself may appear somewhat disputable. Although the scenarios method intends to overcome the limitations of traditional forecasting approaches, based on extrapolation of
Olga Strietska-Iilina

retrospective trends to the future, to some extent the same shortcomings could be observed also in the scenarios method itself. The method is based upon the experts' analysis of the past developments, but also upon their comprehension of the present and future evolution. The human brain has natural limitations in its ability to innovate and imagine the future. This drawback could also be in evidence in other anticipative research based on the Delphi method, which relies on expert judgement – the second-hand testimony of the factual state of affairs.

Whether or not the results of the application of such methods are reliable is a long standing scientific debate, but one thing is certain: it is the added value that the method encompasses, perhaps not necessarily in the result itself only but more so in the process of obtaining the result. The scenarios project as well as several other examples of qualitative research undertaken with an attempt to anticipate future developments and qualification needs managed to put partners from different fields together and make them discuss the problems and possible measures for tackling them. These debates bring about the first step to a common understanding and eventual compromise around very urgent problems, and helps people to start working together on their solution.

The project Regular forecasting training needs: comparative analysis, elaboration and application of methodology (LABOURatory) is led by the Czech National Observatory in cooperation with CERGE (Centre for Economic Research and Graduate Education, Charles University). The project involves a broad trans-European partnership of leading institutions in the field of forecasting and anticipation of labour market needs: ROA (Research Centre for Education and the Labour Market, the Netherlands), ESRI (Economic and Social Research Institute, Ireland), IAB (Institute of Employment and Occupational Research at the Federal Institute of Labour, Germany), and OREF (Regional Employment and Training Observatory, Burgundy) and Quaternaire in France. The partnership further involves Slovenia and Poland. The project, which is in its interim phase and will be completed in March 2001, seeks to elaborate a complex forecasting methodology, based on quantitative and qualitative methods.

Forecasting qualification needs is only starting to be developed in the CEE countries. There have been attempts in Hungary and Poland, and feasibility studies in Estonia (Corcoran 1997), Latvia (Guegnard and Perier-Cornet 1997). Recently the Czech Republic started to develop a methodology based on the manpower requirement approach in the framework of the project Regular forecasting of training needs: comparative analysis, elaboration and application of methodology. The project tries to utilise partners' experience with different methods: the manpower occupational forecast, which takes into account all relevant flows, determining the supply and demand for school-leavers on the labour market; analysis of changing trends in broadly defined occupations and sectors, and future skill requirements for the decision making level to help to elaborate medium-term labour market strategies and educational planning; and expertise in forecasting for the Eastern Länder in the similar conditions of economic transition.

The objective of the project is to elaborate the mid-term (5 years) forecasting methodology for use at a national level by decision makers, guidance services and individuals. However, due to the lack of data and the absence of bridges between classification systems in the fields of education and employment, the results will not be valid at a regional, and a sub-sector level (NO of VET and Labour Market 1999). There is a need to complement quantifying forecasting based on partially available data and a relatively short time span of retrospective data with reliable techniques to estimate the correct figure for a given aggregate. Zecchini (1997) was accurate in characterising the situation of data availability in CEE, saying that 'proper estimation is more useful than incomplete data'(p.4). Therefore, the quantified forecasting models will be enriched with anticipation mechanisms for analyses at a regional and a sectoral level, where experience of OREF and Quaternaire will be applied respectively. The result of the project shall be a forecasting model along with alternative corrective instruments adjusted to exogenous shocks of transition economies, and therefore functional in uncertain conditions.
Forecasting as well as different forms of qualitative anticipation of labour market requirements cannot serve as a direct guide to action but rather as indicators of trends and developments which are to be taken into account by the public as well as by the decision making authorities in planning and strategy development. The strategy elaboration process as such did not emerge by itself in the CEE countries and took place no earlier than the second half of the 1990s, being especially notable in recent years when a wave of conceptual analytical documents were elaborated in different CEE countries. This development was stimulated by a number of reasons.

First, after the completion of the Phare VET reform in its pilot phase, the countries needed a comprehensive evaluation of the results and subsequently an elaboration of a national strategy of further development of the system in the new phase of transformation, when the initial reforming euphoria was left behind, and a new, more pragmatic and targeted approach was needed.

Second, the advancement of the transition process brought the nations from the survival mentality to a definition of priorities and concentrated actions.

Third, the process of preparation for EU accession has fuelled the strategy and planning development.

Finally, the research component itself reached the level of maturity when at least partial intersectoral and inter-institutional cooperation became possible, and this collaboration generated the inter-disciplinary analysis and elaboration of comprehensive studies and concepts.

No matter which CEE country the strategy has been developed in, there are certain domains that are relevant for the whole region:

- the move towards a more decentralised VET system and a system of curriculum development and an elaboration of standards,
- enhancing the role of social partners in curriculum and standards innovation and the anticipation of labour market requirements,
- support for financial and tax incentives to increase access and participation in lifelong learning at all levels and in various forms,
- the provision of targeted support measures for disadvantaged groups to reinforce social inclusion, and to enhance system incentives to promote equality of opportunity in access and participation in lifelong learning,
- continued reform of the systems allowing for more flexibility, horizontal and vertical permeability, and diversification of education offered in order to meet the diversity of needs of economy and learners,
- a system of educational standards and qualifications and a system of quality assurance and accreditation,
- allowing for transparency and compatibility, providing a broad theoretical basis and social/core skills in educational preparation,
- enhancing the modern teaching methods, which develop creativity, initiative, responsibility and independence among pupils by improving teachers training,
- improving the teaching materials, tools and school equipment in response to the needs of a knowledge based and information society,
- support for anticipation analyses of the skill needs to provide employable workforce for the future.

All strategies have been based on the assumption that human resources are a crucial component in the development of the societies in all sectors, and on the recognition of education as an opportunity for the whole society to meet the economic objectives of the community as well as individual aspirations (Cerych et al. 1999; Hendrichova (ed.) 1999; Pusvaskis 1998; Lamoureux et al. 1999 and
6.Conclusions and recommendations

6.1 Conclusions: shortcomings and ‘gaps’

Our initial analysis started from an assumption that the research gaps (i.e. neglected or abandoned areas of research) and the research priorities are determined by the tremendous changes occurring in the countries of CEE. These changes in CEE are a part of the double transformation, where the transition from planned to market economy is multiplied by the challenges of global transformation. We therefore suggested that the gaps and priorities of CEE research would be largely prescribed by the reform process, would concentrate on the requirement aspect of VET and would have much in common among the CEE countries. We also suggested that VET research would have a higher level of production and maturity in the countries where VET itself enjoys a long-term tradition and relative prestige.

Our analysis has brought us to several conclusions. First, indeed the background country reports confirmed that a major demand in research is concentrated in the area of requirement (or contextual) type of research with the emphasis on the needs of the labour market. Nevertheless, at the same time the contextual research with the reference to the labour market requirements was the most frequent in the reports and could be traced in all CEE countries. Somewhat more developed this area seems to be in Poland, Hungary, Czech Republic, Slovenia, Estonia and Latvia, but, to stress it again, it is also well existent in other CEE countries.

Second, our hypothesis about a high degree of accord between the countries in identification of major priorities was confirmed. This demonstrates that although all CEE countries are at a very different stage of the reform process, and have different VET traditions and cultural backgrounds, the principle features of the transition, which are rather common for all countries, determine the current research.

Third, and most important, the VET research in CEE has fairly successfully reacted to the major challenges of the socioeconomic development, quickly responding and adjusting to the immediate needs. A great deal of research efforts have been undertaken as a reaction to major challenges of the transition process: rapidly rising unemployment, growing social and skills inequalities, skills mismatch, and within this context inadequate diversification of VET programmes and the systems themselves, ineffective financing, teaching methods and qualifications of teachers, too narrow vocational specialisation and insufficient mechanisms for innovation of curriculum, standards and quality assurance. The VET research claimed to play its role in the reform process, adopting a pro-active approach and enthusiastically participating in development projects.

Our initial hypothesis of better research coverage and greater maturity of VET research in the countries where VET itself enjoys higher prestige was not confirmed. The analysis showed that there were other factors that influenced the research development in the CEE countries, where the existence of a research institute, development of the university-based research or participation in international granting schemes had a greater impact on VET research than the prestige of VET. We may, however, suggest that the countries, where recent years displayed a shift towards comprehensive conceptual elaboration of the overall system of human resources...
development at the national level in the concept of lifelong learning, enjoyed integration of VET into state or public driven conceptual works. This manifested the most positive development of recent years as far as VET research in CEE is concerned.

Although VET research managed to successfully cover the most acute problems on the agenda of the countries in transitional, the study has revealed an insufficient coverage, inadequate quality, poor methodological approach and inefficient organisation in a number of areas of VET research in CEE:

- Under the turmoil of the reform process, the VET research has tried to find immediate solutions to complex socioeconomic problems. Out of the two components of the transition process, the VET research has rather reacted to the principle demands of transformation towards free market economy and democratic society. The global challenges, imposed by the growing importance of knowledge intensive industries, the services sector, SMEs, and related to these question of access to knowledge, information and ICT have not been tackled to the same extent.

- In the pursuit for quick and immediate solutions, and being under time and financial constraints, the VET researchers and practitioners in CEE often tended to look for ready made answers, which came into being in the form of the models adopted from the West and with the international financial assistance. A thorough systematic analytical work into verification of the feasibility, adjustability and impact of such adoptions was not in place. In spite of the invaluable input of international expertise to the process of advancement of the VET reform, the role of national research in the reform process was often neglected. As the result the VET reform process did not sufficiently contribute to VET research development, especially at the beginning of the transition period. The notions of a primary concern for research in the EU member states are not always adequately tackled by the CEE research. The CEE countries found themselves in the situation where the challenges they have to tackle are primarily the same as in the EU member states but on the top of it they must find quick answers to most urgent questions of the democratic reform process. Being a driving force for change, researchers and analysts happened to be a 'hostage' of the same reform process. The urgent has often prevailed over the conceptually important in a longer term perspective. The recent years have, however, featured a number of positive examples of a thorough conceptual approach in the elaboration of further steps, though still somewhat missing a scientific hand on it.

- The national reports have demonstrated the peculiar domination of the analytical works in the field of labour market requirements over conceptual and theoretical research into aspects of process and outcomes of VET in recent years. This has been strongly determined by the rapid economic change. In spite of the general reproach expressed by all (!) CEE countries about the lack and insufficient development of labour market needs analysis, we may state that the problem was rather a lack of a systematic approach, and effective and efficient methods in such analyses. Moreover, the VET research has been somewhat subordinated to the labour market analysis, while the theoretical research in the field of process and outcomes of VET has been neglected. Slightly more evidence of research into processes and outcomes of VET were observed in Lithuania, Hungary, Poland, Czech Republic, Slovenia, Romania and Bulgaria.

The subordination to the labour market requirement was not a negative development per se but it threw out the baby with the bathwater. What is it that we are trying to harmonise VET provision with the labour market requirements for? It is the life success of the individual, his employability, but also his ability to learn in the future and to be a successful and active citizen. The role of the individual has been somewhat overlooked in the research, where the success of the individual was reduced to his success in employment in
the future. The concept of lifelong learning gives a broader perspective and needs to be better addressed in the research into different fields of VET. Furthermore, the needs of individual learners must be also better addressed in the context of employment – in the framework of CVT and HRD in enterprises.

The VET research in CEE has mainly had an applied or developmental character. Theoretical scientific research has been almost totally abandoned in a majority of the CEE countries; Lithuania was virtually the only exception where theoretical scientific research into VET is well situated in the academic surrounding of the country. Such development in CEE on the one hand appeared as a positive shift from highly theoretical academic research, isolated from reality, towards more practical and developmental research. On the other hand this can turn into a very dangerous development. The absence of theoretical or basic research is not something that could be felt immediately but it may restrain development in the long run. Putting research closer to practice certainly does not mean abandoning theoretical research. The mechanisms should be found how to implement the scientific findings into practice.

To the contrary of our previous statement, several countries reported insufficient development of applied research (Slovakia, Estonia, Albania, Hungary, Romania). The reasons behind the statements are largely caused by the same reasons: a lack of mechanism to follow up research projects and implement recommendations. There is a gap in between “what to do?” and “how to do it?” (Mustafai 1999). Specific types of projects, aimed at the dissemination or implementation of results of the research, are not frequent and must be enhanced.

The VET research in CEE proved to be highly fragmented, where each sub-sector of the VET system or a particular field were researched separately. This was also reflected in the institutional arrangements that separate curriculum research, research on standards from the labour market research, research on initial VET from research on CVT and HRD, etc. Each institution specialises in its domain, in which they would run both research and development projects depending on the context and funding, but would rarely go beyond their scope of operation.

A comprehensive conceptual approach in research started to be developed in recent years and manifested a new qualitative change in the reform process. The national researchers adopted a more cautious approach in implementation of the foreign models and started to look at the research traditions in their own countries. From taking the value of Western models and methods for granted there has started a shift towards a more thoughtful approach, reliance on the national researchers and practitioners, and attempts to look at the education and training in a broader context of lifelong learning, human resources development and global changes. The positive shift must be further supported and promoted where multidisciplinary research and a corresponding inter-institutional collaboration must take a lead.

In the transition turmoil the VET research has had very limited financial sources in CEE. This has contributed to fragmentation of research, brain drain from research, subordination to the immediate and most urgent problems, attempts to find ready-made solutions of complex problems, dependence on the external sources and therefore subject to specific restrictive regulations of the foreign aid. Some countries evidenced insufficient development of the empirical research due to the financial constraints. Where national sources are very limited, efficiency of the research organisation is vital. The research function needs more transparency, coordination and flexible mechanisms of grant support at the national level. Inter-institutional cooperation, coordination of efforts and synergy between different institutional structures, diversification of funding sources and a greater participation of private and civil society sectors in the VET research can contribute to the efficiency.
Under the circumstances of the economic hardship and limited spending on research and development in CEE, the role of international financial assistance is indispensable. It has, however, concentrated rather in the area of development projects than in assisting research to undergo the transition period. It is the duty of each particular CEE government as well as of the international society to help research to overcome the scientific discourse caused by the decades of the realm of the communist ideology. The role of the research as a central support point in the reform process, where research is both cause and effect of the transition, is essential for overcoming short-sightedness and old-fashioned mode of the CEE research.

- In spite of fairly successful reaction to most urgent topics, the introduction of many new research fields in the research agenda, and successful coverage of the issues of concern of the reform process by the VET research in CEE, there have been certain 'gaps' or topics which need further elaboration. These topics are of two types: country specific and general for the region. Confirming our original hypothesis, the vast majority of priority fields are common for the CEE countries. All or most countries state the need in supporting and developing research in the following fields: labour market training and qualification needs analysis, competence-based qualifications, broad-based qualifications, innovative teaching methods, teachers training and personnel development at schools, vocational and occupational standards, evaluation and quality assurance, financing of VET, transition from school to working life, systematic trace studies of graduates (including educational paths and career routes), modular training and its impact, the role of VET in promoting social cohesion, CVT, and HRD in enterprises. It is necessary, however, to add that the major drawback of CEE research is not in its gaps as such, but rather in the mode by which the fields are covered. It lacks a comprehensive perspective where each particular issue or field is considered against the background of lifelong learning and the strategic perspective of the systemic development of national human capital.

The country specific research priorities concentrate on particular problematic areas of VET present in these countries. For instance, a rather high rate of dropouts (over 10%) from education in Slovenia, Hungary, Latvia, Estonia, would suggest that the research into causes and effects of early school leaving as well as the identification of mechanisms to promote integration of the young into education or employment would be useful.

Another important aspect of country specific needs lies in the area of initial stock-taking information and data collection. At the beginning of the transition process the information tools were often inadequate for helping to design the policies, monitor policy effects and identify areas for policy adjustment (Zecchini 1997). After a history of governmental manipulation of statistics, a new approach also needed to be elaborated in the statistical services for the purposes of obtaining an accurate and objective record of relevant social and economic phenomena (Zecchini 1997). While in most CEE countries the initial phase of reforming national statistical services and the minimum requirement of reliable stocktaking data for the monitoring and adjustment of social and economic policies has been mainly fulfilled, in Albania it is clearly not the case. The statistical provision in the latter country hinders research and analysis and the subsequent policy innovation. Thus, statistics on education and the labour market should be urgently improved in Albania. Nevertheless, other countries also suffer from inappropriate data coverage, especially in the area of CVT, HRD in enterprises and financing of initial and continuing education and training by type of sources (including private sources and expenditures on education by enterprises).

Involvement of the CEE countries in the process of elaboration of the common terminology in the field of VET and support to a greater transparency in the VET vocabulary is important for promotion of comp-
parable cross country analyses and stipulation of a benchmarking perspective to each particular state.

The CEE research in the field of VET must harmonise conceptually and methodologically with the foremost international research community by consolidating its great intellectual potential and by relying on its experience in playing a prominent role, which the CEE researchers and other intellectuals have played in supporting democratic developments in their countries.

6.2 Policy implications

The challenges of double transformation, the increased blurring of education and work, the challenge of the knowledge-based society and a lifelong learning perspective impose especial role for research in the field of VET. The research in CEE is in the process of change itself; at the same time it should become a core point of initiation, analysis and elaboration, and expert support in implementation of the major reform steps. This implies the importance to support the research provision and organisation in the CEE countries in the following dimensions:

- It is recommended to support research in the fields, where either country specific or cross country research gaps have been identified (see above). It is equally important to support research in the fields, which have enjoyed relatively high frequency, nevertheless, lack conceptual maturity, methodological excellency and comprehensive understanding. Stocktaking information gathering is equally a priority, especially in the countries where the absence of data hamper efforts of analysts and present an obstacle in strategic conceptualisation.

- In order to facilitate research generation and effectiveness the following institutional measures are recommended:
  - to support the establishment of cross-sectoral coordination and granting structures for research (e.g. research boards) in the CEE countries, where such bodies are not in place yet;
  - to support building project management capacities at research institutes and universities in CEE in order to promote their better participation in national and international research and development activities;
  - to define and publicise national research priorities and strategy on a regular basis;
  - in commissioning grant schemes at a national level a balance must be found between research projects commissioned on order from the top and open calls for proposals aimed at supporting the local research initiative and inter-institutional collaboration;
  - to enhance information provision and wide dissemination on the available research outputs in order to increase inter-institutional awareness and cooperation;
  - the governments shall seek after diversification of financial sources for VET research, promote incentives to increase participation of private bodies, companies, voluntary sector in research into VET.

- International organisations (especially OECD, European Commission, World Bank, ETF and Cedefop) in many cases have been a driving force of information provision and research generation. It is recommended:
  - to broaden the eligibility of international research programmes and analysis to other countries in transition in order to contribute to a better co-operation of research networks across Europe, facilitating exchange of experiences and methods;
  - in the international support programmes (e.g. Leonardo da Vinci, Vth Framework, projects commissioned by ETF) to ensure the suitability of the topics of selected projects to the national priorities and needs; this implies greater and tighter cooperation.
between international organisations on the one hand and the national governments and research communities on the other;

- to support cross/trans-border research projects, international partnerships, international comparative analyses;

- to support the establishment and sustainability of research thematic networks across European countries, both EU and outside.

In order to increase awareness of research results, improve adequacy of research to practice and diversify research outputs, the following types of research should be enhanced and must be taken into account in evaluation of proposals:

- university-based or academic research, linked to the world of work and policy making;

- research initiated by a private and voluntary sector with the involvement of counterparts from the public and academic research community;

- interdisciplinary, multidisciplinary research;

- applied research in a solid theoretical framework;

- comprehensive research which embraces the whole system analysis in a broad perspective of lifelong learning;

- preparatory research, aimed at identification of research needs and subsequent project generation;

- follow-up projects, aimed at implementation of previously done research analyses, tackling outcomes and recommendations of research, dissemination projects;

- prospective, future oriented research and elaboration of methods for such research.

Finally it could be stressed that ‘cross-national studies and increasing transnational knowledge may add to a process of integrating Western and non-Western approaches’ in science, the added value of such cooperation being the increased knowledge about other countries among both the researchers involved in such studies and also those who have access to the results (Oyen 1999, p.190). Our analysis has been only a first attempt to map the research in the field of VET in CEE and we very much hope that further elaboration with a focus on particular topics will bring about greater transparency in the VET research fields and methods in the future.

- Diploma bachelor
- Master/Doctor

This diagram represents the first stage in the ongoing development of a standard graphical model for vocational education and training systems. Further refinement may include the further alignment of terms, student matriculation and dropout figures, and local language terms.
Education system in the Czech Republic

- **First stage**
  - Basic school
  - Pre-school education

- **Second stage**
  - Basic school
  - Secondary general (gymnasia)
  - Secondary technical schools
  - Secondary vocational schools
  - University

- **Special schools**
  - Diploma (exit to labour market)
  - Matura
  - Final exam
  - Absolutorium
  - Final apprenticeship exam
  - Final certificate
  - Diploma/Bachelor
  - Master/Doctor

- **Continuing training**
  - Higher professional schools
  - Follow-up courses

This diagram represents the first stage in the ongoing development of a standardized graphical model for vocational education and training systems. Further refinement may include the further alignment of terms, student movement through dropout figures, and local language terms.
Education system in Latvia

- General secondary education programmes
- Vocational programmes (4 years)
- University
- Continuing training
- Applied professional programmes

Basic education

- Diploma (exit to labour market)
- ISCED Level
  - Secordary Matura
  - Vocational
  - Vocational and Matura
  - Diploma/Bachelor
  - Master/Doctor
  - Horizontal passing
  - Vertical passing
Education system in the former Yugoslav Republic of Macedonia

- Doctorate of Sciences
- (Master's degree and Specialisation)
- Facilities and Institutes
- Two-year colleges
- Specialisation
- High school education
- Four-year vocational for different occupations
- Art school
- Other vocational with programmes of shorter duration
- Education of adults (Elementary and Secondary for different occupations)
- Subject teaching
- Classroom teaching
- Infant-schools
- Kindergarten
- Nurseries
- Post-Graduate Studies
- Higher level education
- Sec. edu. of adults
- Elementary education
- Pre-school education
Education system in Poland

- **Primary school**
- **Compulsory education**
  - Grades: 1 to 8
  - Level: Basic
  - Diploma (exit to labour market)
  - Matura
  - Vocational professional
  - Matura + vocational
  - Master
  - Doctor

- **Higher education institutions**
  - Master
  - Licentiate
  - Engineer

- **Basic vocational schools**

- **General secondary school** (Lyceum)

- **Special schools**

**Vertical passing**

*2 years courses for master degree*

This diagram represents the first stage in the ongoing development of a standard graphical model for vocational education and training systems. Further refinement may include the further alignment of forms, study enrolment and diploma award, and local language terms.
Education system in the Slovak Republic

First stage

Basic school (Základná škola - the equivalent of primary and lower secondary level)

Second stage

Secondary general (Gymnázium)
Secondary specialised schools (Stredné odborné škola)
Secondary vocational schools (Stredné odborné uilište)

PhD study

Diploma (exit to labour market)
Matura
Final exam
Absolutorium
Final/Apprenticeship exam
Final certificate
Diploma/Bachelor
Master/Doctor

Kindergarten

Compulsory education

Grades
ISCED Level
Age

Permeability

This diagram represents the ongoing development of standard graphical models for vocational education and training systems. Further refinement may include the degree of student enrolment and drop-out rates.
## Annex 3

### List of the international institution networks involved in VET research

Abstract
The paper gives an overview on VET research in a number of non-EU countries. It seeks to identify and to structure research undertaken at national, regional and international levels. However, to present a comprehensive and all-embracing study is almost impossible because of the difficult demarcations of VET research with corresponding research activities, the multi- and interdisciplinary orientation in various countries and the heterogeneity of the institutions, associations and researchers involved. In a first step, based on secondary analyses, the most important institutions, networks and research outcomes in the countries, regions and international organisations covered by this paper are described in different depth. Primary analyses have been carried out for the People's Republic of China, Canada, South America and for the IEA. For the other countries and institutions, work focused on stocktaking of relevant VET research provisions (research results, databases, thematic and other networks, information on classification systems, etc.).

The overview shows that, in general, there is an increasing trend to focus VET research on the interrelationships between economic development, labour market needs and vocational training. Purely school-based vocational training is in decline (e.g. in South America) and one increasingly includes research on labour market needs. Besides this, another general research field is pragmatic or policy-oriented research concerning the evaluation or development of existing or planned system reforms. Main fields are curriculum research, didactics, methodologies and media in training.

Universally, the support of thematic networks and the provision of information (databases, research results, etc.) is of increasing importance. Cooperation and taking on board experiences and suggestions from other countries rank high in the promotion and development of national systems of vocational training. Equally, international organisations (in particular ILO, OECD, Unevoc) are important providers of information, documentation and cooperation.

Executive summary

This report attempts to identify and structure the focuses for VET Research in a geographical/political area several times the size of the EU at national (e.g. USA, Japan, China, Russia, Switzerland, Brazil, Argentina, Canada, Uruguay, Australia, Turkey, etc.), regional (e.g. MERCOSUR) and international level (scientific societies: International Association for the Evaluation of Educational Achievement (IEA), international organisations: ILO, OECD, UNESCO, World Bank). It is an exercise reminiscent of trying to square a circle, on account of:

- the virtual impossibility of delimitation of corresponding research activities;
- the multi- and inter-disciplinary set-up;
- the fact that research is conducted by institutions permanently supported by the state or public bodies, by international organisations and societies and by independent researchers.

Thus in an initial drive to establish some lines of demarcation an attempt was made to identify important institutions, networks and research results. For the countries, regions and international organisations listed above, this was done at various levels. For the People's Republic of China and Canada, as well as for South America and the IEA, primary analyses were conducted. For the remaining countries and institutions, the inventory of usable resources for VET Research (research results, data bases, thematic and other networks, information on classification systems, etc.) was the main source.

Was it possible to identify any global priorities? Generally speaking, research appears to be concentrating more heavily on the interdependencies between economic development, the needs of the labour market and vocational education. Purely academic vocational education came in for criticism (cf. example of South America), and hopes are being placed in the results of research oriented towards the needs of the labour market. Besides this priority, which is based more on a change of paradigm, the focus of national or regional activities is obviously 'pragmatic', policy-oriented research related to the assessment or development of available or planned national system structures. Curriculum research as well as teaching, methodology and media were all priorities. Thematic networks are commonly promoted and a wide range of information (databases, research results, etc.) provided. Co-operation and the possibility of drawing on other people's experience are very valuable resources when it comes to promoting and developing one's own national vocational education system. Even the international organisations (particularly the ILO, OECD and UNEVOC) depend on information, documentation and co-operation.

Since the EC area is tied in with the globalisation of this worldwide development, and comparative VET research has always provided for global dialogue alongside national or regional systems development, there is also a need for the EU to act. The experiences of comparative systems outside the EU should be tapped in order to prompt the further development of the highly diverse national VET systems which exist within Member States. Moreover, classification systems (ILO, OECD) and achievement assessment concepts (OECD) indirectly exercise a standardising effect on national VET systems. The involvement of supra-national bodies such as the EU – despite the fact that the individual EU Member States also belong to the ILO and the OECD – is therefore of the essence. Given the importance of global dialogue and the worldwide exchange of experience on VET research, the EU should more actively embrace activities in this field.

Possible flanking measures could include:

- Studying the national research activities of the 'other countries' and the results of meetings of international scientific societies as well as what is provided by the international organisations, using policy-oriented state of the art analyses of more broad-ranging reports;
- Promoting dialogue between vocational education researchers in EU countries and...
the countries, regional bodies, international scientific societies and international organisations covered by this report, through exchange programmes;

- Promoting the setting-up and running of thematic networks and information systems;

- Promoting dialogue and transfer between politics, EU institutions and the scientific community through meetings on specific topics.

1. Introduction and returns, by Uwe Lauterbach

1.1 Areas of investigation and problems with delimitation

In the 1st Report on Vocational Training Research in Europe (Tessaring 1998), the section on the Theory and Methodology of International Comparisons explained how VET research is tied in with many different disciplines. Only a generally accepted definition of vocational training research/VET research can clarify the scale and depth of this field of research.

It deals with the aspects of the education and vocational training system, which are either directly or indirectly related to professions, to gaining qualifications, and to (professional) activities. It also studies the conditions, pathways and consequences of acquiring these specialised and extra-functional qualifications within the context of the cultural, social, political, historical and economic framework conditions, e.g. personal and social attitudes and leanings, which would appear to be important for training and further training and for performing (professionally) organised work processes. Vocational training systems (formal, non-formal, informal) should thereby be regarded as part of the overall education system.

The size of the research field is also demonstrated in the 1st report and the two volumes of the Background report 1998 (Cedefop 1998). The role of this contribution cannot therefore be to carry out a broad-ranging assessment of all the results of VET research worldwide – with the exception of the EU and the Central, Eastern and Southern European Countries (cf. the contribution of O. Ilina, in this volume). The point is more to focus on and tackle the following questions:

1. Is there a particular focus known as VET research in the national research landscape, and if so, where does it lie?

2. Which scientific institutes and university departments carry out VET research?

3. Are there any (scientific, application-oriented, etc) associations/societies/networks, which are primarily involved in VET research (including statistics)?

4. What are the most important results of research, and what do they concentrate on: systems research (e.g. steering, quality research, evaluation of attempts at reform, financing), labour market research (e.g. qualifications research, unemployment and labour management measures), curriculum research (key qualifications)?

5. What are the most important publications (monographs, statistics)?

Simply dealing with these questions alone would entail a research programme spanning several person-years. This bold-looking statement can be easily confirmed using a couple of examples. In the USA there is no one single national society for vocational training research. Interesting research projects are carried out by sociologists, educationalists, economists, and psychologists, to name but a few. In order to get the overall picture, virtually the whole of the research landscape would have to be scanned. Thought would have to be given to which projects actually focus on vocational education, and which lie more within general education, particularly bearing in mind that vocational education can differ very widely according to the cultural context. One example of this would be how in English, French and Spanish speaking countries vocational education distinguishes between actual vocational and technical educa-
tion, and the problems of translating from one language to another.

The term 'Technisch-berufliche Bildung' is rendered in English by drawing a distinction between technical education and vocational education. 'Technical education' refers to areas of training which have traditionally been more theory-based, such as laboratory technicians, technicians, accountants and managers, in other words not only to the technical education which would relate to engineering in a German speaker's mind. 'Vocational education' is separate from technical education, with the former relating to more manual, 'simple' activities. To a certain extent UNESCO also uses these definitions, for example.

Within the European Union a further distinction is drawn between vocational education (school-based) and vocational training (company-based), abbreviated as VET. There is no term to put across the idea conveyed by the German berufliche Bildung which covers the concept of vocational 'learning'. This term, which is based on a theory of vocational learning, covers both basic and further vocational learning in all areas. It also embodies the idea that general and vocational training should be of equal value. (Beck 1995, p.457-464)

This example alone exemplifies the multi-faceted nature of the dilemma. The reason for this lies in the fact that the subject of vocational education is not clearly defined. In many areas there is no point in distinguishing between VET research and educational research. When priorities are established, the delimitations must be thoroughly justified. This integral approach has been achieved in Switzerland. The Swiss Co-ordinating Centre for Educational Research includes vocational education as a heading in its index, and around 5% of projects are identified as VET research. Had other selection criteria been applied, however, the figure could well have been 20 or 30%. But the multi-faceted delimitation dilemma relates not only to the discussion as to whether VET research is a component of educational research, or whether research into vocational education also has much in common with other areas of research such as educational economics, and cultural research. The example of comparative cultural research shows quite clearly which other fields of research could usefully be looked into in relation to questions of comparative VET research (see also D'Iribarne 1999).

But it is not only these difficulties which have to be weighed up. The difficulty posed by the different levels to which vocational education has developed in the countries under investigation also comes into play. Whilst in the USA, Japan, Canada, Russia and Switzerland vocational education in the broadest sense of the term has long been the subject of research, the same cannot be said of Australia, Turkey, or the Latin American countries. Here vocational education is an important factor in the development of the national economy. The same is also true in the People's Republic of China, although, on account of the political framework conditions, it has proved virtually impossible to date to collect and analyse information on VET research.

In the case of international organisations there are at least two types:

a) Those which represent national state roles and bodies, and define political aims as an organisation, such as UNESCO (UNEVOC), the World Bank Group, the OECD, and the ILO.

b) The global scientific societies which also deal with questions of VET research, such as the Comparative Education Society in Europe, the World Councils of Comparative Education, or the International Association for the Evaluation of Educational Achievement (IEA).

The aim of these analyses of the national and international fields should be to pick out worldwide trends and the results of research on commonly recurring priority areas, and at the same time to analyse the shortcomings. There are several aspects to such an analysis of shortcomings:

1. When we made an offer in response to the call for tender we presumed ('we' being the working party on international vocational
Uwe Lauterbach et al.

education from the German Institute for International Educational Research) that our main method of investigation would consist of secondary analyses. Once work had begun, however, we quickly realised that although this assumption was correct in the case of individual institutions, analyses of countries and regions, as well as of international organisations would all have to be carried out using primary sources.

2. As mentioned in the introduction, VET research must first and foremost be defined within the context of the country in question. The essential role here is played by linguistic and cultural framework conditions. The link between national VET research, the respective concept of vocational education and the latter's degree of development has to be brought out in relation to each subject of study.

3. The definition has to be established in relation to the individual countries. The respective essential characteristics of the vocational education system play a leading role therein. In some countries – such as the USA – federal/national, regional and local activities run alongside the research interests of 'independent' researchers from a multitude of disciplines. The term 'structured chaos' is doubtless somewhat exaggerated, but it is a situation which is nonetheless confirmed by researchers with the appropriate experience. Which is why an answer has always to be given to the question as to whether there is any 'national VET research', or whether 'external' research interests transform it from fiction into fact?

4. Although providing the results of research leads to the effect just described in countries which have a democratic research tradition and a corresponding infrastructure for means of communication – such as the USA – the same does not hold for countries which on the one hand cannot provide the necessary technical facilities, and on the other cannot tap into either the experience or the mindset which can be described as the 'democratic Western research tradition'- e.g. China.

5. Snapshots of the state of research are useful, but mean very little in the absence of a 'development-related' dimension which can help to place current results within the correct context and perspective.

6. In the past, international scientific societies played an important role in the development of comparative educational research, thus providing an impetus for the development of VET research and comparative VET research. International comparisons of achievement and the international classification system date back to initiatives taken as of the late fifties by independent researchers within the scientific societies. For well-known reasons, e.g. multi- and inter-disciplinarity, the fact that it was based in different disciplines, the problem of delimiting research fields, comparative VET research has not thus far been able to establish itself as a scientific discipline. Even representatives of comparative education and independent scientific societies lagged behind when compared with international organisations. It is now the international organisations which – largely for economic reasons – hold pole position, particularly those which play a leading role both in politics but even more specifically in economic policy matters.

These comments alone, which crystallised out in the course of work on the main hypotheses in this research study, and which could easily be added to by a series of other aspects, indicate the difficulties involved in tackling the questions worked out with CEDEFOP. As a consequence of these working results the scope of the subjects to be studied and the general depth of the study were amended:

- Efforts at primary analysis were limited to a handful of countries alone, with pragmatic and fundamentally system-related aspects complementing each other in the selection process. Developing and threshold countries (South America: Argentina, Brazil, Chile, Uruguay, Paraguay) and industrialised countries (Australia, Canada, Russia) were studied in more detail. Other industrialised nations such as the USA and Switzerland on the other hand could only
be touched upon. Due to the limited time and working capacities available, African countries could not be included in this contribution.¹

In an initial round the international organisations were sounded out to see whether VET research was relevant to their work. The results were complemented by a description of the emphasis each organisation placed on VET research. It was not possible within the framework of this project to assess and weigh up the results.

In the post-war period the independent scientific societies played a leading role as a driving force in the development of comparative educational research. A series of results would seem to indicate, however, that their position has since become much weaker. In order to check out this assessment, reference was made to the international organisations which dominate today, such as the OECD.

The VET research theme draws no distinction between VET research and comparative VET research. We only indirectly made this distinction in our study. In the country analyses it is VET research which predominates. However, comparative VET research is of more importance for the independent international scientific societies and the international organisations.

1.2 Results of the investigation

The results of the investigation relate to questions (1) to (6) and to the analysis of shortcomings (1) to (6). The amendments explained above and the limitation of the questions which arose as general matters in the course of the study led to attention being focused on the four areas described below.

1.2.1 Links between national VET research, the respective vocational education concept and the level of development of vocational education

The focus of interest in VET research is vocational education. Vocational education became a point of general interest in the industrial society. The link between encouraging the working population to gain qualifications and economic development is self-evident. That apart, politics looked and continues to look out for vocational education because its further development or specific measures taken in the area of vocational education can help to break down or at least ease tensions on the labour market. By way of an example, CINTERFOR was founded because the South American states involved promised thereby to assist in ‘generally raising the level of vocational training, in order to improve the living conditions of workers, and the qualitative and quantitative running of firms’ (see Section 2.7 of this contribution).

VET research is thus very closely related to the present and to what happens in practice, and therefore tied in with the broader contexts of vocational education and everyday politics – particularly educational and economic policy. Reference should not be made here to the ‘classical’ example of Germany – this correlation is also clear in the countries and regions studied. That is why in Australia a National Centre for Vocational Education Research, the NCVER, was set up in 1980. The Montevideo based Centro Interamericano de Investigación y Documentación sobre Formación Profesional, or CINTERFOR, which is responsible for South America (founded 1960) the METARGEM in Ankara, Turkey, or the National Centre for Research in Vocational Education in Berkley/USA also came into being within this context. The most recent example is the Central Institute for Vocational Education in the Chinese Education Ministry, which was set up in 1990.

This correlation between the activities of vocational education policy, the development of vocational education and the founding of central national or regional research institutes also extends to research subjects.

¹ Information on these and other countries not dealt with in this contribution are found in diverse publications and statistics of international organisations and associations (see below).

These are shaped by the respective political framework conditions and system development. In Japan and the USA 'national vocational education policy' enjoys relatively little room for manoeuvre. It acts within the parameters stipulated by the system. In the case of Japan what this means is that even the research bodies in the Education and Labour Ministries must carry out their duties within the framework of the existing vocational education system. In the USA the NCRVE has to concentrate on assessing the federal programmes and on providing advice, in line with the system. Even in Australia the thrust of the system is dictated by politics. Within the framework of these handicaps the NCVER and other research institutes carry out specific tasks of research and documentation, which assist in shaping the system.

On the other hand, research activities in the People's Republic of China, as in Canada, Russia and Latin America, have taken on systems development as one of their subjects. This is also influenced by prevailing conditions, such as the switch from developing to industrialised country, reforms in vocational education, country in the process of transformation, a relatively unstable and minimally developed system of vocational education, etc.

Independent of how the system is composed, research commonly focused in all of the countries under consideration on curriculum research, teaching, methodology, and media. Apart from actual research work, documentation, networking and information are also important tasks.

1.2.2 International organisations and vocational education or the education concept versus the economic concept?

Previous analysis could give the impression that VET research is shaped nationally, and that it is therefore the political framework conditions, which also determine the reality of the vocational education 'system', which are responsible for the focus of research activities. In relation to the current situation this view is certainly correct. In relation to future developments, however, it might be questioned on a number of fronts.

The developments which remain to be verified for vocational education can briefly be sketched out using the example of comparative education. Here co-operation began between the scientific communities of large industrialised nations, and later on academic or scientific societies and international organi-
VET research in other European and non-European countries

sations were founded. Important research priorities included, for example, the comparisons of achievement (IEA) and the development of the International Standard Classification of Education (ISCED).

These independent researchers have since lost their dominant influence. International organisations now predominate, and within this circle those organisations having a sound financial basis can take over many of the roles (see above) which 30 years ago still numbered amongst the original developments of the scientific community.

The OECD has since been working hard to develop the ISCED classifications further. Even the comparisons of achievement which were originally carried out by the IEA have now been taken over by the OECD, and educational statistics in Member States and other interesting countries are collated by the OECD at a differentiated level. This information is then used in the OECD's popular publication Education at a Glance. The specialised public enjoys referring to this handy indicator system. The problems attaching to the classification of areas and levels of national education and vocational education systems in international comparisons are not unknown. We are referring here to the different assessments made of classification and participation rates for vocational education in industrialised nations. Different national set-ups and system philosophies for vocational education are mentioned as essential reasons for this. Indicator systems – as for example in today's OECD format – should therefore be used only with the necessary critical distance. A broad knowledge of the system is required for interpretation. Here it should be noted that major progress has been made in indicator-related work towards placing data within the context of the respective education and vocational training system. This can be seen, for example, by comparing the 1992 and 1998 editions on vocational education. The most highly criticised approaches (OECD 1992 and 1998) from the past have now been dropped. A differentiated system of indicators with a series of comments attached has taken over from the rather cut and dried classification. Differing interpretations of the various classifications also crop up, but on a basis which presupposes more in-depth knowledge of the respective national systems. In continuation of this argument, the only question which remains to be asked is, actual experts apart, who else is still in a position to correctly digest these commendable publications?

A shift of emphasis seems to be taking place within the international organisations which is also affecting VET research. Until the seventies it was UNESCO – supported by the scientific community – which set the pace, but the ILO, the World Bank group, and the OECD have since taken over the running. Apart from the OECD's activities (see above) the ILO is also running a series of highly promising research projects, e.g. Evaluation of Training and Training Policy Analysis. For its part, through the UNEVOC, UNESCO is also beefing up its activities in support of VET research.

This range of research activities would seem to allay the fears (von Recum 1997) which are constantly being expressed in research that, as a result of the economic globalisation of trade, production, services and information flows, those who support the theory that because of this globalisation the world should be seen as a company, and that things political will gradually be swallowed up by the functionality of things economic, will see their influence on VET research grow.

1.2.3 Are there any world-wide priorities in VET research?

Identifying world-wide priorities in VET research requires a knowledge of current activities. In this report we looked at various different levels in order to answer this question:

- nation states;
- supra-national and international organisations;
- international scientific societies.

For the reasons mentioned in section 1.1, we limited ourselves to certain countries and, wherever possible, to the central research
bodies. International organisations were also one of our points of focus. It is almost impossible to say anything in respect of international scientific societies because VET research as a cross-sectional science exists to date in only a handful of countries as a scientific and academic discipline, and the results of academic VET research have next to no influence on international discussions. For the nation states and international organisations, on the other hand, different priorities and results can be identified in terms of the tasks to be carried out.

As has already been stated, national VET research, particularly in the central institutes, is directly tied in with systems development and national vocational education policy. It was not possible within the framework of this first study to work on the priorities established for the individual countries – curriculum research as well as teaching, methodology and media – and pick out recurring themes such as module based training, or self-guided learning. In general terms, however, research seems to be targeting more heavily the interdependencies between economic development, the needs of the labour market, and vocational education. Purely school-based vocational education came in for criticism (cf. South American example). Alongside the priorities which are geared to a change of paradigm ‘pragmatic’ research related to the assessment or development of existing structures clearly represents the main focus of activities.

These research priorities are constantly related to the national level and international organisations, with the addition of information, documentation and networks. It is a focus which occurs particularly in the international organisations. Statistics, classification systems and databases then provide more specific references.

1.2.4 The outcome of VET research (transfer function)

The transfer of national research results into political everyday reality would appear to have been catered for already simply by the setting up of national research institutes and/or the networks created as a consequence. Whether or not vocational education policy actually uses the results of VET research, which tends to be publicly financed, is something which cannot be answered in the framework of this study. It would seem, however, that this dialogue does exist in Australia, the People’s Republic of China, Canada, the MERCOSUR area, Russia and the USA.

The question has to be couched in wider terms when applied to international development and the international organisations. Brian Holmes (1974, p.115-132) summed up the situation in respect of the interest in and important practical research aims of comparative education (a-d), which are directly transferable to comparative VET research. These four priority areas represent the summary of many years’ experience in the area of transfer between policy and research, in particular through practice-related research and policy recommendations.

a) Using the aims, experience, and experiments of other states;

It is impossible to say here whether or not national policy applies the meliorist principle and draws on ‘positive’ examples from other countries in order to shape national vocational education policy. In the case of the People’s Republic of China, which is involved in the framework of co-operation on vocational training with several industrialised nations, the answer is yes. Similar examples of co-operation are also to be seen in the MERCOSUR area.

b) Overcoming the vestiges of ethnocentrism in education questions;

There was little evidence in our study of the attitude according to which one’s own national education system is the ‘best’, and offering it as a ‘prime export’. Ever-increasing knowledge about ‘other’ systems, worldwide co-operation, the international organisations’ information systems and international networks are helping to break down ethnocentric stances. On the other hand, international comparisons of achievement (formerly IEA, now OECD) could play a role in reviving
focus (b), since there is a tendency towards (a) or (b) when the results of international comparisons of achievement (TIMSS, PISA) are used, depending on the results in question.

c) Similar problems in different countries;

Unemployment, including unemployment among young people, school-to-work transition, and the answers provided by vocational education consistently crop up as research subjects in the different countries. The link between technological development, globalisation and staff qualification is almost as common. It is not only through the international organisations and the classification systems which they have developed that equivalence in mutual recognition of diplomas is coming ever more to the fore, but also through common markets (e.g. MERCOSUR). The international organisations bring together some of these themes (databases, thematic networks etc.) and thereby also parcel them up ready for policymakers and educational management. On the other hand, research activities also emerge from the work programmes of national institutes and international organisations. Politics obviously has the upper hand in determining the topics examined.

d) Contribution to the theoretical understanding of training and education and their planned development;

At national level it is pragmatic research rather than theoretical developments and contributions towards future development which tend to dominate. International organisations go someway towards counter-balancing this state of affairs, since classification and indicator systems as well as assessment exercises require a theoretical basis. The ILO and OECD provide plenty of background information (ILO e.g.: Training Policy Reforms, Training Policies and Systems, Evaluation of Training; OECD e.g.: ISCED). Indications concerning possible developments are also raised for discussion within the context of work on education indicators (Education at a Glance). Policy-makers are more interested in the latter.

This section dealt with various aspects involved in the transfer between politics and VET research (thematic focuses of research) and the transfer of results to policies, in full knowledge of the fact that this is an ongoing, reciprocal process if channels of communication are open. It was only possible to provide a provisional answer in the framework of this study, by looking at whether networks, advisory bodies etc. which can provide organisational support for transfer, exist within the national research institutes and international organisations.

1.3 Outlook as an analysis of shortcomings and as a proposal for further research

This study presents the initial results of VET research in other European and non-European countries. The aim was to identify national and international institutions and societies and research themes. In making this choice we were taking on a task which was difficult in many respects:

a) Delimitation of research

VET research has to be defined differently and distinguished from other research areas such as educational economics or general research in education, depending on the cultural and systemic context. These problems of delimitation also arise when further distinctions such as research into teaching and learning, assessment research or curriculum research are made. There is also the question of the multi-disciplinary and interdisciplinary nature of VET-focused research.

b) Researchers and institutions

Just as it is virtually impossible to define VET research, it is also difficult to identify researchers and institutions. A distinction also has to be drawn between research which is publicly supported and defined, and independent research.

c) The geographical and political area

The third level relates to the link with geography and policy. Besides fields of research
defined by national borders there are also regional bodies and worldwide organisations.

Given this three-way challenge in identifying VET research, the first step was to:

a) Identify the central research bodies at national level.

b) Identify the important regional and world institutions which also carry out VET research.

c) Carry out primary analyses for selected institutions as well as geographical and political areas (South America, Canada, China).

d) Draw on results for other important countries (USA, Russia, Australia, Switzerland, Turkey, Japan) produced by other research projects carried out by the DIPF and cooperating institutes.

e) Tap into and document the activities of international institutions (ILO, OECD, UNESCO, World Bank group) using Internet research and experts in the DIPF.

f) Have the development of the IEA described by ‘independent’ international scientific associations.

What then had to be done in the second and subsequent stages was:

a) To continue the primary analyses for more countries (USA, Russia, Japan, Switzerland, Turkey, Australia, Taiwan, Republic of Korea, Malaysia, Mexico) with reference to the central research institutes;

b) To carry out a more detailed study of independent research in selected countries (USA, Australia, Switzerland, Japan);

c) To look at whether or not exchange programmes for researchers exist;

d) To take a closer look at the international scientific associations (e.g. World Council) and independent research establishments;

e) To document in detail the activities of the international organisations (ILO, OECD, etc.) – in depth in respect of certain selected themes (e.g. classification systems) – and to carry out primary analyses;

f) To study existing networks, documentation centres, databases etc. in terms of their input to VET research and to create links with Cedefop’s ‘training village’ (www.trainingvillage.gr).

g) To document the research results in terms of where the emphases lie, and to bring out their relation to vocational training policy (transfer).

2. Countries

The addresses of the institutions can be found in the Annex.

2.1 Australia, by Uwe Lauterbach and Ute Lanzendorf*  

2.1.1 Introduction to the education and vocational training system

Australia is a federal state in which powers are shared between the central or Commonwealth government and the eight States and Territories. Under the 1901 constitution, the responsibility for education falls largely to the State and Territory governments but with significant funding and policy guidance from the Commonwealth.

The federal Department of Education, Training and Youth Affairs ensures national consistency in policy terms and funds national programs in the education system. Since the 1960s, universities have been completely funded by the Commonwealth and are part of a unified national system for higher education. However, schools and vocational education and training (VET) are controlled by the States and Territories. The VET system in each state is based on the publicly funded Technical and Further Education (TAFE) colleges and, increasingly, a range of private training providers. About 80% of vocational education and training is delivered through the public system. At the national level the funding and development of VET is co-

* We acknowledge the verification and substantial revision of the original text by A. Smith (NCVER).
ordinated by a joint federal-state body, the Australian National Training Authority (ANTA).

Since the early 1990s the Australian VET system has undergone a significant process of reform driven by Australian governments' desire to create a more unified national system for vocational education. This process has involved the implementation of competency-based training for VET programs, the creation of a national system of vocational qualifications (the Australian Qualifications Framework), measures to open up the training market to private providers and the introduction of New Apprenticeships to provide structured entry-level training in industries that have traditionally not operated within the apprenticeship system. During this period, the VET system has expanded considerably with enrolments in VET climbing from 1 million in 1992 to over 1.6 million (12% of the Australian population) in 1999.

2.1.2 Research in Vocational Education and Training

The reforms to the VET system have been accompanied by a significant expansion of research in vocational education and training in Australia. Prior to this period, the volume of research in the training and development field was low and projects fragmented. Few statistics were collected and there was no basis on which to judge the relative performance of the Australian public training system and Australian organisations in their provision of training. This situation has changed sharply with both Commonwealth and State governments increasing their expenditure on VET research dramatically.

Although the State Training Authorities commission research to underpin their policy development in vocational education, the main source of research funding is the Commonwealth government. Much of this expenditure is managed by the Australian National Training Authority ANTA funds the collection of a wide variety of statistics on VET and funds a large number of research projects and research centres. Much of this work is managed by the principal Australian training research body, the National Centre for Vocational Education Research (NCVER) based in Adelaide.

The NCVER was established in 1981. Funded by governments but operating as an independent company, NCVER collects and publishes a wide variety of statistical information on the Australian VET system.** NCVER also conducts research projects in vocational education and funds a large national program of VET research carried out by other research organisations in the country. In order to guide the national research program, NCVER has produced a National VET Research Strategy in conjunction with the users of VET research (primarily federal and state training authorities) and the training research community. The first research strategy was published in 1997 and covers the period 1997-2000. The first strategy identified six broad areas for training research. These include:

1. economic and social implications of VET;
2. employment and the workforce;
3. pathways from school to work;
4. outcomes of the VET sector;
5. the quality of the provision of VET.

ANTA also funds four national Key Research Centres in VET directly. These centres are the Research Centre in Vocational Education and Training at the University of Technology in Sydney (focused on vocational learning), the Centre for the Economics of Education and Training jointly sponsored by Monash University and the Australian Council for Education Research (focused on the economics of VET), the Centre for Research and Learning in Regional Australia at the University of Tasmania (focused on rural/regional VET issues) and the Centre for Post-compulsory education and training at Melbourne University and the Royal Melbourne Institute of Technology (focused on the economic and cultural

** More information: www.ncver.edu.au. NCVER has also established an international database VOCED to find the latest technical and VET research information: www.ncver.edu.au/voced.htm.
benefits of VET). These centres represent an attempt to build up a critical mass of researchers in the key areas of VET policy making. Apart from the three national Key Research Centres, there are also a number of smaller training research centres and groups that have emerged in recent years in response to the increase in training research funding since 1990. These centres include the Group for Research in Employment and Training at Charles Sturt University, the Centre for Research in Equity, Education and Work at the University of South Australia and the Centre for Learning and Work Research at Griffith University.

2.1.3 Future issues affecting the VET sector.

The explosion in training research in Australia since 1990 is closely linked to the training reforms that have taken place during that period. State and federal governments in Australia are as keen to pursue the goal of lowering unacceptably high levels of unemployment, particularly youth unemployment, as governments in all the developed nations. Training is viewed by both sides of politics as an acceptable supply side solution to these problems in the absence of a consensus on more direct means of stimulating the economy. Research provides a tool for evaluating the impact of policy and devising further reforms to the system.

2.2 People's Republic of China, by Josef Rützel and Stefan Ziehm

2.2.1 Introduction to the Chinese education and vocational education system

Since the early eighties the political leadership in the People's Republic of China has carried out comprehensive reforms. The transition from a centrally managed economy to a 'socialist market economy' has brought about change in virtually all the socially relevant areas. More attention is being paid to the (vocational) education system in particular. The 1986 Compulsory Schooling Act provided for nine years of compulsory schooling in the People's Republic of China. The Act aims to ensure nationwide, uniform, free school education and raise the general level of education. Educational development hinges on the compulsory 6+3+3 school system (primary, secondary I and II), although there are obvious regional differences between the eastern provinces and those in the north and west. There are major problems in implementing this compulsory schooling in the poorer provinces because of the lack of resources.

The vocational education system is also facing completely new challenges. Although there is no general compulsion to undergo vocational education, the government is clearly striving to upgrade it. During the Cultural Revolution (1966-76), general education was expounded as being the best vocational qualification, many vocational schools were shut down, and thus there was virtually no systematic provision of vocational education. A whole generation was therefore deprived of adequate formal vocational qualifications. The only qualifying provision of a practical nature was a form of apprenticeship. In the informal sector in particular the handing down of knowledge acquired through experience continues to play an important role even today. Small workshops and traders employ 'apprentices' who are instructed by experienced workers rather than undergoing any structured form of training.

Since the early eighties high priority has been given to extending and improving the quality of vocational education. The reforms and restructuring affect the vocational education system as a whole, including types of training preparing for a specific profession, those providing vocational qualifications, higher vocational education and further vocational education. The institutions within the vocational education system, the curricula, teaching and learning methods, responsibilities, funding, and the legal bases are all undergoing a shake-up. It should be noted that the efforts to reform the vocational education system have obviously led to improvements, although there are still marked differences in the provinces. Socially speaking, an academic education is still the 'one best way'. Only when
this is not possible because of restrictive selection procedures in the schools of further education and universities is a vocational training sought.

Basic vocational education takes place at secondary I level in the vocational secondary schools (lower grade). At secondary II level vocational education is provided by the technical secondary schools, schools for skilled workers and vocational secondary schools (upper grade).

The technical secondary schools are full-time and accept secondary school leavers. Training lasts between three and four years. In terms of content it is theoretical rather than practical subjects which dominate, so that when they come out of this type of school students temporarily find it hard to find a suitable job on the labour market because their training was so far removed from practice.

The schools for skilled workers train medium-skilled workers, although they vary widely at regional, sectoral and branch level because of differences in resources, non-standardised qualification of trainers, and the absence of standards. Training lasts three years and is split up into theoretical and practical modules. In most cases the skilled workers’ schools are funded by businesses and enterprises.

The vocational secondary schools (upper grade) were only reconstructed during the period of reform (from 1981). They tend to be full-time. Admission depends on passing an entrance exam and having completed upper school education as a minimum. In general training lasts 3 years, although there are also shorter courses lasting 1-2 years. Vocational practice is not a requirement.

Besides these possibilities for gaining a qualification, a basic qualification was introduced in the form of minimum training. Short courses are intended to provide a minimum level of basic vocational education for all workers, including those who are already in active working life.

2.2.2 VET research

In the People's Republic of China – as in other countries – VET research goes hand in hand with economic, industrial and social development. Chinese vocational education experts date the start of VET research as identical with the creation of the industrial schools in the late 19th /early 20th Century. The upturn in industry sparked a need for qualified workers who had acquired some sort of organised vocational qualification. This need for vocational education led to a need for VET research. In 1916 Yanpei Huang founded the first research institute for vocational education within Jiangsu Province's education committee. In May 1917, along with another 40 well-known scientists, he founded the Chinese Association for Vocational Education. Its aim was to develop the personality through vocational education, to prepare for employment, increase productivity through vocational education and to popularise vocational education. This association was the first ever non-state vocational education research organisation and is still influential today. Its activities led to general and technical training being separated at secondary school upper grade, and to the introduction of systematic forms of school-based vocational education. More importantly, however, the association established the theoretical basis, key ideas and principles for vocational education and carried out research into subject classification, teaching programmes, text books, practical teaching and teacher training. From 1949 to the start of the Cultural Revolution in 1966, VET research supported in particular the development of the technical secondary schools and the skilled workers schools.

The reform of vocational education which was carried out in the late 70s sparked a major increase in the demand for VET research. From Xianxin Tang’s report – which provides the essence of the overview of the VET research situation – it can be seen that VET research is intended to work out the scientific bases for macro-steering and needs planning, concept development, reform strategies and measures. Post 1978, special research institutes for vocational education were set up to meet the need for research. Previously,
research into vocational education policy, the vocational education system, as well as the teaching and provision of vocational education, lay in the hands of the competent commissions, ministries and departments, vocational schools and teachers. Nowadays there are independent research institutes at state level, in the provinces, towns and autonomous areas as well as in the technical colleges, colleges and universities. Vocational education is becoming a discipline in its own right within the field of educational science. The 6th five-year plan only mentioned one vocational education project, but by the 7th the figure had already risen to 11. The figure continued to rise, reaching 42 by the 9th five-year plan. Half of these projects are based in the education ministry.

Some of the most important research institutions at state level are the Ministry of Education's Central Institute for Vocational Training (CIVT), the Occupational Skill and Testing Authority (OSTA), which comes under the Ministry for Labour, various vocational education societies and associations, as well as research bodies in branch ministries and commissions. The CIVT, which was set up in 1990, is a national research institute whose research centres on services with a view to the reform and further development of vocational education. The focus lies with applied research in vocational education policy, financing, job classification, teaching/learning research, media development and teacher training. The CIVT is also responsible for documentation, information and transfer of knowledge. Like the regional institutes (RIVTs) in Liaoning and Shanghai which will be mentioned later, the CIVT is also a project in development co-operation with the People's Republic of China. Nothing more will be said about this here. The most important research work of the OSTA, which is also application oriented, is the development of occupational, qualification and testing standards and qualification of the specialised personnel required.

Some of the national societies and associations for vocational training are:

- The Society for Vocational Education which was founded in 1990. This is a national, public organisation for scientific research, run by the Ministry of Education. Alongside its advisory role and the job of diffusing information, the main responsibility of the society is to carry out scientific research into vocational education, which is done by 10 specialist commissions with only 73 members. The nature of the commissions – e.g. commissions for technical secondary schools, for vocational education in cities, for nationality training, for scientific research – gives some indication of what research actually means, the thrust of research questions and indirectly also the working methods. Apart from the Commission for Scientific Research all the commissions are formed with clear-cut tasks related to individual elements or types of school in the vocational education system, regional or sectoral aspects or specific target groups. This in turn makes the research questions very specific, and they tend primarily also to aim at achieving political objectives.

- The Chinese Association of Regional Institutes at Provincial Level. All the provincial regional institutes belong to it. It was founded in 1997 and primarily coordinates, orchestrates and defines supra-regional and regional VET research involving the CIVT. The fields of research and issues examined cover the whole spectrum of vocational education, according to the role of the respective regional institutes.

- The Association of Research Institutions for Vocational Education which came into being in 1982 has brought together researchers and vocational trainers from the large and medium-sized cities. Its main task lies in the theory and practice of providing vocational education and its methods. Its work concentrates on solving specific problems of teaching the individual subjects,
e.g. electronics, machine engineering, computing, beauty and hairdressing.

At present most of the branch ministries and commissions still have their own vocational education research bodies. Following the re-organisation of the ministries and commissions and the principle of ‘one task, one responsibility’, it is likely that their structure will also change. Examples of these research bodies are the National Association for Research into Agricultural Vocational Education, the Research Association for Technical Secondary School Training in Transport, the Research Department for Technical Secondary School Training in Metal-working, or the Research Centre for Vocational Education in the Ministry for the Energy Industry. These bodies are supported and run by the branch ministries. They differ in terms of their type of organisation and tend to deal with highly specific question areas. Some of them are attached to technical secondary schools or specialised schools as research departments. They are largely responsible for supporting reforms and solving problems in practice.

At provincial level, vocational education research institutes have progressively been set up since 1985. There are at present 23 regional institutes at provincial level which employ around 400 researchers. The majority of these research bodies come directly under the education commissions of the provinces or cities. They are responsible for carrying out applied research, and providing advice and services to support regionally adapted reform. This includes research into vocational education development strategies, organisation of the vocational education system, financing, legislation, curricular development, teaching/learning processes, organisational development and teacher training.

Apart from the regional institutes for vocational education, institutes or departments for vocational education have also been set up within the provincial institutes for educational science. These institutes focus mainly on scientific research. Then there is also a third type of newly established vocational education (research) institute at provincial level within the colleges and universities.

These deal essentially with teacher training, research into teaching/learning processes and studying the principles of vocational training.

At first sight this overview of the research bodies and their roles reveals a broadly institutionalised and established vocational education landscape which varies in terms of its content. It should be noted, however, that there are only a relatively limited number of people working in the institutions. Although noticeable progress has been made in development and expansion, even Chinese experts feel that staff resources are far from sufficient when compared with the quantitative and qualitative requirements of vocational education. On the other hand, however, great store is laid by VET researchers’ qualifications, since many of them hold high level diplomas. It is similarly felt that the theoretical principles and research methods are not broad or deep enough yet either. A distinction is drawn between basic and applied research. However, as yet there are no systematically established theories of vocational education. Theoretical education tends to take a rather philosophical stance, and only gradually is a social science oriented type of VET research starting to emerge. There has been a considerable increase in the number of publications on basic research which cover a broad spectrum of subjects, and they tend to resemble standard reference works. Theoretical reflections and theory-shaping aspects are rare. Moreover, the links between research into principles and the shaping of theory and applied research is a somewhat hit-and-miss affair.

Applied research is the most highly valued. Virtually all the institutions mentioned carry out applied research only. Even within the academies and university institutes applied research takes place alongside basic research. In his report Tang mentions four priority areas in applied VET research:

- Vocational education and social and economic development. This includes research into the strategic importance of vocational education in the development of China, the regions, macro planning, systems development, standardisation and the funding...
structure, as well as legislation governing vocational education and the financing of vocational education.

- **Curriculum development and teaching processes.** Research work is conducted concerning pupils' moral education, educational aims and models, course development, tailoring of subject areas, teaching content, teaching methods and the assessment or evaluation of the quality of learning and the learning process. Model tests are also included in this research work, e.g. on the introduction of the dual system, competency based education and the ILO's MES system. According to Chinese experts, the initial impetus for theoretical education stemmed from this research work.

- **Educational management and organisational development.** These studies look at management systems, organisational structure and development, the distribution of competences and evaluation. Such studies mainly present successful models and reports from experience. They provided important impetus for practical reforms although their theoretical basis is deemed inadequate.

- **Development of information and support systems.** A great deal of attention has been paid to the systematic development and expansion of information networks on vocational education through the Internet and networked communication structures, databases, e.g. on subject-related research work, legal bases, textbooks etc. Research in such areas tends to be the exception, however.

It is not only in the area of educational management, organisational development and the development of information and communication systems that there appears to be a lack of a theoretical basis for applied research. This is also true in other areas. On the one hand, the issues examined appear to be too restrictive and to relate the direct implementation of policy matters, whilst on the other hand the transfer from the theoretical to the applied level has still not been ensured. Furthermore, applied research provides very little impetus for theoretical training. There is not much differentiation in terms of the research design, tools of investigation and evaluation procedures in applied research. Evaluation research, which could provide the corner stone for both the reform process and theoretical education is not very highly developed either.

### 2.3 Japan, by Walter Georg

#### 2.3.1 Japanese Institute of Labour

Since 1989 labour market research, occupational research and VET research have come under the **Japanese Institute of Labour** [Nihon Ródó Kenkyû Kikó], a body within the Ministry for Labour. The new institute was created from the merger of its predecessor, Nihon Ródó Kyókai, founded in 1958, whose research programme initially concentrated primarily on employer-worker relations, and the **National Institute of Employment and Vocational Research** [Koryô Shokugyô Sógo Kenkyûsho]. The latter was set up in 1969 under the aegis of the EPC and carried out labour market and occupational research. To a certain (limited) extent the new **Japanese Institute of Labour** was also charged with responsibility for VET research, whilst at the same time there was a corresponding cut-back in the Institute for Vocational Education's research programme. The Institute carries out extensive studies of its own, has a broad-ranging database covering the field of labour, labour market and occupational research, and supports the governments in the prefectures within the framework of regional labour market policy. In many respects the institute's activities can be compared with those of the German Institute for Employment Research within the Federal Employment Services (Institut für Arbeitsmarkt- und Berufsforschung [IAB] der Bundesanstalt für Arbeit) in Nuremberg.

The Japanese Institute of Labour's most important fields of research are as follows:

- **Industrial relations and labour law** (employer-worker relations, trade union law, legislation and jurisdiction in the field of work and employment);
VET research in other European and non-European countries

- Economic aspects of work (wage increases, employment figures, working hours, female labour);
- Vocational and employment structure (unemployment, mobility and change of company, technological change and changes on the labour market);
- Labour market and forms of employment (worker supply and demand, types of employment conditions/contracts);
- Working life (occupational biographies, the work and everyday life of employees);
- Staff management (company employment policy, wage system, human relations within the company);
- Vocational education (developing work skills, in-company training and further training);
- Occupational guidance and work conduct (individual criteria for selecting an occupation, assessment and evaluation methods for aptitude and inclination);
- Careers advice and information (developing occupational conduct, activity analysis, effects of placement, careers information and advice).

2.3.2 Polytechnic University

The top institute amongst the vocational training bodies which come under the Ministry for Labour is the Shokugyō kunren daigakkō (Institute of Vocational Education) which was founded in 1961 on the basis of the 1958 Vocational Education Act. It has since been renamed Shokugyō noryoku kaihatsu daigakkō/Polytechnic University and comes under the aegis of the Ministry for Labour. Until 1989 it worked in the most important fields of research in vocational education, but now concentrates its activities on staff training for vocational education and on research into teaching and learning e.g. research and development work (developing curricula, audiovisual teaching materials, text books), and on distance learning courses.

2.3.3 National Institute for Educational Research (Kokuritsu kyōiku kenkyūjo-NIER)

The NIER was set up in 1949 as a body of the Ministry of Education, Science, Sports and Culture (Japanese abbreviation: Monbushō).

The main aims of the institute are to carry out basic and applied research in the educational field as well as to provide a range of information and advisory services. In terms of content and organisation the institute comprises ten main departments (e.g. life-long learning, scientific education, educational management etc.). Vocational education is dealt with by part of the Department for Educational Content (the Section for Vocational Education).

2.4 Canada, by Philipp Grollmann

2.4.1 Current priorities of VET research in Canada

This overview provides a brief run-down of the current priorities and institutions for VET research in Canada. It presents not only the 'academic' research activities, but also certain projects and institutions involved in applied research, which are of importance to Canadian vocational education. In the interests of brevity, only a brief outline can be presented here, but the addresses and references to literature which are listed in the annex should help the interested reader to build up a clearer picture.

2.4.2 DACUM and co-operation in international vocational education

First of all, this is a sort of classic in Canadian VET research and in certain respects representative of it; it seems to be particularly characterised by applied research.

2 The basic information for this overview was collected during a research trip to Canada in 1998. The objectives of this report were funded by the Federal Ministry for Education, Science, Research and Technology (Reference: G 9013.007)
Because Canada is a country of immigration to begin with, and also because it is involved in numerous development projects, international VET research and co-operation is a not-unimportant pillar of Canadian VET research. An important player in this respect is the Canadian International Development Agency – CIDA – which regularly issues contracts to Canadian VET researchers.

2.4.3 Vocational education in Canada and VET research in the universities and research institutes

As in other industrialised nations, a large part of the development and present state of VET research can best be seen and understood in relation to the problems and institutional structures in the field of the subject of vocational education itself.

Certain general social trends and thememethod related considerations which also figure on the agenda of other countries are also apparent.

Vocational education in Canada is provided primarily by the Community Colleges. These are post-secondary institutions which appeal to a wide range of individuals through the range of courses and subjects which they offer. Evening top-up qualification courses, co-operative education and vocational education in full-time school as well as technical university style training courses are similarly organised by these institutions. In the secondary sector (pre-) vocational education and training is provided by the senior high schools.

Thus any research which aims to analyse the effects and development lines of these institutions is to some extent always a form of VET research.

This type of research is largely carried out in the Canadian universities, particularly by the faculties involved with teacher training. Apart from the usual teaching and research activities, bigger projects are on occasion also carried out in the universities, as for example the networks for VET research which are referred to later on. An example of a more extensive research project would be the two year ‘Secondary Schools Project’ which was set up by the Canadian Educational Association (CEA) and supported by the HRDC (Gaskell 1995).

Depending on their size, some of the Community Colleges also have their own research and evaluation departments. They carry out evaluation research in particular, with the aim of helping the colleges to better tailor their programmes to students’ needs, or to recognise factors influencing success or failure. Since drop-out rates are at their highest in the first year of the Community Colleges this type of research tends to trade under the name ‘first year experience’.

Software developed specially for this purpose by the evaluation department of Humber College, Toronto, can be quoted here as an example. COMPAS (College Outcomes Management and Performance Analysis System) can be used by college staff to assess what they themselves are offering, whilst also providing an information base for internal and external decision-takers (cf. Dietsche 1998).

2.4.4 School-to-work-transition research and research by Human Resources Development Canada (HRDC)

Because of the relatively high school drop-out rates by international standards, and the range of alternatives as regards both content and institutions in the vocational education field, the role of school-to-work-transition research is as important as in other countries faced with this type of vocational education policy issue. Such research usually tends to have a sociological or socio-psychological slant. Once again, a considerable amount of it is done in the relevant university faculties.

In many cases this research is governed by contracts which are issued by the competent Federal Ministry for Labour, Education and Training: Human Resources Development Canada evolved from the former Ministry of Employment (Immigration and Employment Canada), and acts as a major financier of research in relevant fields, either indirectly or through subordinate authorities. As far as educational matters are concerned, the Ministry enjoys only very limited decision-taking
powers, since educational questions are largely regulated at state level in Canada.

Smaller contracts, e.g. in the field of curriculum development, are therefore also issued by the education ministries and the ministries for vocational education and further training in the relevant provinces (cf. e.g. Wilson).

The renaming of the former Ministry of Employment as the HRDC and the identification of new fields of activity should be seen in relation to the general drive towards change and reform of vocational education and further training in Canada, which either directly or indirectly has brought a considerable amount of research activity in its wake. Since the late eighties there has been a broad-ranging and quite well funded initiative to set up Sector Councils, i.e. branch organisations which were brought into being through the initial injection of some very generous funding. There is also room for numerous research and development activities within the framework of these activities.

Thus skill standards which underlie the development of vocational qualifications and curricula are often established by the relevant Sector Councils or by private consulting firms contacted by them. The basis for creating these skill standards is provided by sectoral studies which look at the general requirements for educational and staff development in a given sector (cf. e.g. Textiles Human Resources Council 1996). These are then followed by occupational analyses, in which occupational activity within a given occupational field is ‘broken down’. This procedure is also applied when occupational profiles are drawn up for apprenticeships (cf. HRDC 1995 and e.g. HRDC 1998).

HRDC also has its own research department, the applied research branch, as well as an evaluation department. The former draws up at four-yearly intervals, for example – sometimes in co-operation with Statistics Canada – transition and location studies on secondary school leavers, and Community College and university graduates (The Class of 1986, The Class of 1990 etc.; EIC 1991, HRDC 1996), whereas the latter monitors and follows up model projects and vocational education policy initiatives in terms of their effectiveness.

In parallel to the reform activities just mentioned, HRDC also amended the entire Canadian occupational classification, which traditionally bore a close resemblance to the American Dictionary of Occupational Titles in terms of its fragmentation and specialisation, but now arranges broader fields of activity horizontally and vertically within a type of occupational field structure (cf. HRDC 1996).

In terms of their scientific quality, projects carried out by HRDC or consulting agencies are not necessarily inferior to university ones. There are on-going communication structures between HRDC and the universities, e.g. through experts being asked to draw up reports (cf. e.g. Krahn 1996).

2.4.5 Political and industrial-sociological labour market research into vocational education and further training

The discussions and measures pertaining to the Sector Councils and Local Training Boards go hand in hand with lively scientific publishing activity: over the last two years two compilations have come out on the subject (cf. Gunderson, Sharpe 1998; Haddow, Sharpe 1997). This research should be seen within the field of political science and industrial sociology. A similar perspective is taken by the Canadian Policy Research Networks on vocational education questions in their last report, which deals in more concrete terms with essential questions related to qualifications in the face of the challenges raised by the future world of work. This is a type of foundation which is supported by donations from sponsors, sets up expert commissions on other areas of public life, and drafts and publishes reports (cf. Betcherman, McMullen, Davidman 1998).

2.4.6 Research networks in the field of vocational education and further training

Over recent years the greater esteem in which vocational education and further training is
held has had a knock-on effect in the field of basic research: thus, following a major call for tender, the Social Science and Humanities Research Council (SSHRC) is supporting four major Strategic Research Networks in Education and Training, which fall within the VET research area. These networks also cooperate amongst themselves and organise calls for tender for researchers with suitable projects who can apply for small-scale financing. Co-operation with vocational education practice also represents an important aspect in the work of these networks.

The five networks have the following titles, which also indicate what they deal with:

- **Training Matters**: Education and Training for New Forms of Work: Canadian Experience and International Perspectives
- **EvNet**: Network for the Evaluation of Education and Training Technologies
- **The Western Research Network on Education and Training**: The Link Between Educational Provision, Processes and Outcomes
- **Relations formation emploi**: analyse des modes de collaboration entre les partenaires de la formation, des effets sur leur organisation et des résultats pour les apprenants (Training-employment relations: analysis of methods of cooperation between the players in the training world, the impact on their organisation and results for students)

A further, relatively new network in the VET research field is the UNEVOC Canada Network, which was founded in close co-operation with UNESCO's UNEVOC project and is supported by it.

The setting up of all of these six networks should also be seen in relation to the constant demands for a National Centre for Research on Vocational Education and Training, NCRVE, along the lines of the American model.

### 2.5 Russian Federation, by Friedrich Kuebarth

#### 2.5.1 VET research

In Russia there is, first of all, a tradition of what is known as occupational education, which sees itself as a scientific discipline and which as a branch of education fulfilled the well-known functions of socialist educational doctrine in the field of vocational education. The theoretical principles were largely laid by the former Academy of Educational Sciences in the USSR (nowadays the Russian Education Academy). Its scope was and in fact still is predominantly the training and further training of teaching staff for the vocational training sector.

Secondly, a form of VET research was also developed which initially concentrated on the development of teaching methods within the scope of the framework plans for the vocational schools, whilst also becoming increasingly involved with matters of policy advice. It is these functions which have come particularly to the fore since the switch in system in the early 90s, in the course of which institutional classifications changed on several occasions.

The important thing to note in this context is that VET research was and continues to be predominantly sector-based, i.e. it is tied in with the various levels of vocational education in Russia which evolved historically, each with its own respective administrative 'super-structure'. Thus even today there are still different research structures for the levels of 'basic vocational education' (formerly: occupational-technical training, PTUs), and 'middle-grade vocational education' (middle grade technical secondary schools, schools of technology, and more recently also colleges). ('Higher vocational education' i.e. the higher educational or tertiary level has its own research and development structures which will not be considered here).

Research and development structures, particularly in the area of curriculum development, are to some extent also to be found within specialised departments which oversee vocational training institutions (e.g. agriculture). Corre-
sponding practice-oriented centres were more seriously built up, particularly by the regions, which sometimes also call on available institutions for the further training of teachers to develop teaching materials and for (vocational) educational development planning.

Recently the state labour administration has also become more deeply involved in vocational and VET research.

Institutes of higher education have only a minor role to play in VET research. This also applies to the teacher training universities/colleges which train teachers for general schools and subjects. The majority of staff for vocational schools or occupation-related subjects are trained at two specialised universities (Jekaterinburg and recently Nishnij Nowgorod) as well as at several technical universities/colleges, and it is only in this area that there is any occupational education/VET research worth mentioning.

Projects and subjects related to the development of vocational education and vocational education policy are also worked on in other research contexts, such as economic (including the economics of education) and sociological research (e.g. youth sociology), mainly within the respective institutes of the Russian Academy of Science.

2.5.2 Research structures

Mainstream Russian VET research is conducted within three structures which are separate in organisational terms. Whilst competing with each other they are also interlinked by the networking of both staff and subject matter.

a) The traditional ‘leading institution’ in Russian educational research is the Russian Academy of Education (RAO). It has the following affiliates to its department for ‘basic vocational education’ (literally):

- The Institute for Technical Occupational Education in St. Petersburg;
- The Institute for Technical Secondary Education in Kasan;
- The Institute for Adult Education in St. Petersburg;
- The Centre for Problems related to Lifelong Learning in Moscow.

The department also promotes regional priorities within the framework of the RAO’s regionalised structure. The activities of the Siberian section deserve particular mention. The Academy is formally requesting that it should be responsible for the nationwide coordination of VET research, but its influence would essentially only extend to the institutions mentioned. (It is additionally responsible for co-ordinating research assistantships).

The work of the research institutes – whose research plans are determined on an annual basis – centres rather loosely on general programme topics such as ‘the development prospects of vocational education’.

b) The Ministry for General and Vocational Education supports:

- The Institute for the Development of Vocational Training (IRPO) in Moscow, and
- The Scientific Method Centre for Secondary Technical Education, Moscow.

Whilst the latter concentrates mainly on developing curricula for the technical secondary school level, over recent years and despite the disastrous framework conditions and also political resistance, the IRPO has managed to extend and consolidate its position as the central body for VET research. Its work involves:

- Basic research related to educational policy and concepts, particularly in terms of policy advice;
- Curricular development work: drawing up the register of training professions, developing ‘standards’ and methodological training bases, text book development, quality assurance methods, new technologies;
- The further training of teaching staff;
- Scientific research assistantships;
International co-operation (esp. with the BIBB);

Publications.

c) The vocational teacher-training universities (see above) which also come under the Ministry for Education train 'engineering' teaching staff (with the emphasis on engineering and the corresponding technical production occupations) as well as experts for specialist practical training in the vocational schools. Their research priorities are determined by these roles, and therefore tend to stress technical teaching methods. The Occupational Training University of the Urals is also strong in occupational psychology and occupational sociology, whilst new university in Nisnij Nowgorod has no clear-cut profile as yet.

2.5.3 Research associations

When the system started to change numerous associations and networks came into being which have in common the fact that they are in reasonably close proximity to the 'official' structures of the Ministry. From the point of view of VET training the first bodies to be noted are:

The Academy for Vocational Education (not to be confused in either organisational or functional terms with the RAO – see above!) which is close to the IRPO in staff terms and is striving to bring together the broad field of research and practice (particularly school heads and regional managers) and to gradually build bridges with the social partners. At the same time, the Academy sees itself as a services company in the publications and conferences field (it produces amongst other things one of the two available specialist revues).

The 'Vocational Education' Association which was born of the RAO and also provides specialist services. Amongst other things it has produced a new standard textbook 'Occupational Education' (1997) as well as an 'Encyclopaedia of Vocational Education' (1998).

Another organisation known by the acronym 'Rosproftech' (Russian technical vocational education) is made up principally of workers in the field and is closely linked to the Ministry.

2.6 Switzerland, by Ulrich Arnswald and Daniela Heipel

Vocational education – insofar as it is regulated by the BBG (Vocational Education Act) – falls within the scope of activities of the Bundesamt für Berufsbildung und Technologie (BBT) (Federal Office for Vocational Education and Technology), which is also in charge of vocational education in agriculture. It comes under the Swiss Department for the National Economy.

The Schweizerische Institut für Berufspädagogik (Swiss Institute for Occupational Education) (SIBP) – which is also a department of the BBT – deals first and foremost with the training and further training of teachers at vocational education schools.

In the whole of Switzerland there are some 125 mostly small-scale institutions working in the field of educational research and school development. The Swiss Co-ordinating Unit for Educational Research (SKBF) (Entfelderstr. 61 in 5000 Aarau, Tel.: + 41 (0)62/8352390) promotes co-operation between educational research, practice, administration and policy.

Within educational research, the SKBF coordinates between the various disciplines and institutions, as well as between the university institutions and teaching sections of the Education Department.

It is linked to the Schweizerische Gesellschaft für Bildungsforschung (SGBF) (Swiss Society for Educational Research). This body pursues its aims through the organisation of annual congresses, standing working parties, and through publication of the review 'Bildungs-
VET research in other European and non-European countries

forschung und Bildungspraxis' (Educational Research and Practice), as well as the scientific series 'Exploration'. At the present moment the co-ordinating unit is running three networks, which promote contact between researchers working in the same field, i.e. in the areas of assessment, secondary level I, and research into adult education. The SKFB is also linked to the Schweizerische Gesellschaft für angewandte Berufsbildungsforschung (Swiss Society for Applied Vocational Education Research), which was founded in 1987.

The SKFB provides information about research and development projects within the Swiss education system, about development trends in education and about the institutions for educational research and school development. A register which comes out every 4 to 5 years lists the institutions for educational research and school development, indicating the main focuses of their work. An index of persons and subjects means that targeted searches for information and contact persons can be carried out on specific questions.

Publications on vocational education:

2. Panorama. Review of the Swiss Society for Applied VET research. Published 8005 Zurich, six times per year.

2.7 Latin America, focus South America, by Daniela Heipel and Ute Lanzendorf

2.7.1 Introduction to the vocational education systems in Brazil, Argentina and Uruguay

Economic, political and social integration in South America came a step closer with the creation of the Mercado Común del Sur or MERCOSUR (Common Market of the South) in 1991. The MERCOSUR brings together a population of more than 190 million, living in an area bigger than the whole of the Euro-

pean continent. The biggest country in South America and also its strongest in economic terms, Brazil covers an area of 8.5 million square kilometres and has 155 million inhabitants. Argentina is the second biggest member of MERCOSUR with 33 million inhabitants, and over recent years has had the fastest economic growth. Paraguay and Uruguay are the smaller partners in every sense. With a gross national product of 8.1 million US$, Paraguay is the weakest member state in economic terms (von Baratta 1997, p. 567). Uruguay, the country with the smallest population – 3.1 million – is an important financial centre in the MERCOSUR, and in 1995 had a GNP of 16.4 million US$.

A description of the vocational training system in the three countries selected here (Brazil, Argentina, Uruguay) – which differ in terms of their economy, size and population – as a background to the details on VET research in the respective countries can provide no more than a brief introduction at this point.

In Brazil, co-ordination of the various public and private providers of vocational education which since 1976 have been brought together under the Sistema Nacional de Formação de Mão-de-Obra, SNFMO (National Manpower Training System), is the responsibility of the Conselho Federal de Mão-de-Obra (Federal Manpower Council). Most vocational education is organised on a private basis through several sector-related and decentrally organised vocational training institutions which are financed through a form of income tax – the Serviço Nacional de Aprendizagem Industrial (SENAI) (National Service for Industrial Training), the Serviço Nacional de Aprendizagem Comercial (SENAC) (National Service for Commercial Training), and the Serviço Nacional de Formação Profissional Rural (SENAR) (National Service for Agricultural Qualification). Teaching takes place in training centres which integrate company training with occupational adjustment. The SENAI, the oldest of the three pillars of the Brazilian training system, was founded in 1943 along the lines of the training system which existed in the railway company. It was set up as an independent institution, financed and managed by the companies in that sector
(industry in the case of the SENAI). In 1946 the SENAC was founded, and 30 years later the SENAR started its work. The training activities of the various institutions are strongly coloured by the respective sector of the economy. Thus the SENAI is responsible for industrial training, the SENAC for commercial training, and the SENAR for agricultural training. Despite sharing a similar organisational structure, the three vocational training institutions have different activities. The SENAI offers multi-annual initial training courses for skilled workers and engineers, within which both occupation-related knowledge and more general educational content is provided. The SENAC provides initial training in the field of commerce and services, predominantly in the classroom, with provision for practical teaching on computers, for example. The diploma is acquired within a maximum of one and a half years. SENAR works exclusively in the field of part qualifications and further training.

Technology training in the general school system includes pre-occupational training in the compulsory sector as well as the three-year courses at secondary II level, technical training at university level and post-graduate technological training. At full-time upper grade secondary vocational schools financed by the federal authorities or states, an initial vocational diploma for occupational groups such as clerical workers, engineers, health workers and teachers is catered for within the compulsory sector. A vocational qualification at this level also satisfies university entrance requirements. Technology training centres offer courses at all levels of the education system, which aim at training middle management levels in particular.

Apart from the occupational training branches at secondary II level, which date back to the military regime, the other full-time vocational schools are the engineering schools, which come directly under the national education ministry. The four-year engineering schools essentially provide training in the technical and agricultural fields, whilst the three to four year secondary level vocational schools teach commercial, care and educational activities as well as technical and agricultural ones. Unlike the engineering schools the vocational education sections of the secondary schools do not usually have sufficient means to provide practical training.

The high drop-out rates and the fall in the numbers of secure jobs, which has boosted free-lance activity, particularly in the informal sector, have – and this applies to all three of the countries in question – led to the ministries for labour becoming increasingly involved in the shaping of vocational education. Essentially, what is provided are programmes for those dropping out of school and the unemployed leading to qualifications for jobs. More will be said about this development below.

The Brazilian government is struggling with the problems affecting all the South American countries. The north-east of the country is the single largest pocket of poverty in the whole of Latin America. Children under 14 make up 18% of the working population and most young people have no chance of finding a regulated training place or job. Thus access to the Brazilian training system is reserved for a privileged section of the population. Young people are expected to start paying their way at an early age, and therefore quit formal education. What is more, even completion of vocational education is no automatic guarantee of finding a well-paid job. There is also a negative attitude towards practical training, with an academic training being preferred wherever possible. Over the next few years the Brazilian government aims to create a national system for technological training by bringing together the existing training establishments under the co-ordination and supervision of the Ministry of Education, to make good the shortage of training places, to improve co-operation between companies, training centres and the government, and to bring the vocational education system into line with recent technological developments. (see Lanzendorf et al. 1996)

Of the South American education systems, it is the Argentinian one which goes back the furthest. Unlike in other Latin American countries, no sectoral vocational education institutions based on private economic initia-
tive have developed alongside the public education system. Initial vocational education was and still is an integral part of the state system. Vocational and technical education in Argentina is therefore marked by the predominant steering role played by the state. Neither employers nor the trade unions have any formal responsibility or take any initiative. Thus people also talk of the ‘secondarisation’ of vocational education in Argentina.

Formal vocational education in Argentina takes place in vocational secondary schools, which until 1995 came under the National Council for Technical Education (Consejo Nacional de Educación Técnica, CONET). In the same year, following the decentralisation of responsibility in the secondary school sector, the CONET was replaced by the Institute for Technological Training (Instituto Nacional de Educación Tecnológica, INET). CONET was a public, decentralised provider with functional autonomy which was founded in November 1959. The vocational education institution came under the Education Ministry, just as is now the case with the INET, and was responsible for the vocational education sector financed by the ministry. Until 1992, the Education Ministry was responsible for around two thirds of vocational secondary schools, some provinces had their own schools, and some were run on a private basis. The establishments for technical training which pre-1959 were ministry-run or those providing apprenticeships from Peron’s era were placed under the responsibility of the CONET. The CONET was in charge of the funds from the apprentices levy which prior to 1959 was managed by the Education Ministry’s Committee for Teaching and Vocational Guidance. During the reform of the public education system in 1995 the CONET, the National Centre for EDP-Training (Centro Nacional de Enseñanza de la Informática, CENEI), and the Centre for Research and Development into the Dual System (Centro Nacional de Investigación y Desarrollo del Sistema Dual, CENID) were merged to form the Institute for Technological Training (Instituto Nacional de Educación Tecnológica, INET). This shifted greater responsibility to the provinces. It is now they who are responsible for the technical schools and training centres, whilst the INET is only responsible for overall planning and assistance and advice on future education strategies.

A distinction is drawn between technical education (educación técnica) in secondary schools and the practice-oriented and market-related vocational training (formación profesional) directed at the unemployed and those who drop out of school. Technical training at a corresponding secondary school centres on training staff for executive activities and supervisory roles at the skilled level. Vocational secondary schools act more as a special type of school leading to university entrance qualifications than as an institution providing the type of qualification needed to enter an occupation. Participants are prepared both for subsequent employment and for higher studies (dual qualification). The poor infrastructure, high drop-out rates and lack of any practical reference are the problems faced by training in the state secondary schools.

A further provider of vocational training is the Ministry for Labour and Social Security (Ministerio del trabajo y seguridad social) within which the Department for Vocational Education (Subsecretaría de formación profesional) was set up in accordance with the December 1991 National Employment Act (Ley Nacional de Empleo). Its role is to develop special training for disadvantaged groups on the labour market, bearing in mind both individual interests in terms of further personal and professional development, and the needs of the company. Generally speaking, in recent years measures directly related to work, aimed at improving skills and which form part of the vocational training system, have increasingly been taken over by the labour administration within the framework of job promotion.

Although the vast majority of Argentina’s active population completes compulsory schooling, only a minority goes on to vocational education. Because of increased international competition, this level of qualification no longer satisfies firms’ requirements. People have realised that, in particular given the context of the MERCOSUR integration process, only an extensively trained, technically
qualified and flexible workforce can guarantee competitiveness in the long term. Measures in the pipeline or in certain cases already implemented, such as the decentralisation of competences in the secondary education sector, should improve the situation. There is also a new approach which aims at involving the social partners in vocational education in order to improve the alternation between school and firm (Lanzendorf, 1997).

Socially speaking, education and training in Uruguay are highly regarded. Generally speaking, occupations which require study are held in greater esteem than manual professions, even though the latter are often better paid. There is a clear preference for the school-leaving exam, with less than 10% of those leaving lower grade secondary school opting for a technical training at the UTU. With an average of seven completed years of education, Uruguay has a comparatively high level of education in Latin American terms. The small size of the country and the concentration of its population in the capital, Montevideo, means that vast sectors of the population have access to the education system. The illiteracy rate in Uruguay (0.4%) is low not only in comparison with other Latin American countries, but also in international terms, and it is still falling thanks to virtual blanket coverage, particularly in the primary sector.

In Uruguay the Council for Technical Vocational Education (Consejo de Educación Técnico-Profesional, C.E.T.P.) under the aegis of the Ministry for Education is the body which provides vocational education at secondary technical level in schools and training institutions. The C.E.P.T. (also known as the Uruguayan University of Labour (Universidad del Trabajo del Uruguay or UTU)) aims to be open to as broad a population as possible and generally to provide vocational education. The UTU is the biggest provider of formal vocational education, covering the whole range of different training levels, which range from the basic level of secondary I, through technical vocational training to technical school leaving certificates.

There has been a noticeable shift in the defining of vocational education from the Education Ministry to the Ministry for Labour, through the creation of the National Directorate for Employment (Dirección Nacional de Empleo, DINAE) and the National Employment Board (Junta Nacional de Empleo, JUNAE), whose role it is to advise the Ministry for Labour on labour market policy, and to provide guidance programmes for the labour market as well as training programmes. The DINAE’s work has led to a process of decentralisation and diversification in the vocational education field, which has resulted in the central role which the UTU played in vocational education and further training for many years being watered down. What is more, the drafting of vocational education programmes has also been split from their implementation. This means that although the DINAE is responsible for financing the programmes, it does not actually implement them. It has also meant that more and newer organisations — under state control — have become involved in vocational education. The UTU had to surrender many of its powers in the course of this process. For decades the UTU — a body which has been in existence since the late 19th century and which in spite of its deceptive ‘university’ title almost exclusively offers secondary level courses — was the sole provider of vocational education courses. Formal vocational education at the UTU was assessed in 1995 under a study by the Inter-American Development Bank, within the context of the development of new technologies and changes to the economic structure. The study came to the conclusion that the courses on offer were in desperate need of an overhaul, since the institution had got out of hand, the quality of courses was very poor, they were badly organised, and the training was too long. Moreover, the lack of teacher training amongst the staff and the fact that the schools were badly equipped also came in for criticism. Since the UTU was no longer in a position to cover the demand for vocational education as a result of these shortcomings, supply on the private market exploded in response to the vacuum. This led to utter confusion in terms of the provision available and a lack of checks on qualifications. Through a decentralisation process in the field of training and through increasing competition from private and semi-state institutions over re-
cent years, the UTU has seen its importance plummet in comparison with what it used to be.

The compulsory secondary I level lasts three years, during which pupils may choose between two different types of schools. Either they attend secondary school (secundaria) which provides a general education, or they opt for the technically oriented UTU, which aims more at young people who subsequently want to enter working life. The ensuing three year cycle concludes either after three years with the university entrance qualification or again with the technically oriented UTU. Here training lasts from two to seven years and is split up into four main areas - agriculture, industry, art/craft, and services. University entrance requirements can also be met along this path under certain circumstances. Those who have not completed nine years of compulsory schooling can still train at the UTU, in vocational training centres (Centro de Capacitación Profesional, C.E.C.A.P.) or through the Ministry for Youth's programmes to unskilled worker level. Upon completion of the nine years of compulsory schooling the majority of newcomers to the employment scene do not have adequate technical or vocational training and the successful use of completed training often depends on training or further training measures in the company.

Apart from formal training provision there is also a whole series of state, non-formal training possibilities, which mainly target socially marginalized young people who have dropped out of the formal training and vocational education system. The courses do not provide for the transition to the tertiary level and are not national in scope. (Heipel et al.)

2.7.2 Themes and trends in VET research in South America

VET research in South America is not an academic discipline in its own right, and as a result interdisciplinary research approaches have sprung up in the fields of sociology, economics, psychology, and to a lesser extent in education science, complemented by individual studies of applied VET research. This inter-disciplinarity means that the institutions involved in VET research are located in very different fields, and there is also little institutionalisation. Thus departments in the Ministries for Education and Labour, universities, non-governmental organisations, and both public and private research establishments all deal with VET research amongst their other research topics. A study of the most recent trends and tendencies in the South American vocational education systems which have already been touched upon, and which affect VET research topics and institutions, should shed some light on the tendencies and content affecting research and the institutions involved in it. This will be followed by a detailed description of the institutes and organisations which are active in national and Latin America-wide VET research. The institutions deal in particular with application-oriented issues intended for political decision-makers, and priorities are determined accordingly, with academic work often being the by-product of independent, non-university research institutes from which the general trends in vocational education can be deduced.

Whereas in the past training was predominantly not geared to practical work or labour market needs and formed part of general education policy - this applied in particular in Argentina and Uruguay - training policy has recently tended to been seen increasingly as an active labour market policy. The reason behind this new line was both the general effects of globalisation on the markets, which along with other developments has resulted in increased competition for firms and the appearance of new employment profiles, as well as high unemployment figures and drop out rates from the formal education system, which led to the Ministries for Labour bringing in short courses providing qualifications for jobs. So apart from the departments in the Education Ministries, Labour Ministries are also becoming more heavily involved in shaping and assessing vocational education.\textsuperscript{3} Cop-

\textsuperscript{3} The institutional reflection of this in Brazil is the National Secretariat for Training and Vocational Development (Secretaría Nacional de Formación y Desarrollo Profesional, SEFOR) and in Uruguay the National Directorate for Labour (Dirección Nacional de Empleo, DINAE).
ing with technological progress and the qualifications which it implies, qualifying microenterprises and workers in the informal sector, co-ordinating technical education and practice-oriented qualifications, co-ordinating formal and non-formal supply taking local and regional requirements into account, the social implications of vocational education, the influence of new technologies on vocational qualification requirements, the needs of disadvantaged groups and the integration of marginalized sections of the population, particularly young people in vocational education programmes, are increasingly being taken as the subject of research.

Since the founding of MERCOSUR in particular, comparative vocational research has grown in stature in South America. Through describing the core functions of the vocational education systems in individual countries, with their overall aims, an effort is being made to draw on developments even in industrialised countries, in order to pick up tips as to how to solve problems back at home. The overriding aim in setting up MERCOSUR was the free circulation of goods, services and manpower. The aims which stemmed from that for the organisation of vocational education were to achieve equivalence in the recognition of diplomas, to create information systems on vocational education systems in the member states and to increase co-operation on vocational education matters.

The institutions which are described hereafter have drawn more heavily on new communication and information technologies. This should allow for better networking within Latin America but also worldwide, and should facilitate access to information for those involved in vocational education.

2.7.3 The Inter-American Centre for Research and Documentation on Vocational Education (Centro Interamericano de Investigación y Documentación sobre Formación Profesional, CINTERFOR) which was founded in 1963 and is based in Montevideo, Uruguay, is an offshoot of the International Labour Organisation which brings together the organisations and institutions responsible for vocational education in the ILO member states in Latin America and also Spain. The objectives at the time the centre was set up were guided by the demands of member states, i.e. to see a general rise in the level of vocational education, in order to improve living conditions for workers, and to improve the quantitative and qualitative performance of firms. Even before the CINTERFOR was founded some ILO member states (Argentina, Brazil, Chile, Colombia, Uruguay and Venezuela) were already trying to create national vocational education services with the support of the ILO, basing themselves on close co-operation with companies, workers and vocational training experts. The efforts undertaken by the countries which concentrated on preparing and publishing the vocational education programmes, preparing educators and building up establishments, demanded comprehensive research work, and the co-ordination and exchange of experience available in the individual countries took on added importance. It was against this backdrop that CINTERFOR was initially brought into being as a permanent centre of co-operation for the national institutions. The role of the centre was to collate documentation from the field of vocational education, to build up contacts, to diffuse information to national centres, to conduct research and to prepare teaching material for educators.

Since its creation the aims and role of CINTERFOR have been extended. The promotion and strengthening of technical co-operation in the context of the development and modernisation of vocational education, assistance in drafting and bringing in vocational education programmes through promoting strategic alliances between the state, the workforce and employers, the development and spread of a regional network for vocational education within the member states, the promotion of research activities, and the conducting of research into the institutional-
sation and setting up of systems and programmes for vocational education with the aim of promoting efficiency, competitiveness and social justice have all been added.

The lion's share of CINTERFOR's work is documented in numerous publications. Examples include the quarterly Boletin CINTERFOR which publishes theoretical contributions related to Latin America by vocational education experts, and the Herramientas para la transformación series in which the results of primary studies, surveys and academic essays are published. The publication Trazos de Formación deals essentially with current themes in the vocational education field, whilst Papeles de la Oficina técnica documents international, national and regional experiences in the fields of vocational education and employment.

The breakdown of funding for the centre reflects the backing of the various groups and initiatives which CINTERFOR has brought together. On top of the annual payments by the ILO and the Uruguayan government there are also voluntary payments by the member states and institutions, and international organisations also contribute to the funding of certain projects. The centre mainly employs experts in vocational education on limited contracts, most of them coming from Latin American countries.

CINTERFOR also runs and organises the Latin American Information and Administration Network for Vocational Education (Proyecto Red de Información y Gestión sobre Formación Profesional para América Latin y el Caribe, CINTERNET). CINTERNET is a network born of a co-operation agreement between the ILO and the Federal Republic of Germany on the exchange of information in the field of vocational education. CINTERNET is intended for the use of those involved in vocational education, and provides rapid access to information on innovation, information and methodology. Such access to information should make it easier for those responsible for vocational education at national level to respond appropriately to new challenges on the labour market. The network documents the current situation and offers rapid access to questions of vocational education in Latin America.

2.7.4 The International Centre for Education, Labour and the Transfer of Technology (Centro Internacional para la Educación, el Trabajo y la Transferencia de la Tecnología, CIET)

The CIET, which came into being in Brazil in 1993 as the result of a joint initiative involving the National Confederation for Industry (Confederación Nacional de la Industria, CNI), the National Service for Industrial Training (Servicio Nacional de Aprendizagem Industrial, SENAI) and UNESCO, acts at national and international level as a centre for observing and documenting the effects on and changes to vocational education brought about by the development of new technologies. The theoretical approach when the centre was founded was the understanding of the fact that the effects of new developments in information and communications technology and more generally the development of new technologies with the resulting changes on the labour market and the appearance of new qualification standards can have both a negative and a positive effect on national industries. Vocational training systems play a key role in positive adaptation:

'As technological development activities become more specialised, complex and dependent on specific information and knowledge more and more adequately trained skilled human resources are required for such special tasks'.

The centre researches, forecasts and formulates proposed solutions in the fields of information, technology, employment, and education in order to provide positive backing for the process of adaptation, and serves as an advice centre, in particular for the CNI/SENAI, which administer 900 vocational schools and 45 centres of technology.

By way of products and services the CIET is involved in developing an information system about international experiences in vocational education, life-long learning and the reintegration of adults and young people, re-
search into the link between education and work and the influence of new technologies on employers and workers, the development of an advisory centre for companies wanting to run vocational education and further training activities, and tracking political discussion of vocational education in Brazil.

The centre is mainly financed by the SENAI and brings in additional funds from courses, seminars and publications. Around 30 people are employed in the centre on a permanent basis, with backgrounds in education, labour, technology, sociology, systems analysis, engineering, mathematics and IT. International experts are also constantly being employed by the centre.

2.7.5 The National Research Centre for Human Development (Centro Nacional de Estudios de Población, CENEP)/ Education and Labour Network (Red Educación y Trabajo)

The CENEP in Buenos Aires plays an important role in national and international VET research. It is from there that the international education and labour network is managed, as well as a database on literature related to vocational education. The FIEL Economic Research for Latin America Foundation (Fundación de Investigaciones Económicas Latinoamericanas, FIEL) also conducts individual projects on questions related to education and vocational education. The centre mainly employs researchers from the social sciences and conducts research in the areas of human development, information technology, technical assistance and the distribution of information. The centre follows an inter-disciplinary approach, develops and supervises projects in co-operation with institutions and organisations. Amongst other subjects, the CENEP researches population growth, mobility, labour markets, education and work, pension systems and social security and health systems and domestic and family development.

2.8 Turkey

METARGEM: The Research and Development Centre of Vocational and Technical Education, Ankara

The Research and Development Centre of Vocational and Technical Education (METARGEM) has been established with the aim of providing or having provided the services of planning, research, development and production required by the Ministry of National Education in order to raise the quality of schools and institutions of vocational and technical education to the level of standards in developed countries. METARGEM also meets the demand for research and programme development of other state and private institutions and organizations.

Some of the main duties of METARGEM are: Conducting research, conducting studies to determine long and medium term goals, preparing an ‘Annual Evaluation and Development Report’, cooperation with domestic and foreign institutions, preparing educational books, and publishing periodicals and news bulletins.

METARGEM has so far provided a number of publications such as ‘Evaluation of the Applications in Multi-Programmed Lycees’ and ‘Vocational and Technical Education in the Turkish Education System’.

As to programme development activities “The process of programme development in Vocational and Technical Education” and “Total Quality Management” should be mentioned.

METARGEM cooperates with international institutions such as the OECD INES Project-Network B and the UNESCO/UNEVOC

\[4\] The METARGEM summary is based on official documents made available by Walter Georg. Ulrich Arnswald was responsible for assessing and summarising.
Project. METARGEM is also continuously exchanging information and material with the ‘European Centre for Developing Vocational Education’ and the ‘European Training Foundation’ established in Turin.

2.9 United States of America, by Uwe Lauterbach

2.9.1 Introduction to the education and vocational education system in the USA

There are various reasons why it is so difficult to identify where the emphasis lies in VET research in the USA and to make general comments on VET research. As in most countries, vocational education is a research subject for the whole range of social sciences. There is no specific institutionalised scientific discipline for labour, vocational and economic education. Besides these theoretical scientific reasons, the research subject itself further muddies the waters in that it distinguishes between vocational education, technical education, vocational training etc, terms which in German are lumped together under the heading ‘berufliche Bildung’.

These cultural and semantic reasons apart, the way in which the federal system in the USA is organised politically makes it even more complicated to describe the state of play in VET research, since responsibility for the education system lies with the individual federal states. Furthermore, there are some 15,500 school districts at local level with local boards of education all having various competences of their own.

Basically, the American constitution does not provide for any federal legislative powers on matters of education. The only competence the central authorities have is on directives covering the educational establishments for the federal administration and the military. Otherwise it may also intervene in matters of race integration or discrimination against certain population groups. The federal government can exert influence through the constitution’s welfare clause. Through target-related grants in aid, the rules pertaining to which are strictly laid down, the central administration has a means of shaping the education system in the individual states. They mean that on this sub-continent with its fifty federal states and 260 million inhabitants, binding minimum standards are respected, which makes comparison possible within the federal system. In vocational education however these mainly take the form of programmes for the ‘disadvantaged’.

Besides this political influence, the work of the federal authorities concentrates heavily on documentation of the state of play in the education system. Many educational policy makers at state and local level would be happy to see the work of the federal government in Washington limited to this role alone.

Apart from the Department of Education at federal level there are a further twenty ministries with competence in this field. Two ministries, the Department of Education and the Department of Labour are in overall charge. Programmes such as career education, initial vocational education (occupational education, vocational education, co-operative education, adult education) and various promotional measures for disadvantaged groups in the population (the illiterate) are handled by the Department of Education.

Company-oriented measures, (on-the-job training, apprenticeship programme), the promotional programmes, anti-unemployment measures through companies, trade unions and other institutions and programmes such as the Job Training Partnership Act come under the Department of Labour and the Employment and Training Administration.

Actual vocational and technical education as such is provided in Community Colleges, Technical Institutes, etc., which come under the aegis of the states or school districts, though it must be said that vocational and technical education is not the preferred path in the education sector by any stretch of the imagination, that is to say that it is not very highly regarded when compared with ‘general’ education.

Even this brief outline of the possible research fields for VET research and the political struc-
tures reveals the difficult framework conditions governing the development of VET research on the one hand, but on the other hand also explains why a state of the art report on VET research would require a degree of effort which was not feasible within the limits of this project. We will therefore limit ourselves here to an overview of the VET research conducted within the framework of national vocational education policy as implemented by the administration in Washington D.C. Two major journals which focus on comparative education were also assessed in order to get a look behind the scenes of ‘free’ and ‘independent’ academic research.

2.9.2 VET research and national vocational education policy

National Centre for Research in Vocational Education (NCRVE), University of California, Berkeley, http://ncrve.berkeley.edu/Default.html

The National Centre for Research in Vocational Education (NCRVE) is the largest national establishment in the USA dealing with research, development and diffusion of subjects related to vocational education. The Centre is financed by the Office of Vocational and Adult Education of the U.S. Department of Education. Since 1988 the Centre's headquarters have been at the University of California, Berkeley, and it has played a key role in working out new concepts in the field of qualifications for the workforce. The centre's main aim is 'to strengthen school-based and work-based learning to prepare all individuals for lasting and rewarding employment, further education, and lifelong learning.' (National Centre for Research in Vocational Education)

The centre focuses on finding new and innovative ways of linking education and work. Training should specifically prepare young people for the world of work. Amongst other things, the centre provides information about pilot projects, curriculum development, qualification standards, further training of teachers and the integration of curricula. The work of the National Centre for Research in Vocational Education is used by teachers and administrations in high schools and community colleges, policy-makers, researchers and employers.

The centre's Work:

- Expert groups which tackle a range of subjects (student guidance through to structuring of schools);
- Support and information to show teachers how to prepare students for lifelong learning;
- Advisors who work together with schools in drafting education and training programmes which are related to the labour market;
- Student and teacher guidance;
- On-line discussion groups;
- Websites with the latest information about the centre and forthcoming events;
- Circulars giving information about the work of the centre.

The centre is comprised of a consortium of eight professors from the University of California, Berkeley, the University of Illinois, the University of Minnesota, MPR Associates Inc., the University of Colombia, the University of Wisconsin and Virginia Polytechnic Institute and State University. The presence of the NCRVE or one of its members in virtually every region of the USA facilitates contact with the various education and training establishments and the labour market.

In terms of training, the main issue at stake for the centre is to offer every student the option of a recognised course which is related to the needs of the labour market, and to promote the development of integrated curricula with the emphasis on problem-oriented learning. Students can thus be encouraged to find a job, train further and become imbued with the concept of lifelong learning (output oriented vocational education).

1998 Work Programme:

To examine the extent to which students' performance has improved as a result of efforts undertaken in the High Schools and Community Colleges to simultaneously prepare students for an activity and also for further training. Research particularly into the degree to
which structuring, organisation and implementation can be brought about in order to reach the planned aims. The NCRVE's work is guided in this by the general aims of the Office of Vocational and Adult Education (with very general over-arching themes: teaching and learning; curricula, career guidance, technology, student support; partnerships and agreement on change; trainees, companies, State, elected representatives, local authorities; organisation and financing, etc.).

Projects: curriculum integration, academic skills, performance at the workplace; development of work-related technological skills.

2.9.3 VET Research outside national vocational education policy

In order to gain an overview, the last five years of relevant journals - Comparative Education and Comparative Education Review - were assessed. The subject of VET research was not explicitly dealt with. The main subjects of research are international matters and theoretical aspects of international comparative VET research.

Comparative Education

Patricia Broadfoot (ed.): Comparative Education. Massachusetts, http://www.carefax.co.uk/ced-ad.htm

International matters, curriculum research, skills research

The quarterly journal Comparative Education which has been in existence for 34 years publishes up-to-date information and analyses of problem issues and trends in educational studies worldwide. Particular attention is paid to the importance of comparative studies concerning the drawing up and implementation of education policy, not only with explicit reference to education, but also combined with related disciplines and social, national and international developments. The journal also deals with issues related to governmental policy, management, sociology, technology and communication insofar as they affect education and training. The journal's administrative board which is made up of nine experts in comparative education meets 3 times per year to discuss contributions with the advice of experts, particularly on international issues.

Comparative Education Review

The journal Comparative Education Review is the official mouthpiece of the American Comparative and International Education Society, an organisation of researchers and university teachers of comparative education, which was set up in 1956 with the aim of improving knowledge and teaching methods in the field of comparative education. The journal comes out quarterly and apart from book reviews it also deals with international matters and publishes theoretical contributions, for example concerning the effects of globalisation and decentralisation on the education sector. There were no specific contributions on VET research.

3. International scientific societies and independent research establishments

3.1 Establishment and organisational framework, by Uwe Lauterbach

It was the political framework conditions which provided the decisive impetus for the establishment of the discipline known as comparative education. Without such organisational roots the sustainable presence of any science or branch of research would be impossible. Thus at this point we will consider in brief whether and how it has been possible to establish comparative education on a permanent basis within the scientific community as well as in the area of transfer between education policy and education administration at national, regional and global level.

The first moves towards comparative education were prompted by 'curiosity' about seemingly incomprehensible foreign education sys-
tems. As a consequence, visits to the countries deemed interesting became increasingly popular. Hilker (1962, pp. 22 ff.) coined the phrase 'the age of educational journeys', which developed from the cultural voyages of the 17th and 18th centuries.

From the second half of the 19th century national and international institutes and organisations which systematically carried out educational documentation crystallised out of this travel activity. National institutes to be mentioned here are: The Office of Education (Washington/USA 1868) from which emerged the Ministry of Education, the Musée Pédagogique/Institut Pédagogique National (Paris/France 1879), the Pestalozzianum (Zurich, Switzerland 1874), the Office of Special Enquiries and Reports (London, Great Britain 1895) and the Zentralinstitut für Erziehung und Unterricht (Berlin/Germany 1914); international educational organisations and institutions include: the Bureau International d'Education (Geneva 1925), the Institut International de Coopération Intellectuelle (Paris 1925), UNESCO (Paris 1946), the bodies of the former Western European Union/European Community/European Union such as EURYDICE (Brussels 1981) and of the Council of Europe such as EUDISED (Strasbourg 1970). Even the World Bank in Washington D.C. has its own Education and Employment Division which backs up the World Bank's political work with scientifically based studies etc. (Hilker 1962; Schneider 1961; Vorbeck 1997; Loxley 1994). Since 1971 the OECD has been running the Centre for Education Research and Innovation (CERI) in Paris, which has a prominent profile on account of its lively publication work, e.g. Education at a Glance, OECD Indicators.

Apart from the national and international documentation centres and research establishments in the individual countries, chairs and institutes for international and comparative education also developed within the universities. Once again the developments here took off in the USA in 1923 with the Teachers College of Columbia University (New York) and researchers such as: Monroe, Kandel, Alexander, Bereday, the Comparative Education Centre of the University of Chicago (1959), Stanford International Development Education Committee (SIDEC) (1965), in England with the Institute of Education of the University of London (1932), Kings College, the Universities of Reading, Oxford and Leeds, and in Germany with the Pädagogische Akademie Bonn (1926), Universität Köln with Friedrich Schneider (chair but not for comparative educational studies).

These institutions, which are integrated into university research and teaching, were and still are of fundamental importance to the shaping of theory and the further development of the discipline in general. The central role of the university institutes in the development of comparative education and its theories is abundantly clear just from the development of comparative education as dealt with in this chapter.

German developments were marked during the age of National Socialism by virtually total isolation from the outside world. After the Second World War, comparative education took off again with renewed impetus. Under the auspices of the French occupying powers a congress was held in Mainz in 1949. The American occupying powers initiated the International Conference on Comparative Education which took place in Chiemsee in April 1949. The Hochschule für Internationale Pädagogische Forschung which was founded in 1952 in Frankfurt am Main also helped to bring German expert circles back into the mainstream of international development. The chair for comparative education at Hamburg University (1950) and the UNESCO Institute in Hamburg (1953) were the first post-war creations in the comparative education field (Hilker 1962, p. 70 ff.; Schneider 1961, p. 65 ff.). Comparative education developed further during the sixties and seventies through the work of the university institutes in Marburg (Froese), Heidelberg (Roehrs) and Bochum (Anweiler). As a result of the growth and development of universities in the wake of German reunification, additional professorships for comparative education were set up at the universities of Leipzig and Dresden as well as at Humboldt University in Berlin.
As a direct result of the conferences on comparative education, scientific societies were founded, such as the Comparative Education Society in 1956, which is today's Comparative and International Education Society (CIES), the Comparative Education Society of Europe (CESE) in 1961, and the World Council of Comparative Education Societies (WCCES) in 1970. The CIES and CESE grew out of the scientific work of the university institutes for educational studies or comparative education (Loxley 1994, p.933-942; Hilker 1962; Schneider 1961). The WCCES brings together the national societies (Comparative Education Society) of which there are now more than 25, whilst the membership of the CIES is made up of individual researchers.

After the Second World War a series of independent research institutes outside the universities were set up. They are mainly financed through national public funding or by international organisations. They are either very empirically organised and provide services for the education administration (e.g. the Centre International d'Etudes Pédagogique Sèvres (CIEP) and the Deutsche Institut für Internationale Pädagogische Forschung (DIPF)), or they are strongly rooted in theory and method (e.g. the Australian Council for Educational Research (ACER)).

The picture is completed by regional or globally organised societies and organisations which were not founded in response to executive or legislative requirements (non-governmental organisations) but rather as a result of the special interest of researchers, e.g. the International Reading Association (IRA) and the International Association for Educational Assessment (IEA).

3.2 International Association for the Evaluation of Educational Achievement (IEA), by Uwe Lauterbach and Brigitte Steinert

Because of their free-floating position the independent international comparative research institutes are better suited to conducting research studies using this methodological concept than are institutes which are tied to national or international administrations or the university institutes which tend to concentrate more on developing theory (Loxley 1994, p. 934). The subject knowledge which links historical knowledge with present-day expertise about education systems with empirical analytical authority can generally be found or can be pooled in supra-institutional networks. Lack of staff—a common occurrence—presents more of a problem in tackling the increasing workload resulting from ever more complicated systems and contexts.

The latest TIMSS study can be quoted as an example (Baumert et al. 1997, particularly pp. 38 f). This international comparison of mathematical-scientific teaching was so demanding that it only came to a successful conclusion thanks to the fact that the project was carried out by an 'independent' international association of researchers, the International Association for the Evaluation of Educational Achievement (IEA) in conjunction with national research institutes (e.g. in Germany: the Max-Planck-Institut für Bildungsforschung, Deutsches Institut für Internationale Pädagogische Forschung), national universities (e.g. the University of Kiel and Humboldt University Berlin), national ministries (e.g. the Federal Ministry for Education, Science, Research and Technology in Germany), and international organisations, e.g. OECD.

The International Association for the Evaluation of Educational Achievement (IEA) was founded in 1959 and is a non-governmental international association based in The Hague in the Netherlands, to which research institutes, universities and governmental authorities from over 45 countries belong. Its role consists of conducting international comparative school achievement studies and thereby developing indicators for learning processes and in particular for the outcome of learning. Through regular observation of the output of education systems a basis of knowledge can be built up for users in education policy, educational administration and educational research, in order to bring about improvements.

The core subjects taught in schools are the main subjects for comparative studies (the years of the main studies are shown in brackets): maths (1964, 1980-1982, 1994-1995), sci-

4. International organisations

4.1 World Bank Group, by Heike Maier and Heinz Bartel

Framework conditions

Vocational education

The role of vocational education in the World Bank has changed since the early 90s. Whilst in the 70s and 80s it was projects in this field that were promoted in particular, nowadays the view is that:

'Vocational and technical skills are best imparted at the workplace, following general education. The private sector should be directly involved in the provision, financing and governance of vocational schooling.' (quoted from Watson 1996, p. 47)

Watson interprets this statement in relation to the real drop in loans to the vocational education sector in the following terms:

'Because VOCED has generally proved to be expensive it is far easier for the Bank to suggest that private employers should take on this role themselves: it excuses the Bank from becoming too heavily involved in that costly area again.' (Watson 1996, p. 53)

The World Bank Group acts first and foremost as a bank, i.e. research, if research there be, is always conducted from an economic point of view. The problem with this is that:

'The research base is largely restricted to that produced by the World Bank staff or commissioned by the Bank. The result is a self fulfilling prophecy: Research data supports the policy that the Bank wishes to pursue because that research has already helped to shape that policy.' (Watson 1996, p. 49; see also: Samoff 1993, p: 181-222)

The importance of the World Bank in terms of VET research tends therefore to be related to its role as a publisher, or in the transfer of knowledge. The (major) World Bank projects are now widely documented on the Internet. Via Topics (Education and Training), Regions and Countries or a server's global search engine, researchers can call up primary information. Pdf documents about the vocational

5 The group comprises the International Bank for Reconstruction and Development (IBRD), the International Development Association (IDA), the International Finance Corporation (IFC), the Multilateral Investment Agency (MIGA) and the International Centre for Settlement of Investment Disputes.

6 A programme against youth unemployment. Young peoples' chances on the labour market are improved by improved training possibilities. Total cost 60.1 million US$.

7 Under the World Bank's reconstruction work 68.86 million US$ is being invested in the vocational education system in the Lebanon, to bring it up to market requirements.

8 The server can be searched e.g. with key words (vocational Chile) for relevant documents.
education systems in individual countries can also be called up.  

4.2 Unesco, by Heike Maier and Heinz Bartel

Framework conditions

In the 1996/97 financial year there were 518.4 million US$ available to UNESCO. With this budget, which is actually no bigger than that of a sizeable university, UNESCO supports projects in 180 countries. Besides this budget, which is financed by the member states, Unesco also receives income from voluntary contributions. For the 1996/97 tax year these amounted to 290 million US$. (http://www.unesco.org (24 March 1999)) More than 35% of Unesco’s funds go into the education sector.

The current priorities in UNESCO’s work (http://www.unesco.org/education/eduecpreg/ prog_idx.htm (1 April 1999)) are lifelong learning and learning in the 21st century. 

UNESCO’s work in the education sector is supported by the following research institutes:

- International Institute for Educational Planning (IIEP), Paris; (http://www.unesco.org/ieip/ (6 April 1999).)
- Unesco Institute for Education (UIE), Hamburg; (http://www.unesco.org/education/uiue/index.html (6 April 1999).)
- International Bureau of Education (IBE), Geneva; (http://www.ibe.unesco.org/ (6 April 1999).)
- European Centre for Higher Education (CEPES), Bucharest. (http://www.cepes.ro/ (6 April 1999).)

Vocational education

Unesco is the only specialised agency of the UN to have a mandate in the education sector. It does not have a monopoly, however. In 1954 the following distribution of labour was agreed upon between the International Labour Organisation (ILO) and UNESCO:

“The ILO is primarily concerned with technical and vocational education and training in relation to occupational activities and welfare of employees. UNESCO is primarily concerned with technical and vocational education as part of the education of human beings (...). Technical or vocational education which takes place within a general education system is primarily a matter for UNESCO, subject to consultation with the ILO concerning the prospective demand for particular skills

9 The Social Protection Team is pleased to make available a groundbreaking set of country study summaries and issues briefs on vocational education and training based on a joint World Bank- ILO study, Skills and Change: Constraints and Innovation in the Reform of Vocational Education and Training.' The views expressed here are those of the authors, and should not be attributed to their respective organisations.' in: http://wbln0018.worldbank.org/HDDNet/HDdocs.nsf/7b5f392774476c0d852566810054d98e/ d5af2502566833c6852566b100014bbb?OpenDocument (18 March 1999).

Uwe Lauterbach et al.

and the requirements to be fulfilled in respect of such skills.\textsuperscript{12}

UNESCO’s work in the field of vocational education is essentially of a statutory nature. The Recommendation on vocational education which was adopted in 1962 was revised in 1974. In 1987 the first global congress on vocational education was held, at which the draft of a Convention on Vocational Education was tabled. This was approved in 1989 and ratified in 1991 by the Federal Republic of Germany, amongst others.

In organisational terms, vocational education within UNESCO has been upgraded. In 1992 the UNESCO Technical and Vocational Education Project (UNEVOC) was set up. In parallel to this development it would appear that the Division for the Renovation of Secondary and Vocational Education (ED/SVE) has become more sharply focused on general questions of vocational education. New subject areas have been introduced, and are organised on an interdisciplinary basis. Currently an attempt is being made to involve NGOs more closely with projects.\textsuperscript{13} The Section for Science and Technology Education (http://www.unesco.org/education/educprog/steframework/activities.html (6 April 1999) (1996-1997) already did this in its 1996/1997 programme\textsuperscript{14}.

The task profile of the UNEVOC project is as follows:

1. International exchange of ideas, experience and studies on policy issues;
2. Strengthening of national research and development capabilities;
3. Facilitating access to data bases and documentation; strengthening of the UNEVOC Network (http://www.unevoc.de/workplan/wp9899-e.htm (6 April 1999).

The board for the UNEVOC project has recommended that the work should continue even once the pilot stage has come to an end (http://www.unevoc.de/events/ev9703hq.htm (27 April 1999). Colin N. Power, Deputy Director-General for Education, made a statement at the second international congress on vocational education in Seoul in 1999, by which UNEVOC also feels bound.

‘Partnerships and networking will also be critical to meet the challenges of globalisation and technological development. Working with the International Labour Organisation and the World Bank, we must adopt an integrated approach to TVE, a vital component of any development programme. At the national level we must encourage ministries of education and labour to combine their theoretical knowledge and practical training and to work closer together for their mutual benefit’. (http://www.unesco.org/education/educnews/99_03_11/letter.htm

\textbf{Specific research opportunities in the field of vocational education}

\textbf{Monetary Backing}

In UNESCO's 1998/99 budget some 86.7 million US$ are earmarked for the scientific programme from the ordinary budget, with an additional 62 million US$ in the extra-budgetary provision. The MOST programme - Management of Social Transformations - lies at the heart of social scientific research. Individual fields of research are as follows:

1. Change in multi-cultural and multi-ethnic societies;
2. towns as places with accelerated processes of social change and migration issues; and
3. local and regional management of economic, technological and ecological change.

Projects which fulfil the following criteria may be presented in the framework of these areas of research:

\textsuperscript{13} Greater account should be taken of themes such as the environment, health, nutrition and social relations in general.

\textsuperscript{14} Amongst other things a 6 year project on Scientific, Technical and Vocational Education for Girls in Africa is being run at the present moment.
Research projects are expected to be comparative, inter-disciplinary, international and relevant to policy. They must be conceived and implemented by groups or networks of researchers in several countries. They must be internationally structured, well coordinated, and cover a broad scope. This implies a solid project framework, as well as a clearly identified cooperation procedure between the groups of researchers. The project proposal must state clearly why a comparison between the countries selected is likely to produce important knowledge for scientific questions and for the political decision-taking process.’ (quoted from: http://www.unesco.de/Info/She.htm#zurück (26 April 1999))

There is also another interesting option for smaller scale projects. Every two years the national UNESCO offices offer Partnership Programmes. 25,000 US$ is granted per project. The choice of subject is free.

**Instruments**

With the International Standard Classification of Education (ISCED) UNESCO has tried to create an instrument which serves ‘as an instrument for assembling, compiling and presenting statistics of education both within individual countries and internationally’. (International Standart Classification of Education. ISCED 1997)

The ISCED classification was revised in 1997. Initial vocational training in the secondary sector is classified as ISCED level 3, whilst vocational training in the tertiary sector comes under ISCED level 5. The aim of this is to ‘make existing international statistics on education more transparent’ (Statistisches Bundesamt Wiesbaden 1997, p. 8)

**Communications**

For scientists working in the vocational education sector UNEVOC is/is becoming a central communications interface. The following interactive activities are currently up and running:

- A mailing list – the UNEVOC E Forum (http://www.unevoc.de/forum.htm (6 April 1999) – which can be used for the general, interactive exchange of information;
- UNEVOC-Info (a free E-journal)\(^{15}\);
- UNEVOC Network covers UNEVOC centres in the UNESCO member states\(^{16}\);
- Publications\(^{17}\).

**Materials**

Materials which are of relevance to vocational education can be consulted using the following databases:

- Innodata (http://www.software-engineering.ch/Infobases/IBE/InnoData/ (6 April 1999)
  The emphasis of the data files is on reports on innovative concepts/projects in the primary and secondary sectors;
- UNESCOBIB (http://unesdoc.unesco.org/ulis/unesbib.html (6 April 1999)
  Bibliography of UNESCO printed documents and publications (reference database);
- UNESDOC (http://unesdoc.unesco.org/ulis/ (6 April 1999)

---

Country profiles can be looked up in this database (full text database).

### 4.3 International Labour Organisation (ILO), by Heike Maier and Heinz Bartel

#### Framework conditions

The International Labour Organisation (ILO) (www.ilo.org (17 May 1999)) Delimitation from UNESCO, see above) which was founded in 1919 is the only UN Organisation whose bodies are composed on a tri-partite basis of representatives of governments, employers and workers. The ILO lays down statutory requirements in conventions and recommendations in the field of labour law, contractual and organisational freedom, abolition of forced labour, etc. Training is one of the organisation’s main priorities. This can be seen for example in ILO Convention 142 (1975) on Vocational Guidance and Training in the Development of Human Resources and in Convention no. 159 (1983) on Vocational Rehabilitation and Employment (Disabled Persons) (www.ilo.org/public/english&60mpfor/over.htm (17 May 1999)). But it also provides concrete support in the fields of vocational education, rehabilitation, labour market policy, labour administration, working conditions, labour law, etc. The organisation’s budget for these tasks amounted to 79,500,000 US$ in 1996/97 (1998/99 estimated 569,080,000 US$) (http://www.ilo.org/public/english/200progr/pb/98/draftbud.htm (17 May 1999)).

Field programmes, technical programmes and action programmes are conducted. The field programmes are represented by continental/regional institutes. The South American region is one of the most active here with the CINTEFOR research and documentation centre and MERCOSUR. The action programmes are basis-oriented and run across the field and technical programmes.

The technical programmes are thematically structured operational units (http://www.ilo.org/public/english/depts/depts.htm (17 May 1999), http://www.ilo.org/public/english/130inst/index.htm (17 May 1999)). The units include the International Institute for Labour Studies (http://www.ilo.org/public/english/10iic/iic83/dg-repc.htm#Heading10 (19 May 1999)) and the International Training Centre. The former deals with international labour market research, the Turin-based Training Centre provides amongst other things (further) training for officials from educational administrations, trade unions, etc.

#### Vocational education

The ILO's main task is that of:

' [...] developing the policy-making capacity of governments, employers' and workers' organisations and strengthening dialogue and cooperation in the field of training. These activities took the form of the dissemination of information to constituents, policy dialogue and the provision of advisory services.’

A survey was conducted in co-operation with the World Bank, looking at the 'best practice in training policies' in 15 countries in the process of transformation. Plenty of advice and technical support was also offered or provided relation to the implementation/further devel-

18 SEAPAT is the Asiatic counterpart of CINTERFOR, although it has not yet achieved the level of professionalism and quality of the latter. http://www.ilo.org/public/english/mdtmanil/index.htm (18 May 1999).

20 Country studies were drawn up for Indonesia, Tunisia, and China. http://www.ilo.org/public/english/10iic/iic83/dg-repc.htm#fn35 (19 May 1999)
opment/assessment of national training systems.21

The Employment and Training Department (EMP-FORM)22 with its Training Policies and Systems Branch (POLFORM) has overall responsibility for vocational education. (http://www.ilo.org/public/english/60empfor/polform/overview.htm (18 May 1999)) A total of 28,000,000 US$ was available from the ordinary budget in 1998/99 (1996/97: 28,000,000 US$). The following projects were amongst those implemented (in partial co-operation with the regional bureaus):

- **Training Policies and Systems**
  ‘The objective of the technical programme... is the improved capacity of ILO member countries to design and put into work-related training policies and systems, contribution to human resource development as a critical element in achieving economic growth and social equity’.23

- **Training Policy Reforms: The Evidence**
  This project was conducted in collaboration with the World Bank. Resistance to and innovation related to reforms in the vocational education field were documented in 17 countries.24

22 The former departments for Training Policies and Programme Development and the Vocational Training System Management were dismantled as a result of restructuring.

23 Gill, Indermit/Flutman, Fred (Publ.): Constraints and Innovation in the Reform of Vocational Education and Training, no page, no year. The countries looked at were: Chile, China, Czech Republic, Egypt, Hungary, Indonesia, Jordan, Kazakhstan, South Korea, Malaysia, Mexico, Poland, Russia, South Africa, Tanzania, West Bank/Gaza, and Zambia. http://www.ilo.org/public/english/60empfor/polform/prog6.htm (18 May 1999).

24 10 countries were studied: Australia, Belgium, Brazil, Canada, Denmark, France, Pakistan, South Korea, United Kingdom, United States. http://www.ilo.org/public/english/60empfor/polform/prog6.htm (18 May 1999).

- **Management of Vocational Education and Training**
  This research project produced a handbook edited by Vladimir Gasskov.

  ‘It (the handbook) provides state-of-the-art knowledge relating to managing and organising vocational education and training (VET) systems and draws upon lessons from experience, current trends, and best practice in the administration of public training service around the world.’ (http://www.ilo.org/public/english/60empfor/polform/prog10.htm (18 May 1999))

- **Evaluation of Training**
  W. Norton Grubb (University of California at Berkeley) and Paul Ryan (University of Cambridge) attempt to provide an overview of theory and practice in the field of assessment in this research project. 25

- **Strategic Partnership in Training**
  A research project on the role of the state and of companies.

  ‘The study indicated that effective partnerships require not only a favourable policy environment and incentives but also greater capacity of the social actors involved, particularly employers and workers and their organisations. This means, inter alia, strengthening worker/employer perspectives- policies, strategies and mechanisms- in order to enable worker and employer organisations to participate more effectively in the governance of training systems and to deliver information and services for their affiliates.’ (http://www.ilo.org/public/english/60empfor/polform/prog7.htm (19 May 1999))

25 http://www.ilo.org/public/english/60empfor/polform/prog5.htm (19 May 1999). 26 countries were looked at: Australia, Chile, Denmark, France, Germany, India, Ireland, Ivory Coast, Japan, Malaysia, South Africa, Spain, United Kingdom, United States.
As a result of this research project POLFROM is currently developing an ‘Action Programme on Social Dialogue on Training’ which should give rise to new, innovative forms of co-operation between the social partners.

‘While training systems and training issues differ considerably from country to country, it was felt that, as in the case of a doctor examining a patient to cure an illness, the method of arriving at sensible policy options need not vary across borders. It was consequently decided to try and develop, on the basis of practical experience, a methodology of training policy analysis in a format suitable for use in workshops and seminars targeted at training system officials in general, and at training policy analysts in particular. (...) A training package, containing six modules, has therefore been developed in the form of an elaborate, computer-aided slide show, using MS-Power Point.’

- Skills Training and Employment in Conflict-Affected Countries

Research opportunities in the field of vocational education

Analogous to the ISCED classification, the ILO provides the following classifications: (http://www.ilo.org/public/english/190bibl/dblist.htm)

- International Standard Classification of Occupations (ISCO)
- International Classification of Status in Employment (ICSE)
- International Standard Industrial Classification of all Economic Activities (ISIC)
- Classifications of occupational injuries (formerly industrial accidents)

- Materials

Materials which can be of relevance to vocational education can be called up via the following online databases: (OECD Annual Report 1999)

- ILODOC
  Database containing more than 50,000 files. ILO material is indexed in three languages. Monthly update (reference database).

- ILOTERM
  Glossary for English, French, Spanish and German specialist terms from the vocational sphere

- NATLEX (ILIS)
  Database which documents national labour law

- LABORDOC
  The database, which contains all the material from the ILO's documentation centre (including non-ILO documents), is currently not available online. A CD-ROM is being prepared for 1999.

4.4 Organisation for Economic Co-operation and Development (OECD), by Brigitte Steinert and Heike Maier

Framework conditions

The Organisation for Economic Co-operation and Development (OECD) which is based in Paris was founded in 1961. Its 29 member states are amongst the richest countries on earth. Its role is to promote economic development, employment and living standards and to contribute to the development of the
world economy and world trade. The organisation sees its main task as being the planning, coordination and intensification of economic co-operation and development, encouraging economic development with full employment and monetary stability. The OECD's current annual budget amounts to 200 million US$, contributed by member states in proportion to their ability to pay. Around 80% of this budget goes in staffing costs. (78) Besides this core budget, countries may also participate in specific projects or programmes on a voluntary basis. Overall there are more than 200 committees, working parties and expert groups which ascertain statistical data, collect, assess and make it available to the public in co-operation with the Secretariat in Paris.

**General and vocational education**

UNESCO, EUROSTAT and the OECD co-operate under the aegis of the OECD to achieve the international comparability of Within the OECD questions on general and vocational education are mainly handled in the Department for Statistics and Indicators in the OECD's Directorate for Education, Employment, Labour and Social Questions. Promotion and support for the development of research activities and the introduction and testing of innovations in the education sector is carried out by the Centre for Educational Research and Innovation (CERI) which was set up in 1968.

Current OECD activities related to educational development and research are concentrated in particular on the areas of educational statistics, developing a framework concept for the international comparison of education systems, and the international comparative measurement of student performance. Since 1992 the OECD has been producing a series of educational indicators – 'Education at a Glance – OECD Indicators'- on a yearly basis, as well as investigations into individual questions on the indicator table as 'Education Policy Analysis'. Within the INES network (indicators of education systems) the individual member states work on and support the drawing up of indicators for central areas of the education sector, priorities may change and include: the demographic and social context, educational expenditure and staffing, costs and returns, participation in education, decision-takers and structures, student performance and diplomas, employment figures. From an analytical point of view for the industrialised nations which belong to the OECD, this collection of statistics and indicators is much more highly differentiated than are UNESCO's Statistical Yearbooks.

Introduction

Vocational education and training has not only been an issue for training, social and employment policies, but is also of paramount importance within the research framework.

Many questions and issues are still unsolved and indicate the necessity for coordinated comparative research for national and European policy making. What are the pathways and bridges between learning and work in Europe and how can they be developed? How do learning strategies and policies integrate with new trends in employment and work?

These research questions – among many others – are addressed in the key action on: 'Improving the socio-economic knowledge base' under the horizontal programme: 'Improving the human research potential' of the fifth framework programme (FP5) for research, technology and development (RTD).

The horizontal programme 'improving the human research potential and the socio-economic base', or human potential as it has become known, has evolved from the research priorities addressed by two former programmes 'training and mobility of researchers' (TMR) and 'targeted socio-economic research' (TSER).

The human potential programme for 1998 to 2002 consists of five distinct actions. Through these activities the programme is at the forefront of enhancing European mobility and cooperation in recognition of the essential role played by education and training:

1) supporting training and mobility of researchers implemented through two lines: research training networks and Marie Curie fellowships;

2) enhancing access to research infrastructures, implemented through trans-national access to major research infrastructures, infrastructure cooperation networks and research infrastructure and research infrastructure RTD projects;

3) promoting scientific and technological excellence, implemented through high-level scientific conferences, distinctions for high-level research work and raising public awareness activities;

4) support for the development of scientific and technology policies in Europe, implemented through strategic analysis of specific political issues and the establishment of a common basis of science, technology and innovation indicators;

5) the key action on 'improving the socio-economic knowledge base', helping to provide a solid research foundation towards a 'Europe of knowledge'.

The research outcomes on 'vocational education and training', all refer to research projects under the key action and its former programme 'targeted socio-economic research'.

1. Description of the key action: 'improving the socio-economic knowledge base'

1.1 Introduction

The key action 'improving the socio-economic knowledge base' is one of the action lines of the horizontal programme: 'improving human potential and the socio-economic knowledge base' of the fifth framework programme (FP5) for research, technology and development.

---

3 For further information on the activities of the human potential programme see Website http://www.cordis.lu/improving.

4 For further information on the key action, see website http://www.cordis.lu/improving.

The overall aim of the key action is to improve through research understanding of the major structural changes taking place in European society, to identify ways of managing these changes and to involve European citizens more actively in shaping their own future.

The key action utilises, builds upon and extends work carried out in the TSER (targeted socio-economic research) programme of the fourth framework programme (FP4). It is implemented through RTD projects, thematic networks, research infrastructures and various types of accompanying measures.

As well as improving the social science knowledge base, this key action aims to mobilise the social science research community in Europe and to develop a process of dialogue between this community, policy-makers at all levels and other key actors. Effective targeting and dissemination of results is a key feature. All the activities are expected to lead to policy relevant insights. As such the key action will help to sensitise policy-makers to the importance of socio-economic research.

1.2 Rationale and objectives of the key action

The European Union draws its strength both from the social and cultural diversities of its members as well as from the similarities of their experiences and common values. The Community also has a solid tradition of research in social and economic science and the humanities, which need to be mobilised to identify economic and social trends and requirements, both current and future, in order to contribute to the Community’s competitiveness and quality of life of its citizens.

In a period of increasing challenges, such as unacceptable levels of unemployment, an ageing population, the globalisation of economies, an increase in inequalities, and a declining relative contribution to the world economy, European society will have to undergo changes towards achieving sustainable socio-economic development, the improvement of the quality of life of all its citizens and to maintain and enhance Europe’s competitive position in the world. Social sciences must therefore be in a position to respond to these challenges, overcome national boundaries, through reinforcing cooperation and enhancing their analytical capacity and thereby supporting policy-making. Furthermore, the process of European integration has given rise to a new object of study – European society – which is different from the sum of its components, although clearly dependent on them.

The objective of this key action will be to improve our understanding of the structural changes taking place in European society in order to identify ways of managing change and to involve European citizens more actively in shaping their own futures. This will entail the analysis of the main trends giving rise to these changes, the analysis of the relationships between technology, employment and society, the impact of new technologies on working conditions, the re-appraisal of participation mechanisms for collective action at all levels of governance and the elaboration of new development strategies fostering growth, employment and economic and social cohesion.

This key action covers a number of subjects linked to the general objectives of the framework programme and aims at defining the base for employment – generating social, economic and cultural development and for building a European knowledge society. These subjects should not be seen in isolation, but as interrelated parts of a coherent and comprehensive framework.

Support will aim at developing a conceptual understanding of the processes described above, built upon empirical, comparative and prospective research, including constructing and integrating data and indicator systems and establishing a common research infrastructure. These activities will therefore contribute to provide the policy decision-making process with a sound knowledge of the challenges facing Europe, of their main consequences and of possible policy options to tackle them.
1.3 Thematic framework for this key action

Societal trends and structural changes

Against a background of profound structural, demographic and social changes, research within this theme will aim at elucidating the complex interactions between societal trends, life chances, changes in family structures, economic changes, labour market institutions, cultural patterns and value systems, taking European regional diversities into account. The analysis will include the phenomena of xenophobia, racism and migration. Attention will be focused on the impact on economic development, social integration, social protection and factors of social inequalities and discrimination.

The study of these interactions will provide a better understanding of the changing patterns of work and organisation of time, of the use of new types of atypical and part-time or temporary jobs, of the capacity of education and training to prepare individuals over their lifetime to a changing environment and to enhance knowledge of the gender issue in European society. Research work will provide a sound knowledge base and contribute to the formulation and development of the relevant European policies.

Technology, society and employment

Research under this theme aims to understand better the relationship of interdependency and embeddedness between technology and society and to contribute to an integrated approach to planning and development. While the need for integrating social, institutional and environmental concerns in the technological development process is now accepted, the possible options vary according to different kinds of technologies, the state of their development and diffusion in society. Research will be undertaken on methods of interaction between the various actors concerned – suppliers, users, advisory bodies, decision makers and public authorities. An improved understanding of the deployment and the impact of technologies in various socio-economic, territorial, institutional, political and cultural contexts in the Union is expected to arise from this work. Research will also examine the role of the public sector in the innovation process and how authorities interact with other partners.

Attention will be paid to the relationships between technology and employment, in particular the new information and communications technologies and the new ways of organising production and labour, including newly emerging professions, the geographical location of employment, changes in working conditions and in workforce skills. The role of innovation in education and training, the concept of lifelong learning, as well as how education and training can stimulate innovation, promote employment, social integration and equal opportunities, will also be examined.

Governance and citizenship

In the context of European integration, there is a need to reassess the role of the different levels of governance in Europe (local, regional, national and supranational). The aim will be to analyse the mutual articulation of responsibility and accountability at all levels and their real capacity as agents of change, whilst allowing for the development of mechanisms of dialogue, deliberation and decision-making to ensure effective cooperation between all the actors concerned.

Research will set out to explain to what extent the various types of economic and social regulation in Europe are the consequences of a specific socio-institutional and cultural construction, in order to define better European integration strategies. It will address both regulation by public authorities as well as civil initiatives and structures such as political parties, public interest groups and social partners. The examination of the role of public authorities will also cover the reassessment of their missions, and of the concept of public service and the notion of public interest. In this framework, analysis of the evolution of welfare systems will be a key element. In these analyses of governance, the notion of political, economic and social power will also be taken into account.
Lieve Van den Brande

The analyses will be accompanied by the study of the concept of citizenship across Europe, and of types and systems of participation of citizens and regulation to which they give rise. Research will also analyse the influence of the various components of culture (traditions, language, history, heritage, religions, migrations) and of educational models on the development of values. Analysis at the level of the individual could complement, where appropriate, research in this area. The role of media in a global economy, in which international audio-visual cultural products are increasingly present, will also be examined. The analyses will examine the inter-relationships between governance and citizenship.

New development models fostering growth and employment

This prospective work will seek to explore new sustainable development models to foster growth, job creation, equal opportunities, the reduction of inequalities and the improvement of quality of life. It will investigate the dynamics of creation and distribution of wealth and the role of the public sector in this context in a globalised economy where 'intangible' and service factors predominate. This will involve the development of indicators and methodologies for assessing the social and economic added value of various production models, identifying competitiveness factors including human capital, and characterising the different policies best adapted to the European economic area, taking into account Europe's regional divergences, and to the evolution of Europe in world economic relations.

Research will concentrate on analyses of issues such as organisational innovations, new types of work and employment including the working potential of the older population, responses to the increasing demand for services, the development of non-profit mutual support activities, and innovations in socio-economic partners cooperation. Socio-economic and demographic differences across Europe and the impact of the development models on economic and social cohesion will be included.

2. Research on vocational education and training

2.1 From TSER to the key action – research clusters

The key action utilises, builds upon and extends the work carried out in the TSER (targeted socio-economic research) programme of the fourth framework programme (FP4) (1994-98). TSER invited proposals for research from the European research community on three main areas of economic and social research:

a) science and technology policy,

b) education and training (ET) and labour market integration,

c) social integration and social exclusion.

The increasingly severe economic and social problems facing European societies required a more coordinated and better funded and targeted research and policy response than before. The main objective of the TSER (1994-98) programme therefore was to build up both the knowledge base and research infrastructure for high quality, policy relevant, comparative European socio-economic research at both national and Community levels.

In Area II, research in education and training, the objective was to help link advances in science and technology and rapid economic/technological change to the effectiveness of the ET systems – in building up human capital, labour market entry and in-firm insertion/training processes for attracting and using high quality labour.

Within this broad area of research the programme had three main objectives – to strengthen the European research base and improve communication and networking amongst European researchers, to develop and strengthen the knowledge base and to

improve its quality and comparability, and to help apply it to the challenges facing European economies and societies.

There were three main objectives of TSER Area II (research in education and training):

a) the nature and extent of skill change and of labour demand in the economy and the effectiveness and nature of the responsiveness of \( \text{ET} \) systems to these changes;

b) the development of \( \text{ET} \) effectiveness/evaluation models and methodologies — both in terms of conventional schooling/training and in lifelong learning/instructional arrangements;

c) transitions from school to work, and the nature and extent to which \( \text{ET} \) systems and their relationships with employment systems positively or negatively affect inclusionary or exclusionary processes.

The implementation of the TSER programme under FP4 and the key action ‘improving the socio-economic knowledge base’ under FP5 is achieved through calls for proposals. The former TSER programme was implemented through three calls for proposals; the key action socio-economic research has already launched one call and two or three others will follow. To date more than 200 projects have been funded.

In order to create synergies and improve added value, these projects have been assembled in a certain number of groups, covering a wide range of relevant themes for research and policy.

Various clusters are actually running and working on issues such as systems of innovation, work, knowledge and the economy; technology and society, employment, work, welfare and exclusion, etc.

Two of these clusters touch on the issue of vocational education and training:

a) ‘schooling, training and transitions and its impact on the low skilled and youth unemployment’;

b) ‘human resource development and competence development in Europe’.

2.2 The cluster on ‘schooling, training and transitions’ and its impact on the low skilled and youth unemployment

From a societal perspective, a growing interest in knowledge and learning is emerging. Issues such as mobility and employability, often stimulated by governments, drive citizens to invest in personal growth in knowledge and competence in order to create better job positions for now and the future. Therefore tools that help citizens to attain these goals have become important not only at the industry level, but also at the societal level.

The education/employment relationship and the transition from school to work has been the subject of substantial research under the TSER programme. More than 25 research projects of FP4 and first call projects of FP5 are exploring and analysing in depth research topics in relation to ‘the dynamics of education to work transitions in Europe and its impact on the low skilled and youth unemployment.’ Clustering work will allow researchers, policy-makers, practitioners and the general public to learn from the work going on within the RTD projects.

These topics have been initiated following concerns raised by policy-makers. First, most European countries have had persistent high youth unemployment rates for almost two decades, with the time between leaving full-time education and securing a regular job also increasing significantly. With a substantial proportion of young people entering the labour market \( \text{(LM)} \) either never finding secure employment or being intermittently unemployed — particularly those with the lowest qualifications— both policy-makers and researchers have focused a lot of attention on the initial school-to-work transition process. Initially, substantial State investments occurred in LM interventions such as State employment and training programmes, but...
gradually these shifted to more active and more effective labour market intervention, as the long-term secular rather than temporary nature of the labour market problem became increasingly apparent. As a result, in many European Union (EU) countries participation in such State programmes became a regular feature of many young people's transition between leaving full-time initial education and either getting a regular job or effectively withdrawing from active participation in the labour market. Besides the immediate social consequences of this, these issues remain highly relevant to policy since, when economic growth resumes, countries will need to ensure the workforce is in employment as there are generally low replacement rates. Even today, labour shortages have emerged in some countries, so that national and EU policies need to be geared to address the medium to long-term effects of declining demographic trends with improving economic growth.

Second, besides the current employment crisis, a rapid upgrading of education and training (ET) is required in most EU countries given the poor competitive position of EU countries for low-skilled production and high global competitiveness for high-skilled production and services, particularly from the USA and Japan.

Given these policy priorities, transition from school to work and more particularly how to overcome youth unemployment and low skills through education and training, has become a very important policy issue in most EU countries. One of the main policy research questions remains whether there is one or a number of different and equally effective solutions to these problems in different EU countries.

The underlying sources of these difficulties in different country labour markets within the EU are difficult to disentangle. They are not equally serious in all countries. They also tend to have different patterns in different countries, and there is no agreement on the exact source of the relative lack of job vacancies for young people. Successful policy interventions also tend to differ across countries. Not all EU countries reacted the same way to the crisis, nor do or can they have the same kind of effective policy solutions: the seriousness and nature of the problem varies across countries; countries have different youth/age profiles, somewhat different economies, and clearly different institutional systems.

In these circumstances, comparative cross-country research is of particular interest to learn to what extent and why some policies may be generalised, while others appear to be effective only in particular country/institutional contexts. This requires that research should aim at a clear understanding of the impact(s) of institutional contexts on education and training (ET) and labour market (LM) outcomes.

The main aims of this cluster of TSER projects on transitions from education to working life are as follows:

a) the cluster reviewed the main research findings, conclusions and general direction of the targeted socio-economic research (TSER) programme under the fourth framework programme of Directorate General on Research, dealing with research on education/employment/social exclusion relationships and, in particular, transitions from education to work in Europe and places it in the context of the wider research literature and policy priorities in the area;

b) the cluster highlighted the main areas where policy needs are well served by research, and other areas where research is poorly developed;

c) the cluster of RTD projects suggests the main areas of research and policy analyses that need to be addressed in the future.

For this cluster close cooperation and coordination was established with Directorate General on Education and Culture to enhance the link between research and ET policies, especially on issues such as employability and the contribution of vocational education and training to innovation and on actions targeted at young persons who left the education system too early without qualifications.
2.3 Cluster of RTD projects on ‘human resource development and competence development in Europe’

Human resource development and competence development in organisations has been a subject of substantial research under the TSER programme in more than 17 research projects of FP4 and first call projects of FP5.

It is a fundamental principle of European economic and social policy-making that prosperity and employment growth in the EU is dependent upon creating and sustaining a highly skilled and adaptable workforce. The European approach on the whole has tended to regard high skills, training, good internal communication and a consensual organisational regime as a part of the competitive advantage of firms. In this context, the concept of the learning organisation captured the imagination of managers and policy-makers alike, in that it proposes a positive framework for managing change for the social partners.

In this context, however, this fundamental principle is challenged by the continuation of contradictory strategies. These emphasise deregulatory, hire and fire, low skill and low-wage strategies. Partly, this is a failure to adapt to the new conditions of global competition, and partly it is because in some cases these strategies offer competitive advantages – in the short term. Consequently, arguments on the importance of human capital and how it might best be developed inside organisations are at a crossroads. Management uncertainty, skill losses and gains, intense periods of change, continued and sustained innovation make the need for policies and strategies of skill and knowledge acquisition all the more crucial for Europe’s future.

More than 17 research projects currently supported by the TSER programme (FP4) and by the key action (FP5) are creating important new empirical and theoretical knowledge in this field.

To gain the maximum advantage from these projects, it was first necessary to identify a set of current policy concerns, which would benefit from interaction with the RTD projects. The EU and national governments have introduced a spectrum of policies aimed at the twin goals of promoting competitiveness in international markets and maintaining social cohesion (in particular, protecting the losers in global competition). A sense of urgency now drives policy debates, because Europe’s economic performance is declining relative to that of the US and many Asian countries. In comparison with these countries, European productivity growth is slow, and its competitiveness in international markets is weak.

The RTD projects encompassed by this cluster are directly relevant to these concerns. Human resource development and competence development have a prominent position in new policies. They stand level with R&D policy, technology policy and infrastructure policy. In part, this is due to a return to human capital theory, the doctrine that the knowledge and skills of a firm’s employees are among its most important capital assets. Consequently, HRD and VET practitioners are now assigned the task of generating human capital, and supplying it to the labour market.

The new role of HRD and competence development is described in numerous policy documents and is closely linked to the European employment strategy, currently the major policy arena for debate on human resource and competence needs. The cluster of RTD projects seeks to inform this policy debate by identifying relevant findings from the fourth and fifth framework programme projects and presenting these at appropriate points in the process of policy development.

However, bridging the policy development and the research programme at European level is no simple matter. The national action plans submitted to the Commission each year record many different ways in which Member States are addressing the issues of HRD and competence development. In these plans, local conditions rather than pan-European trends are the major determining factor.

As in the task of making research relevant to practice, there is a problem of reconciling the
general trends of research with the specificities of actual practice. Nevertheless, on the basis of the collective experience of the RTD projects that have come together to form the cluster, it is believed that many commonalities European-wide exist and that the bridge between research and practice can have major impact.
Synopsis of selected VET related projects undertaken in the framework of the Leonardo da Vinci I programme

Abstract

Out of a list of a number of Leonardo Da Vinci projects (Surveys and analyses strand) we selected those that seemed relevant for several issues dealt with in the second Report on Vocational Training Research in Europe: Training and learning for competences.¹ This list was provided by the European Commission, Directorate General Education and Culture. In spring 1999, we asked the coordination teams to send us their project results (papers, reports etc.) and received those described below. The others were not yet completed at that time or coordinators did not respond.

¹ The compilation was carried out by Silvia del Panta (Cedefop).

Countries: United Kingdom, Finland, Greece, Ireland, the Netherlands.

Summary

The project was undertaken by six educational institutions from five countries. The aim of the project was to examine vocational education in these countries with a view to finding ways of improving its status and attractiveness.

The three main hypotheses were:

a) vocational education in general has a lower prestige than liberal education, because it is perceived to lack the quality traditionally associated with the latter;

b) liberal education at its best has a vocational dimension and vocational education at its best has a liberal dimension; hence it makes sense to integrate both;

c) there are already examples of such integration, but they need to be examined critically and articulated more clearly.

The methodology had three dimensions:

a) the philosophical dimension examined the meaning of liberal education in a modern context. It tried to restate the liberal ideal in a vocational mode and to integrate the liberal and vocational tradition by reconciling academic excellence and economic usefulness, combining sake with practical competence, past heritage with present society needs;

b) the historical/hermeneutic dimension facilitated the analysis, comparison and synthesis of documentary importance. In this manner, key texts in the development of vocational education were identified, analysed and compared in each of the five countries involved;

c) The ethnographic dimension examined good practice examples in the integration of the liberal and vocational traditions, through selected case studies in each of the five countries.

General observations, comparisons and conclusions arising from the research

The two terms 'vocational' and 'liberal', in the context of their development over the centuries, are often employed to denote two different approaches to education, but a precise definition is not easy. There are two distinct educational philosophies: the first, which values knowledge for its own sake, the second, which puts a premium on the way this knowledge is used in practice. They have two educational methodologies, a formal, abstract approach or a concrete, experimental one. The two terms are sometimes seen as opposing and even mutually exclusive, but they can be complementary and mutually supportive.
The starting point of PAVE is the fact that vocational education traditionally had a low status in comparison with academic or general education. In the past, vocational education was often associated with manual or low prestige occupations and was oriented towards non-academic and sometimes socially disadvantaged young people. In choosing this starting point it was hoped that the project would identify factors which can enhance the attractiveness of vocational education.

The curriculum is the attempt to give meaning and to structure the world, to learn something about what is worth knowing and why it is important to make the effort. It is not only about knowledge, pedagogy and assessment, but also about values and relationships. ‘A good school needs to provide the young with a wider vision of values as well as knowledge and skills.’ (Lawton, 1998)

Vocational education was suitable for future manual workers, while general education was needed for future bureaucrats, managers and professionals. Nowadays, with the changing nature of work, these distinctions are breaking down. Young people should be educated as persons, not merely as workers.

Education for citizenship is not just a national priority, it is also crucial to the vision of what it means to be European. Young people have to be actively prepared for citizenship, both national and European. Transforming school into genuine communities, where people learn through living and doing as well as through thinking and talking, is the concrete expression of reconciling the liberal and vocational traditions by bridging the gap between the liberal and the vocational traditions.

The lower status of vocational education has its roots in the way society itself is organised. Vocational education should not only prepare technicians and skilled workers but young people must be given the chance to improve their status by being able to proceed to more meaningful forms of further and higher education. In this way they will find not only the opportunity to improve their vocational ability but also ways of enhancing their own human development.

The fundamental principle is that liberal and vocational education should be regarded as two complementary aspects of the same task and this task is to shape the individual. We need both the liberal and the vocational if we are to develop an educational philosophy and practice that will adequately serve the needs and aspirations of the human personality. The coming together of the liberal and the vocational has to be accomplished in the context of the various institutions, which have grown up in each tradition and which often strive to maintain their separate identities.

National case studies

England

The PAVE case study in England focused on GNVQs (General National Vocational Qualification), new national qualifications in 'general' vocational education that were first proposed in 1991 and introduced nationally from 1993. They were conceived as a major national initiative to upgrade vocational education in Britain. The study focused on two schools: an in-depth case study was conducted in Cranford Community School in Hounslow and a shorter support case study in Leigh City Technology College in Dartford, Kent. The findings are based on individual and group interviews (plus an informal discussion) with students, teachers, parents, management staff and career advisers. These schools, using GNVQ as their vehicle, have indeed narrowed the status gap between vocational and academic education, and they have reduced it by a truly significant amount. There are five overlapping and interacting factors in the schools' success:

a) the more or less immediate relish of 'GNVQ way' with its emphasis on active, responsible and meaningful learning;

b) the experience of good outcomes, especially personal growth in the short-term and access to higher education in the mid-term;

2 Vocational courses and qualifications introduced in 1992 as a substitute for, or an addition to, certain other vocational qualifications. They are studied by approximately 25 per cent of 16-18 years olds nationally. GNVQ can be taken at three levels: Advanced, Intermediate and Foundation.
c) care, ingenuity and patience in dealing with the fears and misconceptions of teachers, students and families;

d) setting high entry requirements;

e) a culture of support and recognition for GNVQ achievement.

The last three factors are, in a broad sense, 'managerial', and that suggests another valid and illuminating way of regarding the finding. We could say that success was produced by the interaction of three necessary conditions:

a) good management. The attitude of the heads and the senior teachers in these schools are determined, focused and deeply convinced: they really believe and they really concentrate. And, also, there is a progressive involvement of ever higher proportions of staff in GNVQ teaching, which is establishing a professional culture of critical respect for GNVQ in the schools;

b) good curriculum. This is the most important condition of all. The schools felt some initial confidence in the educational value of GNVQ courses when they adopted them, but the confirmation of that value from the experience of teaching and learning them has been crucial to sustaining the upgrading project. Essential further confirmation of value came from the growing acceptance of GNVQ by universities;

c) the formal equivalence of vocational and academic. The formal stipulation of equivalence between GNVQ Advanced and A Level may be seen as the government's contribution. Official equivalence was used to powerful effect in these schools; of course, without good curriculum and good management this would not have meant much.

The experimental unit launched, in the autumn of 1996, its 'minimised' form of double qualification programmes (DQ)³ where vocational students study only those academic courses which are indispensable for taking the minimum form of the Matriculation Examination concurrently with their vocational studies. Representatives of the schools were informed about the PAVE project, the aims of the study, the partners involved, the focus on the case study and so on, and both schools immediately expressed their willingness to participate. The case study is based on theme, interviews and informal discussions with principals, teachers and study counsellors and with 6 students from the vocational school.

The operational environment of Finnish vocational education is characterised by strict cultural and systematic differentiation between academic and vocational tracks and an uneven territorial competition between these. Under such conditions, cooperation, as a means of developing new forms of vocational education, is revealed as quite revolutionary and problematic. The Lahti experiment deserves admiration as a very pragmatic response to realities, which exist with all their accompanying irrationalities and cannot be changed locally. As for the attractiveness of vocational education – in the Lahti vocational Institute, in Lahti and in Finland in general – conclusions remain somewhat open.

Finally, it is worth noting that the Lahti model, in its very pragmatism, is far from

³DQ: a minimised form of the double qualification studies was launched in the autumn of 1996. Here the vocational students study only those academic courses which are indispensable for taking the minimum form (four exams) of the Matriculation Examination concurrently with their vocational studies. The DQ studies take 2-3 years; some are more intensive than in the regular vocational programmes. The DQ students study their academic courses instead of the common general studies, optional general studies and free-choice studies included in the regular vocational programmes.
representing an ideal solution to the problem of improving the quality of vocational education. For instance, for various practical reasons, academic lessons must be made the responsibility of the upper secondary school teachers.

**Greece**

The Greek educational system was changed significantly in September 1997; change is continuing and it is unclear what proposed changes will be applied in the future.\(^4\) The case study deals with schools in the Cassandra area of Chalkidiki. This is an area of slow-economic growth, with much emphasis on tourism. The case study is rooted in the evolution of the upper secondary schools of the area. Two lyceums were examined in the study: a technical-vocational lyceum and a general academic lyceum. The objectives involved an investigation of ways in which the change from a technical-vocational lyceum to a unified lyceum would affect the existing balance between the two schools in the area. A satisfactory relationship had already been created between them. The unified lyceum is shaped by characteristics of general or liberal education and has no elements of vocational training. There is a strict refusal of students, parents, professionals and other social agencies to accept the reform, indicating that it does not contribute to the upgrading of vocational education. A liberal dimension can contribute positively to vocational education but the critical issues are the form it will take and the teaching methodologies, which will be used.

Liberalisation in vocational training must be shaped according to the terms of vocational training; the same principal must apply in the general lyceum where vocationalisation should be introduced in a form which does not transform a general lyceum into a vocational one. The concept of a Unified Lyceum does not mean a one-way route; both influences can coexist. School should reflect the real-life concerns and interests of their students, while teaching and learning should be personal and concrete and take into account everyday situations and modern conditions. Finally the world of the school should be more closely connected with the world of work, and work should be interpreted broadly as comprising activities that are unpaid as well as paid. In the end, it was not possible to draw final conclusions from the study, but the findings go some way towards indicating the expected results of the research project.

**Ireland**

The Irish case study is based on the 1995-1997 cohort of students in two schools in different parts of Ireland. School X has a staff of 25 teachers, does not have a guidance counsellor or a home-school liaison officer. School W has a staff of 45 teachers and it has a guidance counsellor and a home-school officer on the staff. This case study proposed to examine the parity of esteem of the Leaving Certificate Applied\(^5\); this is a modular course unlike other Leaving Certificate programmes which comprised two-year long courses. The first part of the study focuses on the meaningfulness of the programme as a learning experience for the students themselves. The second part considers the manner in which the school authorities and the state authorities manage the programme so as to raise its status both within and outside the school.

The Leaving Certificate Applied provides young people with a learning experience that they consider being worthwhile and meaning-

---

4 TEE: this is the New Act (secondary technical-vocational education) that changed significantly the Greek Educational System in September 1997. Under this Act, vocational education has been given the same general aims as primary and secondary education. Vocational schools were also abolished and these were replaced by technical-vocational/ institutions.

5 Leaving Certificate Applied is a modular course whereas the other Leaving Certificate programmes comprised two-year long courses. It is semesterised in that the two-year programme is divided into four segments with ongoing assessments at the end of January and May each year. It is cross-curricular in that students are required to carry out a total of nine cross-curricular tasks on topics that aim to enable young people to relate what they are learning in the modules to their own life experiences.
ful. They become more empowered through developing personal effectiveness, and a sense of community. The position of Leaving Certificate Applied students highlights the disparity of esteem, reflected in both academic and vocational traditions, for people who become marginalised from the formal education system.

Students appear to have joined the Leaving Certificate Applied because they were advised to do so by their teachers or because they wanted to avoid the pressurised learning environment associated with traditional examinations.

While they have benefited educationally from a changed learning environment, they now find themselves facing three major barriers in getting back into mainstream schooling:

a) barriers of structure, in that they are confined to a limited range of further education courses no matter how well they perform in state assessments;

b) barriers of prejudice based on a materialistic value system that places possible future personal power and influence above the dignity of the human person;

c) barriers of didactic learning/teaching methodologies that are not conducive to experience-based active learning.

There are indications from the case study that the majority found the barriers so great that they opted out of the formal system and settled for low-skilled jobs or unemployment depending on local labour market conditions.

The Netherlands

In contrast with other European countries there are no intentions or initiatives to integrate the vocational and general education systems in the Netherlands. The purpose of this case study was to find out if MBO (secondary vocational education)\(^6\) succeeds in qualifying their students for the labour market as well as for further study and citizenship. In consideration of the main issue of the PAVE study, linking general and vocational, the Dutch study focused on general aspects of the MBO curriculum. Vocational education should not only prove itself with regard to job preparation, but also with regard to personal development, social education and development of broadly-skilled, independent citizens. Dutch secondary vocational education gives most of their graduates a very good starting position in the labour market. This results from the good mix of theoretical and practical education, practical activity during a substantial part of the course, and collaboration between MBO and employers. Between 20-40% of MBO graduates continue their study in higher level vocational courses.

In the case study two types of students can be distinguished. The first group can be characterised as ‘late-developers’; they did not succeed in primary school or junior secondary for a variety of reasons and they ‘use’ vocational education as a second opportunity to realise their ambitions. In the second group of students are those who have known for many years what kind of job they wanted in the future and who have had small jobs for family and friends. Many students enter MBO as a consequence of selection; this implies that not all of them in MBO have made very explicit career and job choices.

The main question of this study was: how does MBO succeed in preparing their students for social participation and citizenship? MBO success is in delivery of skilled workers and the most important aspect of social participation is succeeding in the labour market. The student’s future life is not just a working life and it is not inconceivable that general cultural capital, instead of broad job skills, will become increasingly important in the labour market. Vocational education still has to prove that passing on social and cultural capital is also possible by working in a vocational context and by learning by doing. On the other hand, MBO is secondary vocational education in the Netherlands. Education in MBO takes two to three years and it is organised in four sectors: technology, economics, services and health care, agriculture and the natural environment. In school the subjects and other learning activities are very much related to occupational practice.
hand we might wonder if general education succeeds in educating critical and independent citizens. In this respect both systems have to develop new styles of learning and teaching.

A European network of national reference structures for vocational qualification: a feasibility study (NATNET)

LdV Id. 3742

Coordinator: The European Institute of Education and Social Policy, Jean Gordon and David Parkes, c/o Université de Paris IX-Dauphine, Place du Maréchal de Lattre de Tassigny, F-75116 Paris, France, E-mail: ieeps@dauphine.fr

Partners:
- David Parkes and Jean Gordon, European Institution of Education and Social Policy, France;
- Leonard Bill, the City and Guilds of London Institute, United Kingdom; Helen Honk-Kreft, the COLO Foundation, the Netherlands;
- Johan Hougr-Thiis, Ministry of Education, Norway;
- Hannelore Fielhauer, Ministry of Labour, Austria;
- Burkart Sellin and Jens Bjornavold, Cedefop.

Countries: European Union and European Economic Area.

Summary

The EIESP (European Institution of Education and Social Policy) managed a Leonardo-funded project, NATNET, from 1996 to 1998, which was designed to contribute to the transparency of vocational qualifications by establishing a framework for concrete cooperation between expert bodies engaged in awarding, accrediting and developing vocational qualifications at a national level. NATNET was linked to a pilot project, NETREF, established to set up reference structures in the partner countries and pilot the conclusions of the feasibility study. Cedefop contributed its expertise to the work of both projects.

The main objectives of NATNET are the following:

a) to establish the working framework for a network of reference structures among the European Union and the associated countries with the intention of removing obstacles to the transparency of vocational qualifications;

b) in the context of such a network, to assume the function of developing and providing information on vocational qualifications on a transnational basis by establishing a simple methodology to enable data exchange, a human interface and the use of available information;

c) to develop the network in such a way that other countries may be easily integrated, extending the ‘feasibility element’ of the investigation from the original six countries to the European Union and associated countries.

The Austrian and Norwegian case studies

These two countries’ case studies were selected to include one new EU member-state and one of the EEA countries.
The project aimed at investigating the feasibility of the creation of reference structures among the range of public and private constituencies (relevant ministries, local authorities, social partners, intermediary bodies, etc.).

Therefore, the intention was to co-operate to produce in-depth analysis of the issues at stake. It allowed NATNET to test the outcomes and conclusions of the first feasibility study in specific national contexts.

The approach was one of information gathering, analysis and feedback into the NATNET model of information development and exchange.

Information gathering in the two countries took place through:

a) working with an expert in each country;

b) carrying out a survey through interviews with key actors;

c) official and research documentation on the system;

d) discussions and debate at the national conferences.

The analysis and feedback was carried out through:

a) developing the analysis with the two national experts;

b) feedback through bodies and organisations interviewed;

c) the national conferences, which were designed to be a forum for discussing and testing the hypotheses to date.

Two national conferences were organised in each country during 1997. The aim was to test the outcomes of the interviewing in the country, to discuss the on-going hypotheses of NATNET concerning models for reference structures in a specific context, to bring together organisations, bodies and agencies which normally do not work together and to bridge the constraints of the system by providing a neutral territory.

The principal points identified from the Austrian case study are the following:

a) mobility and Austrians: mobility is low in Austria, because unemployment is low and, as a result, people do not need to be mobile;

b) mobility and immigration: Austria is seen as an historic entry point for people coming into Western Europe from central and eastern European countries. Therefore mobility in Austria is associated with immigration;

c) transparency of qualifications: qualifications from some countries, Germany and Switzerland, allow a higher mobility between these countries;

d) at national level there is the need for an organisation to improve the availability of, and access to, information on transparency issues;

e) a national information system should have two main functions: to identify and map the current channels of information; and to develop an overview of international priorities with a view to persuading existing channels to take these into consideration;

f) there is a need for a review of the counselling services in terms of their goals and provision of reliable information;

g) in Austria, regulated occupations are important in the labour market, therefore understanding the detailed characteristics of qualifications offered in other states is essential;

h) developing mobility of employers, i.e. large firms located in states other than the home country increases the need for understanding qualifications.

The conference has not created formal outcomes; it has simulated a number of indi-
vidual organisational responses. The Austrian context is organisationally and politically complex, therefore, cooperation is not easy. It is clear that higher cooperation between the social partners is required.

The main points identified by the Norwegian case study are the following:

a) there is a long tradition of mobility among the four Nordic countries;

b) there is a tendency to avoid recognition of foreign qualifications. Initiatives taken to promote comparability and/or transparency encounter difficulties as soon as they start to work on detailed comparisons or specific areas;

c) it is important to find a solution to the recognition of qualifications of immigrants from countries other than the EU/EEA and, in particular, of refugees;

d) a co-ordinating reference structure among the existing institutions would be helpful. It should provide and acquire information, coordination, advice and updating, i.e. guiding people through the systems;

e) there is a need to simplify entry points and make the system more efficient. At the moment candidates pass from one body to another with too many organisations giving too disperse information;

f) the distinction should be maintained between the government setting rules and the market influence over supply and demand.

The outcomes of the Norwegian conference are:

a) the conference gave individuals and organisations an opportunity to know each other better with reference to their respective roles and responsibilities;

b) there is high-level interest from the National Centre for Vocational Guidance in the project and for the idea of a reference structure.

Conclusion

There is clearly a need to improve information channels and provision. A first task, suitable for a reference centre, would be noticing and mapping channels of information in order to be better placed to guide enquires through the system.

There is also an increasing need for higher mobility, and a condition for that is transparency. The results of NATNET investigations suggest that mutual recognition is nevertheless missing from the agenda. It is necessary to develop the mechanism to improve information flows.

For the partners involved, NATNET has allowed them to raise and debate issues of provision and exchange of information internally and externally among a range of national and sector organisations, which normally work parallel to each other but with little direct contact. The case studies were part of the surveys and feasibility studies. The main outcome has been to open up the debate in both countries so that the idea of establishing structures and mechanisms to improve transparency has been set higher in national agendas.

Quality appraisal and cost-benefit analysis in vocational training initiatives and structures.

LDV n: I/95/1/223/III.2a/FPC- Id.3908

Coordinator: CESOS (Centro di Studi Economici Sociali e Sindacali), Via Po 102 00198 Rome, Italy; E-mail cesos@mclink.it

Partners:

Countries: Italy, Germany, UK, Spain, France.

Summary

The aim of this project was to elaborate and provide a model for assessing continuing vocational training applicable to all European environments. In order to be applicable and operational, and therefore to qualify as a truly European instrument, the model had to meet the following requirements:

a) simple to use, also simple to learn for trainers and training agency staff throughout the EU;
b) to provide consistent meaning given to key concepts and simple, universal, and well defined tools and procedures;
c) to be flexible and applicable to a vast range of situations, sectors and organisational environments, as well as different geographical and cultural areas;
d) once applied, the model should be easily transferable and replicable in other situations;
e) for the above reasons, the model had to be minimal, i.e. consisting of a core that could be easily expanded and broken down according to special or local needs;
f) it had to be designed to ‘capture’ the quality of training schemes, as related to the different agents and actors involved, as well as the many levels, times, functions, etc. associated with the quality of their lifecycle;
g) finally, the model had to focus both on the process and outcome of training initiatives.

In this model, the assessment process tends to coincide with the training process itself, thus becoming an essential component of all the activities and skills involved in preparing, developing and implementing a training initiative. Moreover, the person in charge of the assessment is no longer necessarily an expert living and working in another field.

Instead, the model is finalised at making assessment of skills a widespread practice of the training provider; the person in charge of appraisal is ultimately the same one who co-ordinates the training scheme and should be able to rely on the assistance of all staff involved in its implementation.

The basic principle of the model is that the training initiative is a process and assessment constitutes an intrinsic component of the training initiative. The person in charge of scheme should be able to evaluate it. A framework of parameters and standards should therefore be set up, a priori, for comparative assessment of training supply quality and its improvement.

The model is structured as a varied set of ‘lean’, ‘flexible’ checklists, aimed at assessing total quality in training initiative, with special reference to continuous training. In this light, the model should be used during each time phase in the scheme’s evaluation: the ex-ante phase; monitoring activities; final assessment; and the ex-post phase.

The user is the provider of vocational services. However, the model may also be used by the other actors involved in the training scheme, e.g. the contracting firm, public authorities or bilateral organisations, potential ‘end users’ of the activities implemented, direct beneficiaries, or even the scheme’s financial backers.

The object of assessment is the training scheme itself. However, the model also allows an analysis of production processes at the training agency in charge of the scheme, in order to connect the training initiative to specific details related to the provider of vocational services. The model’s structure is illustrated as follows:

<table>
<thead>
<tr>
<th>Phase in Scheme</th>
<th>Actors involved</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Strategy</td>
<td>Provider-client/end-user</td>
</tr>
<tr>
<td>2. Planning &amp; Design</td>
<td>Provider-client/end-user</td>
</tr>
<tr>
<td>3. Implementation/ Monitoring</td>
<td>Provider-client/ trained end-user</td>
</tr>
<tr>
<td>4. Outcome/Impact trained end-user</td>
<td>Provider-client/</td>
</tr>
</tbody>
</table>
For the each of the above-mentioned phases, there is a checklist of key issues concerning the scheme’s quality. Those involved in assessment should reply to the questions contained in the list, adopting suitable standards, procedures and specific evaluation tools which depend on their initiative. There are two reasons for this choice.

First, only by allowing the user to choose standards, procedures and tools, could the Model aspire to be really universal, i.e. capable of adapting to all training providers and any social or cultural environment. Second, the creation, use and development of standards, procedures and tools whereby users assess the different aspects of quality, constitutes a major advance towards a solid, widespread culture of appraisal, which is the ultimate goal of the model.

For each group of issues in each checklist, quality appraisal may be summarised with a score (between 1 and 5), that reflects a simple qualitative scale (e.g. excellent, good, fair, poor, bad). The score should be interpreted as an index identifying the strengths and weaknesses of each cycle in a scheme’s life, and also as a means of monitoring quality improvements in comparable schemes over a period of time.

The score for each phase in a scheme’s cycle may also contribute to concise evaluation of the qualities of each phase, but also of the project as a whole. In this case, it is advisable to “normalise” aggregate scores by assigning only values between 1 and 5, in order to avoid overestimating phases embracing a larger number of checklists.

The model is completed by a brief ‘User’s Guide’ and a ‘List of Essential Information’, without which the tool cannot be employed to its full potential.

---

**Extended regional further training in Europe (ERFTIE)**

LdV. Id. 445.

Coordination: Andreas Schneider, Innovative Educational Planning and Support Company (Gesellschaft für Innovative Bildungsplanung und Förderung mbH), Gotlandstrasse 5, 10439 Berlin, Germany. E-mail: gbimbh@compuserve.com

Partner organisations:
- Wirtschaftsoffensive Bezirk Voitsberg (WOF), Austria
- Fremdenverkehrsverband Uckermark e.V. (FVV), Germany
- Castel Coldrano Education Centre, Italy
- Institut National pour le Développement de la Formation Professionelle Continue (INFPC), Luxembourg

Areas: Voitsberg (Austria), Uckermark (Germany), Val Venosta (Italy) and Ösling (Luxembourg).

Report of findings: Erweiterte Regionale Weiterbildung in Europa

**Summary**

The aim of the ERFTIE project is to question unemployed women in rural areas about their interests, wishes and attitudes and about the skills and qualifications they have acquired; the results of this survey should help to assess these women’s prospects of re-entering the mainstream labour market, either as employees or through self-employment.

A total of 280 women in the selected areas were questioned, and 60 of them underwent a skills analysis. The findings in terms of their individual educational and occupational histories as well as of their respective personal interests and ambitions provided a largely customised training recommendation for each of the respondents. Experts from the employment authorities in the relevant areas and local training organisations are currently...
Leonardo da Vinci I programme: project synopses

comparing these recommendations with the actual training opportunities that exist at the present time and with the realities of the regional labour markets with a view to drawing up concrete training plans for the women, which would open the door for them to return to work.

As the study goes on, the intention is to use this survey, the skills analysis and a range of further-training modules to create a standardised system that can also be used in other comparable parts of Europe.

The methodology used to reintegrate women in rural areas into working life should have the following characteristics:

1. The women advising the respondents should come from the same social milieu as the latter;

2. The target group should be asked about their interests, attitudes, wishes and skills;

3. A special range of training courses should be developed and implemented;

4. This range of courses should be made available in other comparable parts of Europe.

First of all, the advisers (mentors) were trained and familiarised with the planned course of the project. As part of this training process, they were given a course in communication and counselling.

During the period from July to December 1998, these mentors tried to survey as many unemployed women as possible within their local areas and to recruit them for further participation in the project. Those who were interested were invited to an information session; the local sessions were held in December 1998 and January 1999. Their purpose was to inform the women in greater detail about the object and planned course of the study and in particular about the planned skills analysis. The mentors reported considerable irrational anxiety among the women when they first learned of the skills analysis. At the information session, however, the women were made aware that a housewife and mother possesses a considerable range of occupational skills which can be harnessed by a customised programme of further training.

In February 1999, skills analyses were conducted in each of the four areas. The analysis involved various tests and exercises. On completion, an initial feedback interview took place with each of the women. From the evaluation of the results, there emerged an individual skills profile for each participant, comprising various personal, social and methodological skills. Thereafter, the main focus was on the strengths of each woman and in particular on the question whether these strengths were sufficiently well developed. Weaknesses only came into play in cases where there was some indication of a need for compensatory training courses.

The next step was to formulate training recommendations for each individual woman and to pass these on to the partner organisations. During the current phase (1999), the partner organisations are examining the training recommendations with experts from the employment authorities and from bodies responsible for the provision of further training and comparing the recommendations with local market conditions with a view to drawing up concrete training plans in a second feedback interview with the women.

At the present time (1999), the implementation of the individual training plans has begun, so it is too early to make any pronouncements as to whether the aim of the project has been achieved. Nevertheless, the evaluation of the skills analysis has shown that it gave more than 90% of the women a clearer perception of their own future and raised their self-esteem.

Training processes in small and medium-sized companies

LdV Id. E/1224.

Coordinator: The Basque Institute of Research (IKEI), Antonio Corral Alza, Avda.de la Libertad 20, 2004 San Sebastian, Spain, E-mail: acorral@ikei.es
The general aim of this research is to analyse the reasons of the limited access for the European SMEs to continuing vocational training (CVT) activities, and to identify effective policy lines for the improvement in the training strategies and for the development of programmes directed towards the European SMEs.

The study comprises five sub goals, as follows:

a) investigation of the training practices of small and medium-sized enterprises;

b) identification of the problems and the difficulties that small and medium sized enterprises encounter in their training processes;

c) elaboration of a qualitative analysis of the characteristics of the training offer and of the programmes of support put in practice;

d) comparative analysis of the situation in different countries;

e) recommendations regarding the strategies of support and encouragement, which are most appropriate to the process of training in small and medium-sized enterprises.

The study was designed using a regional approach for two main reasons: first, because there is still a relevant lack of information about the existing CVT practices on a regional basis and, second, because the regional approach allows a more precise treatment of the questions relating to the training supply and to the functioning of the programmes of support than a study conducted at national level.

The research is based on the survey of 75 manufacturing small and medium-sized enterprises per each selected region, and a qualitative analysis of the training supplies available to the same enterprises.

This study is divided into 4 part:

a) description of the surveyed regions;
b) training processes in SMEs;
c) analysis of the existing regional continuous vocational training systems in Europe;
d) assessment of CVT systems and barriers to training.

For a description of the regions surveyed see the final report

**Training processes in SMEs**

The available data show:

a) there is a positive relationship between size and training, very small enterprises carry out less training than small and medium enterprises;

b) the larger the enterprise, the more formal the adopted training approach;

c) training either at the request of the enterprise or the personnel is less intensively pursued in the larger SMEs;

d) the larger the turnover, more CVT activities are carried out and more formal the adopted training approach;
e) the highest proportion of enterprises active in training is in the regions of Iceland and Norway; the regions of the Southern peripheral countries of Spain, Italy, Greece and Portugal are less active in training activities; the remaining regions show a similar proportion of activity SMEs;

f) the regions where the SMEs have a larger percentage of training do not necessarily correspond to those regions whose enterprises are more active in training;

g) a large share of SMEs devote a relatively small percentage of their salary volume to the financing of their training activities;

h) different strategies are adopted by the different regional SMEs: the Italian regional SMEs prefer to devote a substantial amount of training to the benefit of a small share of employees. The opposite is adopted by the Icelandic or the Spanish regional SMEs, who prefer to train as many people as possible even if resources are scarce;

i) most of the surveyed SMEs (66.2%) point out that the training plans have to been elaborated by the enterprise without any aid from external sources and they have individual, annually defined training plans;

j) there are important differences amongst the different regions, due to the existence of ad-hoc policy schemes for supporting training plans.

The different regional approaches to training also provide important dissimilarity in the characterisation of the courses:

a) 50% of the SMEs with a training plan show a preference for custom made courses;

b) only 29.5% of the surveyed SMEs where training is carried out at the initiative of the personnel prefer custom made courses;

c) the use of self-study seems to rare amongst the surveyed SMEs, in the sense that whereas 24.1% of them state that they have used this type of course, 72% of enterprises say the contrary;

d) as far as size is concerned, the larger the enterprise is, the more important the personnel of the company itself and of training centres/associations are as providers.

Concerning the characteristics of the personnel trained, the survey data suggest the following:

a) the personnel that mostly benefit from training belong to the departments of production and management administration;

b) the larger SMEs and those with training plans show a higher diversification in the departments or professional levels of their trained personnel;

c) on average, the surveyed SMEs estimate that employees are willing to be trained;

d) the interest of employees towards training is higher in medium-sized enterprises and in those SMEs where training is carried out according to a training plan;

e) there are many contrasts in terms of departments and professional levels of trained personnel, probably due to the different economic specialisations and training situations amongst the surveyed regions.

The survey data show that only a minor percentage of the surveyed SMEs (31.3%) have received public financial aid. Most of these are larger SMEs and SMEs with a training plan. There is a strong correlation between receipt of public aids and the importance attributed to them: the regions where the aids are regarded as a determinant for developing training activities correspond exactly with those regions where the percentage of SMEs benefiting from aids is lower (the Finnish, Icelandic and Italian regions).

The surveyed SMEs are quite satisfied with the training activities carried out. The satisfaction indicated in the Greek and Spanish regions is particularly interesting attributed, since these two regions have the lowest percentage of SMEs active in training activities.
Analysis of the existing regional continuous vocational training systems in Europe

Several European countries, such as Austria, Finland, Iceland, Norway, The Netherlands and Spain do not have a national/regional legislative framework that regulates and defines CVT. They adopt a 'liberal' approach, where CVT activities are the sole responsibility of the private agreements reached between employers and employees themselves.

Other countries, such as Belgium, France, Greece, Italy and Portugal adopt a more 'interventionist' approach, in the sense that the public authorities play a primary, pro-active role. But there are also some differences between these countries: in Greece and Portugal we find a highly centralised CVT policy structure, where the regions do not have the capability to carry out an own regional CVT policy; in other countries, such as Belgium and Italy, there is a de-centralised model, where the main actors for planning activity and the administrative management of training activities are the regions. France is located in an 'intermediary' position; regional authorities can implement specific supports on CVT activities, though the main orientations and regulations of CVT policy are still primarily designed at central level.

The different existing situations are reflected in the different priorities of the national/regional CVT policies. This notwithstanding, it is possible to identify in most of the regions surveyed an increasing awareness of the importance of CVT for the competitiveness of national/regional enterprises, which explains its current priority status amongst policy makers.

Assessment of CVT systems and barriers to training

This section describes the most important information channels for SMEs relating to training, assesses the available information on training supply and public programmes as well as the suitability of training supply and training programmes to meet SME needs.

The most important information channels on existing training supply are business/sector associations and training centres/organisations. Other relevant suppliers of information are newspaper and suppliers of equipment.

SME assessment of the availability of information on training supply and public programmes suggests that SMEs regard positively information on training supply while information on public programmes is insufficiently regarded in all the regions surveyed.

The distinction by enterprise size and between SMEs that do/do not carry out training activities shows remarkable differences. The larger SMEs and those SMEs that effectively carry out training activities seem to value more positively the suitability of existing training supply and public programmes.

According to the general SMEs own point of view, there are three main reasons limiting the development of training activities:

a) high costs of training courses;

b) problems of internal organisation with reference to attendance at courses;

c) the bad quality/unsuitability of available training courses.

Two other also factors play a role,

a) the lack of interest of the personnel;

b) difficulties in identifying the enterprise's training needs.

There are also different perceptions on the above limiting factors from the SMEs: the small ones are more sensitive to high costs and the bad quality/unsuitability of the available courses; the large SMEs are more sensitive to the problems related to internal organisation.

It is important to underline the fact that SMEs do not perceive the lack of support from the government as an important barrier to training.
Perceptions of the barriers seem to be dependent on the regions surveyed. The experts differentiate between two main groups of barriers:

a) 'internal-to-the-firm', referring to the characteristics of SMEs, internal organisation and size;

b) 'external-to-the-firm', referring to the high cost of training for most SMEs, the lack of transparency that characterises most of the existing training markets.

One of the most feasible solutions to these barriers to training is the creation of inter-enterprise collaborative structures that could at least partly address the problems of insufficient size. It is particularly interesting to know which kind of courses are suggested by SMEs themselves to encourage their training activities. Non-training enterprises offer strong support for custom-made courses and have a better opinion of self-study courses as a suitable method for training; training enterprises resort more often to external open courses.

Conclusions

Having in mind European SMEs CVT practices and existing regional CVT systems, it is possible to suggest several lines of action for the different agents involved in CVT, SME employers, SME employees, CVT suppliers and policy makers.

Suggestions for SME employers and employees are as follows:

a) SME employers have to be conscious that any investment in the competence and skills of the workforce has to be seen in a long-term perspective;

b) training has to be understood as an element of enterprise general strategy;

c) employers have to be involved in the planning process of the enterprise's training policy;

d) SME employers have to acknowledge those employees who request and accept training, in order to motivate employees to take on training;

e) cooperation with other enterprises facing the same difficulties could be an appropriate tool for overcoming obstacles;

f) employees have to be conscious about the need to continuously develop their own skills/human capital during their life, not only as a tool for maintaining their job, but also as an instrument for improving their career prospects;

g) employees have to learn the principle that, in order to safeguard themselves, they have to increasingly contribute to training, even from their own means (for example through self-learning, using holidays).

Suggestions for CVT suppliers:

a) training contents and methodologies have to be continuously updated and improved, moreover, they have to be well aware of enterprises' training requirements.

b) the quality of training programmes has also to be continuously improved, not only from a quantitative but also from a qualitative point of view;

c) CVT suppliers have to make an effort to better inform and advise SMEs on the available options, basically through an intensification of their marketing efforts and an adaptation their language to SMEs.

Suggestions for CVT policy makers:

a) policy makers have to encourage awareness of SME employers/employees regarding the importance of CVT for the competitiveness of their enterprise;

b) future policy has to be designed from the enterprises' perspective, bearing in mind their needs, practices and requirements;

c) CVT activities cannot be isolated from the general education system, links between the two worlds have to be reinforced;

d) information and marketing on the available options have to be improved and ad-
ministrative procedures have to be shortened and simplified;

e) financing of SMEs investments in skill and training development has to be continuously encouraged and strengthened by public agents;

f) employees have to realise that they are the main actors responsible for their own career management;

g) tax relief is one of the most suitable means of support as it is based on the individual enterprise’s initiative and avoids inefficiencies;

h) public bodies have to set up methods and routines for the evaluation of existing CVT supply, so that its quality can be continuously improved and adapted to existing needs and requirements.

Training processes in lean learning enterprises with particular emphasis on lifelong learning

LdV Id.1822

Coordination: H.G. Bauer, Society for Training Research and Occupational Development (Gesellschaft für Ausbildungsforschung und Berufsentwicklung), Bodenseestrasse 5, 81241 München/Munich, Germany. E-mail: gabvab@aol.com

Partner organisations:

- Rubicon Associates Ltd. (Brian Swain), East Sussex TN7 4AR, UK, E-mail Rubicon@compuserve.com;
- Trigon Entwicklungsberatung Ges.mbH (F. Glasl), Sankt Peter Hauptstrasse 208, A-8021 Graz, Austria, E-mail friedrich.glasl@entwicklung.com.

Countries: UK, Germany and Austria.

Summary

In this study three companies were examined: a distribution company in the UK, a large drug store in Germany and a private bank in Austria.

The study examined the operational leanness of the three companies and the development of their business organisation in terms of organisational culture and lifelong learning.

The case studies show that there are no criteria for defining a 'lean' or a 'learning' enterprise. 'Lean thinking' amounts to the concentration of business policies and decisions on the dimensions and processes of wealth creation in the sense of a 'restriction to essentials' involving specification of value, avoidance of waste and of needless effort and expense, focusing on customer requirements and continuous improvement.

A lean learning organisation is characterised by the following attributes:

1. On-the-job learning is supported by planning, implementation, evaluation, working parties, improvement and innovation teams, flat networked management and flexible documentation and, last but not least, by a culture of trust and support.

2. The learning process is designed to take account of the company’s medium- and long-term aims and is facilitated by open and non-hierarchical channels of communication.

3. Supporting staff development is an important company aim and helps to secure the future of the organisation.

The study began by examining the following quantitative factors.

Company development phase: pioneering phase -> differentiation -> integration -> association describes the process by which a business and its style of management develop from a rather informal organisational system into a single focused entity.
Cultural diagnosis: 12 cardinal points within an enterprise. Each of the twelve cardinal points complements one of the others, and they may be represented as polarised pairs of qualities:

- striving for progress but nurturing tradition;
- adopting a visionary approach but striving for efficiency;
- prepared to take risks but seeking security;
- establishing rules and order but always ready to innovate;
- serving single-mindedly but always adaptable; and
- running a tight ship but anxious to promote the common good.

The stakeholder-centred approach: the stakeholders in a business are its customers, its suppliers, its owners or shareholders, its staff and society at large.

Corporate learning, as a means of optimising key processes and as an expression of a company’s stakeholder-centred approach, is at the core of any staff-development strategy. The study examined the importance that the three businesses attach to training, how they identify learning needs, the available training opportunities, the learning processes and how the companies use and recognise the skills and knowledge acquired by their staff.

Aids to corporate learning: the study identified the principles, structural elements and measures that encourage and support corporate learning. A distinction was made between the core and support processes on the one hand and the managerial processes, together with cultural and social subsystems, on the other.

In a ‘lean-rating questionnaire’, six constituent elements of lean enterprises were assessed:

- the human face of the organisation and the priority it accords to its staff;
- the principles of lean production practised by the organisation;
- the pull principle (company policy driven by customer demand);
- the process-flow principle (avoidance of needless effort and expense);
- the muda principle (avoidance of waste);
- the principle of continuous improvement.

Curricular analysis of training programmes: the study categorised company training courses by subject, time input, target learning outcomes and methodology and drew inter-company comparisons.

A qualitative examination based on structured and open-ended interviews supplemented the quantitative indicators. This qualitative analysis related to the company’s development phases, the respondent’s concept of learning, the learning activities in which staff engaged, the place of learning processes within the fabric of the company and the instruction methods used on the training courses. A ‘training questionnaire’ was used to obtain various assessments of training needs and the value of in-house training. Experts from the project team used the collected data to evaluate the extent to which the principles of ‘be lean and learn’ were in balance within the analysed companies.

The individual findings for the three analysed companies cannot be presented in the context of this summary; for details of the study, please see the project team’s report.

Conclusions

The three enterprises featured in the study are by no means object lessons in the perfect execution of a think lean policy. Be that as it may, the study has produced a number of suggestions as to the learning and training implications of a business strategy that is primarily driven by economic goals.
Lean thinking is not an organisational model, although organisational lessons naturally can and must be drawn from it; in fact, it is primarily a matter of attitude. For that reason, the study devoted particular attention to the cultural side of company development.

It is fair to say that the three analysed businesses are at different stages in their development, not only in general terms but also, and more especially, in terms of their individual functional elements.

It is plain to see that, in cases where ‘lean thinking’ is the prevailing philosophy or the ideal that shapes the corporate culture, businesses will tend to seek a value-adding unity of purpose through common ideas and visions. The point is that ‘thinking lean’ does not mean tightening the application of formal rules or optimising systems of centralised control; on the contrary, it is all about the identification of all members of an organisation with its fundamental ideas and values.

Special importance therefore attaches to the issues and requirements arising from this approach regarding the nurtured and spontaneous development of common modes of behaviour and communication styles and regarding a common understanding of the significance and aim of the work performed by the various departments within the organisation.

Virtual enterprises in initial vocational training (ISIS – OSIRIS)

LdV D/97/2/00057/EA/III.2.a./CONTP

Coordination: ISIS project: Wiesbaden Institute of Education (Pädagogisches Institut Wiesbaden) in the Hessian Regional Institute of Education (Hessisches Landesinstitut für Pädagogik).

Term: December 1997 to April 2000

Summary

‘Virtual enterprises’ are business structures which have been created as a response to new competitive demands. They are companies which conduct their business through the Internet or loose associations of independent companies which trade publicly under a common name but whose organisational links are administered exclusively by means of information and communication technology.

The characteristics of virtual enterprises are an extremely customer-centred approach, temporary forms of work organisation, decentralised organisation of the problem-solving team and the exclusive use of the Internet/Intranet or Extranet instead of a fixed place of business.

Three types of virtual enterprise

1. Type A: a virtual enterprises is constituted on the basis of an existing pool of compa-
nies whose management teams know each other (trust).

2. Type B: where a company is short of particular skills, it brings in an external partner, but only for the lifetime of the virtual enterprise.

3. Type C: a virtual enterprise is constituted by companies which have not previously had any dealings with each other, so it is not founded on mutual trust; this is the least common form of virtual enterprise.

Inhibiting factors: the parties lack experience; specialists are tied to a particular company; trade unions are sceptical; it is a complex venture; obstacles arise in the course of cooperation.

Skill requirements for staff of virtual enterprises

- Specialised technical skills: knowledge of ICT (familiarity with applications and networks, knowledge of operating systems, the ability to create and maintain intranet and web pages and familiarity with communication software), linguistic ability and cultural awareness.

- Key skills are: awareness of problems, enterprising mentality and behaviour, a sense of responsibility and the ability to be a team player, to act on one’s own initiative, to take independent decisions and to create an atmosphere of mutual trust.

Virtual enterprises create new forms of work and new workplaces; there are no steady jobs in the traditional sense any more; the demands on employees depend on the work in hand; within a continuous training process, inputs occur as and when required.

Team design is crucial to the success of virtual enterprises; educational, methodological, procedural and behavioural standards have to be defined and established.

Examples of virtual enterprises

- The Virtual Company is a loose association which currently comprises 14 independent small and medium-sized Swiss businesses from the realms of information and telecommunications; these companies form a fixed pool of skills and experience (Type A).

- Virtuelle Fabrik Euregio Bodensee is a combination of 27 companies (large, medium-sized and small) around the shores of Lake Constance.

- Systemhaus Seitz, with 250 member businesses, is a virtual enterprise in the German-speaking countries.

- Personalvermittlung Newplan is a service which finds work for freelancers; it currently employs 150 people.

- PUMA Sportartikel (Deutschland) focuses on the development, design and marketing of sportswear. The logistics and manufacturing of the products are entrusted to a global network of partner companies; a new virtual enterprise is set up every time a new product is introduced.

The organisation of vocational training in virtual enterprises

Virtual training is designed to complement the conventional forms of training. Training loses its stationary character and is networked. Appropriate learning software has to be developed, as must web-based training strategies which allow rapid curricular changes to be effected through the Internet or Intranets.

Media-based learning is the key to success

It is possible to organise a system of vocational training within virtual enterprises. With a fixed pool of employees and instructors, teachers and pupils, a virtual learning community can be created as a mirror image of a virtual enterprise, with each member able to formulate and satisfy his or training needs.

There are various providers of staff training who can meet the needs of virtual enterprises. Users learn the techniques and key skills they require for work in virtual enterprises. Virtual teams form themselves into learning
communities and can also use these technological resources to make their teamwork more effective.

Schools can offer their teaching material through the Internet as a supplement to formal lessons; in other words, a virtual enterprise of type A or B is developed when pupils and teachers work together in a team on the computerised material.

**ISIS project**

The ISIS project was developed in partnership with eight European institutions (see above). The aim of the project is to establish virtual enterprises in the domain of education and training.

The following are the main points regarding the implementation of this project.

- The creation of websites – a public Internet site with general information on the project and a closed Intranet for exchanges between project participants.

- Discussion boards are considered indispensable for communication on technical matters and on questions of content and organisation.

- Many interesting proposals were made at the start of the project, but the establishment of a market-research institute to survey the eating habits of young people in Europe was the only one to be implemented. The input from the surveyed pupils, however, was limited. Because of a lack of agreement among the project participants about a further virtual enterprise, the project management team decided to create its own virtual enterprise. The aim of this venture is the production of a CD-ROM on virtual enterprises in vocational training.

The accompanying OSIRIS project (see above) is based on a cooperative model involving self-determination, autonomy, initiative and shared responsibility.

In order to evaluate the ISIS project, OSIRIS established eight study packages, with various questions under each heading:

1. collection of general data from the respondents;
2. new company structures and initial vocational-training needs, decision-making processes in virtual enterprises and their procedural implications for the vocational-training system;
3. process management and vocational training (e.g. activities, resources, skills, interfaces between the various functional areas of the ISIS project, efficiency and the cost-benefit ratio);
4. communication structures and cooperation procedures in virtual enterprises and their implications for initial vocational training;
5. development of employees' identification with their work and improvement of vocational-training activity;
6. cooperation between cultures and prospects for European integration of vocational-training systems;
7. continuous organisational-development consultancy;
8. information technology in virtual enterprises and IT requirements within the system of vocational training.

**MOSAIC: Managing diversity – innovative research towards mainstreaming equality**

LdV Id.: 1783

Coordinator:
- Professor Teresa Rees, School of Policy Studies, University of Bristol, 8 Priory Road, Bristol BS8 ITZ

Partners:
- Alison Parken, University of Bristol, UK
Countries: Ireland, Italy, Netherlands, Sweden, United Kingdom.

Summary

The aim of the project MOSAIC is to help companies in Europe to become more economically competitive by enhancing their use of human resources. The approach is to learn from case study employers using or introducing a human resource management approach known as 'managing diversity'. This is a model which has been largely developed and implemented in the United States. It has some characteristics in common with the European equal opportunities approach known as 'mainstreaming equality', but there are important differences, too, which the project has analysed.

The principal objectives are the following:

a) to clarify the concepts of managing diversity and mainstreaming equality;

b) to conduct case studies of employers identified as managing diverse workforces;

c) to analyse the results and disseminate them widely.

These objectives have largely been met. A core research team from five Member States has:

a) prepared a series of papers on managing diversity and mainstreaming equality, some of which have been published;

b) distributed the papers to a wider group of ‘validating partners’ such as personnel organisations, employers, trade unions, equality agencies and business development agencies in a wider group of member states to disseminate to their constituencies;

c) prepared background papers on equal opportunities in the respective Member States as a context for analysing the case studies;

d) conducted theoretically sampled case studies of employers managing diverse workforces;

e) analysed the results individually and thematically;

f) clarified the similarities and differences between the two approaches;

The case studies number thirteen, with most of the companies falling within the EC definition of 'large', being more than 250 employees; the exception is an Italian manufacturing company with 120 staff. They were selected to allow comparisons across sector and country and they included:

a) public sector health authorities;

b) post and telecommunication companies that were either new or ex-public sector;

c) white goods, computing and other manufacturing companies;

d) multi-national financial service sector companies.

The case studies in the Mosaic project were identified as examples of employers with active diversity policies. Some stressed this fea-
ture in their human resource management approach or their mission statement in their general or recruitment publicity. Some were actively involved in initiatives or projects with equality agencies. The researchers drew on analyses of company documentation and statistics, and interviews with key actors, plus, in some cases, staff to identify the key elements of the diversity approach.

The key elements of a managing diversity approach were identified as follows:

a) equality vision. Equality as part of the employers' mission culture and value systems, and it should be familiar with company policy;

b) consultation and ownership of equality. Many of the organisations had conducted surveys of their employees to identify barriers thought to impede their progress. Managers at all levels took the findings seriously. Workshops, seminars and training were common features. One of the outcomes was that diversity among women and among men was recognised. Policies that suited some were recognised as not necessarily benefiting all;

c) respect and dignity of employees. The case study employers placed a high premium on the personal dignity of employees. This meant that the culture was one that would not tolerate sexism, stereotyping or harassment of any kind. It was regarded as essential that work relationships were based on mutual respect, and that members of staff were aware that discrimination would be not tolerated;

d) reconciliation of work and family life. The employers tended to be pro-active in recognising that employees might have domestic and family responsibilities and sought to accommodate them. This included paying for or providing childcare and allowing flexibility in hours worked. Family were seen as a positive aspect of employees' lives rather than a hindrance.

e) challenging the long hours culture. Imaginative approaches had been developed in some of the organisations to the issue of time. Creating a culture oriented towards productivity rather than presenteeism was a feature of such approaches. Teleworking from home was one strategy used.

There are clear differences in motivation and approach between the case studies. Those in the early stages of developing diversity policies, and those who have to implement such policies principally because they have an American or multi-national corporate culture committed to diversity, tend to focus simply on gender and address overt discrimination such as racial harassment. They restrict their scope to recruitment, promotion and some aspects of work organisation and culture. By contrast, those at the other end of the continuum have a much wider remit in terms of characteristics: they focus more on developing the individual regardless of their ascribed characteristics. This is expressed through advertisements for recruitment and training programmes aimed at those with international competence. The knowledge of customers, especially ethnic groups, is seen as vital to addressing customer need. Managing diversity for such employers moves beyond human resource management to the development of a market agenda and, in some cases, a social policy agenda. One of the Swedish companies saw addressing racism in the workplace as a contribution to addressing racism in Swedish society more generally.

While all companies had a reputation for managing diversity, the extent to which they embraced the full range of equality dimensions varied considerably. A few had moved little beyond gender but had at least embraced gender pro-actively. Some had engaged with racial harassment as an issue but without valuing racial differences as an asset. Few had innovative approaches towards disability, sexual harassment or age. Indeed, the more sophisticated employers in terms of developed policies and practice shied away from equality groups and used a discourse of valuing the individual, ignoring rather than addressing group disadvantage. This is given as a rationale for not monitoring in some cases. This vision of diversity as individually focused is one of the fundamental
differences between managing diversity and mainstreaming equality.

Most of the case studies are from the private sector and include examples where diversity has been embedded into the organisation and culture. One clear finding is that those employers where diversity was embedded at the inception of the organisation appeared to be particularly successful in establishing a diversity culture.

Advantaged not disadvantage (AND): A project to establish new models of initial training for disadvantaged young people based on the assessment of current provision in 5 EU geographical areas

LdV Id.3886

Coordinator: SQW Segal Quince Wicksteed Ltd, The Grange, Market St. CB4 5QG Cambridge UK, E-mail: mailbox@sqw.co.uk.

Partners:
- the economic and development consultants of SQW, (UK)
- the Research Unit for Sociology of Education (RUSE), Finland;
- the National Social Research Centre (EKKE), Greece.

Countries: Finland, Greece and the UK.

Summary

The principal aim of this project is to establish new models of initial training for disadvantaged young people based on critical assessments of the current conditions in 6 EU geographical areas.

However, the final report concerns three countries: Finland, Greece and the UK.

Some highlights (Finland, Greece, United Kingdom)

Respondents were invited to value the quality of training design, delivery and development. Another objective was to consider the most important external influence on training development, and to suggest possible changes.

All countries share common results: confidence about the content of training was particularly high, but confidence about preparation for work and follow-up was very low. Many respondents did not comment, negatively or positively, because they did not have enough information:

a) definitions of 'disadvantaged' in the three countries differ. In Greece and Finland some organisations do not have formal definitions of disadvantage. In all three countries the commitment towards disadvantaged young people appears very individual and fragmented. Young people needing support are not a specific target group;

b) young people and employers do not play a decisive role in training design, and trainers would like to play a greater role than at present. There is no evidence of a design of training with reference to good practice elsewhere or external comparisons;

c) in all three countries there is little confidence in the quality of vocational guidance. Criticisms are made of pre- and post-training course assessment and guidance support. Most assessments are carried out by training providers in all three countries;

d) young people feel that assessment does not take account of their needs and strengths. Opinions on final assessment experience are different: positive in Finland, patchy in the UK, and poor in Greece. Follow-up systems were not found in any of the three countries.

e) formally valued and recognised training outcomes are funding driven. Policy mak-
ers agree that outcomes are limited and narrow, but respondents underlined a need to broaden outcomes to include social, educational and personal development aspects;

f) formal accountability is almost exclusively with the commissioner and training provider, not with the beneficiaries. It focuses on setting targets rather than focusing on the engagement of young people, good practice, and benefits to young people;

g) quantitative and qualitative monitoring is taken seriously by all agencies in the UK; this is not observed in Greece and Finland. Respondents would welcome greater formal accountability to the beneficiaries of training;

h) contractual cooperation is rare in the UK and in Greece, and absent in Finland. Training and social-care agencies do not work closely together. UK respondents are more involved in cooperation than in Greece and in Finland, where the systems appear more obstructive and respondents are more suspicious of such arrangements. Formal processes of cooperation do not exist in all three countries;

i) budgets are allocated according to projected needs and priorities and to the particular type of training programmes already in place. In the UK and in Finland joint-funding arrangements are increasing. In all three countries the major funders of initial training are national governments. Funding structures and authorities are considered to be remote, centralist and inaccessible to implementers or other stakeholders. In the UK and in Finland the negative impacts of compulsory training policy caused concern.

**Conclusion and recommendation**

Respondents in all countries mentioned government policies and priorities, EU directives and funding requirements as factors to be considered in relation to training design and development. There were also many other factors such as regional and organisational policies, lack of information on youth require-

ments, local needs and local agency management/board priorities.

In summary, the following possible solutions have been identified at national and international level:

a) **definition of disadvantage.** First, a review at national level is needed to arrive at a more specific definition which is relevant to interventions needed. Policy makers have to ensure that definitions are workable. Second, at EU level, the definition of disadvantaged groups should be positive and holistic. After this, an accreditation of individual assets, deficits and needs for assistance should be identified. A development team should be employed to examine what is required to achieve this;

b) **knowledge of disadvantage.** Policy makers should develop stronger national standards for measuring knowledge, skills and competences by a range of criteria. Annual awards should be established for regional centres of excellence and visits, exchanges, and secondments to transfer knowledge should be funded. Commissioners and training providers should be consulted by a group of young people and should establish national systems on the basis of registration networks, chartered organisations, twinning networks, etc. Another important point is the development of a training structure for agencies across the country. At EU level twinning relationships should be established between commissioning and training provider agencies. Interaction on the basis of clear development exchange bids should be developed;

c) **commitment to disadvantage.** Policy makers should commit themselves more at national level and ensure quality provision. Commissioners and providers should foster young people’s involvement in training development, knowl
dge development, joint delivery etc. Funding should not change with political shifts or public opinion. At EU level there is scope to improve national provisions via more demanding European requirements. A European team should review and develop more meaning-
ful definitions of, and criteria for, funding for young marginalised people, involve key beneficiaries in design and development, support monitoring and evaluation and assess impacts and achievement. A development team should also examine how this could be implemented and monitored;

d) design of training. Solutions at national level could be origination of standards for planning and design, of feasibility and piloting of new methods, and the examination of practice elsewhere.

Requirements should be:

- effective control and constant monitoring of working methods;
- involvement of young people and stakeholders in the design, appraisal, awarding and monitoring of contracts;
- assistance for the commissioners to implement such development;
- at EU level, a funding of three yearly awards to one area in every country for joint agency bid should be considered. Aims are: to develop and achieve an improved design of programmes as suggested above; to disseminate the methodology and approach; and to monitor and evaluate the impact and changes;
- attracting and marketing: at national level policy makers should establish agencies to support tailored marketing approaches to young people as ‘training consumers’. Peer-marketing possibilities should be explored to raise awareness in school of vocational training options. At EU level, programmes should be developed to identify pilot projects that explore the development of better marketing strategies of training ‘to develop attractive and accessible training for young people’;

e) guidance and assessment. Policy-makers should guarantee that career guidance and advice sessions are available for every young person, via trained careers personnel, independent of the training provider. Policy makers are responsible for introducing criteria of progression, rewarding such progression, setting up new standards of initial and ongoing assessment, and further appraisal of individual talent, strength and ability by independent assessors. At the EU level, it is important to guarantee that every young person gets the opportunity of initial, ongoing and final assessment;

f) delivery of training. A national a review of quality is necessary. The following initiatives should be undertaken:

- to establish national maps to explain how the entire process works,
- better methods to link supply to demand in the training domain,
- guidelines to select and monitor trainers,
- utilisation of external examiners, young people, employers in the selection process,
- examination of employability success factors of different kinds/ models of training,
- review of incentives and pilot progression reward systems to maximise continued participation,
- new regulation for structural funded training at EU level,
- any training-supported course must have evidence of relative local demand,
- every training course must give a marketing guide/map tool to young people and employers that explains what is offered and what could be expected from the training course.

g) training outcomes. A review of outcomes includes the measurement of how inputs affect outputs, of incentives for commissioners and trainers to broaden scope, and of progress made by individual starting and
personal development changes in outcomes. At EU level there is a need for structural funds to extend outcomes. Also important is the utilisation of the external examiner system to ensure quality evaluation.

h) accountability, management and steerage. Policy makers have to draw up criteria for the satisfaction of the beneficiaries, which the implementers must meet as part of targets. External examiners linked to local areas should advise on the development of accountability. National reviews should examine the impact of trainee feedback on affecting improvement and favouring changes. At the EU level it seems necessary to:

- examine the adequacy of monitoring and evaluation in ensuring accountability,
- develop support systems for projects to design appropriate monitoring systems,
- foster collaboration and partnerships,
- establish commission agencies for the promotion of inter-agency networks,
- reward projects that employ cross agency resources and management,
- review how/if structures facilitate/ obstruction collaboration,
- reward the actions,
- examine good practice in details and disseminate models.

A European directory of contractual multi-disciplinary design for training partnership should be elaborated which includes core information about features and contact details (also on the Internet).

i) funding. National reviews of the impacts of funding, more incentives by identifying good practice and quality inputs are considered as solutions at national level.

j) other measures are to:

- provide incentives for multi-disciplinary/joint resolution of current problems,
- develop systems for consultation throughout planning and reviews,
- change the nature of responsibility, attainment of attendance, tenure, qualifications, etc.,
- penalise delays.

**Route counselling as a means of improving the access to and effectiveness of training and employment initiatives for deprived groups in the labour market**

LDV n: B/95/1/223/III.2.a/FPC – Id. 3898

Coordinator: Ludo Struyven & Jos Mevissen. HIVA Higher institute of the labour studies. Katholieke Universiteit Leuven, 2E E Van Evenstraat 3000 Leuven, Belgium. E-mail Ludo.Struyven@hiva.kuleuven.ac.be

- Johan Wets.
- Giovanna Altieri, Italy.

Countries: Austria, Belgium, Greece, Ireland, Italy and the Netherlands.

**Summary**

Route counselling is conceived as a dominant movement in the area of training, guidance and employment measures towards an indi-
Leonardo da Vinci I programme: project synopses

individualised, longitudinal approach. New forms of reintegration for the (long-term) unemployed have been developed in several countries. The common trend is that, far from being isolated, training and job placement activities are more and more embedded in an integral scheme, aimed at re-integrating various disadvantaged persons or groups in regular jobs through an intensive, systematic approach known as 'route counselling'.

The subject of such 'route counselling' can be an individual person or a target group. This approach involves different organisations or actors together deciding the route. It is increasingly seen as the key factor in reintegration strategies for disadvantaged persons or groups. In addition, the demand side of the labour market has come to discover 'route counselling' as a method of recruiting, training and selecting new personnel from target groups, such as ethnic minorities, and reintegrating women and the long-term unemployed.

The aim of this project is to analyse how far the new approach is being implemented, which instruments and services are involved, to consider the role of success and failure factors and to assess the extent to which different types of practice are transferable. The analysis in this report is based on the current debate and state of the art in six Member States: Austria, Belgium, Greece, Ireland, Italy and the Netherlands.

This report comprises five chapters:

a) chapter 1 gives an introduction to the definition of the key concept, and highlights the key dimensions and basic characteristics of route counselling;

b) chapter 2 provides an overview of the actual situation on route counselling in the six countries, and a broader overview of the institutional and labour market context;

c) chapter 3 deals with the specific situation of route counselling in each country, since the cases from the six countries do not demonstrate just a single type of route counselling project;

d) chapter 4 focuses on the critical factors and the consideration of strengths and weaknesses based on good example;

e) chapter 5 identifies the common functions and tasks necessary to implement route counselling. It provides a profile of the professional roles associated with implementing the core elements of route counselling in the practice.

Over 45: Causes of exclusion and the role of lifelong learning.

Summary

The impact of population ageing on employment and on the labour market is one of the most pressing issues confronting European society. On the one hand there is an increase in the average age of the economically active population in the EU; on the other, the continuous lowering of labour force exit thresholds and the existence of age discrimination.
in the labour market, means that people over 40 are regarded as nearing the end of their working lives.

The European Observatory on Ageing and Older People (EOAOP) was established in 1990 to monitor four key policy areas:

a) incomes and living standards,
b) health and social care,
c) social integration, and
d) age and employment.

The first major EOAOP report identified five relevant forms of discrimination concerning the over-45s, as follows:

a) early loss of employment,
b) discrimination in the recruitment process,
c) exclusion of the older unemployed,
d) exclusion from training,
e) discrimination at retirement age.

This study has provided a picture of the approach of four Member States (Spain, Italy, Sweden and Finland) towards continuous training / life-long learning. The consolidated experience and tradition in educational interventions of the Scandinavian countries may be very important for the rest of the EU, but also Spain shows what can be achieved, even from a relatively low base, when the political element is present.

Recommendations of the research are the following:

a) at EU level, the Commission should disseminate examples of good practice and encourage the Member States to develop continuous training/life-long learning;

b) at national level, each Member State should create a national strategy on life-long learning / continuous training, demonstrate a good practice in the public sphere and, introduce special initiatives such a ‘knowledge lift’;

c) at the enterprise / organisational level, the social partners should emphasise continuous training and its importance for the economy;

d) At the older-worker level, these have to update their skills and to take advantage of the education and training opportunities, which are available.

In the cases examined there are substantial differences among the countries, reflecting the different approaches between north and south. In the two Nordic countries there is already a history of public commitment to training and acceptance of the principle of lifelong learning. These countries have developed a partnership model between governments, municipalities, trade unions and workers. The initiative in Sweden constitutes a good reference for the other European countries, because it shows that even the most excluded older workers can be drawn into continuing education by specially targeted measures.

In Italy, on the contrary, there is no national legislation on life-long learning, participation is low and only since the early 1990s was this recognised as an issue. Spain also records a low participation rate; however, it is more advanced than Italy in terms of vocational training and development of a national strategy for life-long learning. Spain has created a vocational-training system linking the Ministries of Education and Labour to the social partners. In 1997 Spain started a four-year implementation of continuous training agreements, which covered a wide range of training activities.

The 12 case studies (three in each country) chiefly reflect the national frameworks; however these are not national in a narrow sense due to the presence of several multinational enterprises. The report included an analysis of the ‘over-45’ labour market, an analysis of the causes of early exit and of income support mechanisms, and an analysis of adult educational systems, with particular consideration of vocational training mechanisms and lifelong learning practices.
The labour market among 'over 45' workers and lifelong training systems: country reports

Finland

Unemployment is a substantial problem in the more advanced age groups; the 45-64 year group registers higher unemployment than average.

There is a substantial proportion of early retirements: in 1995, the percentage of pensioners in the 45-54 age group was 11.6%, in the 45-49 age group 36.7% and in the 60-65 group 83.9%. The main reason for early retirement is invalidity.

Approximately 40% of people between 40 and 45 years old only have a compulsory school certificate. Social-security provides the unemployed with a benefit system that accompanies them up to early retirement age. Preventive measures are missing and the unemployed over 50 have no access to training, in contrast to younger age groups.

48% of the entire 18-to-64-year population takes part in adult education; this percentage is constantly rising. There are two types of adult education:

a) voluntary adult education covers just 25% of the population group and has a mixed form of funding;

b) personal education covers 70% of the population group and is aimed at re-qualification. It is financed by social security institutions and insurance companies.

The concept of lifelong learning was introduced in the Finnish program in 1995. The main objectives are:

a) continuous training,

b) the promotion of cooperation between work and educational institutions,

c) increasing knowledge in the labour market

d) the development of the European scope of training.

The most important institutions of lifelong learning are the open colleges. They were founded at the end of the 19th century and by 1990 they were 278 in number. Their principal objectives are:

a) to help people in their personal development,

b) to create cultural equity, improve skills and provide vocational training and complementary basic education.

The users are normally graduates, service workers rather than manufacturing workers, and people over 50.

Italy

In Italy there is a low employment rate; in 1996 it was 52.1% compared with the average of 60% to the EU. The unemployment rate for the more mature age groups is lower than in other EU countries. The highest percentage of people seeking a job is among women, though, after 55 years, the proportion is similar between the two sexes. Compared with other developed countries, there is a higher rate of long-term unemployed. The proportion of old people seeking employment decreases with age. People with higher qualifications remain employed longer than those with lower qualifications.

The Italian social-security system protects the working position of almost all dependent workers with a stable contract ('job for life'). This should undergo important modifications, and include a development of active work policies, including vocational training for young and old workers.

The demand for workers with a precise qualification has led to consideration of the role of training in the production process. In the context of reform of its welfare system, training policies are perceived as a potential innovative lever for labour market policies.

The so-called '150-hours' course was established in 1973, following an agreement with metal workers, stipulating the 150 total hours of paid training added to the same number of
hours of the workers' own free time. This can offered a lot of workers the opportunity to get the basic education that they missed.

The ministerial decree no 455 of July 1997 'Adult education. Education and training in primary and middle school' represented an important initiative. It aims to promote collaboration between school and local communities, the world of work and the social partners, and also to activate an integral system between professional education and training.

However, it is not easy to outline the characteristics of continuous training in Italy, because this mechanism is new and still under definition.

Spain

Spain records a very high unemployment rate both among young and old people. There are two types of contracts specifically aimed at the 'over 45s':

a) the permanent contract: this kind of contract, which was revised in 1997, foresees:

- the elimination of the requirement that an individual be registered on the unemployment list for more than a year;
- the right, for the contracting firm, to a discount on the company's fee payable to social security and
- the elimination of the obligation for enterprises to maintain the same personnel for at least three years.

b) the substitution and replacement contract for early retirement: this is a measure to support youth employment. Its purpose is to foster the contracting of unemployed workers to substitute workers who opt for early retirement at the age of 64 (anticipating retirements by a year).

More than 80% of unemployed 'over-45' have taken advantage of this form of contracting that is generally capable of covering the lowest qualifications.

With the industrial crisis of the 1970s, the employment promotion fund (FPE) was created to implement re-insertion policies, fundamental for the re-employment of workers under 55.

The Spanish continuing training system is organised into three areas: initial vocational training (FPR); occupational vocational training (FPO); continuous vocational training (FCO).

In 1997 Spain started the four-year period for the application of the continuous training agreements. This is a combination of training actions carried out by the enterprises, workers or their respective organisations, aimed at improving skills and qualifications and also the re-qualification of workers.

In recent years, the theme of continuous vocational training has been at the centre of interest for the government and the social partners for two reasons: first the recognition of the strategic value of training to increase economic competition, and, second, for the role that FPC can carry out in e social promotion of workers.

The concept of lifelong learning has a vague definition in Spain, because it can encompass a wide range of activities

Sweden

In the post-war period until 1990 the unemployment rate was between 1 and 3%, afterwards it increased to approximately 8% and, in 1997, it reached 9.8%. Most of the unemployed women and men come from the manufacturing and the public sectors. Most affected is the 55 to 64 age group. Those over 45 have a lower degree of education: 83% of the long-term unemployed have a compulsory school certificate (39%) or a vocational school diploma (44%). Those most at risk are women with a low education level.

In Sweden, early retirement means a permanent invalidity pension given to people between the age of 16 and 65 whose working capacity has been permanently reduced by a quarter as a result of either illness or other
physical and mental disablement. In 1990, it was calculated that invalidity pensions awarded to the 60 to 64 age groups were six times greater than for the 45 to 54 age groups. This peak in early retirement reflected the program of professional rehabilitation conducted by the social-security offices as well as the specific crises recorded in the Swedish economy.

Lifelong learning is intended to combine education and learning processes that last throughout the working life. For Sweden we can talk of two generations of lifelong learning approaches: the first one is more humanistic, aimed at improving the quality of life, while the second, which was developed in the 1980s, is more linked to the economy.

The principal objective is to create 'schools for everyone', where knowledge and aptitudes can be developed. However, adult education does not only consist of public schooling, but there are also employment training programs targeting unemployed adults and people in a state of occupational risk.

A new initiative of the Government, the 'knowledge lift' aims at substantially reducing unemployment. The main targeted groups are the people between 25 and 55, who attended or completed three years of upper-middle school. The number of unemployed attending this program is much more pronounced than in any other program aimed at adult education: only 20% of the participants were not unemployed in the last 7 years; of these 28% are 'over 45'.

**Conclusion**

The following points emerged in this study:

a) lifelong learning is an historical, theoretical and practical model of adult education, focusing on the development of the capacity for, and pleasure of, learning and on the quality of life of individuals as well as of the community;

b) educational institutions based on lifelong learning are to be found in places outside the work environment;

c) continuing professional training includes professional up-dating and organising activities, as well as courses in the workplace; it is based on different logical and pedagogical assumptions from lifelong learning;

d) in Italy and Spain we cannot really speak of lifelong learning, but the area of continuing training for adults, in the workplace and also outside, is close to the concept of lifelong learning we find in the Scandinavian countries;

e) both the notions of lifelong learning and continuing training are wide-ranging terms that encompass numerous concepts and activities. In Italy and in Spain continuing training is limited to the workplace: government and the social partners have only recently begun to underline the potential aspects of permanent adult education in relation to production changes and employment crises;

f) the high rates of unemployment generated different reactions: in the Scandinavian countries there is a demand for an educational system for adults, focused on professional re-qualifications and following a more active role in labour market policies;

g) in Italy and in Spain there is an interest in the development of adult educational systems which are more focused than in the past on training 'during the whole length of working life' and, according to very recent developments and agreements, on professional re-qualification.

h) the effects of the interest expressed in lifelong learning cannot be evaluated yet because consolidated practices are still being redefined in Sweden and in Finland, and interest arising from previous experiences is being developed in both Italy and Spain.
Lifelong learning policies in European cities and new employment opportunities for disadvantaged people (POLLlis)

Summary

The main aims of this study were:

a) investigation of major lifelong learning initiatives promoted by European cities;

b) developing tools and methodologies useful for those wishing to initiate new lifelong learning policies or to improve the ones which are already established.

The survey has been structured in two phases. The first is a comprehensive review of European learning cities in countries belonging to the EU and also outside the Community. The second is a comparative analysis of e cities selected as interesting cases and studied in greater depth.

Analysis

The following 20 points have emerged from the analysis of the practices observed and in-depth case studies:

a) lifelong learning is a priority in the regeneration and revitalisation programmes concerning cities and regions affected by substantial industrial crises;

b) most of the successful cases depend, among other things, on the formal legitimisation of city authorities to intervene in the field of education;

c) a formal declaration of willingness to be a ‘learning city’ or an ‘educating city’ often accompanies the effort of coordination and articulation of lifelong learning measures, although it is not rare to find similar policies undertaken in cities that have never made such a public declaration;

d) leading cities such as Barcelona, Turin, Bologna, Gothenburg and Edinburgh have generated affiliation and formal declarations by other cities of the same regions and countries, and have been an example for many others cities both in countries within and outside the European Union;

e) the term ‘Learning City’ is well established in the UK and in the Nordic Countries, but it is not easily accepted in the rest of Europe;

f) six main aims of lifelong learning initiatives at city level were already identified by the OECD study of 1992 “City strategies of lifelong learning”. These, which are confirmed by the POLLlis survey, are as follows:

- linking lifelong learning to community participation;
- creating learning for the whole life cycle;
Leonardo da Vinci I programme: project synopses

- co-ordinating learning institutions;
- making learning more accessible;
- building a learning strategy for local development;
- building a cultural strategy.

g) lifelong initiatives at city level seem to be more frequently embedded in broader policy areas, especially concerning employment and social inclusion of disadvantaged groups;

h) in terms of concrete content of initiatives, the two dominant trends consist of measures to integrate and improve information provision on all learning opportunities in the city and the systematic use of information and communication technologies (ICT) to improve access to the same learning opportunities. These two elements are then combined in multiple ways with other measures contributing to address specific target audience and priority areas;

i) citizens' requirements are considered very important, though in most of the cases the actions observed are the result of initiative undertaken by the city administration without any 'citizens' input';

j) experiments in most of the cities analysed show that a complete coverage of potential target populations is not easy. In most of the cities some classes of users (e.g. long-term unemployed, cultural minorities, women) have absolute priority;

k) strong political sponsorship is a precious resource for start-up and consolidation of an initiative, but it should be as broad as possible to guarantee sustainability;

l) broad representatives of relevant actors in a 'Learning City Board' may certainly help to include a more complete range of possible actions. However, effective policies are often based on a coherent and cohesive group of partner institutions with a limited number of priorities;

m) a politician, a company, an association or an institution take the most of the initiatives as part of their substantial or public relation priorities. Final users could do much more to support expression of ideas and suggestions;

n) coordination is another misleading keyword of lifelong learning initiatives at city level: there is coordination of informational sources on learning opportunities, but coordination of supply agencies is far from being achieved;

o) in some of the cities surveyed there is a 'demand-based' approach, i.e. segmentation of target populations and articulation of learning opportunities specifically directed to each relevant target group;

p) competition among initiatives and promoters in the field of lifelong learning seems to play a different role in a learning city: when the process is starting, competition may be disruptive; in a second phase, when some progress has been made, competition among promoting agents and concurrent initiatives could be a factor of dynamisation;

q) the availability of economic resources is an essential factor in guaranteeing the feasibility and sustainability of lifelong learning initiatives at city level, but it is not certain that additional 'dedicated' LL resources are really a necessary condition of success;

r) there is no culture of evaluation in the most of the cases studied by the survey;

s) owing to the lack of evidence from the initiative results, cooperation among cities is stronger in the design than in the monitoring phase. External comparisons of the results are rare. This gap of comparison builds the fundamental case for the learning cities forum initiative proposed within the PoLLlis project;

t) a general improvement in the availability of information and some rationalisation in the provision of resources for lifelong learn-
ing are necessary steps in building a sys-

tem dimension around the many individual

actions that can be observed in European
cities;

There is also a guideline offering a starting
point of common understanding and experi-
ence for all those people involved, at city level,
in the process of policy-making related to the
theme of lifelong learning. This Guideline
contains:

a) a simple conceptual framework in which
to place the process of policy-making in the
field of lifelong learning;

b) practical suggestions on how to define, de-
sign, implement and evaluate local lifelong
learning public initiatives in an urban en-
vironment, sometimes with concrete exam-

ples of cities studied in the PoLLlis sur-
vey.

**Learning City**

Citizens participate in policy-making to shape
their educational and learning agendas; the
city is responsive to its citizens needs and
provides appropriate learning environments
and opportunities.

"A learning city addresses the learning needs
of its locality through partnerships.... learn-
ing cities explicitly use learning as a way of
promoting social cohesion, regeneration and
economic development, which involves all
parts of the community."

The four main phases of a policy cycle are:

a) orientation: political priorities are accorded
the main aims of public policy and are the
result of the interaction between the main
social and political parties;

b) definition: how to implement the main
goals is the object of studies, comparisons
and selections;

c) implementation: actions and programs are
conducted and monitored, the beneficiar-
ies have to provide feed-back;

d) evaluation: this one is not an isolated
phase, but a continuous process which is
present in the other three phases.

**Policy orientation**

This study identifies six elements of policy
orientation that were confirmed by the
PoLLlis survey and can be found, to different
extents, in most city policies of lifelong learn-
ing:

a) coordination of education and training pro-
viders: cities can play an important role in
coordination, partnership and inter-institu-
tional integration of learning opportuni-
ties for citizens. They can break adminis-
trative and bureaucratic barriers and bring
together the public and the private sectors
with common objectives;

b) making learning more accessible: learning
has to be more accessible to all citizens,
but especially to the socially, culturally, eco-

nomiclly and physically disadvantaged;

c) building a training strategy: learning is
economically relevant, i.e. many lifelong
policies at city level are dedicated to the

generation of competences that would al-
low citizens to find relevant jobs and the
economic system to compete in the global
arena;

d) building a cultural strategy: a cultural
policy has to stimulate participation in cul-
tural activities and to promote an attrac-
tive cultural image of the city;

e) linking lifelong learning with community
participation: citizen participation in de-
cision-making processes may help to regen-
erate the sense of community that is lost
in large urban centres, but this participa-
tion should be closely combined with a par-
ticular attention to the needs of all citizens;

f) creating learning for the whole life cycle:
this idea is an essential part of the con-
cept of lifelong learning, but it implies a
special effort for the citizens that are out
of the education and training processes.
Focusing on the above aims there are many initiatives dedicated to aged people, such as universities for the third age or 'intergenerational' learning. The last has the advantage of not pushing old people into a special 'reserve'.

It is difficult to codify and standardise the policy orientation and there are four risks in this phase, as follows:

plain policy borrowing, without sufficient analyses of what can really be transferred to other city contexts and what cannot be transferred and should be eventually replaced;

ignoring previous experience developed elsewhere and basing priority definition on a local set of references;

concentration on the same aims and target groups, without consideration of the whole scope of lifelong learning;

ignoring or bypassing the limits of city administration institutional competences may bring to unsolvable institutional conflicts with the central or regional administration.

**Policy definition**

Policy definition has to do with considering and finally choosing the best ways to achieve the agreed goals. Several steps were taken to promote awareness and dialogue between citizens and the city as a learning environment:

- a) conducting in-depth analyses of needs, resources, and existing actors;
- b) reviewing existing initiatives and past experiences at local level;
- c) considering examples of concrete measures implemented elsewhere;
- d) defining action lines to implement policy aims;
- e) asking interested actors and citizens for ideas and suggestions;
- f) designing an implementation plan;
- g) developing criteria for selection of proposals;
- h) choosing concrete actions;
- i) designing a basic evaluation plan, clarifying criteria for success and monitoring approaches;
- j) constituting a steering committee and an operational structure to conduct actions.

**Policy implementation**

How to put policy into practice with regard to learning cities; the leading roles in taking forward the learning city from concept to reality are played by people and institutions.

The central ideas are:

- a) partnerships are the necessary basis of any lifelong learning policy and they have to reflect the 'vision' of the learning city, its main goals and agendas;
- b) central coordination to guarantee system impact and rational use of resources; many initiatives should be encouraged and even competition with each other can be productive;
- c) all possible options for finding lifelong learning must be considered, public and private, new project funding but also current funding for education, training, museums, libraries etc.;
- d) the learning city policy has to profile and position its human, intellectual and social capacity in relation to global markets;
- e) the learning city can be considered as a collective 'learning organisation': it has to identify, classify and assess the skills base of the community; to develop plans for effective training and learning arrangements to address 'skills' gaps; to widen the participation for excluded groups;
- f) the involvement of ICT (information and communication technologies) is important to increase participation in learning for
socially excluded peoples, in developing competences and in providing accreditation for informally acquired skills and experience.

Policy evaluation

There are three main steps in carrying out an evaluation; as follows:

a) exploring and planning: the key points are clarity about issues, what is the purpose of the evaluation, who is the audience, what kinds of things need to be focused on and how evaluation will be integrated into the implementation of the Learning City initiative;

b) data collection and analyses or carrying out the evaluation; the main stages involved are choice of the evaluation criteria, the choice of the methods and techniques to use for data capture, managing and co-ordinating data collection, including analysing the results;

c) utilisation and dissemination: it is important to give the participants a sense of how the initiative is progressing and what are its outcomes by running feedback events. Dissemination means not only a circulation of a final report, but different communication approaches such as short summaries of the evaluation; journal articles for other researchers; topical articles in the trade press; workshops for specific audiences; feedback seminars for key decision-makers; a web site, including an electronic discussion group (for example the PoLLlis Learning Cities Forum).

The PoLLlis Learning Cities Forum (LCF)

The LCF is not an association, but an informal, structured and focused gathering of cities that want to work together and to prepare the ground for other partnerships. It is a project generator, a city-based core structure that allows the validation of surveys and analyses.

It was established to design and run joint lifelong learning initiatives and to exchange experiences and opinions on a wide range of issues.

Role and structure

The LCF aims, by means of surveys and analyses, to facilitate the understanding of lifelong learning at city level, to plan and design joint lifelong learning initiatives, to support the formative evaluation of the individual and joint lifelong learning initiatives at city level and to carry out the intermediate and final dissemination of the outcomes to other interested cities.

Through the LCF, a collaborative learning environment has been created at European level which offers the opportunity for interested cities to gather and progress in their lifelong learning policies.

The LCF is composed of a research organisation, with a reputation and experience in the area of education and training, leading the study activities, and the city administrations, leading the learning cities forum that will orient and validate study activities.

Only a systematic research approach integrated with a validation exercise can produce effective progress in the area of policy intervention.

LCF's offers to cities

a) collaboration with consolidated research organisations;

b) 'value added': competence map of learning cities and benchmarking strategy;

c) exchange of information and experience in different fields of lifelong learning;

d) the outputs of the PoLLlis project: the outcomes of the many projects constitute the base on which the LCF is working, facilitating general methodology and studies on which to develop its activities;

e) communication tools available. The website of the project located at the IMFE (City of Granada) is regularly being updated and
introduces information about the general progress of the project and related issues. It will soon offer a chat facility for interested cities.

f) established general contacts with city representatives.

The PoLLLis project – lifelong learning policies in European cities and new employment opportunities for disadvantaged people- has the main aim of documenting and analysing new policies addressing social exclusion and exclusion from the labour market of the disadvantaged in society.
Targeted socio-economic research (TSER)

Project synopses

Targeted socio-economic research (TSER) invited, within the fourth framework programme, proposals for research from the European research community on three main areas of economic and social research:

i) science and technology policy,
ii) education & training (ET) and labour market integration,
iii) social integration and social exclusion.

The increasingly severe economic and social problems facing European societies required a more co-ordinated and better funded and targeted research and policy response than before. The main objective of the TSER (1994-1998) Programme therefore was to build up both the knowledge base and research infrastructure for high quality, policy relevant, comparative European socio-economic research at both national and Community level.

In Area II, research in education and training, the objective was to help link advances in science and technology and rapid economic/technological change to the effectiveness of the linkage/relationship between ET systems - in building up human capital, labour market entry and in-firm insertion/training processes for attracting and using high quality labour.

Within this broad area of research the programme had three main objectives - to strengthen the European research base and improve communication and networking amongst European researchers, to develop and strengthen the knowledge base and to improve its quality and comparability, and to help apply it to the challenges facing European economies and societies.

From 1998 until 2002, the key action (under the fifth framework programme), builds upon and extends the work carried out in the TSER programme. It is implemented through research and technological development (RTD) projects, thematic networks, research infrastructure and various types of accompanying measures.

1 The compilation was carried out by Silvia del Panta, Cedefop

2 For more information on the key action programme, please refer to Van den Brande (2000) in this report.

Introduction to the project synopses

The project synopses below have been selected on the basis of their relevance to the domain of VET. Several projects have also been referred to in several contributions of this background report. For completed projects, reference to core reports is made. Please note that most synopses are based on the original project abstracts. The contents of the final reports may differ from these descriptions. More information and links with each project can be found on the key action homepage.

For more information on the key action 'Improving human potential' visit the website of the Research Directorate-General, Directorate F - Human potential and mobility (http://europa.eu.int/comm/dgs/research/tser.html) or: http://www.cordis.lu/tser/home.html.

There you will find:

- General information about the key action, its major goals and means of implementation;
- A full list of projects that have been funded till now by the TSER Programme (4th Framework Programme) and by the key action, including the composition of consortia, coordinator addresses, synopses and results (if available);
- Publications, proceedings and papers (in some cases also for download);
- Forthcoming events and interesting links to several socio-economic sites, research associations, networks etc.;
- Discussion forum on various research issues.

Website: http://www.cordis.lu/improving/ and in particular the key action homepage: http://www.cordis.lu/improving/src/hp_ser.htm

Themes: Governance, funding and teachers

1. Education governance and social integration and exclusion in Europe

Co-ordinator:
S. Lindblad, University of Uppsala, Sweden
E-mail: sverker.lindblad@ped.uu.se
http://syrpa.khi.is/ed/egsie

Abstract

In the current discourse on education governance there appear to be two overarching contradictory positions:

1. new ways to govern education are necessary in order to obtain a more fair, sensitive and efficient educational system which is necessary in order to get a more developed society who will be able to fight exclusion;

2. new ways to govern education will lead to increased segregation and decreased equity and equality in education as well as in society and will increase the amount of social exclusion.

Both positions can be regarded as based on available empirical evidences in different contexts. Thus, it is of vital importance to analyse the restructuring of education under different circumstances and to make comparisons between cases in different contexts.

The overall objective of this research project is to identify relationships of education governance to social integration and exclusion of youth in European contexts and to discuss and propose policies on governance that will help
to minimise social exclusion and to maximise inclusion. The project will clarify different positions within this field and inform current discourses on education governance in Europe. Of special interest are students transitions between different levels or kinds of education or from education to work or unemployment. The more specific definition of the level or age of students depends on the structure of the current educational system in its socio-cultural context.

In order to reach this overall objective the following subsidiary objectives need to be fulfilled:

- to review and analyse current research on education governance and social integration and exclusion among youth;
- to describe and analyse different national/regional systems of education in the context of educational traditions and governance strategies in different European countries;
- to describe and analyse the discourse on education governance in international organisations and the potential impact of this on national discourses;
- to analyse experiences of and strategies to deal with new governance structures in education among politicians and administrators as well as teachers and head-teachers in different European countries;
- to analyse national and international statistics on social integration and exclusion related to education;
- to describe and analyse implications of education governance for the social integration and exclusion of youth;
- to compare different national cases in Europe with a focus on relations between education governance and social integration and exclusion;
- to inform and discuss results and conclusions of this study with education actors in different context.

### 2. Public funding and private returns to education (PURE)

**Co-ordinator:**
Rita Asplund, the Research Institute of the Finnish Economy, Finland
E-mail: rita.asplund@etla.fi

**Abstract**

The objective of this project is to study the impact of different systems of public financial support for school attendance on observed outcomes in the labour market, particularly in terms of the levels and dispersion of private returns to education and education-related inequality in earnings. This project moves into a territory not yet studied from the perspective of optimal investment in human capital, the role of student finance systems, school admission rules (free or selective entry) and school differentiation.

The project divides into four closely related issues as follows:

a) Analysis and comparison of wage and human capital structures and private returns to education between countries and within countries over time in order to uncover distinct trends as well as similarities and dissimilarities across countries.

b) Analysis of the impact of country-specific trends in educational returns of changes over time in underlying market forces (supply-side and demand-side factors), and of carefully differentiated measures of returns by type and level of education in order to highlight and compare national system of education.

c) Analysis of the structure and evolution of the national systems of education, admission rules and systems of financial support for school attendance to be used as an input in.

d) Analysis of the effects of differing systems of public support for cost of education to individuals and admission rules on the private returns to education and on earnings inequality related to differences in educational attainment.
The results of the project will be of value to policy-makers at both the national and the EU level. It will contribute to understanding the educational implications of the European integration process and to promote the relationship between education and training, the labour market and economic growth, which are set out as two problems areas where new knowledge is needed, and thus to reaching the short-term, medium-term and long-term objectives listed for Area II of the TSER programme. Results from the project will be disseminated via intermediate and final reports, user-oriented seminars and a Web site.

3. Teachers training, reflective theories and tele-guidance: prospective and possibilities in teachers training in Europe (thematic network)

Co-ordinator:  
Wim Veen, Utrecht University, IVLOS Institute of Education, Faculteit Techniek, Bestuur en Management, The Netherlands  
http://www.ivlos.uu.nl/reflect/index.htm

Abstract

This thematic network for teachers training aims to strengthen co-operation in research activities among the partners involved. The research will be carried out on reflective competencies training in initial teacher training for general secondary and vocational education, using teletutoring as an instrument in school based training.

For teacher training institutions will carry out comparative studies of the development of new practices using modes of tele-guidance. These studies will bring together experts in the field of reflection and those in the field of educational telematics in teacher training.

This research includes the following activities:

a) an inventory study of research activities in the field of IT related to the development of reflective competencies in training;

b) four preparatory studies on the use of telematics as a reflection aid. These studies will focus on:

c) development of instruments to measure the reflective skills;

d) installation of the technical requirements for the research;

e) development of hypothesis and research questions. They will focus on effects of telematic intervention of teachers trainers in the reflection process;

f) development of research agenda/ design for future research by partners involved.

Themes:
Learning and competences

4. DELILAH: Designing and evaluating learning innovations and learning applications

Co-ordinator:  
Joseph Cullen, The Tavistock Institute Evaluation Development, UK  
E-mail: edru@tavinstitute.org

Abstract

This project is about educational and learning innovation. It aims at understanding of educational innovations and, on this basis, gathering empirical evidence on innovative education and learning arrangements and developing specific methodologies and guidelines for learning. This broad aim is operationalised through the following objectives:

1. to synthesise the existing research on major cross-cultural, socio-economic and pedagogic factors in education and learning, including new learning arrangements involving learning technologies, and major national policies on education and training, with a view to identify theoretical and empirical gaps in current understanding and establish the consonance or match between major educational and learning innovations and the different learning patrimony or traditions as defined by the aforementioned factors;
2. to assess, in a transnational and cross-sectoral fashion, the contribution of different organisational settings of learning and accessibility of learning opportunities for less favoured groups;

3. to contribute to the development of appropriate policies in the area of education and learning by firstly identifying ways in which policies can facilitate the contribution of new educational and learning arrangement in accordance with the different learning patrimonies, and secondly promoting transfer and the exchange of results across the study areas.

4. to develop methodologies and guidelines for the evaluation of new educational and training arrangements and processes in four education and training sectors.

5. to provide methodologies and tools for more effective mixes of new training products, in particular those involving multimedia.

Publication:

5. European network for educational research on 'assessment effectiveness and innovation'

Co-ordinator:
Hans-W.J. Pelgrum, University of Twente, Center for Applied Research on Education, The Netherlands
E-mail: Pelgrum@edte.utwente.nl
http://www.to.utwente.nl/euaei/index.htm

Abstract

This is a thematic network of 19 participants who elaborate the structure for this research projects. The network aims to realise the following products:

- an electronic database (accessible via World Wide Web) containing information about characteristics of educational systems, descriptions of the participating research institutes, their research programmes and their research projects;

- integration and exchange of conceptual frameworks regarding educational indicators, and the use of expertise from the partners for producing national and European overviews of statistical information on education in mathematics, science and technology.

- exploration and identification of possibilities for cooperative pilot projects.

These products focus on the themes which are addressed in the TSER work programme (Area II), such as: development of output indicators, the 'general education' issue, cultural diversity, minorities, comparisons with Japan, and the USA, added value of schooling, multi-level educational effectiveness models, assessment of basic competencies, science and technology teaching, educational potential of new information technologies, scientific and technology literacy, implementation of science and technology options in education; and methods, tools and approaches relevant to the preparation, monitoring and evaluation of science and technology policies, and the performance of minorities in education.

The added value is the improvement in dissemination and accessibility of up-to-date information about ongoing and completed research in assessment, effectiveness and innovation.

The network focuses on primary and secondary education.

Publication:
6. Forum of European research in vocational education and training (thematic network)

Co-ordinator:
M. Kuhn, University of Bremen, Institut Technik & Bildung, Germany
E-mail: mkuhn@zfn.uni-bremen.de
http://www.itb.uni-bremen.de/projekte/forum/fock.htm

Abstract

The primary aim of this thematic network ‘Forum’ is the establishment of the European dimension specifically related to contents and methodologies of vocational education and training (VET) systems. In contrast to the organisational orientation of informal on-the-job training dominating the Japanese system for skill acquisition and specific task-related training dominating the United States a European dimension needs to embrace the traditional values of European societies embodied in the diversity of traditions, institutions, legislation and cultures that influence vocational education and training in the European Union. Forum associates experienced researchers and academics, in institutions responsible for VET-research and the training of VET professionals, from fourteen countries. The Forum will bring together researchers from different traditions, disciplines and cultures with the aim of defining and exploring a European dimension for VET. The Forum will also play a role in the dissemination of existing research, help to link the different networks of researchers and practitioners, contribute to the establishment of a transnational research community and will integrate the coaching and development of young researchers. It will contribute to:

- the development of a transnational research approach in VET;
- the development of a European dimension in VET;
- discover the cultural diversities as sources of innovative idea;
- improve the dissemination of research results in Europe;
- contribute to the development of a European research community in VET;
- find a European path for VET policy between unification and regionalisation as well as diversion and conversion;
- improve the co-operation between VET research and VET-practice.

The network will examine the pressures to increase the quality of VET, skill levels of those in VET, quality assurance, flexibility, and transnationality, while taking into account different responses to employer involvement, individual funding and changing work organisations.

Five Forum workshops are envisaged:

1. Common practices and values in VET,
2. VET and the labour market,
3. Organisational changes required of vocational training institutions,
4. In-company training and school to work transition,
5. The Learning Organisation.

In all cases the focus will be on the European dimension for research into the capacity for change and adaptation of education systems. Furthermore all FORUM members are involved in national, regional and European projects which will help to disseminate their case studies of good practice.

7. Implementation of virtual environments in training and education (thematic network)

Co-operation:
Juana M. Sancho Gil, University of Barcelona, Spain
E-mail: jmsancho@doe.d5.ub.es
http://xiram.doe.d5.ub.es/IVETTE

Abstract

The central objective of this project is to investigate the issues involved in the implemen-
tation of 'virtual learning environments' (VLE) in post-secondary public educational institutions, as well as in training institutions. The project will focus particularly on looking for a holistic view when tackling the main issues mentioned. Within this context, the key objectives of the project are as follows:

- to map out the teaching and learning approaches in VLE, especially those arising from combining face-to-face and distance education methods in traditional institutions and companies;

- to critically assess the impact of European diversity into international VLE, in relation to common elements of curriculum, language issues, and institutional adaptation of the E&T systems to open and distance learning;

- to contribute to innovation in public educational institutions in relation to the restructuring of its functioning, the co-operation with similar European institutions and with the private sector when implementing VLE.

The network will explore problems and will open perspectives for further research. This will contribute to understand the problems of the new VLE, and to promote innovation in educational and training institutions in a context of European integration and collaboration between institutions.

The intended outcomes are the following:

- Three empirical studies on issues, problems and practices in the following areas: (i) teaching/learning approaches in virtual open learning environments; (ii) cross-cultural and academic dimensions in European diversity and (iii) Institutional/organisational factors in fostering innovation on public institutions and training companies through the implementation of VLE;

- A conference with policy makers, teachers, trainers and representatives of educational and training institutions.

- A report on policy implications addressed to the users groups and the wide academic community.

8. Lifelong learning: the implications for universities in the EU

Co-ordinator:
D. Tsaousis & N. Kokossalakis, Pantio University- KEKMOKOP, Greece
E-mail: akokosa@panteion.gr

Abstract

The general aim of this project is to investigate how the universities in the EU respond to the concept of lifelong learning (LLL) and to analyse the structural and functional implications which the application of the concept is bound to have for the universities in the 'information society'. The study also aims to investigate and discuss policies and goals of the universities relevant to LLL and raise more questions of reformulation of educational goals and strategies at a European level.

The project will identify, analyse and discuss the actual forms of involvement in LLL of the universities concerned. In addition the research will explore actual and potential policies and strategies of universities referring to LLL and will compare them with corresponding policies and strategies of international organisations namely the EU, OECD, UNESCO and the Council of Europe.

The intended outcome is to produce seven national reports, three special reports concerning the major areas of the research outlined above and a major general report synthesising the results of the whole project within a European context.
9. New assessment tools for cross-curricular competencies in the domain of problem solving

Co-ordinator:
Jean-Paul Reeff, Ministère de l'Education Nationale et de la Formation Professionelle, Service de Coordination de la Recherche et de l'Innovation Pédagogiques et Technologiques, Luxembourg
E-mail: reeff@men.lu

Abstract

One of the biggest challenges to educational research and policy is providing relevant information regarding the education system's outcome at different levels. Student outcome indicators are of special interest as obviously this information is a primary criterion for different activities such as teaching assessment, quality improvement programs, evaluation studies, and steering (as expressed by the French word 'pilotage') the educational system. In the last few decades a major effort was exerted at the international level (e.g. IEA, OECD, EU) to develop student outcome indicators for comparative purposes. The most recent of these enterprises, the Third International Mathematics and Science Study (TIMSS) conducted by IEA between 1994 and 1996, exemplifies the progress that has been made.

In the next decade, a major source of information about education will be provided by a recently launched OECD-study in 26 countries (comprising all EU-countries, except Portugal), PISA (Programme for International Student Assessment). PISA addresses student achievement indicators in the fields of Reading Literacy, Mathematics and Science, together with indicators with respect to Cross-Curricular Competencies (CCC). In comparison with the classic contents of school subjects, CCC gain specific attention in a rapidly changing information society. In the field of CCC special emphasis has been given to 'Problem Solving' (PS) as a very central competence. The need for CCC such as PS indicators is clearly also necessary for studies that extend beyond school age, such as the International Life Skills Study (ILSS) dealing with adult competencies. All EU countries (and other European countries) participating in studies such as PISA or ILSS recognise that a common European effort in different parts of the studies is desirable. Consistent with this view, a Thematic Network on CC/PS is being created, directed to:

- connect policy needs with expertise and experience. This requires close co-operation between policy-makers and scientific experts;
- bring together experts from different disciplines who are working with different conceptual frameworks. By finding commonalities and enhancing synergy, new concepts and new assessment tools may be developed;
- stimulate and integrate more participation on both the political and scientific levels, with a special focus on South European countries. Ultimately this shall result in the outline of a larger project on CCC/PS.

10. Work experience as an education and training strategy: New approaches for the 21st century

Co-ordinator:
T. Griffiths, Education and Information Support Division, University of London, UK
E-mail: toni.griffiths@ucl.ac.uk
http://www.eclo.com

Abstract

The proposal is to analyse and develop work experience as a European education and training strategy appropriate to the changing economic and social conditions of the 21st century. Its context is the future and changing nature of work. Overarching questions concern the extent to which work experience can enable young people to understand and prepare for working life and the ways in which educational institutions and companies can work together creatively to deliver relevant learning outcomes.

The formal objectives of the project are the following:
to undertake a European policy study and review of work experience;

to develop a common framework and terminology for understanding work experience;

to undertake case studies of innovative work experience partnerships;

to compare outcomes and develop transferable models;

to develop European quality criteria and a quality framework for work experience;

to undertake an active dissemination programme.

Researchers from the six partner states will work collaboratively in a review of work experience as a vehicle for learning and on a study of current and future policy towards work experience in the 16-19 years age group. The other member states will be asked to join these exercises so as to build up a clear profile at European level.

The research work will focus on the 14-19 age group and will examine the aims, processes and outcomes of work experience in the light of changes in the labour market and trends in workplace requirements and organisation.

The aim is to analyse and test innovative approaches (including use of information and communication technology) to both domestic and European work experience. The methodology will involve researchers, enterprises and leading edge educational institutions working together.

There will be a particular concern with core and transferable skills and attitudes towards lifelong learning and therefore will be a focus on the development of quality criteria and evaluation procedures for work experience which can be applied at a European level.

The project will have practical, theoretical and policy outcomes and benefits. The products will include transferable models of good and innovative practice and will be disseminated throughout the EU and the central and eastern European countries. A series of workshops for key-decision makers will also be organised.

11. Work process knowledge in technological and organisational development

Co-ordinator:
N. Boreham, The Victoria University of Manchester, UK;
E-mail: nick.boreham@man.ac.uk
http://www.man.ac.uk/education/euwhole/home.htm

Abstract

This thematic network is concerned with the impact on the knowledge required of the workforce due to the changes that occur when organisations acquire greater flexibility and introduce new technologies in response to the pressures of competition.

Its main objectives are:

- to identify new working practices associated with these changes;
- to integrate European traditions for conceptualising the ways of knowing needed in the workplace to adapt to these changes – ‘work process knowledge’;
- to generate and analyse policy options for facilitating the development of this knowledge, including new approaches to learning in the workplace, the design of new technology and organisational development within enterprises.

By elucidating the knowledge required in the working environment, and by integrating European traditions for theorising this knowledge, the project will contribute to the development of a European social science infrastructure.

By developing policy options for facilitating the adaptation of the workforce to new working practices, the project will strengthen European science and technology policy in rela-
tion to the problem of achieving sustainable growth.

Theme: Enterprises and human resources

12. LATIO: In-company training and learning in organisations

Co-ordinator: Lennart Svensson & Ylva Kjellberg, Lund University, Sweden
E-mail: ylva.kjellberg@pedagog.lu.se
http://www.pedagog.dk.se/latio/

Abstract

The aim of the project is to develop strategies for enhanced competence development in companies in the EU. The research objectives are the follows:

- to describe and compare learning environments in companies active on the EU arena, within a number of sector and branches;
- to describe and analyse current strategies for in-companies training, organisational learning, development of core skills and competencies within these companies;
- to find and lift forward positive examples of conditions that create successful learning in organisations;
- to distinguish what are critical factors for developing new and successful strategies for in-company training, competence development and learning in organisations.

The project is carried out in an ongoing dialogue with reference groups, both at national and international level. The reference groups at national levels consist of representatives of national organisation for in-company training providers, employers federations and relevant trade union representatives.

The project is divided into four major phases:

- theoretical analysis and studies of contextual national factors;
- empirical studies;
- theoretical and practical results;
- evaluation and implementation of results

The practical contribution of the project is to propose structures and strategies that enhance and facilitate the creation of learning environments, and best practice for in-company training and learning organisations.

Publication to be expected:

13. The role of human resource development within organisations in creating opportunities for life-long learning – concepts and practices in seven European countries

Co-ordinator:
Saskia Tjepkema, University of Twente, The Netherlands
E-mail: tjepkema@edte.utwente.nl
http://www.eclo.org

Abstract

The objectives of the study are:

- to clarify the specific European outlook on the role which human resource development (HRD) in learning oriented organisations can fulfil in lifelong learning, and thus contribute to the discussion on a 'European model of lifelong learning';
- to provide a basis for further research on the changing role of HRD in work organisations;
- to provide practical guidelines for HRD practitioners throughout Europe on how to facilitate employee learning and thus assist their organisations in securing their competitiveness in a continuously changing environment.

The research looks at HRD departments in learning oriented organisations throughout Europe and how they view their own role in
stimulating and supporting employees to learn continuously as a part of everyday work (with the intent to contribute to organisational learning, and thus to enhance organisational competitiveness).

An attempt will be made to show different perspectives between HRD concepts and practices in European organisations and those which exist in the US and Japan.

The research will go into strategies adopted by European HRD departments in realising their envisioned new role. Consequently the research will analyse the facilitative factors as well as the difficulties (the inhibiting as well as conducive factors) they encounter during the implementation process.

In order to provide practical guidelines, the research aims to analyse how practitioners cope with these (inhibiting and conducive) factors.

To enhance the impact of the research, it is intended to publish (additional to the overall report and the case study report) a practitioner's guide. Furthermore, the results can be used in the ongoing discussion on the European ‘infrastructure’ for lifelong learning.

**Publication to be expected:**

### 14. DELOS – developing learning organisation models in SME clusters

**Co-ordinator:**
Ruggiera Sarcina, Fondazione Istituto Guglielmo Tagliacarne della Cultura Economica, Roma, Italy
E-mail: tagliacarne@eureka.it

**Abstract**

The research intended to offer a methodological contribution and operative instrument in favour of E&T and employment policies. Although European SMEs account for 71% of European employment they are unable to formulate detailed training strategies which can guarantee qualification adjustments and increased competition. Hence the need to focus the research on small-firms network (clusters) which represent privileged observatories for the analysis of employment and learning dynamics.

Considering the ‘clusters’ as a learning organisation permits, methodologically, to analyse the information flow and the interactions which, in the cluster, give rise to circular processes of competence acquisition, shared know-how, experimenting and progressive correction of collective intervention. In relation to SME clusters it is the group of SMEs, which acts as the Learning Organisation. It is the aggregation of SMEs on the whole which reacts to challenges of change by adapting in terms of technological professional updating, new professional skills, new service needs, new market strategies. The path followed by the ‘organisational learning’ is complete in the SME cluster circuit, but instead of taking place within one large company, it takes place in a number of enterprises and also involves a number of different bodies (companies, associations, training institutes, etc.). The ‘interorganisational’ learning processes which develop in the SME clusters have not yet been systematically studied from the point of view of implications of collective learning, shared development of knowledge and intervention models. Indications and ideas for further research come from studies on the dynamics of interorganisational collaboration in technological innovation processes, or from surveys describing aspects of entrepreneurial learning processes during the occasion of co-operative initiatives on topics such as, internationalisation.

It is opportune to focus attention on the distinct characteristics and on specific organisational learning processes, which arise through co-operation between SMEs, so as to clarify their nature and to build support methodologies to increase conscious interventions on these issues.

The project objectives therefore are:
verify the modalities through which the SMEs clusters intervene as learning organisation and investigate the organisational learning processes that arise through clustering;

give ‘working’ indications capable of supporting training and occupational policies in favour of SMEs methodology.

After a preliminary scouting phase, through an ad hoc methodology, 12 different clusters have been analysed throughout six different countries. Finally, the modelling phase provides to rationalise the overall results.

Final Report:

Publication:

15. Small and medium enterprises in Europe and East Asia: Competition, collaboration and lessons for policy support.

Co-ordinator:
M. Fransman, Institute for Japanese – European Technology Studies, University of Edinburgh, UK
E-mail: m.fransman@ed.ac.uk

Abstract

This two year study evaluates the competitiveness of European SMEs vis-à-vis their counterparts in East Asia (Japan, Korea and Taiwan), using enterprise benchmarking to identify the nature of their technological differences in selected low, medium and high technology manufacturing activities. The project traces:

- observed differences within comparable activities to variations in human resource availability, development and management;
- the strength and relevance of network linkages with SMEs and with large enterprises;
- the nature and sophistication of consultancy and advisory services;
- links with the S&T system;
- the financial system supporting innovation;
- and cross-national, national, local and municipal government initiatives to support productivity, skill development and marketing.

The detailed firm-level analysis and benchmarking allow the identification of ‘best practice’ models of SME technology development; it also provides data that can be used in statistical analysis to identify rigorously the extent and causes of deviation from the technological frontier. This will clarify the nature of the emerging competitive challenge facing European enterprises from the Asian ‘Tigers’, and the prospects for fruitful collaboration between them. The analysis of support systems in Asia, which are known to be strong and pervasive, but whose detailed operations are not well understood, lead to policy recommendations for strengthening the science and technology support system for SMEs and improving the efficiency of networks and clusters in Europe. The project creates a data bank on micro-level technological activities studied; this data base can later be expanded to other activities to provide inputs into S&T policy analysis in the EU. Local collaborators in each of the three Asian countries have been selected from local research institutes. The dissemination of results will be undertaken within Europe and Asia.

Publication:
16. Small business training and competitiveness: Building case studies in different European cultural contexts.

Co-ordinator: Alfons Sauquet, Fundación ESADE-Escuela Superior de Administración y Dirección, Spain
E-mail: sauquet@esade.es

Abstract

The objective of this research is to identify learning processes that lead to increased competitiveness of small and medium sized enterprises (SMEs), and to describe how these learning processes are shaped in different European cultural contexts.

The analysis will be done by selecting and monitoring projects that companies undertake such as project development, technology innovation, environment adaptation, which aim at maintaining or developing sustainable competitiveness.

SMEs are the focal point of this research since learning processes should be relatively easy to identify and observe. In small companies learning experiences sometimes take place without the benefit of any formal training programme. Conversely those who have undergone training might have a relatively high chance of applying what they have learned.

The approach adopted will first build a conceptual framework of the different factors involved in the countries participating in this project. After this phase, the participants will conduct in depth empirical fieldwork within their communities using structured interviews and case studies. The results will be analysed for each country with the purpose to identifying learning processes, their relationship to cultural aspects and the contribution of such processes to building competitive advantage of SMEs especially through networking.

A comparative analysis of the learning processes in different countries building on case studies will be undertaken to identify best practice at both the national and European level.

The outcomes of the analysis is aimed not only at SMEs themselves in demonstrating how they can build competitive advantage through networking but also it is addressed to policymakers active in this area.

17. SME policy and the regional dimension of innovation

E-mail: arne.isaksen@step.no
http://www.step.no/info/Projects/Projects.html#Reg

Abstract

The SMEPOL (SME policy and the regional dimension of innovation) was a collaborative activity including seven research institutions in Europe. The project evaluates almost 40 existing policy instruments of promoting innovation activity in SMEs in 11 regions in eight European countries in order to identify ‘good practice’ policy. The aim is to construct a sound and organised knowledge base about existing practices, qualify their appropriateness and efficiency in order to identify ‘good practice’ principles, in a relative sense, and help to see how they can be adapted to other environments and situations.

In order to achieve this objective the project consists of four work packages:

1. the objective of the first work package is to establish a sound theoretical basis and a common analytical framework in the research group, in order to obtain comparability between the single evaluations of programmes and politics carried out in the project. The theoretical framework is based on the concepts of the interactive innovation model;

2. work package two contains evaluations of selected policy instruments in regions in eight countries to identify best practice policy in each case. The instruments to be evaluated reflects both linear and non-linear innovation models, endogenous and exogenous policy approaches, and sector
specific and non-sector specific policies on regional, national and EU policy levels. The evaluation studies have the same main questions and horizontal themes, use the same theoretical framework and similar methods;

3. work package three pools together material from the region and country specific evaluations. The different policy instruments and regions are classified according to a taxonomy developed in the project, and best practice policies will be analysed for different regions and instruments;

4. the objective of work package four is to produce a consolidated synthesis report and organise seminars and workshops aiming at policy makers at EU and national level. Workshops in each country or study region are also arranged during work package two.

SME innovation support policies in the EU regions, thus, could substantially be improved by three key principles:

1) Matching the context and SME needs’ with the policy tools in each region.

2) Confronting the policy tools with the lessons and theory and practice.

3) Comparing results achieved with a range of policy instruments in different environments.

The SMEPOL project gives concrete inputs on all these principles. However, achieving progress in this direction would be best handled through the involvement of policy makers themselves, in benchmarking and evaluation exercises. One salient element of the conclusion is therefore the need for more ‘policy intelligence’ in this complex field, that is why at the end of the project a seminar will be organised involving policy makers and other end users.

Publication to be expected:

18. Self employment activities concerning women and minorities: Their success or failure in relation to social citizenship policies

Co-ordinator:
Ursula Apitzsch, University of Frankfurt, Department of Social and Political Science, Institute for Socialisation and Social Psychology, Germany
E-mail: Apitzsch@soz.uni-frankfurt.de

Abstract

The project focuses on the evaluation of social citizenship policies in relation to self-employment activities implemented by member countries of the European Union. Those policies examined which aim to promote self-employment as prominent active social integration strategies, targeting to women and minority groups, as groups most likely to be threatened by exclusion and also as groups with a growing propensity towards self-employment.

The research is based upon the explicit hypothesis that active social integration policies aiming at the promotion of self-employment of unemployed women and migrant minority members can only be successful if their specific socialisation under unstable biographical and work conditions is recognised and compensation is provided for their discontinuous working careers. The empirical methodology of this project will challenge this hypothesis through the systematic collection of life-histories and work-histories from samples of women and migrants who participated in programmes geared to active social integration. These samples will be matched with samples of migrants and women who have become successfully self-employed without benefit of these programmes and policies.

The project want to establish an European-wide research infrastructure with the instruments of a common database and software training in qualitative data analysis. Policy makers and administrators will be equipped with well grounded answers for questions arising by the development of consultation and training programmes.
Theme: Employment and the labour market

19. Educational expansion and labour market (EDEX)

**Co-ordinators:**
Catherine Béduwé & Jordi Planas, Université des Sciences Sociales LIRHE & CNRS, France/Spain
E-mail: beduwe@univ-tlse1.fr
jordi.planas@uab.es
http://edex.univ-tlse1.fr/edex

**Abstract**

The main objective of the EDEX research programme is to examine the effect of the substantial increase of high education workers on the functioning of the labour markets in five European countries: Germany, Spain, France, Italy and UK. The analysis takes also into consideration the comparison between Europe and the USA, where the education is regulated, more than in Europe by the study fees.

The research describes the trends of the different national systems in terms of training and employment; explores the reactions of the enterprises vis-a-vis the improvements in the level of education; and tries to prepare an analysis for the medium-term.

The project comprises five stages, of which the first three, i.e. analysis of the educational structures; analysis of the distribution of qualified people in the labour market; and, analysis of the employers' reactions; are preliminary to the fourth one, in order to establish the scenarios for the evolution of the job-training system; Finally the fifth one represents the summary of the main findings.

Every stage results into six reports of comparative international analysis. Each report will be discussed in the network international meeting, which will also be open to external partners such as academic experts, national and European policy makers, training experts and representatives of the enterprises.

20. Full employment in Europe (thematic network)

**Co-ordinator:**
J. Huffschmid, University of Bremen, Institut für Europäische Wirtschaft und Wirtschaftspolitik
E-mail: huffschmid@ewig.unibremen.de
http://www.barkhof.uni-bremen.de/kua/memo/europe

**Abstract**

The general objective of this thematic network's project is to re-introduce and substantiate the concept of full employment into the economic policy discussion in the European Union, on the Community as well as on the national and regional/local level. More specifically this includes the following three sub-objectives:

1. the development of an analytical understanding of the endogenous and external reasons, why full employment has been widely abandoned as economic policy goal;

2. the elaboration of the necessary modifications and differentiation's which must be made in a full employment strategy in contemporary Europe as compared to the three decades after World War II;

3. the concretisation of the instrumental and institutional side of an appropriate full employment strategy as a multi-layered policy on the European, the national and regional/local levels, paying particular attention to the mutual links between the different levels.

The thematic network will proceed in four working groups (WGs).

1. In the first WG the conceptual, historical and institutional dimensions of full employment and the development of these dimensions since World War II will be explored, taking into account the far-reaching changes of the structure of the workforce as well as of the international competitive environment.
2. The second WG deals with the macro-economic requirements for a sustainable strategy for full employment including, apart from well-established fields like monetary and fiscal policies, also questions of income distribution and of ecological requirements.

3. In the third WG the role of working time arrangements in a strategy for full employment will be discussed; this includes the analysis of different models of working time arrangements in various countries (e.g. the Netherlands, the United Kingdom, Germany et al.).

4. The fourth WG thematises structural aspects of full employment policies. It will firstly deal with regional policy in the EU on a national and on the European level. Secondly the field of technology policy will be addressed.

The thematic network organises working group meetings to which interested experts will be invited and public annual conferences which will discuss and synthesise the findings of the working groups. Intermediate papers of the working groups and the results of the network will be published.

Report:

21. TRANSLAM - social integration by transitional labour markets: New pathways for labour market policy

Co-ordinator:
Günther Schmid, Wissenschaftszentrum Berlin für Sozialforschung GmbH, Germany
E-mail: gues@medea.wz-berlin.de
http://www.wz-berlin.de/ab/projects.en.htm#Project

Abstract

This project aims to develop a theoretical analysis of the nature of transitional labour markets, including the types of transitions which occur under different institutional arrangements, and performance indicators on an aggregate level for social integration and exclusion.

In this framework the main aims are as follows:

- to examine the transitions provided by flexible working time arrangements, in particular part-time work;
- to evaluate active labour market policies in terms of their capacity to prevent social exclusion and to support social integration;
- to examine the performance of education and training systems with regard to the provision of basic skills and competence, as well as access-inequalities to education and training, over some length in a person’s educational and occupational trajectory.

The project gives rise to the appearance of four publications:

a) ‘Social integration by Transitional Labour Markets, Theory and Evidence’

b) ‘Social Integration and Working Time: International comparisons of part-time work’

c) ‘New Pathways for Active Labour Market Policy’

A conference was organised in November/December 1998 to present and discuss the chapters of these publications.

Publication:
22. Innovations in information society sectors – implications for women’s work, expertise and opportunities in European workplaces

Co-ordinator:
Prof. James Wickham, Trinity College Dublin, Ireland
E-mail: jwickham@tcd.ie
http://www.tcd.ie/erc/Servemploi/index.htm

Abstract

The project examines the key innovations implemented in eight countries (Britain, Denmark, France, Germany, Ireland, Spain, Italy and Sweden) in the retailing and financial services sectors. It should do this through two interlinked research activities in each country: case studies of retailing and financial services firm, examining the work performed, the expertise deployed, and the personal development prospects enjoyed by female non-managerial employees; and a longitudinal study of selected women moving within firms, between firms, into or out of employment, or becoming self-employed.

The main objectives were:

- to examine the patterns and dynamics of innovation operating in two sectors of the Information Society: retailing and retail financial services;

- to investigate the significance of these innovations as part of the emerging European Knowledge Economy, specifically for the work done and knowledge content in the work of female employees in these sectors;

- to assess the opportunities for these employees to develop and utilise expertise in their work in the context of these patterns of innovation;

- to assess their consequent ‘employability’ and opportunities for personal development, within firms and beyond them to compare and contrast patterns of change and experiences across member states.

During the project there will be two European ‘employment roundtable’ as well as a concluding policy conference. These will involve representatives of social partners from the two sectors. The roundtables will be based on the findings of the project up to that point and the discussions will feed into the ongoing work of the project.

23. New forms of employment and working time in the service economy

Co-ordinator:
Gerhard Bosch, Institut Arbeit und Technik, Abteilung Arbeitsmarkt, Mannheim, Germany
E-mail: bosch@iatge.de
http://iat-info.iatge.de/projekt/am/nesy-engl.htm

Abstract

The overall objective of the project is to analyse the effects of new forms of employment and working time in the service sector and service activities on the opportunities for a redistribution of work likely to promote employment.

This project covers ten European Union countries: Belgium, Denmark, Finland, France, Germany, Italy, the Netherlands, Portugal, Sweden and the United Kingdom.

Its quantitative parts include the analysis of data relating to the diffusion of new employment and working time forms in the individual service industries, i.e. deviations from the traditional permanent, full-time employment relationship with standardised working time. Data analysis will also include individual working time preferences, broken down by employee category, family structure, income, etc., as far as possible.

The qualitative parts include case studies which will help to identify basic industry and activity specific reasons for the emergence of certain new forms of employment and working time in selected service industries and
activities. Selected examples of innovative policy approaches and their practical implementation on the establishment level shall be covered.

The final analysis will tackle the question of what new opportunities for the collective regulation of individual working time preferences are emerging.

24. The strategic role of knowledge-intensive services for the transmission application of technical and management innovation

Co-ordinator:
Peter Wood, University College London, Department of Geography, UK
E-mail: p.wood@geography.ucl.ac.uk

Abstract

This thematic network has brought together organisations from nine member states of the EU to undertake a collaborative exchange of understanding about the contribution of knowledge-intensive service consultancies to the commercial competitiveness and growth of client organisations in different sectors, types and sizes of firm, and core and peripheral regions. A series of interim reports, arising from each work package, have examined the application of this understanding to economic policy, especially as applied to the promotion of technical and organisational innovation.

In targeting areas of policy, it has addressed:

1. The impact of the international integration of European service markets on the availability of consultancy expertise to clients in different parts of the Union.

2. The diversity of national experience, including the significance for consultancy activities of variable regulatory and corporate regimes, patterns of business organisation, including the corporate use of in-house expertise and the position of SMEs, and prevailing patterns of consultancy supply.

3. The degree and patterns of regional inequality in consultancy provision and use, their causes, and their significance for public agencies wishing to enhance regional technical and organisational innovation and competitiveness.

The outcome of the thematic network is a policy-orientated analysis of best practice in the employment of consultancy skills to support technical and organisational innovation, taking account of the needs of various sectors, large and small-medium enterprises, and the work of public agencies in different nations and regions. Proposals are made for further research into the changing corporate context of technological and managerial innovation involving growing consultancy inputs. The work programme of the network over 18 months consisted of five sequential work packages; each focused around a workshop. Four (work packages 1-3; 5) are based on international meetings among the participants, and one (work package 4) took place simultaneously in each participating country.

Publication:
Final Report: SOE1-CT95-1017 The strategic role of knowledge-intensive services for the transmission and application of technical and management innovation (KISINN), Peter Wood, 1999, 110p (TSER023)

25. Regional innovation systems: Designing for the future.

Co-ordinator:
Philip Cooke, Centre for Advance Studies in the Social Sciences – University of Wales, UK
E-mail: scpnc@cf.ac.uk

Abstract

The central question of this study concerns the extent to which regional innovation systems could be identified in eleven European regions. The authors have studied regional innovation systems by exploring their differences and similarities, and relating their systemic structure to the contemporary needs of global industrial competitiveness and innovation foresight, and learning capacity. The study has also tried to identify the nature of
the key design elements of institutional innovation network architecture appropriate to supporting the main anticipated innovation needs of regionally clustered firms for the foreseeable future. In order to achieve this goal, the research work focuses on three levels:

1) at firm level – in what ways have conditions for competitiveness and innovation changed? What organisation innovations occur?

2) at institutional level – What changes in policy by private or public institutions occur?

3) at innovation and technology policy levels – What kind of support is provided by intermediary and public institutions, how, and is this changing?

The policy objectives were:

- to provide policy-makers information of good practice for enhancing regional growth projects;
- to help policy-makers assess different kinds of European regional innovation practices and to judge their tendencies towards convergence or divergence;
- to stimulate learning effects regarding transfer of endogenous innovation potential for sub-national and EU policy-makers;
- to raise awareness of the need for new or adjusted EU and other programmes.

Five workshops (month 1, 6, 10, 18, 23) have been implemented for the preparation of each workpackage and presentation of the final report.

**Publication:**
Abstract

European countries vary widely in their education and training systems and in the factors shaping transitions from initial education to the labour market. To date, no comprehensive research exists on the nature and consequences of this variation in education to work transitions across Europe. The objective of this research is to develop a more satisfactory framework for understanding transitions in the different European systems and to use this framework to analyse the factors affecting success and failure in education/training outcomes and labour market integration in the different countries.

This project will be the first major comparative study focusing on recent developments in school to work:

- transition processes across a range of European countries. The project will use a particularly rich source of data on transitions, regular school leavers' surveys in Ireland, Scotland, France and the Netherlands, and will place these data in a broader European context by drawing on the Labour Force Survey. Together, comparative analyses of these two sources of data will significantly advance our empirical and theoretical understanding of the relationship between education/training and labour market systems. It will provide a stronger empirical basis for studying the process of initial labour market entry, the factors influencing successful integration or exclusion, and the interaction of these factors with institutional and societal variables. The improved understanding of the diversity of education/training systems and their relationships to labour markets is indispensable for more successful needs assessment, policy planning and implementation of policies on a cross-national basis. In this sense, the results of the project will help to

- underpin the development of more effective education and labour market policies which fit the varying contextual conditions across Europe. Only precise knowledge of the specific mechanisms through which various groups become advantaged or disadvantaged in the labour market can lead to the development of more effective policies which are appropriate to the varying conditions in different countries. At a more practical level, the project will directly contribute to the OECD's current Thematic Review of the Transition from Initial Education to Working Life. In addition, the project will develop existing cross-national data sources on school leavers, encourage the greater harmonisation of national transition surveys and facilitate the expansion and standardisation of data collection in other European countries.

28. Schooling, training and transitions: an economic perspective.

Co-ordinator:
Catherine Sofer, University of Orleans, Centre de Recherche sur l'Emploi et la Production (AR2T), France
E-mail: Catherine.sofer@univ-orleans.fr
http://www.univ-orleans.fr/DEG/LEO/TSER

Abstract

The research is about schooling, training and transitions at various points of an individual's life cycle.

The primary objective of this research is to bring together the work and experience of European economists who have contributed to the field of education and training. Its aim is to exploit the wealth and diversity of European institutions and data to develop further an expertise in comparative analysis and a deeper understanding of the mechanisms which have shaped schooling and training systems, and labour market transitions (from school to work, and from job to job), somewhat differently across countries.

The research incorporated these new developments by looking precisely at the production of established knowledge and skills, their allocation to individuals and jobs, and how well they fit together in each society depending on its specific institutions and other relevant characteristics. Special attention focused on the high school and undergraduate
level because most of the tensions generated by the regulation of schooling systems and labour markets seems to lie there nowadays.

A theoretical and empirical investigation of three related topics should be achieved:

1. a comparative analysis of schooling systems;
2. the transition from school to work;
3. training and labour market flexibility.

The economic equilibrium approach is based upon the idea that quantities, like the number of students or of trainees, for example, and prices, like wages, result from the comparison of a market demand. Depending on the question under consideration, the kind of market assumed in the analysis may vary from perfect competition to heavy institutional regulation (as is the most often case for education). This framework offers an aural way of understanding the interactions between the schooling system (supplier of education), the learning organisation (which demands specific skills and supplies training), and the individuals (demanding for education and supplying the skills) whose transitions reveal the costly adjustments that took place to match the supply of education and training with the demand for skills.

The aim of the research is to develop a good European expertise of education and training systems (first topic), gather comparable data and make some policy evaluations on transitions from school to work and from job to job (second and third topics) and give some new theoretical insights on institutions and labour markets.

29. Enhancing the participation of young adults in economic and social processes: Balancing instrumental, biographical and social competencies in post-school education and training

Co-ordinator:
Danny Wildemeersch, Katholieke Universiteit Leuven, Belgium
E-mail: Danny.wildemeersch@ped.kuleuven.ac.be
http://www.northampton.ac.uk/solar/tser/country

Abstract

The overall objective is to generate a more comprehensive understanding of the potentials and limitations of current approaches to post school education and training for unemployed youth and young adults.

In this line of thought, the main objectives of the research are the following:

a) to explore the different kinds of assumptions that give direction to the actions of educational policy makers, educators and participants involved in schemes aimed at (re)orienting or integrating young adults (in) to the labour market;

b) to identify ways in which particular educational practices, in the context of particular socio-political, economic and cultural contexts, impact (or not) upon how young people construe their choices and opportunities for social and economic inclusion and exclusion;

c) to extend current understanding of the experiences and perspectives of socially differentiated groups of unemployed youth/young adults with regard to education and training programmes that seek to widen choices and opportunities for participation in social and economic processes;

d) to illuminate how the assumptions that give direction to the actions and choices of policy makers, programme investors and designers, and educators/trainers may be understood and acted upon from the perspective of young people;
e) to consider how, in the different regions involved, balances between skills-integration, social integration and biographical integration do or do not come about and to explain how these may relate to structural, economical, historical and cultural particularities and policies of the regions;

f) to generate and further develop innovative educational concepts and practices which will address the social and biographical dimensions of economic participation and exclusion.

The project will juxtapose and explore the espoused aims and assumptions about 'education and training effectiveness' amongst those who are responsible for educational programmes, and investment therein, with the different ways in which their choices, practices and messages are being understood and negotiated in the life-world of the learners. The project is situated within a framework of assumptions about research quality, ethics and rigour that combines features of collaborative action inquiry and participatory research, with narrative, life history and case study research. It places an emphasis on research with, and not on people, and it builds on developments around the use of narratives and participatory action research in the context of situated case studies, as a reaction to overly deterministic reproduction theories of schooling.

30. Employment and exclusion (thematic network)

Co-ordinator:
Pierre Desmarez, Université Libre de Bruxelles, Centre de sociologie du travail, de l’emploi et de la formation, Belgium
E-mail: pdesmar@ulb.ac.be

Abstract

The principal objective of this research is to compare results from various countries on the links between different types of employment and 'exclusion', to control for the effect of key variables, and to identify approaches that will assist policy-makers tackling social exclusion.

There is now considerable data available on different types of employment and their evolution, while exclusion has also been widely studied in Europe. However the articulation between these two remains problematic, and it is very important to understand better how and why different types of employment, particularly precarious employment, leads to exclusion. International comparisons on linked themes suggest that this articulation varies according to the country; it also varies depending on individuals' gender, age, national origin and level of educational attainment.

Access to social protection is at the heart of the process of exclusion. We are therefore particularly interested in this aspect. From this angle we wish to examine the extent to which different degrees of access to social security systems relate to the employment context; contexts which range from the long-term unemployed to those in the most stable and best paid jobs. The same issue is posed by issues of access to old age pensions.

The understanding of the articulation between different types of employment and exclusion will allow to reply to a series of questions that are rarely considered when thinking about exclusion, and which suggest the existence of many connections between research domains that are generally developed separately.

These questions concern how legal and collectively agreed definitions of work regulations, the significance of government policy and the effect of restructuring and of sectoral changes impinge on the mechanism of exclusion, and also whether qualifications play a part in structuring employee attitudes towards precarious atypical jobs.

31. Globalisation and social exclusion

Co-ordinator:
J. Whalley, University of Warwick, UK
E-mail: j.whalley@csv.warwick.ac.uk

Abstract

The principal objective of this project is to determine the role played by international
trade in influencing the employment and relative wages of unskilled workers in Europe. This task will be undertaken using a combination of data analysis, econometrics, case studies and simulation modelling and will take account of differences in industrial structures, social policies and technological change and labour markets and labour market policies in individual EU member states.

The project will investigate how firms and industries in Europe have responded and adjusted to increased international competition from low wage economies. The implications of this analysis for the design of appropriate strategies for responding to future supply surges of low-skill products onto European markets from low-wage economies will be fully explored.

A key element of the project will be the collection of the most suitable data on trade, industrial characteristics (output, prices, investment, employment, wages), technology, labour market structures and national tax and social policies. These data will be collected together and made available as a single database.

The results of the project will be widely disseminated, in the first instance via the discussion paper series of the participating institutions, and later through conferences for both the academic and the policy-making and business communities.

32. Growth, inequality and training

**Co-ordinator:** David Ulph, University College London, Centre for Economic Learning and Social Evolution, UK
E-mail: d.ulph@ucl.ac.uk

**Abstract**

The aim of this project is to provide a better understanding of the interaction between growth, innovation, R&D and inequality. It will do this through developments in economic theory, and through a comparative international empirical investigation of the experience and performance of a number of carefully selected EU and non-EU countries.

The main objectives of this project are the following:

a) To extend the recent discussion of the changing distribution of skills and wages in the workforce by incorporating both demand-side and supply-side factors.

b) To look, on the supply-side, at both the evolving distributions of the supply of skills in different countries, but also the factors that determine the acquisition of skills, and hence the responsiveness of skill supply to technology shocks.

c) To provide a coherent intellectual framework in which to understand the links between growth and inequality.

d) To provide a systematic analysis of policies that can enhance long-run economic performance, where the measure of performance will encompass both growth and distributional considerations.

e) To undertake all the above analysis at macro, meso and micro level, through a combination of theoretical, econometric and case studies.

33. Information society, work, and the generation of new forms of social exclusion

**Co-ordinator:**
G. Schienstock, University of Tampere, Finland, E-mail: ytgesc@uta.fi
A. Brandao-Moniz, University Nova de Lisboa, Portugal
http://www.uta.fi/laitokset/tyoelmaisowing

**Abstract**

The central question in this project is: 'What are the social but also the micro-economic implications of the emerging information society?', and the principal aim of it is to find an answer to this question. It focuses on developments in the domain of companies, assuming that the informatisation of work is a key factor behind the emergence of information society.
The project represents a break with traditional technological determinism as it is based on a 'bottom up' approach, analysing the concrete processes of building up an information society by implementing modern information and communication technologies within companies and in inter-organisational networks. This will shed light on the possible emergence of Europe-specific ways to an Information Society.

'Technological practice' is used as a key concept; this describes specific ways of embedding information and communication technology applications into organisational forms and cultural patterns. The project will analyse the development process of such technological practices in different intra- and inter-organisational fields, including co-operation within work groups up to regionally based networks of companies and supporting institutions. It will further investigate the ways emerging technological practices within companies are influenced by and exert influence over the institutions of regional and national environments. It will also analyse the social and micro-economic implications of different technological practices. As regards social implications, the project will focus particularly on the aspect of social exclusion and integration. In the project a mix of different methods will be applied including case studies, secondary analysis of existing data sets, a company survey, and a comparative analysis.

Based on the results of the research project an answer can be given to the question whether a common European model of information society is emerging, or whether different countries follow different paths into the information society.
will include, on the supply side, factors such as work skills, number of years of labour market experience, education, language skills, age, gender, cultural factors (including religion), urban experience, and social background (family characteristics); and, on the demand side, variables representing factors such as economic structure (qualifications, 'ethnic' jobs, etc.), degree of market integration (the 'EU effect') and business cycles.

Institutional factors will be taken into account through an examination of immigration and integration policy, labour market and unemployment policy, and policies for education and vocational training.

35. New employment opportunities in the third sector: An evaluation of innovative policies for social integration in Europe (NETS)

Co-ordinator:
M. Mellano, Università di Roma
‘La Sapienza’, Italy
E-mail: mellano@secc.eco.uniromal.it
http://www.lunaria.org/tertium

Abstract

The aim of this project is to identify the contribution to social integration and employment creation in Europe which may come from what (for ease of use) is called ‘third sector’ (non profit, socially useful activities also known as ‘third system’, ‘social economy’). Their job creation potential and their ability to address new needs will be assessed, and alternative policy actions will be evaluated, considering their economic efficiency and effectiveness, and the impact on social integration.

The survey will be carried out in three European countries – Germany, Italy and Spain – representative of the different problems and institutional frameworks present in the European Union. The results of the surveys will be combined with information from the sources already available and with in-depth interviews to major player and policy makers in the field.

A database containing empirical data will be produced for both researchers and policy makers and a wide audience book will be published. During the project a strong interaction is envisaged between researchers, representatives of third sector organisations and policy makers at the national and European level in order to assure consideration of all contributions to the policy debate and the widest dissemination of the results of the project.

Publication to be expected:

36. Technology, economic integration and social cohesion

Co-ordinator:
Luc Soete and Bart Verspagen, Maastricht Economic Research Institute on Innovation and Technology, Universiteit Maastricht, The Netherlands
E-mail: bart.verspagen@merit.rulimburg.nl
http://meritbbs.unimas.nl/tser/

Abstract

The project aims to provide insight into the impact of several important and interrelated developments on social cohesion and exclusion in the European Union. The issues analysed are:

a) Technological change as the single most important factor shaping the quantitative and qualitative dimensions of the fundamental economic factors influencing social cohesion, such as employment and economic growth;

b) Globalisation, broadly driven by technology (e.g. telematics) and by the liberalisation and deregulation of trade and capital flows. This globalisation trend leads to qualitative changes in the form and effects of the exposure of countries to foreign competition, not only in the form of trade, but also through increased foreign direct investment flows.
The project discusses a number of implications for different policy areas at the European level. With regard to macroeconomic policy, it is suggested that the EU economy is now well placed to adopt a more expansionary economic policy. The key point, however, is that a policy framework in which decisions affecting the demand-side are taken without considering the supply-side will be less effective.

With regard to the regulatory system, it is argued that especially in the emerging areas of ICTs and biotechnology, the early adoption of appropriate standards and the manner in which regulations are framed can have a crucial impact on the pace at which the industries develop.

Europe needs to adopt a wider and more inclusive definition of science and technology policy than in the past. EU sponsored Framework Programmes have played a useful part in financing and encouraging specific scientific research. Little effort has, however, gone into promoting capability amongst ‘users’ of ICTs and in providing a social and institutional setting that encourages their implementation.

With regard to labour market policies, the project follows a twin strategy of targeting those occupations or professions which support competitive advantage in order to boost economic growth, while having a separate strategy for job creation aimed at cutting unemployment. It is hard to avoid the conclusion that the bulk of new jobs must come from expansion of personal services in areas such as care.

It is evident from the project that in responding to the challenges of the new knowledge economy, many policy areas are asked to give directly or indirectly a significant contribution. Therefore, there is a need for more intra-European policy co-ordination both between different sector policies and across different territorial areas. In other words, important policy issues arise in determining the level at which policy should be implemented so as to be the most effective.

**Publications:**

Studies: TSER004. The globalising learning economy: Implications for Innovation Policy, BA, Lundvall- December 1997

**37. Youth unemployment and processes of marginalisation on the Northern European periphery**

**Co-ordinator:**
Torild Hammer, the Norwegian Social Research Institute Nova, Norway
E-mail: t.h.a.@isaf.no

**Abstract**

The main aim of this project is to develop a clearer knowledge of processes of marginalisation affecting young people through comparative research among the countries within the northern European periphery. The research will highlight strategies and processes, which protect against marginalisation, as well as trajectories, which carry a high risk of subsequent unemployment.

In order to conduct this study, representative sample surveys are carried out for between two and three thousand young people in each of the seven countries (Denmark, Finland, Iceland, Ireland, Norway, Scotland and Sweden).

Representative samples will be drawn from national unemployment registers in each country with eligible respondents defined as young people between the age of 18 and 24 who have been unemployed for a period of at least three months over the previous year. The samples will therefore consist of young people with a variety of work histories that, at the time of the interview, are located in a full range of positions inside and outside of the labour market. This survey design will allow a comparison of young people with unemployment experience some whom have managed to establish positions in the full time labour market, others who have re-entered full-time education and others who...
have remained unemployed, withdrawn from the labour market or become marginalised in some other way.

### 38. Youth unemployment and social exclusion in Europe

**Co-ordinator:**
Torild Hammer, Norwegian Social Research Institute, NOVA, Norway
E-mail: Torild.Hammer@isaf.no

**Abstract**

The main objective is to study how different welfare strategies and fiscal structures in different countries influence the risk of social exclusion among unemployed youth. The following research questions can be identified:

a) Do non-standard forms of labour force participation, such as part-time or temporary work or work in the informal economy, represent a step towards social exclusion and labour force marginalisation or can they be regarded as a step towards permanent work careers?

b) Comparative data will enable us to study young unemployed probability of entry to post compulsory education in countries with different educational systems. What are the proportion of unemployed youth that return to education, and what kind of factors seems to influence such careers?

c) How do different welfare strategies with mixes of public (insurance systems) and private (family) support influence job chances of youth unemployment in different countries?

d) To what extent do unemployed youth feel integrated in their society and how does this impact on the rights and responsibilities of citizenship? Are unemployed youth excluded politically in the sense that they do not participate or engage themselves in politics, and what kind of political attitudes do they have?

e) Previous research has revealed large differences in work ethics or work involvement between European countries. What is the relationship between stigmatisation, mental health, and work involvement and job search activity?

f) The project will also analyse young peoples’ experience with different measures in a comparative perspective, and assess the extent to which such measures increase job chances or return to education.

In each of the countries involved, researchers will disseminate findings widely among practitioners and within the academic community continuously through the project period. The project group will also give priority to keep in contact with practitioners and national government’s ministries, and other interested parties to be able to provide information about main research results which have implications for policy. A European conference of youth unemployment involving both policy makers and the research community will also be arranged at the end of the project.

### 39. Youth unemployment and social exclusion

**Co-ordinator:**
T. Kieselbach, University of Bremen, Research Unit Work, Germany

**Abstract**

The project aims at empirical research on the causes and key mechanisms of social exclusion, and among them, especially unemployment. The empirical research work in six European countries is, on the one hand, dedicated to different national problems of youth unemployment, and on the other hand follows different scientific orientations and methodologies, namely sociological, psychological, psychiatric and cultural.
This project will be undertaken on the vulnerability of specific groups of young people and on the processes and stages of social exclusion often associated with unemployment.

The project aims to identify critical steps in the process of victimisation in order to formulate social options counteract it; it follows the concept of victimisation on three levels:

1. the loss of social features connected with employment;
2. the experience of continuous exclusion from paid employment with accelerating 'daily hassles';
3. the selective evaluation of the unemployed by their social surroundings.

Each partner contributes specific expertise to the project. In particular, the partner from a public health institution will study self-perceptions of shame associated with financial difficulties, and the partner from a university hospital will research attempted suicide (the most radical form of self-exclusion from society). Other partners will focus on labour market factors (the weak bands of the labour market for youth), and the cushioning effect of the informal economy which is for many young people the only entrance to the labour market. A number of issues will be addressed such as the relationship between family support and control. A more psychological approach is to identify the stages of victimisation.

The project is carried out in three phases which are terminated in common workshops, at which the results and contributions from the six countries will be compared and discussed:

1. the definition of concept of social exclusion: analysis and description of the forms it takes in the six countries;
2. empirical research (data analysis and qualitative interviews) with different socially excluded groups or groups-at-risk;
3. the identification and evaluation of innovative options of institutional and political intervention and counteraction.

Abstract

The quality of the skills of EU citizens is crucial for the European productivity. Thus is a top priority for European governments is to ensure that every young person gets at least a basic level of skill, and that disadvantaged adults have reasonable opportunities to make up lost ground.

The purpose of the project was to contribute to the basic framework for the design of these policies. The first step was to document what is happening and to diagnose its causes. This involves a clear analysis of what is happening to labour demand, as well as an understanding of why the pattern of supply does not always respond adequately (inadequate student motivation and institutional constraints). The next step was to distil from this experience what are the most effective ways for developing the necessary skills-both in terms of curriculum and teaching methods (including the newest technology). The aim was to work towards defining a Europe-wide definition of the 'platform for learning' with which every European citizen should be equipped.

The project brought together an interdisciplinary team of economists and education specialists from five EU states: the United Kingdom (UK), France (FR), Netherlands (NL), Portugal (PR) and Sweden (SW) and the programme of work consisted of four specific studies as follows:
1. the demands for labour by skill in the EU (FR, SW)

2. the factors determining the supply of and demand for labour by skill in the EU (NE, UK)

3. the profile of education and training provision at the basic level in the EU (PR, SW)

4. Defining a minimum learning platform for the EU (NE, UK)

Methodology work on these areas was led by one or more researchers from one of the five participating EU states (indicated by abbreviations above), and all project participants were involved in the investigation of date sources, in the collection of data and in the work defining a minimum learning platform. The team produced improved datasheets linking earnings, qualifications and employment using labour force survey and similar surveys and to analyse their interaction over time. The relative significance of a number of factors influencing supply of and demand for skills have been analysed and assessed using, among other sources, data from the OECD Adult Literacy Survey. The profile of educational provision at the basic level was investigated at the level of curriculum content, pathways and progression for young cohorts. Work on the minimum learning platform involves an extensive literature survey, consultation with governments, employer and employee representatives and field work samples of companies.

41. Changing working life and training of older workers

Co-ordinator:
T. Tikkanen, University of Jyväskylä, Department of Education, Finland
E-mail: tikkanen@campus.jyu.fi
http://www.nvi.no/prosjekter/worktow.htm

Abstract

From the points of view of education, training and learning, the research focuses on individual and organisational effects, needs and opportunities emanating from the intersection of two trends: the ageing of populations and the changes in working life.

The key objectives of the research project are:

a) to investigate the extent to which the knowledge, skills, experience and attitudes of older workers (45+) can be recognised, valued and utilised in work and learning situations;

b) the ways in which older workers learn within work settings;

c) the extent to which human resource development (HRD) practice and educational interventions involving older workers can facilitate lifelong learning and productivity;

d) the ways in which the diversity of the workforce in these terms can contribute to the development of learning organisations in the work context and, more generally, to the creation of the learning society;

e) through case studies and comparative analysis of good practice in different countries the ways in which the above objectives can contribute to the flexibility and productivity of the European older workforce and to social cohesion generally.

In order to achieve these objectives, cases of work organisations representing different work types (industrial work, office work, service work) in small and larger SMEs are selected in each participating country. The research work (quantitative and qualitative) comprises:
The main objectives of the project were:

a) to develop a set of hypothesis with regard to effectiveness;

b) to test these hypothesis in order to identify the important parameters (e.g. organisational characteristics, contextual conditions);

c) to develop a multilevel model (several parameter model) of effectiveness of training;

d) to investigate and interpret the differences between countries;

e) to develop a monitoring instrument for individual managers of programmes to assess the effectiveness and quality of their own training programme.

The project encompasses the following three stages:

1. Case studies. On the basis of an inventory and description of relevant training programmes per country, two cases per participating country are selected for this multiple and comparative case study. In the case studies, trainers, (former) trainees and employers (who employ trainees and have participated in the selected training programmes) were interviewed; major issues of the interviews are the characteristics of the training organisation and programme, the experiences with and evaluation of the training programme. The result of the case studies serve the refinement of the developed conceptual model and hypothesis.

2. Survey Study. This stage of the study aims at a test of the conceptual model by means of a large scale survey design. Based on the outcomes of the case studies, questionnaires were designed for the collection of data among trainers, (ex-) trainees and employers.

3. Development of a monitoring instrument. On the basis of the results of both the case studies and the large-scale survey study, (preliminary) monitoring instruments have been developed for managers of train-

Abstract

This research project concerning the effectiveness of labour market oriented training for the long-term unemployed, focuses on the question of what works and does not work in training for this target group. More specifically, it focused on the process variables – that is the organisational, curricular and instructional characteristics of training programmes – that might make one training programme more effective if compared with another training programme.

43. Employment precarity, unemployment and social exclusion

Co-ordinator:
Gallie Duncan, Nuffield College, UK
E-mail: Duncan.Gallie@Nuf.ox.ac.uk
http://www.nuff.ox.ac.uk/

Abstract

This project examines the processes that link employment precarity, unemployment and social exclusion. It involves a comparative research in eight EU countries: Denmark, France, Germany, United Kingdom, The Netherlands, Ireland, Italy and Sweden.

The project focuses on three main issues:

1) the cumulative disadvantages associated with employment vulnerability;

2) the causal relationship between employment situations, economic poverty and cultural and social poverty, including household and social relations;

3) the relationships between the form of the welfare state provision and the extent of cumulative disadvantage/opportunities for re-integration in order to provide theoretical interpretation of the results of the statistical analysis.

The project leads to the provision of standardised variables across a range of national data sets, new statistical tabulations and a set of interpretative papers.

This is the background publication of the second report on vocational education and training (VET) research in Europe published by Cedefop in 2001. It contains a number of contributions on current research in the framework of generating and using skills and competences. The basic theories, methodologies and results are presented and the main implications for future research, policy and practice are discussed within each contribution.

Some key issues addressed include:
- steering VET systems, funding and the changing roles of VET professionals;
- learning and training within the context of lifelong and lifewide learning;
- training, employment and development of human resources from a company perspective;
- labour market dynamics and their impact on skills and competences;
- individual performance, social exclusion and transition from education/training to work;
- VET research in selected non-EU countries.

We hope that this publication coupled with the complementary synthesis report, will enhance understanding of research undertaken within Europe and contribute to closer cooperation between researchers and decision makers at all levels.
