The Professional Development Center (PDC) manages the field-based teacher education program at TWU, and the LINKS technology integration project builds on the existing curriculum for teacher preparation. Each semester approximately 300 future teachers progress through university coursework, technology seminars, and field-based placements in Intern I, Intern II, and Residency. Responsibility for preparing students is divided among technology seminar leaders, university liaisons, and mentor teachers. The LINKS Technology seminar leaders support the LINKS preservice strand utilizing a distance delivery approach from the TechTrek website designed for use with this population (http://venus.twu.edu/~f_snider/techtrek/main/index.html). As preservice teachers progress through Intern I, Intern II, and Residency, competencies related to four technology cornerstones (foundations, connectivity, productivity, and integration) are documented through course portfolios, classroom logs, desktop conferencing, and professor validation. Technology lab sessions and one-on-one interventions are offered to interns as they document their progress. All Intern I and Intern II preservice teachers are required to attend three whole-group technology seminars related to the four cornerstones; to participate in bi-weekly desktop conferencing groups that extend discussion related to course readings and indicators; to submit completed technology requirements and weekly reflections through e-mail; and to attend at least one lab session per semester that supports the development of their skills or relates to completion of the required indicators. As students complete coursework in their interdisciplinary major, they document demonstrated proficiencies in their LINKS Technology Passport a comprehensive metacognitive tool.

In addition to the preservice teacher population, full-scale implementation is achieved by orienting mentor teachers to the LINKS project goals and tools, and by extending professional development efforts to instructors on the university campus. Training opportunities, resources, and electronic means are provided to support instructors as effective models of technology use, in web-based course delivery, and in electronic communication with students. The instructor strand of the LINKS project assists university instructors with the preparation of web-based course delivery via Blackboard, the university's web-based course delivery template.

Methodology

In the first year of the project (fall 1999-spring 2000) implementation and outcome data were collected for events involving three populations: preservice educators, mentor teachers, and university instructors. During the fall 1999 semester, the first cohort of preservice students enrolled in Intern I (N=99), and participated in three technology seminars, bi-weekly conferencing groups, and documented proficiencies in the Technology Passport. Pre- and Posttests were administered to assess changes in technological proficiency and use, as well as attitudes and concerns. Nonparametric matched pairs tests were utilized for analyses of quantitative data for 67 students with complete data sets. Within this cohort group, 30 students were placed with mentor teachers in rural districts for field-based internships. Mentor teachers (N=30) participated in six, on-campus training sessions and received assistance designed to enhance positive attitudes and receptivity toward their intern's technology use. Mentor teachers completed pre-and posttests to assess their technological proficiency. Nonparametric matched pairs tests were utilized for quantitative analyses. For both preservice teachers and mentors, qualitative analyses were conducted for open-ended items on session evaluation forms. A volunteer sample of university professors (N=20)
agreed to participate in five whole-group professional development sessions. Sessions focused on an orientation to the Links project and resources, and the preparation of web-based course delivery via Blackboard—the University’s web-based course delivery template. Pre- and posttest data were collected on the Stages of Concern Questionnaire (SOCQ) and data on the Levels of Use (LoU) were collected by individual interviews after the last of the five training sessions. Due to attrition, the final sample included 13 instructors. Analyses involved descriptive statistics and the creation of profiles.

Data sources

Implementation data were obtained from reviews of project documents, attendance records, evaluation forms, and information on LINKS-related web sites. Complete data sets were available for preservice teachers (N=67), mentor teachers (N=28), university instructors (N=13). The instruments utilized as data sources for the three populations are listed below.

Preservice teachers. Three quantitative measures were administered at the beginning of the fall and spring semesters. The measures included: Basic Technology Competencies for Educators (BTCE); Self-Evaluation Rubrics for Basic Teacher Computer Use and Internet Use, and the Stages of Concern Questionnaire (SoCQ). Nonparametric dependent-sample tests were used to determine whether significant differences existed across semesters. Qualitative data were derived from course evaluations to assess changes in attitudes about technology.

Mentor teachers. Mentor teachers complete the Self-Evaluation Rubrics for Basic Teacher Computer Use, Advanced Computer Use, and Internet Use at the beginning and end of their semester as mentors. Nonparametric dependent-sample tests were used to gauge changes in skills and use. Qualitative analyses were conducted for open-ended items on questionnaires completed by e-mail and on session evaluation forms.

University instructors. The Concerns Based Adoption Model (CBAM) was used to assess university instructors’ progress toward the use of Blackboard. Pre- and posttest data were collected for the SoCQ. LoU ratings and open-ended Statements of Concern were collected by individual interviews after the last of the five training sessions.

Results

These findings represent preliminary analyses for the evaluation of the first semester of project implementation under the three-year grant. Results for preservice educators revealed that participants (N=67) considered themselves more technologically proficient after experiencing the integrated technology component of their professional development coursework. There were statistically significant pre- and posttest differences for all domains of the BTCE, 10 out of 11 domains on the Basic Teacher Computer Use, and all domains on Internet Use. Future teachers moved toward high impact concerns and relatively low self-concerns as measured by the SoCQ. Qualitative analyses revealed generally positive responses in relation to acceptance of and comfort with technology, as well as confidence in ability to integrate its use in curriculum delivery. Many preservice teachers were, however, concerned because they seldom saw technology use modeled in public school classrooms, and they believed access to technology would be a significant barrier to technology use.

Mentor teachers showed significant growth toward technology use in the classroom and more positive attitudes toward technology use. Statistically significant pre-and posttest results were obtained for 23 out of 27 domains on the self-evaluation rubrics for Basic Teacher Computer Use, Advanced Computer Use, and Internet Use. Qualitative analyses of open-ended items indicated that mentors were generally positive about program participation. Concerns related to time, scheduling, applicability, and involvement with interns. Mentors reported limited use of technology in the classroom by interns. Therefore, LINKS now plans for joint sessions for classroom pairs of interns and mentors. Mentor training for the next semester will be provided in a two-day workshop held on the TWU campus. Since this revised training provides for direct interaction between the mentor and the intern, it is consistent with the LINKS Management Plan for mentors and the goals of the PT grant. This revised plan addresses the major concerns expressed by the mentors in this pilot and emphasizes the immediate applicability of new learning as well as effective use of professional time. Both mentors and interns indicated their support for working together in such an effort.

The primary goals for the university faculty were introduction of the LINKS standards and resources, and support for instructor delivery of web-based courses as models for the future teachers. The descriptive statistics and
profiles for the SoCQ suggested that the instructors had relatively high informational and personal concerns as well as rather intense consequence and collaboration concerns. Changes reflected in exit interviews related to the variance in beginning use and the individual differences in progress attained during the semester. All individual instructors made significant progress in levels of use, although they began at different levels. Qualitative analyses of open-ended evaluation questionnaire items revealed four key instructor concerns: (a) the need for, and management of, time, (b) their individual technical proficiencies, (c) the applicability of Blackboard to their own teaching, and (d) their need for continuing support. To address expanded support, 14 training sessions are now projected for 2000-2001. University instructors will be supported over the entire academic year, and they will be provided with laptops for this effort. The outcome in the near future will be a web-based course offered by each participant. Support from the LINKS team during and between training sessions will be expanded and documented for evaluation purposes.

**Educational Importance**

Findings for the first year of LINKS implementation supported the efficacy of the system and the program being utilized. The three populations (preservice teachers, mentor teachers, and university instructors) made notable strides toward using technology in their own teaching and learning frameworks. All participant groups showed substantial improvement in their technological proficiencies, and participants provided valuable feedback that allowed the LINKS team to refine the program further to address their concerns and needs. These findings provide implications for increasing the technology proficiencies of entry-level teachers as well as providing a model for other universities undertaking similar changes in teacher preparation programs. Further, the resources created by LINKS are available to other institutions on the project web site. Findings have particular relevance to explain how university professors can be supported as effective models of technology use in web-based course delivery and electronic communication with students. The documentation of learner-centered standards for preservice teachers through the Technology Passport provides a much-needed model to monitor and assess changes in preservice teachers’ technological proficiencies.

As the PT's sponsorship continues, the number of technologically proficient future teachers will increase, more university professors will use technology in course delivery, and ultimately, more future teachers will be prepared to integrate technology in K-12 classrooms. The LINKS team is committed to the facilitation of those changes. The first year’s progress is reflected in the quantitative and qualitative findings, in program enrichment and expansion, and in the systematic design of management plans that addressed the identified needs of each population.

Acknowledgements

For contributions to the implementation of this project, Drs. Sharla Snider and Vera Gershner and would like to express appreciation to Dr. James Monaco, Superintendent, Aubrey ISD, and Dr. Linda Monaco, Assistant Superintendent, Little Elm ISD. Additionally, appreciation for assistance is extended to Kelly Shapley, external evaluator, Southwest Educational Development Laboratory. The Director of the Professional Development Center at Texas Woman's University, Donna Crenshaw, is applauded for her efforts in providing support for the implementation of this project. Funding was provided at the implementation level through the Preparing Tomorrow Teachers to Use Technology (PT3) initiative sponsored by the United States Department of Education.
Development of an ePortfolio Builder for Teacher Education

Abstract: This paper describes and discusses designing and developing a prototype ePortfolio building system called iFolio that supports the online assessment and tracking of a pre-service teachers' ability to meet technology standards throughout their teacher education program.

Introduction

As information technology becomes ubiquitous in our society, schools have struggled to keep pace. While many reasons can probably explain this, one key reason is that teacher preparation programs have not been successful at adequately preparing preservice teachers to integrate technology into their chosen profession. The National Council for Accreditation of Teacher Education (NCATE) in their 1997 report stated: "Bluntly, a majority of teacher preparation programs are falling far short of what needs to be done ... teacher education faculty have insufficient understanding of the demand on classroom teachers to incorporate technology into their teaching." In response to the problem, the Department of Education has launched a major funding initiative, called PT3 (Preparing Tomorrow’s Teachers to use Technology), which is directly aimed at supporting "the transformation of teacher preparation programs into a 21st century learning environment" (Department of Education PT3 Grant Overview, 1999).

At the same time, the International Society for Technology in Education (ISTE) has developed technology standards to help prepare teachers for technology-rich teaching and learning. They provide teacher education programs with standards describing what new teachers should know about and be able to do with technology when entering the classroom. These standards are likely to be adopted by NCATE and state and local educational agencies throughout the nation.

In this paper, we describe and discuss the experiences at Utah State University with designing and developing a system to help pre-service teachers document and track how they are meeting technology standards throughout their entire professional teacher education program. In particular, we describe a prototype ePortfolio building system called iFolio. Funded by a PT3 grant, this tool supports the online assessment and tracking of Utah pre-service teachers’ ability to meet national and local teacher-technology standards throughout their entire professional teacher education program.

The design of the system is motivated by several design goals:

1. Provide an ePortfolio assessment system which is linked to national technology assessment standards, and is not limited to a single course, but can track student progress across the entire 2-3 years of their professional program.
2. Provide an online ePortfolio builder and extensive digital library system, which will permit students to easily enter and edit electronic portfolio items over an extended period of time in a password secure environment.
3. Provide a reflection and self-evaluation system that will help students take greater responsibility for their own professional development in meeting technology standards.
4. Provide a peer and professional review system within the iFolio system, where students and teacher education faculty can review and evaluate the technology artifacts and practices included in ePortfolios from other partner institutions.
5. Provide a system that organizes and links the digital artifacts and annotations with the related personal goals, reflections and peer review information.
6. Provide a means to output the resulting portfolio onto a CD-ROM or DVD disk for personal and professional use by the student.
7. Provide a metadata and collaborative filtering system for searching, ranking and recommending specific instructional objects stored within the iFolio digital library.

The project views the development of an ePortfolio by a student as a work in progress rather than a final culminating experience. Meeting the current national teacher technology standards is not an event that has a particular ending - pass or fail - point, but rather the standards become a target that challenges preservice and inservice teachers to constantly improve and update their skills in hitting the center point of the technology integration target. While the iFolio system establishes a minimum level of competency that each preservice teacher will be expected to attain, the system is designed to encourage its users to constantly reflect on the artifacts they have included in their portfolio, and to seek out ways to improve and extend their portfolio throughout their teaching career. The portfolio assessment system is built around a "levels of development" rubric that permits users to assess -- at various points in their program -- where they are in their personal development process.

The iFolio system allows the preservice teachers to:
1. View an online tutorial system that includes: a) instructions for using the iFolio system, b) context sensitive online help, c) recommendations for developing an effective portfolio, d) samples of model portfolio items, e) copyright and ethical information and guidelines, f) information about the ACOT stages of development.
2. Enter a personal statement containing their related professional goals, and an organizing framework and overview for their electronic portfolio.
3. Enter and edit portfolio artifacts throughout their preservice program within a password secured environment.
4. Include annotations with each artifact describing: where and when the work was done, conditions and constraints in place during the artifacts development, their role in the development of the artifact, and the scope of the overall project the artifact was selected from.
5. Associate artifacts and elements within the portfolio to specific technology standards.
6. Reflect on how each element or artifact represents achievement of the standards/goals and project future direction in advancement of that standard.
7. Reflect on items that are contained in other peer portfolios for useful ideas, and strengths and weaknesses found in those portfolios.
8. Link to the anonymous peer/professional review system.
9. Organize and link the digital artifacts and annotations with the related personal goals, reflections and peer review information.

Each portfolio must also include a statement affirming that each item in the portfolio represents their personal work as indicated in the annotations. Upon completion of the preservice ePortfolio requirement, student will be provided the option to output the resulting portfolio onto a CD-ROM or DVD disk for personal or professional use.

In addition to the student portfolio building components of the system, the iFolio system will provide:
1. A graphical standards completion tracking system to help individual students monitor their progress in meeting all of the required standards at acceptable levels.
2. A peer and professional review system to provide outside evaluation of student portfolios.
3. A metadata indexing system for items stored within the digital library.
4. A collaborative filtering system for ranking and recommending specific instructional objects stored within the library.
5. A limited authoring environment where the learning objects contained in the iFolio library can be combined and used in a variety of instructional settings.

The system is flexible enough to permit students to include a wide variety of print and multimedia instructional artifacts in their portfolios. Artifacts might include such this as: lesson plans, an electronic resume, verification of meeting the university's Computer Information Literacy (CIL) requirements, web sites they have developed, or digital video recordings/case studies of students doing technology related activities. It also might include: audio captures lesson experiences, technology related literature reviews, technology resource collections...
and instructional objects, exemplary assignments that integrate technology, articles for publication, technology related senior projects, electronic presentations, CBI projects, evaluations and/or technical reports, or conference presentations. Since the university’s portfolio requirement will cross both curriculum and K-12 boundaries it is designed to accommodate as wide a selection of technology options as possible within digital storage and Internet delivery limitation inherent in such a system. Artifacts can be stored as Acrobat PDF resources, digital video/audio resources (10MB limit), linked resources, and text items.

The development of the iFolio system relies extensively on prior work in designing and implementing Internet-based educational digital libraries. A primary goal of these libraries is to provide users (including teachers and students) with a way to search for and display digital learning resources commonly called ‘learning objects’. Examples of such educational digital libraries include www.smete.org, which offers a comprehensive collection of science, math, engineering and technology (SMET) education content and services to learners, educators, and academic policy-makers (Muramatsu, 2000). In Europe, the ARIADNE project has been developing a Europe-wide federation of repositories of multi-lingual, digital, pedagogical resources (Duval et al., in press).

As part of these efforts, researchers are developing digital library cataloging systems. Much like labels on a can, these labels, or data elements, provide descriptive summaries intended to convey the semantics of the object. Together, the data elements usually comprise what is called a metadata structure (LTSC, 2000). Thus, in typical educational digital library applications, learning objects are stored and labeled with a metadata record. This metadata record usually contains basic information about the object. This may include, for example, a description, technical requirements, rights management, and author demographics. These metadata records support searching and discovery of relevant objects.

We have chosen to view the iFolio system as a kind of educational digital library. As such, we are using the technical infrastructure of the smete.org digital library for our iFolio builder. We are defining student-generated portfolio artifacts as a type of learning object. Thus, throughout their pre-service career, students can contribute to and grow their own digital library collection. The learning objects that they store consist of technology-related projects that they complete during their education. In this way, their individual collection represents a documentation of their growing technology competence.

In addition, ISTE specified technology standards are used to define metadata elements to annotate and describe portfolio learning objects. Thus, as students add objects to their collection within the digital library, they are asked to describe how the object is linked to technology standards. In particular, as objects are added, students use a Web-based fill in form to associate them to specific standards. They are also asked to provide personal annotations (metadata) describing where and when the work was done, their role in its development, and other relevant information. These kinds of meta-comments about object development are stored as metadata for the contributed portfolio object.

For example, a student may choose to include a digital-video-case in their ePortfolio that shows them and their students during their student teaching / internship experience in an exercise where technology is playing a critical role in supporting instruction. The student may choose to annotate various segments of the video-case with short statements of how that portion of the case demonstrates their ability to meet the ISTE standards of: “plan strategies to manage student learning in a technology-enhanced environment,” or “use technology to support learner-centered strategies that address the diverse needs of students,” or a variety of other related standards. A single iFolio artifact can be used in this way to demonstrate and support the students’ ability to meet a number of technology related standards.

As is usual in a digital library, students can search their portfolio collection, as well as those of their peers, to find and display objects. The portfolio metadata provide multiple search mechanisms for finding objects. For example, the metadata elements provide a way to search for artifact elements by standards requirements. In addition, the metadata provide a tangible means for tracking and assessing students’ emerging competence in technology standards. Such assessment can be used to devise personal learning plans for meeting unfilled standards. Finally, the iFolio library can be accessed by professionals and/or peers at partner institutions for further review and comment.

Abstract: The Graduate School of Education (GSE) at George Mason University (GMU) is committed to developing new teachers who not only have the skills they need to develop and teach lessons with technology, but who also have the knowledge needed to distinguish between effective and ineffective uses of technology. In order to help the faculty achieve this goal, a concerted effort was needed to ensure that faculty’s use of technology included a variety of advanced learning applications. We submitted a proposal and were awarded a Preparing Tomorrow’s Teachers to Use Technology (PT3) Implementation Grant. This project involves pairing GSE faculty with K-12 teachers already proficient in technology for one-to-one mentoring. The K-12 teachers are helping the faculty redesign the teacher education curriculum to include technology, providing models for effective technology use, and demonstrating instructional software programs. The one-to-one support is being supplemented with Webcasts and “best practices” videos on integrating technology.

Acknowledgements

This project is supported by a Preparing Tomorrow’s Teachers to Use Technology (PT3) Grant from the U.S. Department of Education awarded to Debra Sprague. The data presented, the statements made, and the views expressed are solely the responsibility of the authors.

Introduction

Despite the increasing demand for technology use in the classroom, many teachers (preservice and inservice) still feel they are ill-prepared to integrate these tools into the school curriculum. The ideal way to prepare teachers for incorporating technology into classrooms is by integrating technology-based learning environments into the college curriculum, with university faculty modeling usage (Sprague, Kopfman, Dorsey, 1998). However, a survey by the Milken Exchange (1999) revealed that most faculty, whether in colleges of education or in the disciplines, do not model the use of technology in their courses.

Even if other faculty do not offer a model of technology integration, it is imperative that faculty in our colleges of education take a leadership role and provide prospective teachers with the opportunity to observe uses of technology in classrooms. However, many faculty members do not know how to effectively integrate technology in their courses. Although they may have basic computer skills, there is a sizable gap between personal technology use and use in teaching. It is much easier to learn basic computer applications, which are often covered in workshops, than to find - or even know where to seek - effective models of technology use that will improve learning. A concerted effort will be needed to move faculty use of technology into a variety of advanced learning applications that can improve education.

Such improvement in education cannot occur through “one-size-fits-all” workshops, especially when it comes to the integration of technology. Faculty members need time to reflect on their own teaching practice and beliefs. They need to explore software appropriate to their content area and need support as they begin to implement new teaching approaches. The most effective way to move faculty members from personal use of computer applications to the integration of technology into their courses is through working one-on-one (mentoring) where individual needs can be addressed (Thompson, Hansen, and Reinhart, 1996).
Mentoring has often been used to provide support for beginning teachers. Mentor teachers take on a wide range of roles in helping new teachers become familiar with procedures and instructional matters and providing emotional support when needed. “Key features of the mentoring approach are that assistance is provided within the context of a personal relationship and focused on the individual needs of the protégé” (MacArthur, et. al, 1995, p. 47). A mentor helps the protégé obtain knowledge or skills needed in order to prosper in their chosen profession. To improve technology usage in preservice education, faculty members need a mentor who can enable them to use technology effectively and understand their anxiety about change. Such a relationship can provide faculty members with the support they need as they move from personal use of computer applications to the integration of technology in their courses (Sprague, Kopfman, Dorsey, 1998).

Preparing Tomorrow’s Teachers to Use Technology Grant Project

In June 2000, the Graduate School of Education (GSE) at George Mason University (GMU) was awarded a Preparing Tomorrow’s Teachers to Use Technology (PT3) grant by the U.S. Department of Education. The goals of the project are to: (1) fully integrate technology in the instruction of preservice interns; (2) ensure that preservice interns are skilled in and have experience with integrating technology into K-12 classroom instruction; and (3) disseminate broadly the resources and best practices this project develops for integrating technology in preservice teacher preparation.

Through this project, we hope to develop beginning teachers who will be able to distinguish between effective and ineffective models for using technology in education and who are able to develop and teach lessons that include technology as a tool to support teaching and learning.

Providing Mentors

This project involves pairing K-12 teachers with faculty in one-to-one mentoring relationships. The K-12 teachers were selected from three partner school districts (Arlington Public Schools, Fairfax County Public Schools, and Prince William County Schools). They were chosen based upon their effective use of technology to support the learning of their students and were matched with faculty based on content area and grade level. These teachers are providing models for the effective use of technology, are demonstrating various software and web-based programs that can be used in education, and are assisting the Graduate School of Education (GSE) faculty in redesigning their teacher preparation courses.

Each participating GSE faculty member has been assigned at least one K-12 teacher who serves as a mentor for one year. During the Fall semester, the faculty member spends time during the school day observing the teacher in his/her own classroom. The faculty member witnesses ways of teaching with technology and is exposed to a variety of software and websites. During the teachers’ release time, the faculty has the opportunity to discuss what was observed.

Participating faculty will choose one course taught during the Spring or Summer semester that they want to revise to include the effective use of technology. They will spend time looking at resources provided by the teachers and reflect on ways they could use these resources in their course. They will also discuss these resources with the teacher and observe the ways teachers use these resources in their own teaching. During the following semester, the faculty will teach the newly revised course. The teachers will provide assistance to the faculty as they begin to integrate technology ideas in the course. The teachers will attend the course and serve as support for the faculty, providing technical assistance and making suggestions for improvement.

These same K-12 teachers will also work with the preservice interns during their field experiences. While working with the interns, the K-12 teachers will model effective uses of technology and help the interns use technology in their own teaching. This two tier approach will allow the preservice interns to see technology modeled in their teacher education courses by the GSE faculty, see the same kinds of models at their field experience sites, and practice these models with K-12 students. This should allow GSE to produce highly qualified teachers who are knowledgeable about technology and its role in teaching/learning and who have the skills to effectively integrate technology in their own teaching.

In order to ensure participation by the K-12 teachers and GSE faculty, incentives were included in the grant. K-12 teachers are being paid a substantial stipend and awarded three hours of class release time so they can meet with the faculty person assigned to work with them. Classes are covered by two GSE Doctoral Candidates who are assigned to assist with this project. Faculty were offered a course reduction for their participation. Sixteen
GSE faculty members and twenty-one K-12 teachers (some faculty chose to work with more than one teacher) are currently involved in the first year of this three year project.

Webcasts

In addition to the mentoring, training will also be available through the use of Webcasts offered by a local non-profit organization called Kidz Online (http://www.kidzonline.org). Kidz Online’s mission is to teach all children about the technologies that will play a major role in their future, so that they will view technology as an opportunity and not as a threat. Its educational programs have “kids teaching kids” and are focused on out-of-school learning. Kidz Online’s young volunteers from the suburbs teach at-risk children from inner city after-school programs basic on-line skills. It also has developed a computer graphics and animation program to teach more advanced multimedia skills for high-demand careers.

Through our partnership with Kidz Online we will produce a series of Webcasts, video-on-demand, and videotapes that will focus on teaching technology skills and integrating technology in K-12 classrooms and university courses. A revolutionary new technology and a key component to the project, Webcasting replaces the production equipment found in a high-end television studio, including multi-camera switching and special effects such as animation. Webcasting provides the power to simulcast live events such as corporate meetings, newscasts, conferences, classroom training, trade shows or even a talk show. These Webcasts may be viewed live which will allow for real-time interaction between the presenters and viewers via e-mail or chat.

The Webcasts will be twenty minutes in length and will focus on teaching technology skills and integrating technology in K-12 classrooms and in university courses. Curriculum for the Webcasts are being developed by K-12 teachers and faculty within the Instructional Technology Program in GSE. Webcasts will begin January 2001 and will be shown monthly. Webcasts will be available for faculty in GSE to use with their preservice students. Preservice students will be able to ask questions and interact with the host of the Webcasts using e-mail and chat. These Webcasts will be archived on the project website (http://www.techrnentor.org) so faculty at other universities and K-12 teachers may have access to them.

Currently, we are in the process of developing curriculum for the first series of Webcasts. This series will consist of three 20 minutes segments and will focus on the use of idea processors in K-12 and university settings. The first segment will introduce idea processors and demonstrate the use of Inspiration. The second and third segments will focus on the integration of idea processors in Math, Science, Social Studies, and Language Arts curriculum. Discussion by the moderator will be complemented by video footage of K-12 students using Inspiration to accomplish curricular goals. Future Webcasts are being planned for Web Quests, On-line Resources, Databases, Spreadsheets, and Virtual Communities.

Recruitment of Participants

In August 2000, the project director (Dr. Debra Sprague) sent an e-mail message to GSE faculty asking for volunteers to participate in the project. Sixteen faculty members agreed to participate (Dr. Steve White was one of them). Dr. Sprague met with the faculty and explained the purpose of the project. She emphasized the importance of using technology to teach in a new way as opposed to adding “technology for technology’s sake.” She provided the faculty with suggestions of appropriate activities for using technology in their courses. Dr. Sprague asked the faculty to send her an e-mail with the title of the course they wanted to revise and any special considerations they wanted her to take into account when finding a teacher. For example, several of the faculty already knew a teacher in their content area who was using technology and asked to be paired with that teacher while other faculty members supervise interns in a particular school and requested to be paired with a teacher from that school. Wherever possible these requests were honored.

School personal from each district served as the liaison for locating appropriate teachers. The teachers were chosen based on the following criteria. First, they needed to be a good teacher who happened to use technology effectively in their classrooms. Second, to ensure their technology skills and knowledge they needed to have either conducted a technology workshop or taught a technology course for their school, district, or the university; have completed a Master’s degree in instructional technology; or obtained a reference from one of the technology coordinators in the district. The twenty-one teachers selected to participate had met the criteria.
Status of the Project

Because of the high number of participants in the project we have run into some unexpected obstacles. First, during the 1999-2000 academic year, GSE redesigned all of its teacher licensure programs due to changes in state regulations. This led to new courses being developed and taught for the first time during the 2000-2001 academic year. Several of the faculty felt they were unable to give up a course due to this redesign. They felt they needed to teach the new courses at least once before hiring an adjunct to cover the classes. As a result, many felt they could not take advantage of the offered course release. This initially discouraged some from participating this first year. To try to assist the faculty and provide incentive to participate, the Dean's office agreed to allow faculty to count the course release toward summer payment (faculty receive summer money as though they had taught a course) or to use the funds for travel money so faculty could share what they had developed in their courses. This led to several faculty members agreeing to participate who had originally declined the invitation.

The second obstacle that needed to be overcome involved the difficulties of schedules. The teachers and faculty often found it difficult to schedule a time when they could meet. Some of the faculty were traveling and were not able to connect with their mentor right away. When they returned their mentor was busy with after school projects and could not always accommodate the faculty's schedule. Some of the pairs chose to meet on the weekends to discuss ideas for using technology.

Another obstacle involved some of the teachers who seemed confused as to the goals of the project. They did not understand that the faculty were going to visit their classrooms. This led to confusion by the faculty and the teacher. Originally, the advisory committee had planned a kick-off reception that would allow the faculty and teachers to get to know each other. This was canceled because the teachers had not yet been identified. As a result, faculty were given the names and contact information for their teachers and were told to contact them and arrange a visit. Had the reception been held, some of the confusion would have been clarified. To solve this problem Dr. Sprague met with the teacher-faculty pair and discussed the goals of the project. A timeline was developed and given to both the faculty and the teachers. This helped to clear-up the confusion.

Despite these obstacles we are seeing some success with the mentoring relations. Several of the faculty participating have expressed satisfaction with their assigned teachers. Two faculty members are in the process of developing new materials for use in their courses. One faculty member who teaches Science Method courses is developing a video on the use of probeware. Another faculty member who teaches Foreign Language Methods is developing a WebQuest to use in her courses. Upon completion of her WebQuest, preservice candidates will create a WebQuest of their own. The rest of the faculty are still exploring various aspects of technology and have not yet decided how they want to integrate technology in their courses. However, the majority of the faculty have expressed enthusiasm and excitement about this opportunity to improve their own teaching.

Because this project is just beginning it is too early to draw any conclusions about its effectiveness. The project is being evaluated by an outside consulting firm, Rockman et. al. The evaluation consists of on-line surveys, interviews with the participants, and observations of the university courses. Several PhD. candidates are also conducting research on the effectiveness of this project. Summaries of these research projects will be posted on the project website (http://www.techmentor.org) once they are completed.

Conclusion

This purpose of this paper was to describe the development and implementation of one PT3 grant. The process of developing mentoring relationships between the faculty and K-12 teachers was discussed. Specifically, the selection criteria for selecting K-12 teachers as mentors for university faculty along with the goals and potential outcomes of the mentoring relationships were described. Discussion of the Webcasts that are being developed to focus on teaching technology skills and integrating technology in K-12 classrooms and university courses was shared. Specific obstacles that were encountered by project participants were also discussed. Strategies that were used to address and overcome different obstacles were included to further illustrate how ongoing communication and problem solving has been used to focus on the overall goals of the project.

Abstract: A major challenge in engaging faculty members and K-12 teachers in in-service technology activities is the many demands and constraints on their time during the school year. A summer technology camp offers one approach for addressing this challenge by providing time for participants to interact and focus on technology in a relaxed atmosphere. This paper describes a technology camp that brought faculty members, K-12 teachers, and teacher candidates together for three days of technology related activities. A sampling of participants has been surveyed now that they are back in the classroom to determine the ways and amount they have used information and skills obtained in the camp. Practical suggestions based on the evaluations and the implementation of the camp will be described at the session to assist other educators interested in creating a similar camp.

The capacity building grant awarded by the U.S. Department of Education under the Preparing Tomorrow's Teachers to Use Technology initiative to a consortium led by Harris-Stowe State College provided a variety of professional development activities that brought together preK-5 teachers, college faculty members and teacher candidates. A major challenge in engaging such a diverse group in in-service technology activities is the varied demands and constraints on time combined with different academic calendars and schedules. One professional development activity designed to meet that challenge was the creation of technology learning communities (Stephen & Evans, 2000). A second strategy used to meet the goals related to professional development in the grant was the sponsoring of a summer technology camp.

Participants in Camp ETC, named for the project Edu-Tech Connect, met for three intensive days in August for workshops and hands-on activities designed to increase participants' expertise with technology and understanding of ways to integrate it into instruction. The camp format offered several advantages for the participants. These included a relaxed and casual atmosphere for learning, time to use information learned in workshops to develop materials for use in teaching, and a schedule that allowed participants to choose from a variety of workshops and activities. The camp also provided a setting in which faculty members, classroom teachers and teacher candidates could interact and exchange different perspectives on ways to use what was being learned in teaching.

From the very beginning, members of the camp planning committee found themselves confronted with a series of challenges and decisions that threatened to impact the success of the camp. The two main institutions, Harris-Stowe State College and Gateway Elementary Math, Science & Technology Magnet School are relatively small institutions with different schedules. They are not within walking distance of each other. In addition, while computer platforms at the two institutions are the same, the two institutions do not always support the same software for applications.

The first issue the committee confronted was the selection of dates and location for the camp. Administrators at Gateway Elementary offered to make two state-of-art computer labs available in either of two weeks following the conclusion of their summer school for use in the camp. Unfortunately, the summer session at Harris-Stowe overlapped those two weeks, but one of the college's computer labs was available for use during either week. The dilemma that the members of the camp planning committee faced became how to offer
a schedule that would not eliminate participation by Harris-Stowe faculty members and teacher candidates involved in the learning communities, but also involved in the college’s summer session. Since few of the college’s classes met on Friday and other classes followed a Monday-Wednesday or Tuesday-Thursday meeting pattern, the decision was made to schedule the camp for three days, Wednesday through Friday and to offer camp workshops at both locations on Wednesday and Thursday. This schedule enabled college faculty and students involved in summer school to participate in at least some camp activities.

An even greater challenge arose when the committee tried to plan workshops that would satisfy a range of interests and technological expertise. Since participants did not receive compensation for their involvement in the camp, planners were challenged to be creative in designing three days that would appeal enough to possible participants so they would be willing to commit their time freely to the camp. A variety of strategies was used to accomplish this, including early input from potential participants on topics of interest, a schedule that allowed participants flexibility in selecting topics and activities ranging from in-depth workshops to short activities such as using the computer to make mouse pads, plenty of vendor supplied free items, opportunities for fellowship and even a technology-related version of “Who wants to be a millionaire?” game. A survey of potential participants at both institutions resulted in the identification of some common areas of interest: strategies for using search engines, web page design, creation of electronic portfolios, use of presentation software, and creation of projects using graphics packages. While members of the planning committee had expertise to teach these sessions, the decision was made to contract the teaching of the courses through the director of technology instruction for a consortium of local school districts. This offered several advantages including freeing committee members to participate in sessions and to act as trouble shooters when needed, the ability to use and tailor already created workshops to meet the participants’ needs, and the availability of workshop instructors who regularly worked in the prek-12 environment. In cases when the institutions used different software for particular applications, such as web page design, similar workshops were held simultaneously at both sites, but using the software supported at that site. Beginning workshops followed by more advanced workshops were offered on topics where participants had different levels of expertise. In the all-day formats, mornings were devoted to more structured instruction, with the afternoons focusing more on time to develop materials to meet specific instructional needs with the workshop instructor available for assistance.

Members of the technology learning communities were targeted initially for participation, with additional spaces made available to other faculty at the college and magnet school. Student members of the learning communities worked in various capacities at the camp. Resources were available for 50 participants. While members of the planning committee feared that splitting the sessions on the first two days between two different sites might lead to separation of college faculty and students at the college facility and classroom teachers at the magnet school facility, that fear turned out to be unfounded.

Participants were asked to complete evaluations on a daily basis and a summary evaluation form at the end of the camp. In addition, in early November a sample selected from camp participants was asked to comment upon what they had learned at the camp that they have been able to use in their teaching. The evaluation forms indicated that camp participants had found the camp of value for several reasons. Among the reasons cited for the success of the camp were the quality of the workshops, usefulness of technologies introduced, manageable number of participants in each workshop, opportunity for increased collaboration between the schools, and the overall structure of the workshop. All but one participant, who was undecided, indicated that they would like continuation of this project. Each participant selected to participate in the November survey listed specific skills and information they had learned at the camp and were currently using in teaching. Several participants asked that the camp be expanded next year.

A major benefit of the camp, in addition to the practicality of what had been learned by the participants, is the good will and collaboration that was established among the participants. This will serve as a catalyst as additional activities are planned under the consortium’s implementation grant.

Abstract: The primary aim of the Viewing and Doing Technology (VDT) Project was to situate field-based secondary preservice teachers in a learning environment in which university faculty demonstrated skillful teaching with technology and offered students rich opportunities for visualizing and infusing technology in teaching. This project involved 10 secondary teacher preparation faculty who developed and conducted professional development workshops for each other. Workshops included developing online course materials, creating WebQuests, peer editing with word processing software, developing video cases, creating multimedia course materials, and photo editing. Graduate assistants, two computer science majors, provided technology support. Data collection included email messages, faculty created web pages, observations, and interviews. Results of the data analysis indicated the faculty developed a connected community of learners who worked together to learn new ways to use technology and incorporated what they learned into their teaching.

Infusing technology into classes throughout the teacher preparation program assures that preservice teachers experience how technology can be woven into daily classroom activities (Halpin, 1999). This modeling of technology integration provides a foundation for students as they develop the skills and confidence to use technology in their own classrooms. This requires that teacher preparation faculty know how to use technology to enhance their own teaching. However, teacher preparation faculties oftentimes do not receive the professional development, hardware, software, specialized support, released time, and recognition to develop the technological skills needed to infuse technology into their teaching.

In order for teacher preparation faculty to infuse their teaching with technology, they need professional development opportunities to learn to use technology and to learn to teach with technology. Effective technology staff development requires, among other things, immersion in learning over extended periods of time, active involvement, a community of learners, a focus on the learners' needs, and time for reflection (McKenzie, 1991). Additionally, effective professional development focuses on how to use technology to improve teaching and learning (Cottrell, 1999). The workshop facilitators must take into consideration the concerns and feelings of the participants (Linnell, 1994). Using the cognitive apprenticeship approach in professional development assures that instruction is relevant, focuses on authentic problems, and provides ongoing support after the workshops (Ritchie & Wiburg, 1994).

Just-in-time (JIT) direct instruction is one means of providing ongoing support. JIT is assistance that is provided when it is needed, is specific to the learners' needs, and is usually under the learners' control (Willis, Stephens, & Matthew, 1996). Further, JIT direct instruction teaches the learners a basic skill needed to solve a current problem and enables them to move beyond an impasse. This personal support for learners is crucial for faculty members as they learn to use technology. Immediate, specific technology support can be provided by students who know how to use technology and are immediately available to assist faculty members (Gonzales et al., 1999; Hruskocy, Cennamo, Ertmer, & Johnson, 2000; Thompson, Schmidt, & Hadjiyianni, 1995).

Learning to use technology and to infuse it into the curriculum in meaningful ways requires ongoing support from a connected community of learners who use technology. A community of learners provides not only the resources and technical support required to use technology but also the confidence to teach with technology (Ginnis, McRobbie, & Stein, 1999, Hruskocy et al., 2000). This community of learners may include both students and teachers. Tom Carroll's, Preparing Tomorrow's Teachers to Use Technology (PT3) Program Director at the U. S. Department of Education, vision for teacher professional development includes intergenerational collaborative learning between teachers and students whereby they learn from one another (Sanford, 2000).
Teacher preparation faculty members do not infuse technology in their classes in part because they lack professional development opportunities, proper equipment, and support. This research sought to determine if providing professional development workshops, proper equipment and a supportive community of learners would create a technology rich learning environment for preservice teachers. Hence, the Viewing and Doing Technology (VDT) Project was conceived as a way to facilitate this process by enrolling select faculty at Southwest Texas State University (SWT) in workshops that would help them learn and practice ways to use technology effectively. The ultimate aim of VDT was to situate field-based secondary preservice teachers in a learning environment in which university faculty demonstrate skillful teaching with technology and provide students with rich opportunities for visualizing and infusing technology in their teaching.

Methodology
Participants

Participants in this study were 10 secondary teacher preparation faculty, 4 males and 6 females, teaching in professional development schools. Faculty members had been teaching at the university level from 6 months to 25 years. They ranged in age from 35 years to over 55 years. All participants except one reported having a home computer that they used on a daily basis, checking their email daily, and using the Internet daily. These faculty members taught field-based courses at four area high schools and one middle school. Because they spend 15-20 hours at their respective school sites, they had few opportunities to learn and practice new technologies as well as limited time to work together to develop into a community of learners. The establishment of a "Visions Center," at one of the field-based sites served as a model for using current technology and developing constructivist-teaching practices. Participants received a stipend for participating in the workshops.

Procedure

The faculty members engaged in a faculty-teaching-faculty series of workshops. That is, they developed and conducted professional development workshops for each other. The five-hour workshops were held on Fridays during the course of the academic year and were led by one of the 10 faculty members with expertise in a particular area. Prior to the workshops, faculty members communicated by email to discuss the workshops. These email communications provided the workshop facilitator information about the concerns and expectations of the participants and assured that the workshops would meet the needs of the participants. Some faculty members placed workshop materials on-line prior to their workshops. Content of the seven faculty workshops included developing online course materials, creating WebQuests, peer editing with word processing software, developing and using video cases, creating multimedia course materials, and photo editing.

Workshop facilitators provided direct instruction, which included not only the necessary technological skills but also information and examples demonstrating how the technology was incorporated in the facilitator's university classes. Participants were then provided opportunities for guided practice to assure that they not only learned to use the technology but also understood how the technology could be adapted to their own classrooms. Two graduate assistants, computer science majors, assisted the faculty members during the workshops and were also available to assist faculty in their offices and in their field-based placements at area high schools.

One workshop was presented in the "Visions Center;" the others were conducted at a campus computer lab. The "Visions Center" provided faculty with access to the latest technology and was located on site at one of the local high schools where two members of the faculty were field-based. The campus computer lab provided a familiar environment for the faculty members and for some participants, workshops conducted here required less travel time. Coffee, soft drinks, and other refreshments were available to the participants throughout the day. At the start of the workshops lunch orders were placed and lunch was delivered to the site.

Results

Data collection included email messages, faculty and VDT project web pages, observations, and interviews with the faculty members and graduate assistants. Content analysis was used to determine common themes and patterns across the data sources.
The adoption of technology is a complex, nonlinear process that develops over time (Wesley & Franks, 1996) and faculty members involved in this project were cognizant of this fact. They understood that learning to infuse technology in their teacher preparation classes required a long-term commitment, would at times be frustrating, and would require that they become a connected community of learners who would learn together and teach each other. When asked about the impact of VDT on their teaching, faculty members reported that it was a good foundation for the next step. They were looking forward to more technology professional development and receiving additional equipment to use at their field-based schools. Faculty wanted input as to the what technology was to be purchased so they could have a choice in computer platforms and to be able to get what they wanted to use in their classes. Faculty members realized that integrating technology into their curriculum required a long-term commitment and would require them to continually learn new ways to use technology in their teaching.

Workshop topics were selected based on the participants' needs and focused on the effective use of technology to enhance teaching and learning. Participants were actively involved in the workshops and in the adaptation of the skills learned to their own classroom teaching. Faculty members reported that they thought it important that they were able to decide on the workshop topics themselves, as it was important that the workshops be specific to their needs. Not included in the workshops was a session on PowerPoint, because as one faculty member noted, "Everyone is using PowerPoint." Additionally, it was noted that using PowerPoint does not change instruction; professors just put their notes in PowerPoint and continue to lecture to students. Faculty members understood that to effectively use technology in their teaching would require them to change the way they taught.

A connected community of learners was formed as the participants made their workshop materials available on the web, communicated by email, and assisted one another as they encountered problems. Links to workshop materials were available from either the VDT web site or from the workshop instructor's homepage prior to the workshops. Participants were encouraged to preview the materials to assure that they had some understanding of the concepts to be presented and that the content of the workshop met their expectations. For example, prior to the workshop on web forms and web tests a web page was placed on-line with links to some existing web based forms for the participants to preview and the pretest for the workshop. Participants were asked to think about how they could use web forms in their teaching and were asked to bring to the workshop a form or test they would like to deliver via the web.

The faculty instructor for the PhotoShop workshop challenged the participants to construct the rationale and the design for the workshop to assure that it would be meaningful to them. To encourage the participants to think about what they wanted in the workshop, he posed a series of questions to them via email. Just as faculty members communicated with one another via email they also used email to communicate with their students. Faculty members commented that students have more access to email than previously and require students to use it for communicating with the professor and with one another.

Faculty members relied on one another for technical support. One faculty member commented that when helping another faculty member with a computer problem it is important to help them develop troubleshooting skills to enable them to solve future problems. This type of assistance empowers the faculty member with the skills to think through future problems and possibly solve them on their own. When teaching faculty about computers this faculty member introduces them to the control panel where they can make simple changes and teaches them about extension conflicts. He also cautions them about what leave alone.

Workshop facilitators were colleagues who took into consideration the levels of expertise of the participants and knew the unique problems faced by faculty members teaching in professional development schools, which assured that the material presented was relevant. Workshops included direct instruction in necessary skills, guided practice with written directions, and opportunities to work together to explore and create materials for use in their classrooms. The presentations were focused, yet relaxed and participant input was encouraged. The facilitator, the graduate assistants, and any participants who were somewhat familiar with the content of the workshop provided assistance.

Time for reflection was an important component of each workshop. Prior to each workshop, participants completed a pretest on the material to be covered in the workshop either online before coming to the workshop or on paper prior to the start of the workshop. At the beginning of the workshop faculty members talked about their expectations for the workshop and reflected on the email messages they had sent to one another about the workshop. They discussed how they thought the skills to be learned in the workshop could be used to enhance their teaching and possible ways to share their new knowledge with their students. As participants worked they shared comments back and forth on how they could use what they were learning as well as concerns about possible problems in using their new skills in their teaching. At the end of the workshop participants completed a posttest on what they had learned. Answers to the questions were discussed and participants reflected on what they had learned and how it could be used by their students. Workshops concluded with a brief discussion of the content and expectations for the next workshop.
Ongoing support for the faculty members was provided by graduate assistants who worked with the faculty in their offices and in their field-based classrooms. The graduate assistants were computer science majors, who provided technical assistance to the faculty and taught them to use various pieces of hardware, such as scanners and digital cameras, and software, such as PageMill and FrontPage. Their duties also included setting up new hardware as it arrived and loading software on computers. During interviews they commented on teaching the faculty to create web pages. The students preferred to use HTML for creating web pages, but learned FrontPage and PageMill in order to teach the faculty members how to their own create web pages. They realized that the faculty members would not be able to easily learn to create and maintain their own web pages if required to use HTML. They were pleased that the faculty members could now create and maintain their own web pages. While the graduate assistants were originally dismayed at how little the faculty members knew about computers when compared to their own knowledge of computers, they took great pride in what they had been able to teach the faculty members. They realized that the faculty members were willing and eager to learn about technology. Observations were made of the assistants teaching faculty members to download photographs from a digital camera. The assistants patiently explained the procedure and then allowed the professors to attempt the process on their own. The assistants hovered close by to guide the professors and to answer any questions they had about the process. The assistants were also available to support other university professors not involved in the VDT project. The just-in-time instruction they afforded faculty members assured that as problems and concerns arose they were quickly addressed.

When asked to provide examples of how they were incorporating what they learned in VDT workshops into their teaching, the participants were eager to share their students' work. One professor had students turn their projects into web pages, which were placed on-line to be shared with their classmates. She commented that students loved being able to see their projects on-line. Another professor created a HyperStudio stack on theories of adolescent behavior. Then, the students added cards to the stack that reflected a practical application of the theory. Their stacks were saved on zip disks, put on the college computer network, and shared with the other students in the class. Another professor shared how he had used Inspiration software to create a map of his course materials on moral development. Professors also cited the usefulness of learning to create web pages and creating web pages for their professional development sites. Not only were the university students using the web pages to check for their assignments, but so were the cooperating teachers, who wanted to know what they should be expecting from the students. Some professors stated that they had not been able to use all of the things they learned in the workshops because they did not have access to the equipment and software at their professional development schools. The lack of time to incorporate all they had learned was also noted.

Faculty members commented that each year the students they teach are coming to them more computer savvy than the last group and that students manage to find access to technology when it is required for their courses. They also recognize that as professors it is their responsibility to know about software and be able to guide students as they learn to use various pieces of software in their teaching. They keep examples of past students' work to show their present students possible ways to use different pieces of software in their teaching.

Conclusions

Faculty members and graduate assistants formed a connected community of learners who provided each other the technical support and the confidence to teach with technology assuring that their preservice teachers learn in a technology rich environment for visualizing and infusing technology in their teaching. This connected community of learners challenged each other to use technology and supported each other as they worked to use technology to improve teaching and learning. The VDT project provided participants opportunities to immerse themselves in learning to use technology relevant to their needs over an extended period of time, through active hands-on workshops followed by ongoing support provided by other participants and graduate assistants. Additionally, VDT workshops allowed participants time to share and reflect as they learned to infuse technology into their teaching. The workshops provided faculty members time to visit and share success stories and challenges encountered in their field-based teaching.

Faculty members found the workshops relevant to their teaching and cited examples of how they were able to incorporate what they learned into their classes. Some noted that the lack of resources at their professional development sites prevented them from incorporating all that they had learned. However, not being able to immediately implement something in their teaching did not affect their enthusiasm for learning about technology. One indication of the success of this project is that once the funding ended faculty members decided to continue their collaboration in order to further develop their technology expertise.

Introduction

This paper reports on the first year of a Preparing Tomorrow's Teachers to use Technology Capacity Grant Project designed to provide preservice teachers greater exposure to the instructional uses of technology (Maddux, 1984). Skills in the application of communication, presentations, microworlds (Jonassen, 1996) and CLE technologies are explored to bring to the classroom real-life examples (Cognition and Technology Group at Vanderbilt, 1990) and situations that provide the contextual framework so important to learning (Brown, Collins, and Duguid, 1989).

Goals for the project include:
- curriculum revision for college science methods courses to integrate more use of technology,
- integrating similar technology into both college and public school instruction,
- providing technology training and pedagogical mentoring for college teacher education faculty and participating public school teachers,
- exposing students and faculty at both the college and public school to current software and hardware offerings,
- providing leadership for technology rich instructional unit development, and
- enhanced experiences for pre-service teachers in teaching with technology in the classroom.

The participants in the consortium consisted of three professors at Westminster College, and two science and three math instructors, the technology specialist, and the principal at Bryant Intermediate School. This paper will report on the attitudes, experiences, and techniques of the science methods professor and the project administrator at Westminster College (who are co-authors of this paper), the two science instructors at Bryant Intermediate School, and elementary and secondary pre-service teachers.

Background Narrative

The overarching plan for the project involved the following timeline. During August participants met to discuss individual broad goals, and to discuss technology needs and skills to be developed before curriculum revisions. A final timetable of meeting dates, workshops, and assignment due dates was established. September brought the initial workshop to help develop skills for all consortium partners in technology applications integrated with instructional and learning methods. Participants explored issues of computer anxiety in students (Maurer and Simonson, 1994), factors contributing to successfully evaluating
software, computer simulations in the classroom (Jonassen, 1996), and principles of instructional design (West, Farmer, and Wolff, 1991).

Through October to December participants met as a consortium, with the project director facilitating meetings, every other week for about three hours. As participants developed their curriculum, changes were reviewed with suggestions made as to how to further integrate technology.

As this period unrolled, participants' roles evolved. The project director administered the grant and scheduled and provided technical assistance and teaching with technology expertise. Westminster science faculty became mentors for school participants, and school participants either bought into the project and found ways to challenge themselves in their curriculum revision or did not. Each meeting was conducted in a manner conducive to free and open democratic discussion and input. This was a key feature of the design of the grant so that the public school teachers who became consortium partners would feel, and be, in a true partnership. As this period progressed it was planned that students from the college who were enrolled in the fall educational technology course would demonstrate the use of educational technology instructional strategies to the consortium members to help them make informed decisions about the curriculum change process. In early December the consortium met to decide on conferences that would further enable the learning process and to plan technology purchases funded by the grant. Purchasing decisions were made by common open vote with an attempt at equality of access to the purchases by all participants. Before Christmas the developed unit plans and curriculum changes were reviewed by all and technology purchases began. Presenting and teaching these enriched units was planned for specific days in the next year so that preservice teachers could attend. The goal here was to present preservice teacher exposure to classrooms where real teachers were teaching real technology enriched lessons.

From late January to May participants taught their revised curriculum with other consortium members and/or preservice teachers in attendance. The goal was then to deconstruct the curriculum and revise as necessary. These revisions would then become models from which to draw expertise for further more extensive revisions the following year with even more technologies learned, and integrated into practice.

Method

All partners in the consortium were required to keep journals detailing their experiences, thoughts, and actions as they engaged in the project. Additionally, participants were surveyed and interviewed at the beginning and end of the school year about their inclinations and abilities to use technology, and to use it in teaching. The interviews were audiotaped and transcribed for analysis. Additionally, the project's outside evaluator (a co-author of this paper) conducted classroom observations in methods courses and intermediate school classrooms and informal interviews with consortium participants. Data from these sources provides the basis for formal evaluation of the effectiveness of the grant, and for this paper.

Narrative

Between October and December 1999, the consortium met regularly to revise curriculum. Our hope, both at the college and intermediate school level, was to infuse meaningful technology into similar units of study. Through our collaborative meetings in late 1999, we found that the science methods professor and the science instructors at Bryant were planning units of study focusing on various ecosystems. This resulted in significant changes in our teaching practices. In the science methods course, pre-service teachers set up experiments that addressed questions concerning animal and bacteria life on the Great Salt Lake. In order to conduct the experiments, the pre-service teachers used an array of technologies including field microscopes, conductivity meters, temperature probes, water testing kits, video microscopes, and several web sites.

Each of the pre-service teachers worked with the technologies during the science methods class sessions; however, the three pre-service teachers who had field placements at Bryant were also able to assist the science instructors there when the same technologies were introduced in their units on ecosystems. Eventually, two of the pre-service teachers helped facilitate "stations" on a culminating eighth grade field trip to the Great Salt Lake, to study ecosystems. At each station the students used temperature probes and conductivity meters to ascertain the temperature and salt concentration of water and soil in the surrounding area. Additionally, the students used the water testing kits to gather data on the pH of the
water and soil at each station. The field microscopes were used to observe salt crystals, brine shrimp and algae. At a later time, the students videotaped these organisms with the video-microscopes.

All pre-service teachers in the secondary methods course were required to create a lesson on the Great Salt Lake using many of these technologies for their final assignment. These pre-service teachers were then able to experience teaching with technology when 70 eighth grade students came to Westminster College to participate in the pre-service teachers’ lessons.

During this period from January through May technology purchases were made according to our plans and by a collaborative decision making process. Participants attended conferences partly funded by the grant and where necessary substitute teachers were provided to allow further workshops to take place. It was also during this period problems began to arise. Though the planning for the project called for a very democratic partnership it became evident teacher participants struggled with this notion of equality. With their years of experience advising teachers to defer to authority, whether it is real, or assumed through presumed superior knowledge, the teachers were unable to maintain a democratic partnership. In instances of planning curricular change the teacher participants deferred continually to their college peers. They were often late to meetings sometimes expressing a subservient truculence to perceived authority. As this continued science faculty and the Project Director did in fact assume more authority to get the project completed. This became an issue as the year came to a close and the teachers were largely left on their own to deconstruct and revise their new curriculum. Where college faculty naturally assumed this task as part of the grant project agreement, perhaps because such acts are a regular part of their profession, the teachers did not push forward with revisions without heavy encouragement to do so from the project director.

Another issue revolved around issues of control dictated by the school district of which Bryant is a part. When Westminster donated ten Pentium computers to Bryant the district would not support the machines by providing technical assistance. The machines were examined by a technician who claimed they were stripped and needed hard drives when in fact only the operating system needed to be loaded. To overcome this problem one teacher, perhaps used to handling such issues, with the full support of the other teachers, did the work herself. This was done surreptitiously so not to offend district technology personnel. Effectively, while technology shortages existed at the school, the district would not supply support for donated hardware nor provide timely support for district approved hardware purchases. Though the district was supposed to be an active partner of support for the grant, they provided very limited support for their teachers involved in the grant. Further problems arose through the billing practices of the district. Routinely it took the district several months after the receipt of purchased items to bill the grant. Though efforts were made to correct this problem, several months after the grant expired the district forwarded bills totaling in the thousands for hardware purchased ten months earlier.

Results and Implications

The opportunity to participate in a coordinated technology rich experience between their methods course and their field placement, allowed pre-service teachers to focus on the issues of teaching with technology rather than on just becoming familiar with the technology. Pre-service teachers expressed an increased awareness of the parameters involved in using and teaching with technology. They found the experience of first learning with and then teaching with the same technologies to be an important influence on their thinking about integrating technology into the curriculum. This was reflected in their post interviews and surveys, as well as in the final units of instruction they created and taught.

This said there were problems. Scheduling the preservice teachers to be in the participant teachers at times when the technology enriched lessons were taught proved difficult. An issue evolved around the selection of a faculty member to supervise these students as they visited classrooms. Unfortunately the faculty member with this charge had a very limited understanding of the value of technology for teaching and learning. She encouraged the students to be very critical in their observations of classroom practice. This negativity resulted in a number of preservice teachers jaundicing their view of technology as useful to teaching and learning. A key issue here is to be sure when engaged in a collaborative project, such as this, that both formal and informal participants buy into the goals of the project. A single negative perspective can induce problems of lasting longevity for new teachers, and influence the whole nature of a collaborative experience in an unwanted direction. More and better exposure to the planning involved in making the classroom experience a rich learning milieu for both participating preservice teachers and attendant faculty might have reduced this problem. For the following year plans were laid for the project
director to work closely with students and faculty intent on visiting these technology rich sites. It is hoped that by making the students part of the curriculum design experiment they will view the project as theirs and thus view the classroom teacher’s efforts in a more positive light.

Trying to provide a truly democratic partnership through collaboration also proved problematic. While levels of previous experience with technology varied, initial enthusiasm for teaching with technology united instructors at the college and intermediate school as they began this project. These instructors were convinced that integrating technology into their curricula would enhance learning experiences for their students, i.e. the pre-service teachers and the 8th graders. However, what was intended to be a democratic partnership with all members of the consortium participating equally in curriculum design and development, and in mentoring pre-service teachers, evolved into something less. As stated earlier, as the school year progressed, collaboration diminished. To overcome this problem the consortium chose to put in place a video conferencing system to enhance communication and perhaps to view into each other’s classrooms. Through sharing successes and trials a bond of common ownership for the process of teaching with technology will be attempted.

Another issue here is the role of the school principal. Through the year of the grant project the principal remained a peripheral player. Through the request of preservice and teacher participants the principal and other key personnel in the school and from the college will be asked to make a much stronger effort to watch teachers and faculty at work teaching with technology. Beside the “feel good” gain of being in the spotlight, teachers and faculty expect this move to make their efforts on behalf of the school, the college, or future teachers, recognized and valued. There will be a major effort to this end in future years of the consortium.

Another significant issue for the preservice teachers was the minimal measure of technology support from the district for the participants. It was widely understood that hardware and software purchase and support for the intermediate schoolteachers was not timely or sufficient. This could have been remedied through increased guidance and effort from the technology support personnel from both the college and school district. Preservice students questioned the level of support they could reasonably expect to receive when they became practicing teachers. After all, why learn to teach with technology, spending hours revisiting traditional curriculum, if district technology support fails to permit timely use of hardware. A further issue is that the preservice teachers observed that participant teachers felt a lack of preparation for using and teaching with the technology. This will improve as the instructors at both schools continue with the project. Finally, Bryant teachers did not fully understand their expected role in mentoring pre-service teachers, and college based partners were not sufficiently involved in the actual classroom experiences of the pre-service teachers at Bryant. Careful planning should overcome these issues.

What next?

First year jitters associated with using initially unfamiliar technology, teaching a newly revised curriculum, and forging a partnership between college and public school instructors is now behind the partners in this project. The participants now intend to develop more curricular units that will provide pre-service teachers more opportunities to experience and participate in teaching with a greater variety of technologies. They also will be adding more public school teachers to their partnership in order to provide exposure for more pre-service teachers to this coordinated experience in learning and teaching with technology.

This growth in project team members, and their locations in additional public school sites, creates new challenges in administration and communication. The consortium has stepped up their communication technology capability to address the potential problems in coordinating efforts between members of a larger group. An issue in the year of this grant was that the Project Director, was the administrator, workshop leader, curriculum designer, peacemaker, purchaser, and arbitrator, without decrease in faculty load. For the coming year an Assistant Director as well as a technician has been hired as the project continues as an Implementation grant. Also, decreasing required faculty load has increased project administrator involvement time. Additionally the project administrator’s responsibilities have also shifted toward more specific direction of the project activities.

It is this year when the outcomes to the consortium project will affect preservice teachers more broadly. Faculty who participated in the consortium last year is being joined by others with expertise in language arts and creative arts in revising their curriculum to a technology rich standard. Incoming faculty
has been apprised of the trials and successes of last year’s efforts and are reaping the benefits of what we now refer to as our pilot year. Along with this the educational technology course that all preservice teachers must take to complete and earn their teaching license is under full revision to include the lessons learned by the consortium about teaching with technology. This means more in-depth exposure to video-conferencing as a communication tool, greater emphasis upon the web as a source of data for lesson development, and most importantly a shift in perspective from teaching in a traditional fashion with technology replacing a text or the chalkboard, to teaching with technology as a metaphor for teaching as a curriculum designer. This change may positively alter many teachers’ views of continuing in their profession. If so, this approach may indeed have consequences upon teacher socialization and teacher desire to continue to practice.

Project goals for years subsequent to this reflect the findings ground out through careful planning, happy circumstance, and sometimes unrealistic expectations. More data is needed to ascertain just how effective this project becomes in providing preservice teachers the knowledge, skills, and desire to use technology in their practices. To this end Westminster College has dedicated time and faculty to follow teacher candidates as they begin their practice. Through personal contact, further mentoring, and surveys details of the role of technology in teaching for these graduates will emerge, be presented and published.

Further research will focus on the working partnerships between college and public school instructors that develop as a result of this project. Also, findings from the initial year of the project will be used to guide further research into the effects of specific aspects of the project on pre-service teachers’ inclinations and abilities to integrate technology into their teaching, as well as to how this process affects their inclination to continue as teachers.

Abstract: The mini-grant concept, used at many universities, was identified as a "best practice" in a study of teacher education programs deemed exemplary in their integration of technology (Strudler & Wetzel, 1999). It is designed to address the obstacle identified by faculty as the biggest impediment to technology integration—time for professional development. Planned in collaboration with UNLV's Teaching and Learning Center, our mini-grant program provides faculty time outside of their normal work schedule to gain new skills and plan and develop technology-enhanced learning activities for their classes. Ten mini-grants were awarded last summer as part of our PT3 Capacity-building grant. Now, our Implementation grant includes 36 mini-grants per year for three years--24 within the College of Education and 12 to faculty in other colleges across campus. Overall, we feel that the mini-grants offer a wonderful "next step" as a follow-up to the faculty workshops that we've offered. This paper will document the process and outcomes of our mini-grant program to date. For more information and examples of faculty projects please see: http://www.unlv.edu/projects/THREAD/.

Introduction

Project THREAD, funded through a PT3 Implementation grant at the University of Nevada, Las Vegas (UNLV), was designed to make technology infusion a systemic part of preservice teacher education. One key ingredient necessary to accomplish this goal involves a range of professional development activities for UNLV faculty. In addition to providing a series of workshops and follow-up support, a mini-grant program has been initiated to provide faculty with the time and support necessary to integrate technology into courses in significant ways. This paper will describe our efforts to implement this mini-grant program, document outcomes achieved thus far, and discuss future directions for the initiative.

Background

A needs assessment was conducted in fall, 1999 that documented the attitudes towards technology by UNLV College of Education (COE) faculty and their use of technology in teaching. Virtually all faculty rated technology in teacher education as "very important" (68%) or "somewhat important" (30%). Despite this finding, survey results indicate that faculty use of technology in teaching is limited. When asked what factors restrict or constrain their use of technology in teaching, 63% of the COE faculty cited time for professional development. This finding is consistent with the literature pertaining to impediments to technology integration in teacher education (Strudler & Wetzel, 1999). By and large, UNLV College of Education faculty have stated in a series of planning meetings that with the provision of time, professional development, access to technology resources, and follow-up support, they will commit to moving forward with technology integration in the COE.
Time for Professional Development

The literature on technology implementation in schools is unequivocal—professional development is critical to achieve widespread technology integration. While workshops and follow-up support are key components of our professional development program, they do not directly address the number one need identified by faculty—time. Whereas in early technology integration efforts access to technology resources was cited as the major obstacle, time has emerged for many educators as the most pervasive impediment (U.S. Congress, 1995). To address this need we are implementing a mini-grant program that provides faculty time outside of their normal work schedule to gain new skills and plan and develop technology-enhanced learning activities for their classes.

About the Mini-grants

This mini-grant concept, used at many universities, was identified as a "best practice" in a study of teacher education programs deemed exemplary in their integration of technology (Strudler & Wetzel, 1999). Planned in collaboration with UNLV's Teaching and Learning Center, our mini-grant program provides a $1500 stipend for selected applicants to work on campus when school is not in session—during winter break or during the summer. Ten mini-grants were awarded last summer as part of our PT3 Capacity-building grant. Now, our Implementation grant includes 36 mini-grants per year—24 within the College of Education and 12 to faculty in other colleges across campus. Contingent upon continued funding, the mini-grant program is planned through the 2002-2003 school year.

To obtain a mini-grant faculty must submit proposals that identify how they plan to enhance components of their courses with technology. A review committee composed of project staff and members of Project THREAD's Advisory Board review the proposals. Criteria for rating the first round of proposals were based on the quantity and quality of learning for the faculty involved in the project, the degree to which the proposal meets specified ISTE/NETS for Teachers' standards and addresses gaps in preservice teachers' learning experiences, and the expected impact the mini-grant will have on preservice teachers. To foster integration in coursework and throughout programs, faculty may submit collaborative mini-grant proposals. Support for the mini-grants is being provided by Project THREAD staff as well as by UNLV's Teaching and Learning Center.

Results

Our first call for mini-grants was posted in Spring 2000 and was promoted in the various Project THREAD workshops. We received proposals from 15 faculty, 10 of which were accepted based on the criteria discussed above. In a few instances, before accepting the proposals, Project THREAD staff "negotiated" with the applicants and suggested revisions that would help the proposals better meet the project's goals. In the case of applicants whose proposals were not accepted, feedback was given and applicants were encouraged to revise and resubmit their proposals during future iterations of the mini-grant program.

Applicants whose proposals were accepted were sent an agreement form that specified the expectations for the award. Upon signing that form, participants were given an initial payment of $500 in the form of stipends or equipment. The remaining $1000 was held pending completion of the proposed activities. Documentation of completion included a written lesson plan, revised syllabus, and a brief presentation to members of the Project THREAD staff. The presentations, which were approximately 20-30 minutes long, gave recipients the opportunity to show and discuss what they had accomplished as a result of the mini-grant. Project THREAD staff also had the opportunity to ask faculty about their experiences as mini-grant recipients.

Descriptions of each of the mini-grants can be found at: http://www.unlv.edu/projects/THREAD/mierapss00.html. At the bottom of each of the mini-grant pages is also a detailed evaluation of the syllabus that was revised as a result of the project. In addition, the requests for proposals are available in the Mini-grant section of the Project THREAD web site: http://www.unlv.edu/projects/THREAD/.

Lessons Learned
The actual implementation of the mini-grant program presented a myriad of challenges for recipients and project staff. In some instances, the professional development needs pertaining to the proposals took project staff to the edge of their experience and expertise. This was especially true in the case of digital video projects. In addition, we experienced our share of challenges in procuring some of the equipment and getting it all installed and functioning in a timely way.

We are currently completing in-depth interviews with the mini-grant recipients to learn more about their experiences with the mini-grants and how they may have affected faculty’s knowledge, skills, and dispositions. Results of these interviews will be reported at our SITE 2001 presentation.

Our second call for mini-grants incorporated some revisions based on our experiences. For one thing, we opted not to include equipment procurement as part of the program. Thus, while we will continue to consult with faculty about what software or equipment may contribute to their proposals, faculty will be responsible for purchasing the materials themselves with the stipends that they receive. We anticipate that this change will free up time for the Project Coordinator to focus on her main role in the mini-grant–professional development.

Other enhancements of the mini-grant process include clearer expectations for program priorities. For one thing, the revised RFP requires faculty to complete a planning form that asks them to identify what National Educational Technology Standards for Teachers are addressed in their courses. Since the mini-grants have proven to be a viable incentive for faculty, we are trying to be sure that we take advantage of this “carrot” to support the implementation of some of the less desirable elements of our project—namely, being systematic in our planning. Other program priorities encouraged in the RFP include projects that: (a) are outcomes-based, model technology integration for preservice teachers, and expand students’ opportunities for active learning; (b) meet goals established by faculty the curricular areas; (c) are designed to affect systemic change—e.g., projects with potential to impact multiple sections of a course or programmatic changes; and (d) use some of the new technology resources of the College of Education including our portable, wireless lab of I-Books that were purchased for the project.

Spreading the Word

One strategy that we’ve used to “spread the word” has been to highlight the accomplishments of mini-grant recipients at College faculty meetings. In two successive meetings this fall, we’ve arranged for short presentations (15-20 minutes each) in which faculty demonstrate what they’ve done and talk about their experiences. We believe that our recent mini-grant recipients are serving as our best ambassadors and doing an excellent job of spreading their enthusiasm. Since many of the presenters are not seen as techies, they serve to dispel the notion that our professional development activities are geared only those who are technologically inclined. Following these faculty presentations, we’ve received many questions and inquiries from faculty about future mini-grant offerings.

Overall, we are thrilled with the results of the mini-grants thus far. We believe that they offer a wonderful "next step" as a follow-up to the many workshops that we’ve offered. While workshops can be very effective in helping faculty establish a vision for what they might do with technology in their classes, a substantial investment of time is necessary for faculty to expand their skills and plan changes in their courses. When compared to other professional development models, we believe that the mini-grants provide a cost-effective way to carve out time for faculty to extend their work with technology in substantial ways.

The United States Department of Education has made clear the growing need for well-prepared, technology-proficient educators. The need is greatest among low-income communities, rural areas, minority groups and areas characteristic of what is now known as the "digital divide." The situation for Valley City State University (VCSU) and its partners within the Sheyenne Valley fits this description in every way.

The strategic theme at Valley City State University the last eight years has been dramatic change to help meet the needs of students and the state. Such a change began in 1996, when all students and faculty gained access to full-time use of a laptop computer, with networked facilities and renovated classrooms to promote maximum use of the computers as tools for learning. VCSU was the second four-year university in the nation to take this initiative. More importantly, VCSU was the first teacher preparation institution in the United States to implement a universal laptop initiative. With the administrative structure in place, the learning tools in use, and faculty with over four years of laptop experience in the classroom, we have moved to the next educational step—a collaborative experience with K-6 schools to better meet the needs of our preservice teachers.

To respond to this need to produce technology proficient teachers, the VCSU Elementary Education program has formed a partnership with six other educational entities to strengthen and improve learning with technology and to ensure that there is continuity between the VCSU Elementary Education technology requirements and K-6 needs. To help achieve this continuity, the VCSU Elementary Education Department applied for and received PT³ implementation grant from the U.S. Department of Education.

One of the main goals of the grant is to provide opportunities for VCSU Elementary Education faculty, preservice teachers and inservice teachers from the consortium to work together to integrate technology into their courses and to create a learning community among themselves for the purpose of using technology to improve learning and develop complex reasoning and problem solving skills.

Cooperating teachers representing the various consortium school buildings are collaborating with VCSU faculty and preservice students to restructure learning experiences in their classrooms that reflect current best practices for using instructional technology strategies and tools. Curriculum teams begin by
choosing one unit of study. They develop and organize units that focus on cross-discipline, student-centered projects that use technology to enhance and expand student experiences. These restructured units are being put in place and working to change the way education is delivered not only in the K-6 consortium classrooms, but also in the practicum and student teaching experiences of the preservice teachers. Maximum use of web and communication technologies is also in the process of being implemented.

The teams consist of one K-6 teacher, at least one university teacher, VCSU students and a Center for Innovation and Instruction (CII) advisor. The teams select specific projects to work on and develop. The teams also develop a formative and summative evaluation process that takes place throughout the projects. The design of the evaluation process is project specific. The projects are implemented and evaluated in the classroom and are published on the grant web site (http://www.vcsu.nodak.edu/projects/pt3_grant/).

Teams of VCSU and K-6 faculty will also be participating together in an intensive three-day session focusing on technology integration and collaborative project building in the classroom. The session will move them through levels of awareness, application, integration and assessment. This will expose the educators to a combination of technology use and integration methods and ideas, including instructional strategies for complex reasoning and problem solving, telecommunication resources, multimedia hardware and software, cross-discipline and project-based content, and authentic assessment.

Elementary Education students will also create material specified by K-6 teachers to be used in the collaborative projects and other classroom activities. These products will include multimedia, CD-ROM, web pages, digital portfolios, and other information technology products. Each product will follow a real world production model: planning, producing, implementing, evaluating (both formative and summative) and revising.

VCSU faculty will develop on-line, asynchronous support material using courseware blackboard (Bb). The modules will be available to preservice and inservice teachers to help them improve learning. For example, a language arts teacher may produce a module on the writing process as a problem solving strategy or the educational technology teacher may develop a module on a Bb to develop a complex reasoning activity.

The Elementary Education faculty will undergo extensive training on the design process for course software for developing on-line methods distance education modules. Faculty will be provided with release time or other appropriate incentives to develop the modules. Each module will be pilot tested with a sample group, evaluated, revised and published on the grant web site (http://www.vcsu.nodak.edu/projects/pt3_grant/).

Another goal that we are working toward is directed specifically toward the preservice teacher. We would like each Elementary Education graduate to be able to use technology to help their students improve learning by developing complex reasoning and problem solving skills. To achieve these goals the following objectives have been established.

1. The consortium partners will compile a web-based, fully accessible annotated research base consisting of current successful practices for developing complex reasoning and problem solving skills in collaborative and non-collaborative environments on line and off line. University faculty, K-6 faculty, VCSU students, K-6 students, and the CII will be involved in the research and assessments. The software evaluation process will use a standard evaluation form from CII. The evaluation will also include a descriptive tool for evaluating computer-based instruction. The research base will be available on the grant web site. The research base will be used to inform all the grant projects.

2. Faculty will integrate complex reasoning and problem solving projects into their courses. Students in their regular coursework must be engaged in higher order thinking skills in order to develop their own projects. University faculty must be models for the students and their course assignments must engage students in higher order thinking skills. Projects created in this integrated curriculum will require students to apply the university's abilities to more complex problems (http://www.vcsu.nodak.edu/offices/titleiii/guide/cdport.htm).

3. Students will design and develop their own projects to demonstrate using technology in teaching complex reasoning and problem solving skills. These projects will be designed to help the preservice teacher to become more effective and efficient in their teaching with technology. Students will use a process based on the following steps.
   a. determine goals and objectives
   b. identify potential projects
   c. select projects to be developed
d. develop formative and summative evaluation process

e. select products from the research base to use with project

f. develop project

g. implement project

h. evaluate and revise

i. publish on web site

The success of the PT³ grant is a reflection of the direction Valley City State University has been moving the past eight years. VCSU has been a national leader in instructional technologies and the resources available at VCSU ensure that successful efforts will be continued and the university will be an example for others to follow.

Furthermore, Technology and the New Professional Teacher: Preparing for the 21st Century Classroom, a report of an NCATE Task Force on Technology and Teacher Education, recognizes and underscores the influence that the VCSU teacher education program and its faculty members exert at the national level. Referencing the report, Arthur Wise, President of NCATE, sent VCSU President Ellen Earle Chaffee a letter dated September 11, 1997, that states, in part:

The report derives its credibility from the expertise of its members and their selection of exemplary practices to highlight. The task force cited a project at your institution as a case illustration. Your selection makes clear that you are at the cutting edge of teacher preparation practice. Your inclusion in our report should extend your influence and help to change the norms of practice.
Pre-service Teacher Responses to the Restructuring of the Traditional Educational Computing Course

Abstract: The primary focus of this paper is the perceptions of currently enrolled students regarding a new course format. Data has been gathered from students currently participating in CUIN 3111, Technology in the Classroom, through a qualitative ethnographic interview process and through the medium of a web-based newsgroup application. Through this data we will understand the perceptions of our pre-service teacher students regarding their experience of the new technology course and will then be able to incorporate any changes necessitated by these observations into designs for future classes in the upcoming Spring semester.
Context

Educators involved with the preparation of new teachers throughout the final decade of the Twentieth Century have repeatedly recognized the need for a strong technology component for pre-service programs. They have experimented with a variety of learning models that integrated technology (e.g., Beichner, 1993; Carr, 1992; Falba et al., 1999; Munday, Windham, & Stamper, 1991; Persky, 1990; Rodriguez, 1996; Smith, Houston, & Robin, 1994; Thompson, Schmidt, & Hadjiyianni, 1995; Willis, 1997). While some successful projects have indeed been celebrated, there is agreement that new teachers are generally not being prepared to effectively integrate technology into their future classrooms (Office of Technology Assessment, 1995; Strudler, Quinn, McKinney, & Jones, 1995; Willis & Mehlinger, 1994). There is agreement on the following inadequacies of the efforts of pre-service programs:

- It is no longer enough to prepare new teachers only with one disconnected technology-in-education course; introductory courses should instead be project-based and meaningful, followed by appropriate modeling and use in content methods courses and field experiences (Handler, 1993; Wetzel, 1993).
- True modeling of how objectives can be accomplished by using technology for instruction is rare in pre-service programs (Bosch & Cardinale, 1993; Office of Technology Assessment, 1995; White, 1994).
- Pre-service teachers want to learn strategies for integrating technology tools into their teaching (Mowrer-Popiel, Pollard, & Pollard, 1992; Oliver, 1994), and expect to use computers in their teaching (Marcinkiewicz & Wittman, 1995) but express their feelings of frustration at their lack of technology proficiency (Francis-Pelton & Pelton, 1996) and a lack of understanding of effective technology use in contemporary classrooms (Balli, Wright, & Foster, 1997).

In response, a standards-based movement has developed which brings a clearer vision to the preparation of pre-service teachers. Teacher education programs across the country must finally acknowledge the long trend of research findings and recommendations in order to design appropriate learning environments that challenge long-standing curriculum structures through the cooperation of all faculty involved with teacher preparation. Without the purposeful creation of collaborative, authentic, and content-focused learning environments in which future teachers are empowered to develop content, pedagogy, and technology strategies concurrently, new technology standards will be meaningless.

Process and Procedures

Our appointment as Technology Fellows for the PT3 grant at the University of Houston began in the Summer of 2000. At the outset, we were charged with responding to the problems described in the preceding paragraph. The development of CUIN 3111, Teaching with Technology, required that we create a course which was standards-based and yet true to constructivist principles, which allowed pre-service teachers to develop their technology skills while accommodating many different levels of technology expertise, and which enabled us to gather input from our students to better structure the course to their needs. The course would also be given meaning by linking it to the content methods courses in which pre-service teachers were concurrently enrolled. Given the number of objectives involved, this commission seemed somewhat daunting at the outset.

Course Design

Prior to Fall 2000, the College of Education at the University of Houston required its undergraduate education majors to enroll in a three-hour course, CUIN 3312, “Information Technology for Young Children.” In an effort to fulfill grant objectives, the original one semester course was divided into three one-hour courses spanning three semesters. The elimination of prescribed assignments stands as a major change in the requirements for the newly structured technology course. In the new model, technology assignments support required education course activities, thereby demonstrating through practical applications how technology should be integrated into classrooms. Students are searching out ways to meet
course requirements using technology even when they are not specifically required to do so by their professors. Early student responses indicated that this model fulfilled the intent of the restructuring effort.

I think that I am finally beginning to understand these high tech computers. Hopefully by the end of this course, I will be able to get an even better understanding than the understanding I have today! I am looking forward to a great semester!! (Hypergroup posting, student, September 18, 2000)

Student enthusiasm for the new course design was apparent almost immediately. The students liked being given the freedom to design their own learning. One way in which we allowed for student input in the design process was through collaborative development of the rubric, the evaluation mechanism used for each of the reflective papers the students submitted.

...the majority of you have been exposed to the standards and the rubric development process. I’d be really interested to know your honest opinions on both. Do you think you would develop rubrics in conjunction with your students? As a teacher it can be a really scary process because you never know what your students are going to come up with. We should have a working prototype of the rubric to show you by next class and you should definitely see the influence of your ideas within it. (Hypergroup posting, tech fellow, September 8, 2000)

As instructors, we felt that we had achieved the initial goals that we had set forth at the outset of this experience. The structure had been established; it was now essential to record student responses, both positive and negative, to that structure.

Hypergroup

Established at the beginning of the semester, the Hypergroup allowed for ongoing exchange between students and instructors as well as facilitated the development of peer relationships. Through this medium, we encouraged feedback and collaboration among our students throughout the semester.

This is your online discussion group. You will use this area to ask questions, share ideas, and communicate with your peers and instructors...Your instructors will be reading and posting discussion topics to help you get started. We are looking forward to working with all of you this semester. (First Hypergroup posting, Tech Fellows, August 23, 2000)

For instructors restructuring their undergraduate technology courses for pre-service teachers, an important consideration should be the inclusion of a communication tool that promotes positive peer interactions. By the second month participation in the Hypergroup was going strong with future teachers sharing ideas, posting resources, and communicating common concerns. The Hypergroup, originally intended as an example of a mode for teacher communication, has turned into a true community-building tool.

Don't panic! I know it seems a little confusing but you can handle it. The structure of the class has been a little confusing and you kind of have to do things on your own. If you take time to read the ISTE indicators you can break things down and develop a 1-page reflection. I will be more than happy to help you in any way I can. Feel free to e-mail me and ask for suggestions. We might just be able to help each other out with the class (Hypergroups, student, November 16, 2000)

Interviews

Interviews conducted at the middle and end of the semester by a research associate affiliated with the PT3 grant but not directly involved in the instruction of CUIN 3111 allowed instructors to gather anonymous input regarding course structure. Interview transcripts, summarized and presented to the instructors, revealed that students were deeply invested in their progress and roles as co-developers of the course format.

I’m a student in the CUIN 3111. I would like to thank you for coming in to interview the students in the class because it really gave us an opportunity to give our input about
the course. Also with this program being new, I think the interview will allow the students a chance [to] take part in molding the course (Hypergroups, student, October 11, 2000)

One student, when asked to develop a metaphor to describe the experience of the new course design, stated:

It's like jumping on a boat not knowing how to sail but someone more experienced will help you along, so it isn't like sink or swim (interview, student, September 25, 2000)

Skill Development

Our development as instructors in this course correlates directly to student feedback from two qualitative research methods: ethnographic interviews conducted by an outside interviewer and from a web-based newsgroup application (Hypergroups). Because this class is based on the ideas described by action research, we seek to provide an atmosphere of trust and openness that allows us to record, evaluate, and respond to student perceptions regarding their own learning (Lawler, 1985; Stringer, 1999).

Direct Instruction

Student interviews revealed a wide range of perceptions regarding the new class structure. Some students indicated that the structure of the course allowed freedom to work at their own pace, whereas others felt that the class was directionless and lacking in focus.

Students who are not accustomed to the process of defining their own learning are likely to feel a sense of frustration because they are not receiving the direct instruction with which they have grown familiar. In that sense, student responses are somewhat encouraging in that we have remained true to the constructivist principles. While we wish to maintain the constructivist approach we also acknowledge that student expectations play an important role in their success. Our students have asked for and will receive more direct instruction. Our plans for future semesters will include scheduled mini-workshops based on needs expressed by students. Students will have the option to participate in these lessons based on their needs.

Connections

One of the stated goals for the new course was to connect technology experiences in CUIN 3111 to methods courses in which students were concurrently enrolled. Some success in this effort is apparent, however, student responses still indicate a significant gap between technology expectations in the new course and those of instructors of their methods classes. While we have attempted to ameliorate this discrepancy by allowing students to complete projects for personal use rather than direct relationship to other coursework, our ultimate goal remains unfulfilled. We will continue our efforts to increase technology diffusion throughout the pre-service education program and hope to see the effect of these efforts in future semesters.

Deadlines

At mid-semester, it became painfully apparent to both instructors and students that a schedule for submitting the reflective papers was necessary and advisable. This requirement was expressed numerous times during student interviews, through Hypergroup postings, and in conferences with the instructors. Therefore, the decision to require that half of the reflections be submitted by mid-semester seemed intuitive.

Resources

Students also indicated a need for resources related to the course to be located at a central site for easier access. To that end, construction of a course website that includes all current resources has been ongoing. This website will be launched at the beginning of next semester and will include items requested by students such as examples of model reflective papers, ideas for project completion, tutorials for basic
applications, and helpful websites. The site will be updated according to the needs expressed by the students. As such, the web site will become another tool for student response to the structure of the course. In addition, a textbook containing examples of technology-based lessons and ideas will be adopted.

Hypergroup

Interviews revealed that the Hypergroup established for the students was accepted favorably. Students stated that the Hypergroup gave them access to information and helpful web sites as well as allowed them to communicate regularly with instructors and peers. Due to these resoundingly positive responses, the Hypergroups will stay intact for these pre-service teachers throughout their teacher education program and into their first year of teaching where it is hoped that these teachers will become a part of other online peer resource groups.

Future Goals

According to action research methodology, the recording of student response requires evaluation, synthesis, and response by the instructors. As described above, we have distilled student responses and formulated our own response that will become the kernel around which the next semester’s course will develop. Summarized below are the actions that will be taken to change course design; all of these changes are based on student responses.

- Continue working to achieve concurrency between methods courses and CUIN 3111.
- Publish a course web site which provides greater access to resources.
- Provide direct instruction by way of mini-lessons and hands-on workshops on a bi-weekly basis.
- Incorporate concrete deadlines for blocks of reflections.
- Continue utilization of the Hypergroup.

The expected outcome of these changes should yield a new series of responses which can then be employed to further refine the structure of the new computer course.

Abstract: This paper is a report on the results of a pilot project funded through Preparing Tomorrow's Teachers to Use Technology (PT3) Initiative. Project PICT (Preservice Infusion of Computer Technology) was piloted during the 1999-2000 academic year and focused its efforts in technology infusion on the elementary education program. The project is described in the context of the ISTE (2000) Essential Conditions for technology integration. This paper describes ISTE's essential conditions for technology integration, how Project PICT fulfills these conditions, evaluation methods used by PICT, pilot results, and implications for further research and practice.

Introduction

As educational institutions have attempted to utilize technology as a learning tool, researchers have consistently identified numerous barriers that impede the training, development, and implementation process of technology infusion (Parker, 1996; Seminoff & Wepner, 1994; Wetzel, 1993). With these results in mind, ISTE has identified ten essential conditions—shared vision, access, skilled educators, professional development, technical assistance, content standards and curriculum resources, student-centered teaching, assessment, community support, and support policies—that "are required to create learning environments conducive to powerful uses of technology" (ISTE, 2000). These conditions form the framework for Project PICT (Preservice Infusion of Computer Technology), an initiative that seeks to prepare preservice teachers to effectively use technology as a learning tool by infusing technology in Bowling Green State University's teacher education programs. Funded through the Preparing Tomorrow's Teachers for Technology (PT3) initiative, Project PICT was piloted during the 1999-2000 academic year and focused its efforts in technology infusion on the elementary education program.

Creating a shared vision of technology infusion among stakeholders and leaders has been difficult for many institutions due to the evolving nature of technology and subsequently the varying purposes for using technology in the classroom (Valdez, et al, 1999). However, as research on the impact of educational technology use has been conducted and disseminated, policymakers, funding agencies, administrators, and educators are espousing a vision in which technology is a tool used to engage students in meaningful learning, understanding, and exploration (Cifuentes, 1997; Nicaise & Barnes, 1996; Perkins, 1992). Thus, Project PICT sought to facilitate a dynamic and constructivist vision of technology infusion where an assortment of technologies and applications were used to enhance the creation of products, facilitate problem solving, and assist exploration. This vision was introduced to Project PICT participants (HE faculty, K-6 educators, K-6 administrators, technology coordinators, and preservice teachers) at the very first workshop where technology-using educators presented example lessons and products that demonstrated how they had effectively used technology as a learning tool. Participants were directed to resources that exemplified constructivist uses of educational technology. Training sessions also facilitated discussion on meaningful uses of educational technology and appropriate instructional methods for technology infusion. Activities that established this shared vision were cited by PICT participants as the most motivating among the project.

Despite the billions of dollars spent annually on technology in our nation's schools, access continues to be a barrier for many educators and students (USDE, 2000). Access has been cited as a primary impediment to faculty...
development of technology infusion since faculty may not have the necessary equipment, software, or network access to practice applying skills and methods learned during training (Parker, 1996). Such on-going training and practice is necessary for educators to feel comfortable with the newly learned technologies and confident in implementing them in the classroom. Project PICT addressed the issue of access by providing each participant with a laptop computer that included all the necessary software as well as modem and network cards. K-6 teachers had laptop use only during their participation in the grant; whereas, HE faculty were allowed to keep their laptops after they completed one year in the project and continued as BGSU faculty. Another area of access pertinent to HE faculty was classroom access. Although BGSU has numerous computer labs, access to these labs is difficult due to class demands. Consequently, Project PICT in collaboration with BGSU developed five electronic classrooms in the College of EDHD. Each classroom housed a ceiling mounted projector, a laptop, and Internet connection. The electronic classrooms allow HE faculty to demonstrate and model effective technology uses. A portable system (laptop and projector) is also available to faculty not scheduled in an electronic classroom.

Professional development was a primary focus of Project PICT as it sought to train general faculty, education faculty, and K-6 teachers in methods of technology infusion. Project PICT’s Training Model sought to prepare technology-using HE faculty and K-6 teachers, who would model effective technology infusion by demonstrating technology applications and facilitating student use of technology. The training model was based on several beliefs and research findings: 1) Professional development should "center on creating sustained learning communities where participants have an active voice in determining goals and activities of the project" (Beyerbach, Walsh, & Vannatta, In Press); 2) Training should be focused and on-going; 3) One-on-one mentoring programs have effectively prepared education faculty for technology enriched instruction (Thompson, Hansen & Reinhart, 1996); 4) Training programs should consistently communicate expectations and requirements (Topp, Mortenson, & Grandgenett, 1995; Vannatta, 2000). Consequently, the Project PICT Training Model included the following components:

- **Creation of shared vision** of technology infusion through workshops on meaningful technology use, NETS-Students, NETS-Teachers, and performance-based assessment.

- **Team collaboration** in which team members supported one another in lesson development and implementation. Each team was required to develop and present a team plan for technology integration. Teams were formed by participants and consisted of K-6 teachers, preservice teachers, education faculty, and arts & sciences faculty.

- **One-on-One mentoring/collaboration** in which preservice teachers were assigned to K-6 teachers for methods and student teaching. During this year-long placement, pairs completed training together and were required to develop and implement four technology-enhanced lessons.

- **Focused technology training** on applications and methods for technology infusion. Participants were required to attend five sessions on multimedia and Internet applications. During sessions, participants were presented numerous examples of technology-enhanced lessons, discussed classroom management issues and methods of implementation and assessment.

- Since PICT participants volunteered, consistent communication of expectations was integral in recruitment and retention efforts. Participants were required to attend all training sessions; participate in team collaboration activities (development and presentation of team plan); development and implementation of two technology-enhanced lessons/units; submit technology rich course syllabi, lesson plans, and student products; and participate in data collection activities. These expectations were communicated with the long term goal of systematic technology infusion throughout the teacher education programs.

Technical assistance is such a crucial component of any technology endeavor. For technology infusion within teacher education, technical assistance must be provided at nearly every aspect of the process: orientation, training, practice, development, implementation, and revision. Project PICT utilized several methods to provide technical support. Optional Tech Support Nights were provided, in which project participants could attend to receive one-on-one assistance on equipment, applications, and/or instructional methods. Another method of support was providing participants with access to several technology-savvy graduate students, who could attend technology-rich lessons or events. Their presence often alleviated a great deal of anxiety among the novice-level educators.

Finally, project staff were available on an individual basis to answer questions or visit classrooms.

The preparation of teachers requires the instruction of a multitude of content areas. Consequently, effective training on methods of technology infusion must address these content areas. Project PICT provided numerous technology-rich examples (lessons, products) for various content areas and grade levels. These examples were presented within training as well as the Project PICT website. The project website also provided numerous links to other educational technology-rich sites by content area. The website continues to grow as participants continue to submit appropriate lessons and products. Participants also received a copy of Connecting Curriculum to guide lesson development and implementation.
Facilitating a constructivist vision of technology infusion includes the adoption of student-centered teaching. Within training sessions, participants learned about ways in which technology could facilitate active, cooperative, and project-based learning (ISTE, 2000). Example lessons and products demonstrated student-centered approaches. Implementation of student-centered teaching and technology infusion often raises concerns regarding assessment among educators. Project PICT addressed the issue of assessment from several directions. First, participants were introduced to methods of performance-based assessment. In addition, appropriate assessments were required of all lessons submitted to the project. Second, participants were introduced to the NETS-Students, which allowed them to develop grade-appropriate lessons and assessments. Finally, participants were introduced to the NETS-Teachers. Since a long-term goal of the project was to create an assessment system of technology infusion for preservice teachers based upon restructured teacher education curricula, HE faculty needed to become aware of how these teacher technology standards could be addressed and assessed within their courses. The pilot of Project PICT allowed for curricular experimentation among HE faculty.

Although instruction and modeling of technology infusion within the university setting is necessary to develop technology-using educators, future teachers also require the opportunity to observe, develop and implement technology-enhanced lessons in the K-12 classroom. Such community support can only occur with adequately trained K-12 teachers, who effectively use technology as a learning tool. Consequently, Project PICT also sought to better prepare area K-12 teachers for technology infusion. As these classroom teachers begin to integrate technology into the classroom, their growing expertise assists education faculty in understanding K-12 technology use and ultimately infusing technology in their education courses. Such assistance/collaboration may be demonstrated by: education faculty utilizing K-12 technology-rich lessons as models and examples; fieldtrips to the K-12 and/or university classroom; K-12 teacher presentations to preservice teachers; video-conferencing between the K-12 classroom and the university classroom.

Finally, developing support policies and providing incentives is essential to gaining support and momentum among educators. PT3 funding allowed Project PICT to provide a reward structure for participants that not only provided incentive but also alleviated several barriers to technology infusion that are often cited in the literature. For educators, one of the primary barrier to learning and implementing an innovation is lack of time (Parker, 1996; Seminoff & Wepner, 1994; Wetzel, 1993). While the idea response to this barrier would be to provide time through course release, unfortunately a faculty shortage does not allow this. To address the issue of time, participants are paid a stipend for the time that they commit to the project. K-6 teachers received $2,000 per year, while HE faculty received the equivalent of teaching one course during the summer (10% of base salary). Another incentive that addresses the barriers of time and access is providing participants with laptop computers. The laptop provides convenience for practice and development. Although the pilot project did not provide laptops to the participating preservice teachers, incentives included: advanced training on technology infusion, opportunity to collaborate with a K-6 teacher for the year, experience in developing and implementing technology-enhanced lessons that could be exhibited in one's professional portfolio, and a $200 stipend. Finally the project also provided stipends of $500 to the technology coordinators at the participating schools, since they supplied additional support for participants.

Evaluation

Research Questions

The following questions guided the evaluation of this project.

1. Do technology training and planning activities increase technology proficiency and implementation among HE faculty and K-6 teachers?
2. How does the experience of serving as a preservice technology collaborator impact technology proficiency and view of technology infusion?
3. Does technology integration in methods courses increase preservice teachers' technology proficiency?
4. Does technology integration in methods courses impact preservice teachers' view of technology infusion?

Participants

Eight HE faculty members participated in the pilot of Project PICT. These instructors varied in rank and were from either the division of teaching and learning or the college of arts and sciences. Ten K-6 teachers also participated in the project and taught at two well-established professional development schools. Ten preservice teachers majoring in elementary education also volunteered to participate as technology mentors/collaborators. Finally, nearly 125 preservice teachers enrolled in elementary methods participated in numerous technology-related activities throughout spring 2000. Ninety-five completed pre and post surveys.
Methods
Evaluation activities were conducted throughout the grant period. Quantitative and qualitative methods were utilized to fully understand the project and its impact on participants. Pre and post surveys were administered to all participating HE faculty (N=8), K-6 teachers (N=10), preservice technology collaborators (N=10) and selected preservice teachers enrolled in methods courses during the spring semester (N=95). These surveys measured technology proficiency, use of technology by instructor, and use of technology by student. Survey results were analyzed using descriptive and inferential statistics. T test of related samples were conducted to examine pre and post differences. In addition, preservice teachers were asked to describe their vision of technology integration. HE faculty, K-6 teachers, and preservice technology collaborators also participated in focus group interviews at the conclusion of the project. Interview questions elicited information regarding the technology activities they implemented, the degree of support they received, the grant activities that most facilitated their technology integration, and their vision of technology infusion. Group interviews were conducted by a project co-director with 3-5 individuals from each group (i.e., faculty, K-6 teacher, preservice technology collaborator). Observations were conducted of technology activities implemented in the education courses and K-6 classrooms. In addition, lesson plans, student projects (preservice and K-6) were analyzed.

Instrumentation
Two instruments were utilized in the evaluation of this pilot project: the Faculty Technology Survey and the Preservice Teacher Technology Survey (Vannatta, 2000). Both instruments were similar in content and format as they measured technology proficiency and integration/experiences in courses. While the directors recognized that development of individual technology proficiencies does not necessitate a constructivist environment, proficiency of at least 1-2 applications coupled with an understanding of instructional methods is essential for constructivist integration. In addition, the directors were interested in determining which proficiencies and uses were targeted by the participants. Consequently, nineteen items asked participants to report current proficiency using computer equipment, applications, and instructional methods for integrating technology. These items utilized a Likert scale of 1-4 in which 1 represented no proficiency and 4 represented high proficiency. Participants were also asked to identify, from a list of seventeen computer applications/activities, which specific activities were currently being utilized by the instructor in their classrooms. These items utilized a Likert scale of 1-4 in which 1 represented no use and 4 represented frequent use. Participants also reported the degree of student use of technology in the classroom. These seventeen items applied a Likert scale. HE faculty and teacher participants were also asked to report the degree to which they use technology for six different administrative tasks; a Likert scale was also applied. Finally, an open-ended questions was posed to all the participants as they were asked to describe their vision of a technology-rich classroom.

Due to the various participant groups, surveys were administered in different settings. Participating HE faculty, K-6 teachers, and preservice technology collaborators completed the pre survey in September 1999 and the post survey in April 2000 during project meetings. Preservice teachers enrolled in methods courses during spring 2000 were administered pre (January 2000) and post (April/May 2000) surveys during their methods courses.

Results
Impact of HE Faculty and K-6 Teachers
Participating in training together, collaborating to develop and implement technology-enhance lessons, and teaming to support one another in the professional growth process, HE faculty and K-6 teachers reported significant increases in overall proficiency and infusion in the classroom. Proficiency significantly increased in all but five (distance education, database, spreadsheet, website development, and Internet) of the nineteen technology areas (see Table 1). Instructor use in the classroom significantly increased in ten of the seventeen technology areas as well as overall infusion (see Table 2).

Table 1: t-test Related Samples Results for Technology Proficiencies

Table 2: Teacher-Technology Use in the Classroom Reported by Participating Faculty and Teachers (n=18)

Analysis of observations, lesson plans, and student artifacts revealed that participants were able to transfer many of the technology ideas presented to them in training to their classrooms. Example lessons for K-6 teachers addressed: creating trading cards of historical figures, events, and/or innovations using KidPix; developing book reports using HyperStudio; creating student "yellow pages" using digital camera and word processing; creating presentations using HyperStudio. Readers are encouraged to visit the Project PICT website (www.bgsu.edu/colleges/edhd/LPS/EDFI/PICT/) to view lessons that resulted from the pilot. Example lessons integrated in education courses included: creating community profiles using a digital camera and PowerPoint; having elementary students visit the university classroom to train preservice teachers on KidPix; using the Internet to find technology-enhanced lessons; simulating several of the K-6 technology-rich lessons.

Focus group interviews revealed evolving views of technology use in the classroom. Prior to involvement in Project PICT, the majority of teachers indicated a perspective limited to drill and practice applications. After participation, teachers and faculty expressed a more constructivist view in which technology was used as an instructional tool to facilitate student motivation, exploration, creativity, communication, and problem solving.
"Technology can open up doors where some students may never get an opportunity." Although HE faculty were familiar with a constructivist perspective of technology infusion even before the project, they indicated that their participation made them realize that "the vision is something that could be accessible for both classroom teachers and methods students."

**Impact on Preservice Technology Collaborators**

The preservice technology collaborators played a unique and integral role in this project. Ten preservice teachers volunteered to be placed with a K-6 teacher for both methods field experience and student teaching. These students completed a typical elementary methods block that consisted of four elementary methods courses during the first eight weeks of the semester and full time fieldwork in a K-6 classroom during the second eight weeks. In addition, the preservice technology collaborators attended all technology training and team meetings with their cooperating teacher. Spring semester provided a twelve-week student teaching experience. These participants were expected to develop and implement at least two technology-enhance lessons/units during student teaching. Since the preservice technology collaborators worked so closely with their cooperating teachers to infuse technology in the classroom—an amazing relationship was revealed. While the cooperating teachers were extremely knowledgeable of classroom curriculum and management, the preservice technology collaborator was somewhat more knowledgeable about technology applications and definitely more of a technology risktaker. The marriage of these strengths developed a supportive, creative, and exciting classroom environment for technology development and implementation.

Analysis of the focus group interviews with cooperating teachers and PT collaborators revealed two primary themes—emotional support and instructional support—that describe how this relationship was essential in facilitating technology infusion. Several of the participants cited how important it was just having a second teacher in the room to manage the various activities (e.g., cooperative learning groups, learning centers, troubleshooting) involved in a technology-enhanced lesson. The collaborative process also provided a great deal of emotional support. Participants cited a sense of security and comfort in working with someone else while trying something completely new. One teacher stated, "Working with my intern [PT collaborator] was the component that meant the most to me. To have someone who knows more than I do and who’s there to help lead me into finding the answer made all the difference for me!"

This experience had a profound impact on the preservice teachers serving as technology collaborators. Survey results revealed significant increases in overall technology proficiency, knowledge of instructional methods, and proficiency of 7 of 18 technology applications among the PT collaborators (see Table 1). However, the greatest impact came in how these future teachers view technology infusion and their prospects in the classroom. Prior to PICT, nearly all the technology collaborators viewed technology use in the classroom as using games, drill and practice, and possibly the Internet. Following PICT, several participants indicated that, "I now see technology as a key facet in the information age. I hope to have my student using computers as a tool to collect data, organize information, and create product."

**Impact on Preservice Teachers Enrolled in Methods Courses**

Participating HE faculty were required to develop and implement at least two technology-enhanced lessons for their methods courses. The impact that this infusion had on preservice teachers enrolled in these courses was measured through pre and post surveys. Survey results indicate that technology infusion in the methods courses had a significant effect on technology proficiency (see Table 1). Overall proficiency as well as nine of the nineteen areas of technology proficiency significantly increased during the semester. Changes in vision of technology use were also assessed through open-ended survey questions. Responses indicated that the majority of students felt that technology is an important instructional tool, however, most were still vague about how technology could be used to facilitate learning. Several comments focused on the hardware necessary to have a technology-rich classroom and not the pedagogy in using it as a learning tool.

**Conclusions**

The pilot of Project PICT had an impact on technology proficiency, infusion, and vision among the participating HE faculty and K-6 teachers. In addition, project activities had a significant effect on technology proficiency among methods students. Project PICT has received funding through PT3 to expand its endeavor to secondary and special education programs. ISTE's essential conditions continue to serve as the foundation of the project's activities.

Abstract: Integrating technology into the classroom is an evolutionary (if not revolutionary) process for most educational institutions. In rural Western Pennsylvania three State System of Higher Education universities formed a consortium to address the need to increase faculty understanding of the advantages of using technologies in teaching, their competencies in specific technological applications, and their level of comfort in using them. The universities created learning and technology centers to provide technology-rich learning environments for university faculty and K-12 teachers.

A $1.7 million Preparing Tomorrow's Teachers to Use Technology (PT3) implementation grant provided funding for new methodologies for infusing technology in the classroom. A "technology chalkboard" model was developed to provide diverse classroom learning opportunities. Technology modules incorporated foundation training on specific software or technologies, application training on how the technology is applied in the classroom and integration training on how the technology enhances student-centered learning.

Introduction

The Advancing the Development of Educators in Pennsylvania through Technology Training (ADEPTT) consortium, representing three public universities (Clarion, Edinboro and Indiana Universities of Pennsylvania) in rural, economically disadvantaged communities is implementing a model for infusing instructional technology throughout the teacher preparation curriculum. Initially funded by a 1998 $500,000 Bell Atlantic grant, the universities created learning and technology centers to provide technology-rich learning environments for university faculty and K-12 teachers. Each ADEPTT center is comprised of a core team including a director, instructional designers, administrators, and faculty representatives from disciplines in the colleges of education, arts and sciences and business. Over the past three years the core teams have assisted one another in establishing centers devoted to teaching excellence, instructional design and the use of instructional technology to move from a teacher-centered to a student-centered learning environment. Through the ADEPTT consortium the universities have formalized their relationship and greatly expanded their ability to work together to develop materials and training for all faculty at each institution.

The ADEPTT Centers provide basic and advanced training in computer literacy and numerous software applications and web tools. The first year the centers focused primarily on foundation training for faculty offering a total of 182 workshops across the consortium in eleven key competencies (Fig. 1). However, it became apparent that knowing how to use the technology was not enough to effect change in instruction and that incentives were needed to break down the barriers to widespread participation.

Figure 1: Key competencies address basic needs for infusion of technology into the curriculum.

Barriers and Challenges to Integrating Technology in the Classroom

- Faculty and K-12 teachers have little time to develop technology-based instructional materials, which reduces the likelihood they will integrate technology into their courses.

- Relatively few teachers are prepared to integrate educational technology into the classroom. In a 1990 national survey, 81% of the student teachers surveyed rated their undergraduate preparation in technology use as inadequate (Fratianni, Decker & Korver-Baum 1990). Even though schools are slowly increasing the amount they spend on training, just eight percent of schools say the majority of their teachers have advanced skills and are able to fully integrate technology into their curriculum (Weiner 2000).

- An Office of Technology Assessment report revealed that while half of recent teacher education graduates reported being prepared to teach with technology in drill and practice, tutorials, games, and writing and publishing centers, less than one in ten felt they could use such formats as multimedia packages, electronic presentations, collaborations over networks or problem-solving software (Thomas, Larson, Clift & Levin 1996).

- New technology standards (NCATE/ISTE) at the state and national level are leading schools and universities to realign their teacher education curricula to include technology components.

- Universities and schools are reluctant to offer release time due to the difficulty in obtaining replacement instructors and substitute teachers for their classes.

Preparing Tomorrow's Teachers to Use Technology

Overcoming the barriers to integrating technology necessitated the pursuit of additional funding. Through collaborative efforts the consortium received a $1.7 million Preparing Tomorrow's Teachers to Use Technology (PT3) implementation grant in 1999 to infuse instructional technology into the teacher education curriculum. The goals of the PT3 grant complemented the ADEPTF strategies already in place to support faculty and K-12 teachers in integrating technology. The goals—to infuse instructional technology more deeply into the teacher education curriculum, to integrate instructional technology in the consortium's pre-service observation and field experiences, to provide a variety of professional support opportunities for faculty and pre-service teachers, to enhance the technological infrastructure of the consortium members to better support the project objectives—are being addressed in a number of ways.

The PT3 funds provide professional development opportunities and instructional design support for education core/methods faculty and personnel to deliver application and integration training for faculty and pre-service teachers. Application and integration training facilitates the development of lesson plans, materials, and resources to infuse technology in the classroom. Modest numbers of early adopters are
beginning to add technology-enhanced assignments to their courses and are serving as models and trainers for both their colleagues and their students. The barrier of time and scheduling, however, continued to be a problem for faculty. A new model was conceptualized to deliver an intensive technology-rich experience during the summer, at a time when faculty are more likely to be available for training opportunities. Thus, the “technology chalkboard” model was born.

**The Technology Chalkboard Model**

Technology chalkboard was initially developed for education core and methods faculty as a week-long immersion in technology applications that includes foundation, application, and integration strategies for the classroom. Its modular approach was designed to lower the entry level for faculty and teachers to enable them to be comfortable in exploring the technologies. No prior experience in using technology was required.

The model incorporates the use of a combination of educational technology applications. The nine technology modules (Fig. 2) each focus on three areas:

1. foundation training on the basics of the software or technology
2. application training on how the technology is applied in the classroom
3. integration training on how the technology enhances student-centered learning

For example, the videoconferencing module includes an explanation of videoconferencing as a type of distance education. The opportunities, theories, and applications of videoconferencing in K-12 education are presented and case studies are examined where videoconferencing has been used successfully. Preservice teachers and their cooperating teachers learn how to use the equipment and demonstrate this knowledge in the creation of a videoconferencing event.

*Figure 2:* Nine technology chalkboard modules incorporate foundation, application and integration of technology.

The format for the technology chalkboard model is based on a hands-on approach with workshops, demonstrations and practice during a one-week period. The Learning and Technology Center at Clarion University held the first technology chalkboard series for education faculty July 17-21, 2000 in a smart classroom equipped with 30 Macintosh PowerBook computers, ethernet connections, and a teacher station with a laptop, projector and smartboard. The workshop schedule featured two technology chalkboard modules each day that were divided into the three focus areas: foundation, integration and application. To augment the classroom experience, participants were enrolled in a specially created online course supplement using Blackboard’s CourseInfo software that provided them with a student’s perspective to using online courseware. The online component provided participants with a syllabus, course documents, discussion areas and links to related information that they could continue to use after the workshop ended.
Lunch was provided each day and speakers were invited to discuss current topics on technology. The on-site lunches promoted discussions and sharing in ways technology could be used in the classroom. It was hard to get participants back to the workshops on more than one occasion. The presentations reflected the daily technology themes; for example, Dr. Gail Grejda, Dean of the College of Education and Human Services, "Educational Standards: A Changing Mosaic"; John Sikora, Apple account executive, "Integrating Digital Video into the Curriculum"; Sonja Heeter, technology coordinator, Riverview Intermediate Unit 6, "Seeing is Believing!?"; Dr. Helen Barrett, University of Alaska, "Creating Electronic Portfolios: Building a Standards Based Portfolio" and Dr. Sanjay Rebello, physics department faculty member, "Student Surveys on Web-Assisted Instruction".

Presentations by outside speakers and members of the consortium were found to be an important component in the model by providing valuable insight into how technology can be used in the classroom. In particular, Dr. Barrett’s presentation executed via desktop video, the Internet and conference phone enabled the participants to interact with her while she was at home in Alaska at 6:00 a.m.

One of the participants evaluated the experience in this way; “The entire week was the most beneficial of all the computer course work I have had to date. I just wish I could have yet another week to become more proficient. Thank you so much for being patient and helping me to become more aware of what is available to me with technology in my classroom.”

Due to the success of the technology chalkboard model, funding is being pursued to create an online module for each of the technology chalkboard components that will be used to supplement the pre-service teacher curriculum. The modules will be Web based to allow for anytime, anywhere learning, meeting the needs of the pre-service and in-service teachers. The modularized units will be based on International Society for Technology in Education (ISTE) standards to promote the use of technology in the student’s field experience and make connections between the technology and the curriculum.

**Implementing The Online Model**

Three faculty from each consortium member institution, working closely with the ADEPTT centers, will develop nine technology-rich online modules based on the “technology chalkboard” model. The modules will incorporate International Society for Technology in Education (ISTE) standards of instruction providing foundation, application and integration skills through a common design. The modules will incorporate three basic components:

- **foundation** – tutorial format – “how to” use the technology
- **application** – align lesson creation with state/national standards
- **integration** – student created technology-rich lesson plans

Each of the nine modules will be shared among the institutions. They will be developed for Web delivery (Blackboard, WebCT, etc.) and shared through the consortium’s ADEPTT/PT3 Web sites. Three cooperating faculty at each institution will incorporate one of the online modules in their courses during the Fall 2001 semester. To facilitate the course development process, faculty will attend sessions held by their respective ADEPTT centers on creating online courses. To encourage participation, cooperating faculty will receive a small honorarium. At the completion of the course, faculty will review the modules through the completion of a short survey and a written evaluation.

Students will complete at least one of the online modules as part of the teacher education curriculum prior to their student teaching experience. Cooperating teachers will be paired with pre-service teachers and complete the modules online during the same period. To encourage participation in the project, the cooperating teacher will be paid a stipend to participate in the program and may also receive ACT 48 credit. Both the pre-service and cooperating teacher will be required to create a lesson plan for the module based on ISTE standards that will then be used in the K-12 classroom during the student teacher experience.
Exemplary lesson plans that have been developed by the pre-service and in-service teachers will be included in an ADEPTT database developed at Edinboro University and on the consortium's ADEPTT/PT3 Web sites to provide K-12 teachers in Pennsylvania with technology resources. Technology modules will be available to all faculty at the consortium institutions. All nine modules may also be developed into a special topics course culminating in the creation of student electronic portfolios. The program model may also be disseminated through the State System’s Center for Distance Education and through presentations by ADEPTT/PT3 locally and at state and national conferences.

Abstract: With unprecedented emphasis being placed on preparing pre- and inservice teachers to integrate technology into their classrooms, schools of education are facing increasing pressure to provide students with experiences and faculty who can adequately prepare them for this task. This paper presents details on how one college of education in a small liberal arts university is meeting this challenge. Using the National Educational Technology Standards for Teachers (NETS-T) as a basis, education faculty worked together to implement a faculty development program that culminated in the measurable integration and utilization of technology in the program’s professional studies classes. The outcome of this semester-long collaboration was that the methods faculty involved were better prepared to (a) utilize technology as a tool for instruction, (b) train their students/preservice teachers to utilize technology in the classroom, and (c) serve as technology mentors to other methods faculty.

Introduction

As a member of a statewide consortium of Alabama schools of education, the University of Montevallo received PT3 grant funding to create and implement a faculty development plan designed to lead to the successful integration of instructional technology in professional studies methods classes in its Teacher Education Program. Additionally, the implementation, evaluation, and refinement of this structured technology integration plan could potentially serve as a model for other schools of education throughout the state. This plan was based on the National Educational Technology Standards for Teachers (NETS-T) as offered by the International Society for Technology in Education (ISTE).

Through this project, one faculty member from each of two methods classes, math and social studies, and the college of education’s director of instructional technology worked together to implement a series of planned steps designed to culminate in the measurable integration and utilization of technology in teacher preparation classes. The two methods faculty met biweekly for one semester with the technology director in a series of discussions and hands-on lessons related to technology integration. In addition to these regularly scheduled meetings, the technology director routinely assisted the two faculty members in developing various technology-based projects.

For the two methods faculty involved, the commitment was the same. Both would attend all seven of the scheduled meetings, work collectively and individually on assigned projects, keep a journal of their reactions to the overall experience, and be willing to serve as technology mentors to other faculty in the future. Each also received paid release time from one fourth of their required academic responsibilities. The technology director’s
responsibilities were to develop and facilitate the training sessions and to work as needed with the two participating faculty members on the creation and integration of their projects. The scheduled topics for each session were as follows: Equipment Setup and Operation, Using PowerPoint for Instructional Support, Planning for Effective Technology Integration, Incorporating Educational Software in Teaching and Learning, Incorporating the Internet in Teaching and Learning, and Resources for Teachers.

About the Project

From the beginning, each scheduled meeting during the project was characterized by an active exchange of information and concerns involving the use of technology in the college and elementary classroom. While both methods faculty were excited about utilizing technology in their courses, each remained very practical in their intentions for its use. Whether the topic was equipment setup and operation or the advanced features of PowerPoint, both educators consistently directed the conversation toward issues of practicality and educational effectiveness. This became an underlying theme for all meetings and conversations regarding technology throughout the project. Too often, training programs aimed at helping teachers with the integration of technology focus solely on technology operation while overlooking the practical matters of successful integration, leaving the teacher no more prepared to integrate technology than he or she was prior to the training. It is extremely important for anyone considering this type of faculty development program to insure that the training places strong emphasis on practical concerns.

In addition to the hands-on training, much time was spent sharing ideas and examples of the successful use of technology. For instance, during the sessions covering PowerPoint, both methods professors were provided with a disk containing unique or atypical examples of PowerPoint presentations. This served as a springboard for the two faculty members to begin discussing and formulating plans for their own presentations. The examples clearly helped them break away from thinking of PowerPoint merely as a tool to present lecture notes to students, which is the only way they had used Power Point prior to this experience. Throughout the project, this sharing of ideas and the discussions that ensued had a pronounced impact on the faculty member's plans and consideration for technology integration. In fact, this type of sharing and opportunities for technology-related discourse were perhaps the most valuable component of the entire program.

Another important facet of the program was its flexibility. As previously stated, specific session topics were scheduled, however, the group frequently deviated from these planned topics. It did so to accommodate the needs and interests of the two methods faculty. For example, their curiosity regarding unique uses of PowerPoint required several sessions as opposed to the single session planned. The group decided that rather than rushing through a topic merely for the sake of covering it, its time would be better spent by providing more in-depth coverage of those topics perceived as most useful. They felt that they would rather walk away from this project with one good technology tool for classroom use instead of several superficial projects that would never be implemented.

In the final activity of the project, the three group members, using the NETS for teachers, discussed and developed course syllabi that contained specific NETS performance indicators. This culminating activity was very useful in that it allowed the two methods faculty to begin planning the implementation of their newly developed skills, knowledge, and ideas relevant to technology.

Conclusion

The results of this semester-long collaboration were that the selected methods faculty were better prepared to utilize technology as a tool for instruction in their own classrooms and to train their students/preservice teachers to utilize technology in their classrooms. Additionally, with the knowledge, skills, and confidence gained through the project, these educators can now serve as effective technology mentors to other faculty.

In addition to increased skills, knowledge, and attitudes regarding technology use, the project yielded many other more tangible outcomes. For example, both professors have now set up their own faculty web page, created and posted online materials for their courses using Blackboard.com, and have a variety of projects and presentations ready for implementation. These types of products will not only be useful in the immediate future, but will also promote the continued development and modeling of technology-based instructional tools. Perhaps the most gratifying outcome of the entire project, however, was that it simply provided time, incentive, and opportunity for those involved to think about and discuss technology use in the classroom.

Abstract: The PT3 Utah consortium includes Brigham Young University, Utah State University, and Westminster College. It provides members with unique advantages: opportunity to be informed of each other's projects to the subsequent benefit of all; to share resources of local expertise and material assets; to strengthen inter-college activities through joint publications and presentations; and to help each other out when moments of challenge arise. The leaders hope to impact teacher preparation and technology use in schools across the state of Utah. This panel discussion will focus on areas of common interest, and how the collaboration has strengthened their work.

Introduction

Brigham Young University, Utah State University, and Westminster College have joined together collaboratively as they implement their PT3 grants. The leaders have discussed the similarities and differences in their grants, and have worked to support each other rather than duplicate effort. They hope to impact teacher preparation and technology use in schools across the state of Utah. This panel discussion will focus on areas of common interest, and how the collaboration has strengthened their work. Nancy Wentworth and Rodney Earle are co-principal investigators for the Brigham Young University
implementation grant. They are working to systemically restructure the Brigham Young University Teacher Education Program to meet the proposed NCATE Standards for technology in teacher preparation programs. The participants are working to design technology-rich curriculum for both the teacher education program and K-12 schools and the mentor BYU faculty and BYU students in the use of the technology-rich curriculum. Steven Soulier is the principal investigator for the Utah State Implementation Grant and Tim Smith is the co-director of the School for the Future at Utah State University. They are working to ensure a fully collaborative, technology-infused curriculum across 31 academic majors in five university departments. David Stokes is the director of the Westminster PT3 project. Wanda Carrasquillo is the project manager. After a year of working on a PT3 Capacity Building grant, Westminster has an implementation grant that will emphasize student participation in integrating technology into content courses, student teaching experiences and the first year of teaching. The ultimate goal is to turn Westminster College’s 250 teacher candidates into active technology users and improve student achievement for K-12 students in the Jordan and Salt Lake school districts.

PT3 Grant of Brigham Young University

The purpose of Brigham Young University’s implementation grant is to systemically restructure the teacher education program to meet the proposed NCATE Standards for technology in teacher preparation programs. This will require the design of technology-rich curriculum for both the teacher education program and K-12 schools and the mentoring of BYU faculty and BYU students in the use of the technology-rich curriculum. It will also require ongoing collaboration of all participants in sharing successes in curriculum development and implementation. These goals are addressed through three major project activities: (1) creating design and mentoring teams, composed of university education faculty, content specific methods teachers, cooperating teachers, and instructional design and technology specialists who will simultaneously re-design our current teacher preparation curricula and public school K-12 curricula, (2) using teacher-student electronic networks (email listserves and website development) that will allow project participants to share newly developed curricula, and (3) holding yearly summer institutes focused on the infusion of technology into learning. These three activities are shaped by a philosophy that emphasizes curriculum integration, problem solving, data collection, information management, communications, presentations, and decision-making in teacher preparation and public school curriculum.

Design and Mentoring Teams

The McKay School of Education created design and mentoring teams of faculty and technology specialists to mentor undergraduate and graduate students in the development of K-12 curriculum that meets the National Education Technology Standards for Students (NETS). The NETS Project (1998) is an International Society for Technology in Education (ISTE) initiative funded by the U.S. Department of Education, the National Aeronautics and Space Administration (NASA), the Milken Exchange on Education Technology, and Apple Computer, Inc. The primary goal of the NETS project is to guide educational leaders in recognizing and addressing the essential conditions for effective use of technology to support PreK-12 education.

The first objective of the teams is to “plan and design effective learning environments and experiences supported by technology” (NETS Standard II). BYU student and faculty are examining Utah State K-12 Core Curriculum for lessons rich in uses of technology. BYU students and faculty are developing lessons for a McKay School of Education Webpage that meet the Utah State K-12 Core Curriculum and that “use technology to support learner-centered strategies” and “develop students’ higher order skills and creativity” (NETS Standard III). BYU faculty and technology specialists are mentoring BYU students on how to evaluate the lessons based on the NETS standards. BYU undergraduate and graduate students will review each other’s learning activities based on the NETS standards. As a result of the mentoring program BYU undergraduate and graduate students will produce 120 learning activities for the David O. McKay School of Education Curriculum Webpage that meet the NETS Standards.

The second objective of the teams is to help BYU students integrate technology into curriculum and instruction in the public schools. BYU students are implementing at least one technology-enhanced activity while they student teach in the public schools. With the help of a faculty and technology specialists
BYU students will produce an electronic portfolio of teaching with technology during their student-teaching experience. The technology specialists and graduate assistants will mentor them in this process. BYU graduate students are reviewing the electronic portfolios of undergraduate students based on the NETS standards. As a result of the design and mentoring program BYU students will produce 60 electronic portfolios of teaching with technology in a public school classroom.

The third objective is to mentor graduate students and undergraduate students in the research of technology on teaching and learning. Mentoring teams are defining research questions on the effects of technology on teaching and learning. Mentoring teams are collecting and analyzing data to answer the research questions on the effects of technology on teaching and learning. BYU undergraduate and graduate students have submitted research proposals on the integration of technology in curriculum to regional and national conferences including Northern Rocky Mountain Educational Research Association, Utah Association of Supervision and Curriculum Development, Society for Information Technology and Teacher Education, and International Society for Technology in Education. As a result of the mentoring program at least 10 BYU undergraduate and 6 graduate students will present at regional or national conferences.

Electronic Networks

All participants in the grant are being linked through listserves and websites to provide continuing support for the curriculum development and technology integration. Models for such websites have been drawn from other efforts around the country in which electronic dialogue complements classroom learning. Excellent website examples include The Utah Education Network Olympic site, http://www.uen.org/2002/, and the NASA Learning Technology site, http://learn.ivv.nasa.gov/. The teacher preparation program will include requirements of students to develop technology integrated curriculum that could be included on a refereed BYU problem-based learning website. BYU faculty can submit curriculum ideas and research on integrating technology into teacher preparation to the website. Teachers from around the country will be able to upload curriculum to a data base where technology specialists in the Partnership will review and select curriculum to be included on the site. An ongoing network of teacher graduates from BYU will be created for further sharing of technology-rich curriculum. Approximately 100 BYU preservice teachers do their student teaching in the inner city of Washington, D.C, Mexico, the South Pacific, and China. The electronic network will connect them and their students to developed curriculum and to other students using technology in their classrooms. BYU will supply laptop computers to these sites.

Summer Institutes

Schools of education and public schools will draw upon the creative work of all design and mentoring teams as they bring technology integrated curriculum and cohort participants together. Summer institutes will provide an excellent environment for mentoring BYU faculty from one cohort to another and from one year to year. Students will learn from other students and faculty as they focus on effective approaches to technology integration in learning. Participants in the institutes will become part of the creative energy of the overall project as they work with mentors, especially Clinical Faculty Associates, to create their own inquiry-based approaches for their classrooms. The summer institute will involve all cohort participants in the teacher education program and will be extensions of the design teams. They will collaborate with project staff in pilot-testing newly designed instructional approaches. Nationally recognized leaders in technology integration, including Dr. Brian Page (Apple University Consortium) and Dr. Michael Connell (Society of Information Technology and Teacher Education), and Dr. LaMont Johnson (Editor, Computers in the Schools) will participate in the institutes. External evaluators will collect data from participants during this time.

PT3 Project at Utah State University

Steven Soulier is the principal investigator for the Utah State Implementation Grant and Tim Smith is the co-director of the School for the Future at Utah State University. They are working to ensure a
fully collaborative, technology-infused curriculum across 31 academic majors in five university departments. The consortium of participants at Utah State University is working to (1) establish a staff development plan to train teacher education faculty and give further support through a Teacher-Education Faculty Assistance Center; (2) create a standardized, online assessment tool to track student progress in meeting technology standards; (3) insure that the responsibility for meeting technology standards extends to the entire campus; (4) develop an online resource bank and an online, collaborative learning community; (5) use video conferencing to expose students to model K-12 classroom practices; (6) ensure the use of technology in student field experiences; (7) upgrade teaching stations; and (8) require students to document their technology skills in an electronic portfolio.

PT3 project at Westminster College: Content Methods Curriculum Revision

This project represents an instructional model designed to provide preservice teachers at Westminster College in Salt Lake City, more opportunities to integrate educational technology into all content areas during their teacher preparation program and first year of teaching. The project is a joint venture of a consortium comprising Bryant Intermediate, Clayton Middle, and Lincoln Elementary Schools from Salt Lake City School District, Majestic Elementary School from Jordan School District and Westminster College.

With current funds from a Capacity Building Grant, classroom teachers from one consortium school and faculty members who teach math and science methods formed a cohort to engage in collaborative curriculum development. Common hardware and software were purchased for both sites. New syllabi that incorporate the use of educational technology for the methods courses and school courses were designed and are being co-taught and revised through a formative evaluation process. The Implementation Grant extends the opportunities for the math/science cohort to do further curriculum revisions and allow all faculty members who teach language arts, creative arts, reading and social science methods to form similar cohorts with classroom teachers who teach these subjects in the three additional consortium schools.

The School of Education at Westminster College has placed preservice teachers at these consortium sites for several years. Many teachers in these schools serve as mentors during semesters of early field experiences as well as student teaching. The principals serve as a part of Westminster's Local Partnership Oversight Committee to examine existing and future collaborative initiatives among these sites and other partnership sites we are developing. Faculty at these consortium sites and Westminster College are coming to understand the power computer based technologies provide for achieving the goals of the cognitive movement in education. They know that skills and knowledge are too often taught out of context, as ends in themselves. To overcome this, there is a growing recognition that computer based technology and particularly multimedia bring to the classroom real-life examples and situations that provide the contextual framework so important to learning (Brown, Collins, & Duguid, 1989). Anchored instruction (The Cognition and Technology group at Vanderbilt, 1990), the capability to demonstrate real world applicability of knowledge, is less prevalent than hoped. Findings that suggest computer-based learning environments reduce learning time significantly (perhaps as much as 80%), and that achievement levels are more than a standard deviation higher (Kulik, et.al. 1991, 1985) have been largely ignored, if known.

As more understanding about how technology tools can distribute learning across persons and expand a more diverse group's capacity for innovation and invention, the need to explore the performance and pedagogical uses of technology are clear. Even though teacher education faculty and their students regularly discuss the role of social interaction in knowledge construction (Vygotsky, 1978), faculty feel there has been insufficient planning to ensure preservice teachers the opportunities to work with veteran teachers and together help K-12 students meet content standards through the use of instructional and learning technologies. At Westminster educational technology applications are formally presented in a required course for all teacher education students, but often the preservice teachers separate these applications from educational practice. Additionally the classrooms where preservice teachers complete their field experiences for content methods often do not have hardware and/or software which promotes application of strategies learned on campus. In short our preservice teachers tend to view what they learned on campus about educational technology as not relevant to the practical world of K-12 teaching when it is not integrated into the formal methods course work and related field experiences. The application of this grant was hoped to alleviate this problem.
Project design

After review of the recently completed Capacity Building Grant project to develop a new instructional model to improve the quality of teaching and learning in math and science methods with Bryant Intermediate School, the consortium set out to: 1) complete the instructional model that has been developed in math and science with Bryant Intermediate School; 2) extend the model to the content areas of Language Arts, Reading, Social Science and Creative Arts methods with 3 additional consortium schools (Clayton Middle School, Lincoln Elementary and Majestic Elementary). To bring this about the consortium developed a four phase project.

Year 1 (2000-2001)

The math/science cohort have moved into their second phase of continued curricular revisions in the science and math methods courses on campus and the science and math courses at Bryant Intermediate School. The model provided by this cohort will be replicated by language and creative arts faculty and consortium teachers. Each will in turn investigate technology as an instructional and learning mechanism and develop new technology enriched units for an extensive curriculum revision. While this is happening the math/science cohort will target the following as means to further integrate technology into their curriculum.

- Providing for a networked learning community; affordable configurations of portable computers and wireless connectivity
- Providing video-taping conferencing services so that preservice teachers will be able “sit in” on practicing teachers’ classes
- Emphasize development of “Project Based” curriculum to integrate content
- Explore on-line courses
- Integrate more fully the technology enhanced components of special education and diversity into methods courses
- Provide preservice teachers with technology rich experiences in methods classes, field experiences and student teaching

Additionally during this phase funds provided by the grant permit a technology center designed specifically to the needs of the grant. With information technology support and expertise from the educational technology specialist in the School of Education, preservice teachers, faculty and partner teachers will have the means to move through phase one, to phases two and three. Each phase brings its own unique technology needs, from software particular to a method cohort, to vital online communication equipment allowing development of real time field project units. These needs are partly to be fulfilled by the creation of the technology center. The technology center will be: 1) a place for development of integrated technologies into curriculum; 2) for practice in teaching with technology; 3) an active classroom demonstrating technology enhanced curriculum; 4) a video-conferencing center; 5) a place where pedagogical and technological theories can be effected into learning; 6) a place where web based instruction will be developed.

Year 2 (2001-2002)

The math/science cohort will move to the third phase that includes teacher induction and supported use of the technology center. The language arts cohort and the creative arts cohort will move to the second phase which includes continued, focused curriculum revision, and the reading/social studies cohort will begin the first phase of the project to explore technology tools. The education technology center will continue to serve all the subject area cohort participants, preservice teachers and first year teachers. The math/science cohort participants will make decisions about their continued work together. The grant funding will no longer support their time for curriculum revisions. To promote their continued dialogue and ability to access information that will continue to technologically enrich their curriculum and instruction, the cohort participants will be encouraged to use the technology center. The technology center will provide
instructional support staff services on a daily basis. Some of the services that they will provide are: 1) a place to test the effectiveness of curricular change; 2) technology staff support to help with additional curriculum changes; 3) a place that creates and sustains web pages that reflect the progress of consortium outcomes.

Year 3 (2002-2003)

The language arts cohort and creative arts cohort will move to the third phase with the math/science cohort who have already reached that phase. They will no longer have grant funding to support their time for curriculum revisions, but they will have access to the technology center for continued support. The reading/social studies cohort will move into the second phase for continued curriculum revisions.

Year 4 (2003-2004)

All consortium members will be in phase four of the project. This allows for continued mentoring of graduated first year teachers and provides access to the technology center which will continue to be funded by Westminster College.

Project activities to support goals

It is important to note that during the each phase of the project, every subject area cohort will impact approximately 500 students at a school site and 40 preservice teachers from Westminster College as they are actively involved with the methods courses and field experiences. At the end of the three-year period, all of the 250 preservice teachers at Westminster College will complete technology-enriched content methods courses and many will have enriched field experiences. Approximately 2000 K-12 students and their teachers will be working with our preservice teachers using technology enriched curriculum and instructional practices each year. Drawing upon multiple sources of information these future teachers should be able to:

- Promote real-world collaborative inquiry
- Attend to multiple learning styles
- Explore content applications related to standards and the core curriculum
- Use media in new assessment models that enable educators to assess the application of learned skills and concepts in authentic settings
- Develop multimedia portfolios
- Create web based learning experiences
- Use modeling and simulations as teaching strategies
- Extend the power of inquiry-based learning, and multiple forms of reasoning through content-based activities that utilize various appropriate technologies (e.g. use of field microscopes, probes, graphing calculators, computers, e-mail).

Conclusion

Math and science faculty through the Capacity Grant experience have found their perspectives of teaching and learning to be fundamentally changed. Using KaleidoMania and Shapemakers, Geometers Sketchpad, video microscopes, along with virtual labs has demonstrated student engagement and learning. Technology applications are now clearly understood to allow students multi-tasking capabilities as they engage in real work oriented projects. Math and science faculty now look to technology as a means "not to an answer but a way to find answers." And further, "Every time we create an integrated unit in our methods courses, we now look for a way to incorporate a piece of technology to add depth to understanding and create questions. As an example, because of our use of the CBL to measure the rebound of a [bounced]
ball, we have more questions to ask about the graphing of data". Math and science syllabi now reflect this change. It is our expectation that similar changes will take place in other content areas.

The project remains on track to effect lasting substantive change in ways school of education faculty, preservice teachers, and consortium teacher participants view technology applications for the acquisition of knowledge, teaching and probably professional lifestyle. Evaluations as they progress are expected to bring rich data to the fore useful in the form of technology rich teaching units, assessment methods congruent to this new mode of teaching and learning, and perhaps a handy prescriptive record of changing faculty views towards technology for teaching.

Summary

The organization of the PT3 Utah consortium provides each member with unique advantages. These include: opportunity to be informed of each other's projects to the subsequent benefit of all; to share resources of local expertise and material assets; to strengthen inter-college activities through joint publications and presentations; and to help each other out when moments of challenge arise.

Abstract: This qualitative study reports on the Arizona Classrooms of Tomorrow Today project, a component of a Preparing Tomorrow's Teachers to Use Technology project. In conjunction with five partner school districts, Arizona State University West developed five technology-rich K-8 classrooms that serve as models for preservice students and university instructors. This study reports on the changes occurring as the AZCOTT teachers learn to teach in technology rich classrooms. Generally, the researchers found that technology has become an integral part of each classroom. Factors contributing to implementing change in these classrooms are discussed. The researchers also discuss the progress made toward using these classrooms as models for preservice students.

Introduction

Buying technology for K-12 classrooms is expensive, but a relatively straightforward procedure. Much more difficult is changing the way teachers teach so that they use technology effectively. This is one purpose of the Arizona Classrooms of Tomorrow Today (AZCOTT) project, a component of Arizona State University West's Preparing Tomorrow's Teachers to Use Technology Project (PT3).

Educational changes can involve products such as computers or processes such as constructivist teaching. Also, change often is not centered on one innovation but many (Hall & Hord 2001). Similarly, Fullan (1991) describes three components to the implementation of change: (a) the possible use of new or revised materials, (b) the possible use of new teaching approaches, and (c) the possible alternation of pedagogical beliefs. The three aspects are necessary because together they represent the means of achieving a goal. In this study the authors will describe changes occurring as experienced elementary teachers learn to teach in technology rich classrooms.

Another purpose of the AZCOTT program is to improve the preparation of preservice students to integrate technology in their future classrooms by inviting their university instructors to participate in the AZCOTT training because they in turn encourage their students to visit and participate in the AZCOTT classrooms.

Program Description

In conjunction with five partner school districts, ASU West developed five technology-rich K-8 classrooms that serve as models for preservice students and district teachers. Five college of education instructors participated in at least two days of the AZCOTT training along with the K-8 teachers. These instructors as well as the student placement coordinators encouraged preservice students to observe in and select these classrooms for practicum experiences.

AZCOTT teachers were selected based on their answers to key questions about potential student use of technology in the classroom. In January 2000, children began participating in five Arizona Classrooms of Tomorrow Today (AZCOTT). In addition to the technology already in their classrooms, these teachers have received 4-5 multimedia computers with Internet access, software, some type of projection system, and
technical support from our school district partners, and they have received more than 100 hours of training from the PT3 project.

The Spring semester and summer training consisted of an initial two day workshop followed by four half days of training throughout the semester and three days in June. The curriculum addressed new technologies and creating and implementing the curricular units called Units of Practice (UOP) (Sandholtz, Ringstaff, & Dwyer 1997) that integrated technology into elementary content areas. Participant's UOPs and the rubric can be viewed at www.west.asu.edu/pt3. Time was also provided to share ideas and reflect on practice. Between sessions, participants communicated using an on-line conference. The second semester of training began in September 2000 and consisted of every other month half-day meetings and participation in a graduate course on using the Internet in the classroom.

Methodology

Using qualitative techniques, the authors describe changes resulting from the teachers' participation in the AZCOTT program.

Subjects

Five teachers, one from each school district that is a university partner, were selected to participate in the first cohort of the AZCOTT program. These teachers were initially selected because it was thought that they would provide exemplary models of technology integration for preservice teachers and district teachers. A brief description of each classroom follows.

Mr. B taught 27-second grade English as a Second Language learners in an urban inner city school where all of the students are receiving free or reduced lunches. His students stay with him for two years beginning with second grade. He has been teaching for 4 years and is a technology mentor for his school. As a technology mentor he helps other teachers with technology before and after school.

Ms. Lo taught 120 sixth graders science and language arts in an urban school with 35% of students receiving free or reduced lunch. She was a technology mentor for her school.

Ms. T taught 110 seventh graders mathematics and pre-algebra. Fourteen percent of these students were receiving free or reduced lunch.

Ms. Li taught 31 fourth graders in an urban elementary school with 50 percent receiving free or reduced lunch. She is a technology mentor for her school.

Ms. V Taught 100 seventh- and eighth-grade, gifted students in urban schools with few students receiving free or reduced lunch.

Data Collection

The data for the study came from multiple sources. First, during the AZCOTT workshops participants shared their questions, concerns, curricular ideas, and implementation attempts. These teacher reflections and discussions were audio or videotaped and transcribed. In addition participants participated in a FirstClass on-line conference that provided support as they implemented technology use in their classrooms. Between each workshop session participants used this on-line conference to react to a chapter in Teaching with Technology (Sandholtz, Ringstaff, & Dwyer 1997) often comparing their situations to those described in the chapter. These messages were aggregated using a summarize feature of FirstClass, printed and analyzed. Also an external evaluator visited several classrooms and collected data as he observed in the classrooms and interviewed the teachers. The external evaluator submitted a report summarizing his findings. Additional data sources were video vignettes taken in each classroom of the AZCOTT teacher and students, and the impressions of the PT3 project manager who visited each classroom and took notes on her visits.

Data Analysis
Using the constant comparative method (Strauss 1987), data analysis began as data were first collected and continued throughout the study. The first and second authors independently read the transcripts and on-line conference printouts and identified patterns and categories. Subsequently they met to discuss patterns they observed in the data and questions that arose after the readings. After collecting this data, the authors re-read all the transcripts and re-categorized the data. Each highlighted the portions of the transcripts addressing each category. They met to compare the answers to the questions and the categories that arose as they read. Then they compared key categories and re-read the transcripts to see if the selected categories worked to describe the experiences of the AZCOTT teachers. The themes that emerged were: teacher change, student change, classroom change, and school change.

Results

The data from selected aspects of the themes (teacher change, classroom change, student change) will be reported in this section.

Teacher Change

The researchers found the following types of teacher changes: changes in teaching methods, curriculum (UOP), and teacher leadership. Changes in teaching methods will be discussed below.

Changes in Teaching Methods

As teachers became involved in the training, workshop reading and sharing with peers, they questioned their approaches to teaching. For example:

"What AZCOTT is forcing me to do is to look beyond what is comfortable and ask where and if my current practices fit and if they don't what can I do to alter them so that they do fit. It is a very reflective practice that can be a little scary. I try to accept that I may not have all the answers and hope that I am flexible enough to accept any needed changes." (March 9 Online Discussion, Ms. T Gr. 7 math)

Changes in teaching methods included movement from a teacher-oriented approach to other approaches that involved student collaboration. A teacher explains,

"Instead of doing a lecture where I used to stand there and just give them scads of notes and they would all walk out grumbling, I give them the study guide research sheets and in groups they work to find the answers using the [computer] program. (March 11 Discussion, Ms. Lo Gr. 6 science)

Classroom Change

The researchers found changes in the area of classroom management, student engagement, and levels of classroom noise. Using the actual words of teachers, student engagement and noise levels are discussed below.

Student Engagement

AZCOTT teachers arranged for students to help each other and describe students working together within the context of projects that captivate their attention. For example:

"Today I was watching students working in all corners of the room. While I was helping one (group of) students edit their animal report, I looked around and everyone was busy, helping each other with typing, getting ideas synthesized into paragraphs or finishing up poems and drawings for their reports. There was plenty of activity and noise, but everyone was on task." (February 25 Online Discussion, Ms. Li Gr. 4)
"I have students now getting involved that were not before." (February 25 Online Discussion, Ms. Li. Gr. 4)

"I see 110 seventh graders comfortable working with each other . . . . They became the experts. Collaboration was amazing between them . . . . They are willing to take risks. They are on-task, engaged." (April 29 Workshop Sharing, Ms. T Gr. 7th math)

**Noise Levels**

However, with the student engagement and conversations, there was also a general unease over the amount of noise in their classrooms. For example:

"... I now see the value of students sharing. My classroom is noisier." (April 29 Workshop Sharing, Ms. Li Gr. 4)

"It’s a tremendous amount of conversation. The noise level is always up. I don’t have a problem with that. It bothers some of my colleagues, so I have to deal with that, and I do." (February 26 Discussion, Ms. T Gr. 7th math)

"I feel I’m heading in the right direction. My kids are younger, so self control is hard for them. The noise level grows and the kids will argue. I’m having to get used to this. I get impatient." (April 29 Workshop Sharing, Mr. B Gr. 2-3 looping)

**Student Change**

Student changes were noted in the areas of student learning, student attitudes, student collaboration, and students as helpers. Student attitudes in regard to collaboration and helping are discussed below.

**Student Attitudes**

AZCOTT teachers discussed attitudes students acquired that illustrate their disposition toward learning and helping others. For example:

"Students come up with ideas on how to use the laptops and software (Inspiration). They always go beyond what I asked them to do." (Workshop Sharing May 20, Ms. Lo. Gr. 6)

"Already the kids have said, "Well, you know, can we stay after school sometimes and do the extra work?" (Workshop Sharing, Sept. 23, Ms. Lo Gr. 6)

"The biggest impact has been socially. It has allowed them to do projects for other teachers and they are now role models . . . . last year my students helped build the school website . . . . this year I don’t have time to maintain that. Two of my students called me during the summer and asked me for a letter of recommendation to take a college course on programming. I approached them at the beginning of the year and I said do you want to be the web masters. How would you like to maintain the website? It is already built and talk to the new teachers on campus and . . . . coach some teachers along on how to build their own web pages . . . . They are thrilled to death those two kids . . . . even though I am not there, they are . . . . talking to teachers now and giving them suggestions for getting them set up. That’s very exciting for me to empower students to take a technology lead at the school and sort of model that . . . ." (Workshop Sharing, Sept. 23, Ms. V Gr. 7-8 gifted)

**Discussion and Implications**

In this study we found change occurring in areas that are similar to those discussed by Fullan (1991): new teaching approaches, new or revised materials, and the alternation of pedagogical beliefs. Aspects of each of these areas are discussed below.

**Teaching Changes**

The regular AZCOTT meetings provided time for teachers to learn new technologies, design lessons, share ideas, and reflect on their teaching approaches. Often the participants noted changes in their approaches
to teaching that were less lecture oriented, more project oriented, more collaborative allowing students to work in small groups, and more collegial in that students became experts and worked with other students and teachers.

**Curriculum Development**

Teachers created curricular plans (Units of Practice) and implemented them. The workshops were effective in helping the participants prepare their Units of Practice. At the conclusion of each workshop day participants completed evaluations called exit tickets. These comments exemplify the value of the training:

“Collaborative/sharing set-up was extremely helpful and useful.”
“We (as a group) have so much to say—we should (as a group) try to use FirstClass more to share all these great ideas and focus more on the topic at hand.”
“Just speaking for myself, I would like to have our Saturdays be longer, perhaps six hours. I would use the extra time to work with my group on our project.”

All teachers appreciated the training provided by the AZCOTT program. It helped them think about all of the components of a planned learning activity and thus prepared them to implement the integration of technology in their curriculum.

**Student Engagement**

Across the classrooms, we found positive changes in student engagement. Teachers noted that students were excited about learning. They displayed initiative by going beyond the assignment and by asking to use computers during free-time and after school. We also found general teacher concerns about noise levels in their classrooms or at least the beliefs that others would find the noise levels in their classrooms inappropriate. First it should be noted that these AZCOTT teachers had been in the program for only one year and were learning new classroom management techniques needed to organize student use of the added technology. Second the noise that accompanies student engagement may be a good problem, but it also was a real issue that continues to be on the minds of the participants.

**Student Learning**

Teachers described many forms of student learning from students doing better on tests to the students with difficulties who were able to learn more than before. Examples of the latter included improved students writing, improved comprehension by deaf students, and improved relations among emotionally handicapped students in part because they brought technology expertise to their groups and other students wanted to participate with them.

**Teacher Leadership**

Initially when this group of teachers applied to become AZCOTT teachers, the school district and university partners looked for candidates who would be leaders in their schools. It is quite clear that these teachers were taking what they had learned and sharing it with other teachers. They teach after school technology classes and often assist their peers to solve technology-related problems. This was primarily evident at the school level, but it also occurred at the district level. For example, at a district technology staff development event, the superintendent of a school district with an AZCOTT classroom remarked “What a difference Ms. T’s room has made to the district” and said they would find teacher substitutes for those wishing to visit and participate in that classroom. In another district, one teacher was selected to become a district technology integration specialist as well as continue teaching a section of her grade 7-8 gifted class.

**Beginning Preservice Participation**
One of the disappointments of these teachers is that more ASU West student teachers and practicum students hadn't visited and participated in their classrooms. They expressed the hope that they would be able to provide models for them and inspire them too. It should be noted that the PT3 project leadership, now in the second semester of the project, is aware of this issue and is working on marketing strategies. One unexpected outcome of the project is that each AZCOTT teacher has been invited to talk to preservice students as part of their university courses or workshops and share scenes from their classrooms through videotaped vignettes. Recently, an AZCOTT teacher took part in early childhood workshop for preservice students. After the workshop the students were asked to complete evaluation questions. They found the AZCOTT teacher sharing helpful and requested additional opportunities to dialog with other AZCOTT teachers.

What Worked?

It appears that technology has become an integral part of each classroom rather than a time set aside to go to the computer lab 40 minutes a week. We think this early success is due to the project's ability to address multiple interventions. Hall and Hord (2001) point out that change often is not centered on one innovation but many. In this case AZCOTT teachers had the support of their principals, participated in over 100 hours of high quality workshop training distributed over the course of a year, attended two local educational technology conferences, received technical support from their school districts, benefited from online support through interactions with their peers and PT3 project staff, enjoyed technical and curricular support from the project manager and her site visits, and received adequate access to technology and the internet. Additionally, the teachers were selected because they were experienced teachers who were interested in constructivist philosophies associated with active student participation, collaborative workgroups, and meaningful projects. Although we noted signs of early success, experts on the change process have found that the implementation of change often requires 3-5 years (Fullan, 1991; Hall & Hord, 2001). We plan to revisit these classrooms after the second and third years of the project and trace the developments of the teachers and the preservice students influenced by the AZCOTT classroom examples.

Abstract: A large-scale faculty development project focused on the integration of technology for teaching and learning at Marquette University's Colleges of Letters and Science, Communication and School of Education is described. The project includes 1) a website with multiple resources to help faculty integrate technology into their teaching; 2) faculty consultants for technology planning; 3) "just in time" support; 4) workshops that promote technology integration for learning; 5) mini-grants for course redesign.

Despite the explosion of technology in schools as well as the huge volume of knowledge available electronically, most teachers still use a limited number of technological tools in fairly traditional ways. In a recent survey on technology use in classrooms (Milken Exchange on Educational Technology, 1999), for example, it was found that typically teachers use video to present information and computers for basic skills practice and word processing. Newer technologies like desktop publishing, computer simulations, multimedia projects, videoconferencing, electronic chats, and electronic information gathering are much more rarely used (Office of Technological Assessment, 1995) even though these technologies offer great potential to enhance student engagement and achievement (O'Neil, 1995; Tharp, Estrada, Dalton & Yamauchi, 2000).

Numerous studies of technology in teacher preparation point out that future teachers cannot learn how to use and integrate technology effectively in a single course. They need a technology-infused program that involves not only entire schools of education but faculty in the humanities and sciences who can collectively model technology integration for future teachers. For this reason, we have begun a long-range faculty development effort at Marquette University that focuses on 1) helping professors in arts and sciences, communication as well as education integrate technology into their instruction to improve student learning and 2) expanding leadership roles among faculty to model and mentor integration of multiple technological tools into student-centered instruction.

Currently, this staff development program includes: 1) a website with multiple resources to help faculty integrate technology into their teaching; 2) faculty consultants for technology planning; 3) "just in time" support; 4) workshops that promote technology integration for learning; 5) mini-grants for course redesign.

Faculty Website

The goal of this recently launched faculty website has been to create an ongoing, dynamic, web-based educational portal for university faculty that will include online tutorials, listservs and online discussion forums; examples of faculty technology integration projects; and links to web resources for curriculum design and pedagogy that integrates technology. Current and planned tutorials on the website include how to integrate electronic databases, e-mail, desktop publishing, presentation managers, multimedia, electronic portfolios, videoconferencing, computer conferencing, the Internet, digital and video cameras, and assistive technologies into teaching and assessments. After reading and discussing articles on the application of constructivist and brain-based learning principles into teaching, professors taking the
tutorials are expected to experiment with the integration of the technology in a course and use both faculty consultants and a faculty listserv for support and discussion about the technology. Currently, for example, the faculty listserv includes faculty members who teach courses in the arts and sciences as well as courses in education who are implementing the use of Blackboard, an online courseware package, into their courses.

Faculty Consultants For Technology Planning

Two full time faculty consultants lend their technical expertise to help faculty members identify and acquire the technology they need to meet educational objectives. The Learning Technology Consultant helps faculty members address instructional design and curriculum integration issues and the Technology Coordinator helps faculty members address and troubleshoot all of the technical issues related to the particular hardware or software technology they are trying to implement. For example, currently two professors in the Foreign Language Department are designing a project for their Spanish History course which requires students to create a multimedia presentation. They needed advice on both the purchase of a multimedia workstation as well as various curricular aspects of the project. Both of the consultants met with the professors to determine their needs and were able to recommend the purchase of necessary hardware and software with very detailed information about specifications. At other times, technology planning involves making mid to long-range decisions about how existing curriculum may be improved through the integration of educational technology. In such a situation a faculty member and the Learning Technology Consultant can combine their expertise in both content and technology to make decisions about integrating technology in the curriculum in ways that improve learning. For example, an Education professor had used journals to encourage students to reflect on their impressions of schools they were visiting. In an attempt to enhance the effectiveness of this course requirement, the professor sought a technological solution that would allow students to share their experiences and reflections with other students in the class. The Learning Technology Consultant was able to suggest a number of web-based applications such as e-mail, threaded discussions and discussion boards and explain the pros and cons of each. Given the situation, the professor was then able to determine that the discussion board would work best in supporting the particular educational objective.

Just in Time Support

When the integration of technology is used to enhance the learning experience, even more preparation time is required to schedule and set up equipment or to create multimedia or digital presentations. “Just in time” customized faculty support provides the resources necessary to integrate technology into a learning experience on short notice (Oblinger, 1998). The Learning Technology Consultant is available on-demand to provide strategies and guidance for technology use that support learning objectives and the Technology Coordinator is able to allocate and set up necessary equipment just in time for class. In short, just in time support, with its commitment of personnel and equipment, facilitates the serendipitous use of educational technology.

Workshops

In addition to the wide range of technology knowledge and use among faculty at Marquette, there is also a wide range of how faculty thinks about teaching and learning and how technology can be used to enhance particular paradigms of teaching and learning. For example, one teacher who sees teaching as largely the transmission of information might use PowerPoint to build better lectures, while another teacher who subscribes to a more constructivist (Driscoll, 2000; Perkins, 1991) view of teaching and learning might offer students the opportunity to use PowerPoint to share and engage others in what they have learned.
Based on faculty interest, the Learning Technology Consultant has been conducting workshops for small groups of faculty on technology topics that go beyond a purely “how to use” approach. Workshops promote the use of technologies like PowerPoint and web pages to create complex learning environments with activities that are relevant to the learner (Driscoll, 2000), ample opportunity for social negotiation of meaning (Persichitte, Caffarella & Tharp, 1999; Vygotsky, 1978), multiple ways to learn (Gardner, 1983), metacognition (Duffy & Cunningham, 1996) and student-directed learning (Perkins, 1991).

**Mini-Grants for Course Redesign**

Over a three year period (2000-2003) faculty members in the Colleges of Arts and Sciences and Communication as well as the School of Education will be given the opportunity to apply for summer mini-grants as an incentive to redesign a course in a way that models the use of technology to support teaching and learning. To obtain the grant, faculty members are required to submit a proposal that presents a significant plan for technology infusion in a course that they teach to future teachers; demonstrate interest and involvement in technology; and explain how the revised course will model good teaching and learning principles. Currently, faculty members in Biology, Chemistry, Physics, English, Mathematics, Communication, Foreign Languages, Philosophy, Theology and Education are using these grants to revise their courses.

Technology Integration in K-12 Classrooms: Evaluating Teachers’ Dispositions, Knowledge, and Abilities

Ron Zambo, College of Education, Arizona State University West, USA, Ron.Zambo@asu.edu
Ray R. Buss, College of Education, Arizona State University West, USA, Ray.Buss@asu.edu
Keith A. Wetzel, College of Education, Arizona State University West, USA, Keith.Wetzel@asu.edu

Abstract. As part of the evaluation of PT3 sponsored technology integration workshops conducted at Arizona State University West, a Likert-type questionnaire was developed to collect information about teachers’ beliefs and skill levels related to technology integration. This presentation will include a description of the questionnaire that is being used to collect pre-test and post-test data from preservice and inservice teachers. The instrument contains several subscales targeting teachers’ perceptions of their confidence and skill level for using technology, knowledge of technology standards and the Unit of Practice (UOP), and beliefs about the best use and effects of technology integration. The focus of the presentation will then shift to the results obtained from its first administration. Quantitative results and conclusions about the effects of the technology training are presented.

Introduction

Background

In the PT3 grant developed at Arizona State University West, we devised three separate, but related components. First, we devised a professional development component, which focuses on university faculty development. Second, in partnership with local school districts, we established model technology-using classrooms, which our students and local teachers can visit to observe high-level technology use and integration. Third, and the focus of this paper, we included a professional development component for inservice, mentor teachers and preservice teachers who work together in field experiences and student teaching. We believe the third component is critical for ensuring that students in our programs see and have opportunities to employ technology in classroom settings as they proceed through our program. These initial experiences and opportunities to see and use technology are critical to subsequent use of technology because future educators are influenced by what they observe in practicum classrooms or by their own school memories (Darling-Hammond, 1995, 1998).

Rationale/Need

Advances in teaching expectations outlined by various professional organizations, which require teachers to integrate curriculum and incorporate technology into instruction attest to the continuing need for professional development (AAAS, 1993; NCTM, 2000; NRC, 1996; Thomas [NCATE], 1995; Wiebe & Taylor [ISTE], 1997). For example, NCTM (2000) guidelines prescribe hands-on, student-centered teaching and authentic, performance-based, instruction-driven assessment. Similarly, AAAS’s (1993) Benchmarks stipulates both the content and the nature of instruction that are to be employed in science learning. Because both require a substantial focus on problem solving and active participation by students, meeting these guidelines will require substantial professional development.

Finally the need for professional development is particularly substantial when one considers the issue of integrating technology into current instructional endeavors. Thomas (1995) and Wiebe and Taylor (1997) have written extensively about the integration of technology into instruction. In their presentation of the revised ISTE Standards, Wiebe and Taylor (1997, p. 7) discuss the importance of technology integration when they state, “candidates will apply computers and related technologies to support instruction in their
grade level and subject areas. They must plan and deliver instructional units that integrate a variety of software, applications, and learning tools.”

Although such mandates ultimately will prove to benefit students, inservice teachers are not currently prepared to meet the mandates. For example, research summarized by the United States Congress, Office of Technology Assessment report (USCOTA, 1995) indicates teachers are not prepared to integrate technology into instruction. More recently, the CEO Forum’s School technology and readiness report: Year 2 builds a strong case for providing additional professional development for inservice teachers so they can use technology more effectively during instruction (CEO Forum, 1999).

Method
Subjects

Participants (N = 21) consisted of two groups, 13 university students who were completing their professional education preparation program as student teachers and 8 inservice teachers. The majority of students were in Elementary Education programs including Elementary, Bilingual, ESL, and Early Childhood Education. The inservice teachers had been teaching 13.4 years on average. The eight inservice teachers were serving as mentors to eight of the student teachers.

Technology Questionnaire

A 42-item questionnaire, which assessed teachers' beliefs and skill levels related to technology use and technology integration was developed. Respondents rated each item on a 6-point Likert scale, where 1=strongly disagree, 2=disagree, 3=somewhat disagree, 4=somewhat agree, 5=agree, and 6=strongly agree. Higher scores indicated greater skill or more positive attitude. Examples of items follow. “I can develop lessons that integrate the use of video, digital cameras, or scanners.” “I can use the National Educational Technology Standards (NETS) to design instruction.” “Computers are an integral part of classroom instruction.” In addition, one open-ended item assessed participants' “vision” for using technology by asking, “Over the next five years, how do you see yourself using technology in your classroom?" The questionnaire was based on one developed for the Interactive Video Project (Wetzel, Zambo, Buss, & Arbaugh, 1996). In that study, the researchers developed a technology questionnaire to evaluate preservice students' preparation to teach with technology. For the present study, that questionnaire was revised to: (a) reflect the recent National Education Technology Standards for Teachers (ISTE, 2000); (b) ensure appropriateness for both preservice and inservice teachers; and (c) include items which assessed participants' knowledge and beliefs about the Unit of Practice (UOP) and the integration of technology.

Items were developed to provide coherent sets, which formed subscales that could be more readily analyzed. Twelve subscales were developed including: general confidence in using technology, confidence in computer setup and general operation, confidence in using non-computer equipment, confidence with software selection and use, confidence in addressing students with particular needs, confidence in developing lessons with technology, beliefs about appropriate use of computers, beliefs that computers are integral to classroom instruction, perceived cost effectiveness of computer integration, knowledge and beliefs about the technology standards, knowledge and beliefs about UOP, and level of technology use observed in university courses. In addition, a total questionnaire test score was computed.

Procedure

Participants completed the questionnaire on two occasions. They initially completed it in January 2000 prior to their participation in a set of workshops (18 hours of workshop and follow-up meetings) delivered to increase participants' skills in using technology and integrating it into the classroom setting. Participants
completed it a second time in May 2000. For the students, this administration followed the completion of their student teaching semester.

Workshops consisted of learning about the Unit of Practice and using it as a basis for developing a curricular unit, which integrated technology, and which was implemented during the student teaching experience. In addition, other topics addressed by the workshops included: National and State Standards for content areas including technology, Website evaluation strategies, school district resources, internet resources, preview of various software and video discs, use of the digital cameras, use of PowerPoint for presentations, and management techniques for limited computer classrooms.

**Results**

Using pre-test data, Cronbach's alpha for the total test was 0.93. Individual subscale alphas, with the exception of one outlier ($\alpha = .55$), ranged from $\alpha = .69$ to $\alpha = .90$ with a median of .81.

Results showed mean scores were relatively high for all subscales, both pre-test and post-test, generally ranging from 3.8 to 5.0 out of 6. There were significant between-subjects differences for group (student teachers vs. inservice teachers) and significant within-subjects differences for time-of-testing (pre- vs. post-test) for subscale and total test scores.

Differences in group (student teachers vs. inservice teachers) scores were noted for two variables. The effect for group was significant for knowledge and beliefs about UOP, $F(1, 19) = 4.59, p < .045$. Teachers, $M = 5.32$, felt more positively disposed toward the UOP and its benefits for instruction than were student teachers, $M = 4.80$. Moreover, the effect for group was significant for level of technology use observed in university courses, $F(1, 19) = 38.65, p < .001$. Student teachers, $M = 3.79$, indicated they had observed more use of technology in university classes than their inservice counterparts, $M = 1.43$.

Mixed ANOVAs indicated three subscale scores increased significantly from initial testing, prior to the workshop, to testing at the end of the semester. Confidence in using non-computer equipment such as laser disc players, digital cameras, capturing video, etc. increased significantly, $F(1, 19) = 4.67, p < .018$. Means for the two times of testing were 4.06 and 4.44. Similarly, confidence with software selection and use increased significantly, $F(1, 19) = 6.15, p < .023$. The pre-test mean was 4.25 and the post-test mean was 4.72. Confidence in addressing students with particular needs (i.e., second language learners and students with special needs) increased significantly, $F(1, 19) = 15.93, p < .001$. Means for the two times of testing were 3.81 and 4.06 for the initial and final time-of-testing, respectively.

Participants' pre- and post-test vision statements were analyzed to determine whether changes occurred. Fifty percent of the participants exhibited a post-test vision statement that demonstrated a higher degree of technology integration compared to their pre-test vision about the integration of technology. For example one participant provided the following pre-test and post-test responses, respectively: "I do not see myself designing lessons with technology in mind..." and "I would like to use technology on a regular basis as a method of teaching in my classroom. I would also use technology as a resource for information for my students."

**Discussion**

Results showed that the overall questionnaire was reliable. Further, the subscales, which were developed to assess specific areas related to technology use, technology attitudes, technology integration, and so on, were consistent and coherent as demonstrated by the strong reliabilities. The subscales allowed the researchers to explore components of technology use and integration with a greater level of specificity.
Such specificity provides a more detailed view of inservice and preservice teachers' beliefs, attitudes, and skills regarding technology use and integration.

Group differences were apparent on the subscale for the Unit of Practice. Teachers were more positively disposed to the UOP and its benefits for instruction compared to students. This may be attributable to the fact that the experience of inservice teachers provides them with a greater knowledge of planning at the long-term, unit level; whereas, relatively inexperienced, preservice teachers may be operating on a short-term, day-to-day basis. Moreover the effect for group was significant for level of technology use observed in university courses. This is not surprising, given that the inservice teachers who had been teaching on average 13.4 years, would not have observed substantial levels of technology in their coursework.

Significant increases occurred in confidence using non-computer equipment, confidence in software selection and use, and confidence in addressing students with particular needs. These increases could be attributed to three factors. First, participants were provided with opportunities during the workshops to learn about technology materials related to these three areas, for example, specific training was provided on the use of non-computer equipment such as video discs and digital cameras. Second, this new knowledge was directly applicable to classroom settings, as a result participants tended to incorporate this new knowledge and adapt it to their specific needs as they developed their UOPs. Third, students and their mentors had the opportunity to put into practice their new knowledge during the student teaching semester as they implemented their UOPs. Consistent with the professional development literature, opportunities to learn, adapt, and implement technology innovations are essential to fostering change and to promoting the integration of technology in classroom settings.

The research reported in this paper is based on a project being funded by the U.S. Department of Education through a Preparing Tomorrow's Teachers to Use Technology (PT3) Grant # P342A990351. The views and conclusions expressed in the paper are those of the authors and no endorsement by the U.S. Department of Education should be inferred.
Problems and Pitfalls of Directing a PT3 Grant

David Zimmerman, James Madison Univ., USA

In June 2000, President Clinton announced the award of $43 million to fund 122 new grants to train future teachers to use technology effectively in the classroom. These PT3 grants (Preparing Tomorrow's Teachers to Use Technology) are to be administered by the U. S. Department of Education. James Madison University will receive $493,554 over a three-year period to produce 36 digital video units that will eventually be placed on the World Wide Web.

This presentation will follow this project from initial writing of the grant, through organization of the personnel tapped to participate in the production of the digital video units to the production of the learning activities that will be placed on the Web. Various problems encountered by the project director while working with the various individuals will also be summarized.

Three school divisions from the Harrisonburg City/Rockingham County area have contributed nine elementary school teachers to work on teams, led by four faculty members from the JMU Early Education Program. One of the nine teachers will work with the JMU Center for Assessment and Research Studies to design and implement assessment rubrics to be applied to each of the 36 instructional units. Central to this assessment will be the National Educational Technology Standards for Students and for Teachers. At the local level (i.e., Virginia) assessment standards will include the Virginia Technology Standards for Instructional Personnel and the Virginia Standards of Learning. We believe these web-based video models can serve not only Virginia educators, but also pre-service teachers and teacher preparation faculty throughout the US and beyond.

This presentation will include examples of the video units produced to-date as well as "out takes" to demonstrate the challenges of videotaping students in the elementary classroom.
Collaborative Action Communities for Preservice Technology Integration

Abstract: With a successful field-based preservice program aimed at effective strategies for teaching diverse urban youth, the University of Houston is implementing an action research process to actively collaborate with area school districts to establish networked learning communities of university faculty, preservice teachers, and school-based educators to support the development of future teachers. The College has restructured its required 1 semester, 3-credit-hour technology course to a series of 3, 1-credit-hour technology sections tied directly to methods courses to allow students to develop appropriate content-based technology proficiencies based on ISTE standards. To ensure that all members of our learning community are effectively prepared for appropriate inclusion of technology in content methods courses, faculty and students participate in a comprehensive support model of classroom instruction, workshops, and field-based experiences with the aid of a cadre of trained Technology Fellows.

Educators involved with the preparation of new teachers throughout the final decade of the Twentieth Century have repeatedly recognized the need for a strong technology component for preservice programs. They have experimented with a variety of learning models that integrated technology (Falba et al., 1999; Willis, 1997). While some successful projects have been implemented, there is agreement that new teachers are generally not being prepared to effectively integrate technology into their future classrooms (Office of Technology Assessment, 1995; Strudler, Quinn, McKinney, & Jones, 1995). It is no longer enough to prepare new teachers only with one disconnected technology-in-education course; introductory courses should instead be project-based and meaningful, followed by appropriate modeling and use in content methods courses and field experience. True modeling of how objectives can be accomplished by using technology for instruction is rare in preservice programs (Office of Technology Assessment, 1995). Professional development opportunities are needed for College of Education faculty to effectively integrate relevant technology use into their curriculum strategies and content standards (Office of Technology Assessment, 1995; O'Bannon, Matthew, & Thomas, 1998; Sprague, Kopfman, & Dorsey, 1998). Preservice teachers want to learn strategies for integrating technology tools into their teaching (Oliver, 1994), and expect to use computers in their teaching (Marcinkiewicz & Wittman, 1995) but express their feelings of frustration at their lack of technology proficiency (Francis-Pelton & Pelton, 1996) and a lack of understanding of effective technology use in contemporary classrooms (Balli, Wright, & Foster, 1997).

The Twenty-first Century finds us poised for widespread, concerted action on the subject of effectively preparing future teachers as complete professionals who are able to adeptly use and integrate into the curriculum all available learning tools. State and national organizations are leading the accountability push by implementing standards for the use of technology by teachers (Handler & Strudler, 1997; Wiebe & Taylor, 1997). In 2000, the International Society for Technology in Education (ISTE) brought this trend to a culmination with the release the National Educational Technology Standards for Teachers (NETS•T), a blueprint for the design of preservice technology programs developed through the extended collaboration of representatives from various stakeholder groups with interests in how new teachers use technology (Thomas, 2000). As this standards-based movement brings a clearer vision to the preparation of preservice teachers, teacher education programs across the country must finally acknowledge the long trend of research findings and recommendations in order to design appropriate learning environments that challenge long-standing curriculum structures through the cooperation of all faculty involved with teacher preparation. Without the purposeful creation of collaborative, authentic, and content-focused learning environments in which future teachers are empowered to develop content, pedagogy, and technology strategies concurrently, new technology standards will be meaningless.
The PUMA Program

The University of Houston (UH) College of Education has a history of providing innovative teacher education programs, grounded in research and effective practice, for urban, at-risk populations. UH is located in the heart of Houston, the nation's fourth largest city, in the Third Ward, an inner city poverty area of Hispanic and African American cultures, which has been identified as a federal Empowerment Zone. Approximately 450 elementary and secondary teachers graduate from UH each year, with minority students constituting 37% of the College's undergraduate enrollment.

The UH teacher preparation program is predicated on a belief of learning throughout the career of a professional educator, beginning with effective preservice preparation and successful entry into the teaching profession. To that end, the Pedagogy for Urban Multicultural Action (PUMA) program was designed to develop new teachers who can demonstrate current best practices, understand the needs of diverse youth within a constantly changing society, and reflect on their own learning and experience. Based at Professional Development Schools (PDS), PUMA provides authentic classroom settings in which preservice teachers can learn and practice effective teaching strategies, while working with university faculty and qualified School-Based Teacher Educators (SBTEs).

The four-semester sequence of PUMA is offered in three phases: Pre-PUMA, Phase I PUMA, and Phase II PUMA. The Pre-PUMA program, the two junior year semesters, includes courses in the theories and practices of effective classroom management, and understanding the psychological needs of learners. Phase I PUMA consists of a one-semester set of field-based courses that focus on the basic study of the history and philosophy of American education, and the development of professional planning, instruction, and evaluation skills. Phase I preservice teachers are placed at PDS schools to participate in methods courses and classroom placements on alternating days, permitting students to integrate theory directly with practice. Students who successfully complete Phase I are approved for admission into Phase II, a 14-week student teaching/internship placement, in which students demonstrate those sets of knowledge, skills, and attitudes reflective of a beginning professional.

Areas of Need

Despite receiving both local and national acclaim, several significant challenges remain related to improving the coherence of the entire PUMA program through the integration of technology in appropriate ways to meet the needs of our diverse student population. Using an approach grounded in the tradition of community-based action research (Stringer, 1999), we identified key technology leaders in the Houston-area school districts and invited them to identify and propose solutions to these challenges. We believe that for lasting program change to occur, this effort needs to be collaborative, rather than directive from the university perspective. Long-standing collaborative relationships among the 32 schools in the Houston Area Teacher Center served as the foundation of this focused and recursive inquiry and decision-making process. Our plan for program evaluation, rather than being an afterthought external to program activities, is integral to the collaborative decision-making among stakeholders.

As we analyzed baseline data from extensive surveys and focus group interviews of representative participant groups, a set of challenges became clear. The first challenge we face is identifying the best ways to create access to technology among our widely diverse urban student population. Although 73% of our students have home access to computers, only 3% own a portable computer that can be used in flexible groupings with other students and teachers for both campus and field-based coursework.

Another challenge is a lack of coherence and the disconnection between the Pre-Puma courses and the rest of the PUMA program. Little across-course planning among the instructors gives our students the impression that these courses are separate entities - merely a set of academic hurdles, rather than a meaningful sequence of preparation. Furthermore, unlike the highly structured field experiences of PUMA Phases I and II, there is no field-based experience and sparse technology integration in Pre-PUMA. When queried, our students indicated a strong need for accessible networking for communication between campus-based and field-based experiences and resources. The third challenge that consortium members identified is that in our current plan, we address educational technology with a single course taken typically during the Pre-PUMA phase of the program. This placement is not ideal for several reasons, including the fact that such a "one shot," disconnected course does not allow students to see ways in which technology can be seamlessly integrated into content area strategies. When surveyed, UH preservice teachers
perceived the importance of technology, but were unsure as to the benefit derived from the single course currently required. A majority reported, however, that they are rarely required to use technology in any other methods courses.

The fourth challenge facing our college is a lack of faculty confidence and skill with technology. Although data from a faculty survey revealed 100% computer ownership for 5 years or more, actual instructional computer use in the classroom dropped dramatically. A majority of faculty expressed a desire to utilize more technology tools to improve their classroom teaching, however even those faculty members who are technologically proficient express concern about teaching technology strategies in addition to their already very full curriculum. Further, little effort has been made to collaborate with faculty in other colleges across campus that teach preservice teachers prior to acceptance into the PUMA program.

**Design for Improvement**

Our plans for program improvement emerged from the needs identified by our stakeholders. Those needs led to revised program goals and objectives, which led to proposed actions, anticipated outcomes, and ultimately, multifaceted, interpretive, and participant-focused evaluation strategies. The process we strive to build is an inclusive action research-based model that spirals from our initial need through the stages of Listen, Think, and Act, with the logical subsequent dissemination stage of Share to complete the sequence and feed the next spiral in the process. We define action research as a systematic process through which stakeholders work together to frame questions about teaching and learning, to problem-solve, to implement proposed solutions, and to document and evaluate the subsequent results of their actions (Stringer, 1999). This process embodies the reflective decision-making among learning communities, which is integral to the PUMA program.

**Goals of this Project**

Networked learning communities provide collaborative and supportive environments in which preservice teachers share and develop content, pedagogical, and technological expertise.

Learning communities (Fullan, 1999) of preservice teachers, university faculty, and K-12 teachers are in the process of being established to support beginning teachers from initial coursework through induction teaching years. Students entering the PUMA program are invited into these smaller, more nurturing subsets of the larger program, giving immediate support to new members and a virtual place to learn that is available from anywhere and at anytime. More experienced members can offer guidance and insight to new students, while newer students can constantly challenge more experienced members to reconsider previous conceptions. Technology will play an invaluable role by connecting those at various distant locations and asynchronous occasions. All community members have opportunities to learn and practice effective online communication strategies through email, Web-based discussions, video conferencing, and chat. An additional benefit of constructing strong and progressive learning communities is that students can remain in contact throughout the student teaching experience, a time when students often feel isolated from campus colleagues.

All students have access to current-model portable computer technology on a regular, immediate, and flexible basis.

Preservice teachers use computers both as students in university-based courses and as teachers in their field-based classrooms, however we strongly believe that technology will prompt changes in teaching and learning habits only when it is available regularly and immediately for flexible learning opportunities. We consider laptop computers to be the most effective way to encourage spontaneous learning anywhere at any time. In fall 2000, wireless hubs were installed in classrooms through the College of Education building. Three 10-unit mobile, wireless, laptop stations were purchased for use by PUMA faculty and Technology Fellows in campus-based courses in conjunction with the hubs in any classroom in the building. Our goal is for students to regularly experience the versatility of portable computers, thus creating an understanding of the need for portable computers in their learning and teaching. PUMA admissions guidelines for school year 2001-2002 will require the lease or ownership of a laptop computer; reasonably-priced laptops with accessible leasing and financing plans will be made available to students through COE relationships with relevant business partners.

The College offers a comprehensive, connected and extended technology experience.

To provide an environment, in which our future teachers can come to see the appropriate and exemplary use of technology in education, we have implemented structural changes to our technology component. We have
restructured our current three-credit hour required technology in education course into three one-credit-hour sections to be taken over the three-semesters leading up to the student teaching experience. Campus-based students are exposed to technology appropriately in methods courses, and also attend a one-hour weekly lab to reinforce content-related technology strategies, while field-based PUMA I and II students will receive site-based workshops and electronic support. PUMA I students will additionally be placed in classrooms with identified technology mentors when possible, and when not, will have access to technology mentors within the district. By extending the exposure to technology interwoven with pedagogical strategies, we believe our preservice teachers will more thoroughly integrate technology into their future teaching.

Students have comprehensive and coordinated opportunities to develop standards-based technology proficiency.
Entering PUMA students will be required to demonstrate basic technology proficiency, so that efforts during PUMA can focus more effectively on the use of technology in instruction, rather than taking precious time to instruct on basic operations. Recommendations for such general preparation for students is found in the new ISTE NETS standards (ISTE, 2000), and we have found, as have others (Kirby & Schick, 1998), that students are now entering preservice programs with some experience with basic word processing and communication technologies. To ensure that students possess general technology skills sufficient to participate in the program (Rodriguez, 1996), their skills will be assessed through a performance-based pre-test. Those who are lacking the required skills will have ample opportunities to develop basic skills prior to PUMA admission through a series of topic-specific workshops, recommended courses, and other support. Throughout PUMA, students see and use various technologies, in the context of methods strategies, to reinforce basic skills, personal and professional productivity, and effective instruction.

Students compile and maintain electronic portfolios throughout their preservice experience.
While traditional grades are still required by the university, an electronic performance-based portfolio system has been established to allow students a venue through which to reflect on and demonstrate growth, the development of pedagogy (Carroll, Potthoff, & Huber, 1996), and a professional voice (McKinney, 1998). Portfolios have been shown to be a flexible assessment format capable of addressing criteria not a part of traditional assessments, such as continuous student reflection, individual assessment of growth and change, iterative evaluation of learning goals, and the contextual examination of created products in relation to complex teaching processes (Levin, 1996; Snyder, Lippincott, & Bower, 1998; Wade & Yarbrough, 1996). Not only will portfolios give students an authentic example of assessment that they might use in their own teaching, but students will graduate with a tangible record of their experiences and a better understanding of their own abilities. Students might also include representative examples of work produced by the students they teach (Hoelscher, 1997). Faculty and Technology Fellows will work with students to design content products that reflect both discipline-specific and technology standards. Students will receive instruction on technical procedures, style guidelines, and ethnographic strategies for selecting representative examples of their own work.

Virtual field experiences are being developed for campus-based students.
Unique campus resources are being developed for field-based students.
Video experiences are being developed to provide campus-based methods instruction with real classroom contexts. A collection of virtual field experiences using a variety of traditional and emerging video technologies is being developed, implemented and evaluated. Methods and IT faculty are in the process of identifying exceptional teaching and technology integration examples in collaboration with SBTEs. IT graduate students and staff are collaborating to plan, record, prepare, and compile high-quality video scenarios for use in on campus-based classes and in online training. While preservice teachers participating in the field-based PUMA programs benefit greatly from being immersed in authentic classroom settings, there are instances when the widely distant PDS locations prove problematic. It is difficult, for example, for certain expert speakers to regularly travel to all field sites. Certain courses deemed unique and valuable will be taught to students in the field by campus-based experts through technologies such as video, online streaming video, videoconferencing, and web-based communication. IT graduate students and staff are collaborating with faculty experts to plan, record, and prepare the presentations.

Faculty and students are participating in new models of teaching and learning for the purpose of developing technology proficiency.
Faculty are being assisted in developing skills and confidence in appropriate uses of technology for content areas through short workshops during the semester, and intensive workshops during intercessions, summer, and weekends.
Handler and Strudler (1997) suggest a collaborative process in which content methods faculty work with instructional technology faculty to align content strategies and resources with technology standards using a matrix technique. We feel such a collaborative alignment process not only capitalizes on our faculty's full range of expertise, but helps to establish our collective meaning of technology integration for everyone involved with teacher preparation at the University of Houston. Faculty also have opportunities for continued support through the Academic Technology Support Center (ATSC), being developed to provide all UH faculty with training and support to enhance teaching and learning with new technologies.

Of prime importance to the success of this program is the one-on-one collaboration that PUMA faculty have available from Technology Fellows, who are Instructional Technology graduate students specially trained in such skills as content-area technology integration, mentoring, and adult learning theory. Similar to student-faculty mentoring plans proposed by others (Sprague, et al., 1998) Technology Fellows collaborate with and support PUMA faculty members in content areas to identify technology strategies that can be used to teach and demonstrate content-related concepts, to assist with set up and operation of necessary technology, and to generally help faculty gain confidence in their own personal technology skills. In addition, Technology Fellows are accessible to students in campus-based methods courses, during weekly computer lab workshops, and electronically via e-mail. After the first year, the Technology Fellows will commute to PDS sites with the PUMA students to maintain consistent student contacts, ensure properly functioning technology, and facilitate university-school relationships onsite. Completing our learning community concept, such relationships make a school-based learning environment feasible and at the same time give our IT graduate students valuable experience in authentic teaching environments.

Ongoing Assessment of Program Success

These program change efforts were designed to increase the technological readiness of future teachers through an action research-based process. We recognize that any changes to our current program will also simultaneously cause other, unintended changes, both welcome and otherwise. To monitor and continually adjust our efforts, we have developed an evaluation plan to address both process and product outcomes according to our inclusive action research approach. First, we established baseline data by having preservice teachers, university faculty, and SBTEs complete a questionnaire on attitudes toward technology, use and perceived skill, and learning style with technology. Technology representatives from consortium school districts participated in focus groups to identify needs and propose solutions. Data from these multiple forms of needs analysis will be used to provide baseline data. Then during the first year of this program, working with action-research consultants and through a collaborative stakeholder effort, we will identify more in-depth, qualitative assessment strategies to reassess the need and the strength of our research process. In our action research-based framework, formative evaluation is a key and ongoing process that will involve all stakeholders.

To ensure that the program is progressing toward the goals, we will: (1) ensure that national and state standards concerning content, pedagogy, and technology integration are met; (2) demonstrate that program curriculum supports the standards; and (3) base student assessment on the standards, through state assessment instruments (EXCET test) and local assessments, such as rubrics (developed collaboratively by preservice teachers, faculty, and the evaluation team). Questions to be considered during formative assessment will also be derived directly from program goals and outcome measures, as well as identified through ongoing community-based collaboration with consortium members. The process itself will be repeatedly assessed so that it accurately represents stakeholder needs, interests, and strengths. We consider this unique teacher preparation approach ideal for the longitudinal study of the development of pedagogical skill and technology proficiency of new teachers. The rich context will support numerous research projects, yielding data from a wide range of procedures and instruments, including questionnaires, performance assessments, examination of student- and teacher-produced products, learning and teaching journals, observations, interviews, focus groups, video and audio recordings, anecdotal records, and open-ended critiques. Other data will include course syllabi and evaluations, documentation of professional development and support available to PUMA faculty, documentation of support provided to PUMA students, archived electronic communication, and databases of instructional resources. Finally, we plan to follow our graduating teachers out into the field to assess the effect such a comprehensive preparation program has on their ability to effectively teach in 21st Century classrooms by collecting state ExCET scores, electronic portfolio rubrics, and teacher evaluations at the end of the induction year.
Conclusion

Our program was redesigned to include several critical factors for success. The use of an action research approach ensures that progress towards goals and objectives will be continually assessed and evaluated. The purposeful creation of collaborative, authentic, and content-focused learning environments in which future teachers are empowered to develop content, pedagogy, and technology strategies concurrently is a critical factor in the design of preservice teacher education programs. Modeling strategies for accomplishing objectives by using technology for instruction is a significant part of the instructional process, addressed through a variety of professional development opportunities for both faculty and preservice teachers. Finally, technical support is available both for on-campus courses and field-based experiences. The University of Houston's history of innovation and leadership in teacher education, as well as on the close working relations established with relevant stakeholders committed to improved education of urban, low-income, at-risk children and youth, gives us great optimism that these program improvements will have tremendous potential for long-range, systemic reform.

Collaborative, innovative ways to use technology to support literacy teaching and learning are examined in these papers. Software applications have been designed and developed to enhance instruction for students who are learning foreign languages including Japanese, Chinese, Portuguese, Spanish, French, and English. Some papers focus on learning workplace literacy skills for communicating with technology. University faculty members teaching reading and language arts classes to preservice and inservice teachers describe how they have provided their students with multiple opportunities to collaborate with each other and K-12 students as they explore ways to seamlessly integrate technology into their classrooms. Researchers discuss the online communities of K-12 learners that have been created to furnish students' opportunities to respond to literature in collaborative ways. Web-based resources to enhance literacy learning are described in some of the papers. Papers in this section cover a wide range of literacy topics of interest to faculty members teaching students in kindergarten to graduate level classes.

Fukuda and Nakamura describe the trials and tribulations of designing a learning system to teach middle grade Japanese students Kanji. Their original attempts involved a PDA and eventually the system evolved into a web-based program. The program is designed for either self-study or as an enhancement to classroom teaching and learning. Senquan uses technology to teach reading and listening comprehension strategies in Chinese with KEY software. KEY is a multimedia reading comprehension tool, which includes a Chinese/English dictionary and a text to speech module. EquiText, an interactive groupware tool, allows foreign language learners to participate in collaborative writing activities on the web. Costa, Galli, de Almeida, and Guedes used EquiText with Brazilian college students who were learning French, English, and Spanish. Students worked in teams using EquiText to produce significant written discourse. This paper reports on promising research using collaborative writing to support students as they learn a foreign language.

Slobodina reports on the integration of technology in a business English class for the English for Specific Purposes (ESP) practitioner. To participate in the world business community, university graduates need to be proficient in both English and technology. In this class students use software and hardware for a variety of authentic learning activities to assure that they are well prepared to meet the challenges of the English speaking international business community. Slobodina also explains how movie excerpts are used to demonstrate authentic examples of real-life business communication. Electronic business communication is the focus of Hemming, Symons, and Langille's paper. Their paper describes a course that teaches students workplace literacy skills for communicating via email and discussion groups. Direct instruction is given for electronically explaining/expressing a viewpoint, asking pertinent questions, and writing effective responses. Through guided and independent practice students use the strategies in their coursework.

Bhattacharjee and Chen compiled a list of software available for use in bilingual classrooms. While working with preservice and inservice bilingual teachers as well as parents of bilingual children, these authors discovered that teachers and parents need information about using the computer to support bilingual students' learning. The authors describe software applications to support the literacy learning of bilingual students.

Akanbi has placed graduate course materials for Reading Strategies for the Content Fields in WebCT. Additionally, the WebCT communication tools have been used to establish an online learning community for the teachers enrolled in the class. Glassman shares his experiences with using the web to conduct his undergraduate reading course and explains his distinction between teleteaching and telelearning.

Understanding that preservice teachers need field based opportunities in order to develop their expertise in technology integration, Royer developed a telecollaborative project between preservice teachers and inservice teachers.
and their students. In her study preservice teachers moderated an online writing project for K-12 classroom students and through the experience learned how to integrate technology into the classroom to accomplish curricular objectives. Winters’ preservice teachers also had opportunities to experience integrating technology into the classroom curriculum. His students used web-based technology to create reviews of children’s books and they corresponded by email with students as they both read and responded to the same novel. The results of these authors’ projects indicate that participating in these technology experiences increased the likelihood that their students integrate technology into their future classrooms.

Nolte, Leech, and Monteagudo report on Vermont’s innovative online project that provides support and resources for teachers and students. The goal of the project is to improve student performance in the arts, humanities, and social sciences through the collaborative efforts of an online learning community. Another innovative online project is Literacy Junction, an interactive web site for students in third through eighth grades. Cuper, Spires, and Crissman report on how Literacy Junction enhances students’ achievement in reading and writing while increasing their technology skills. Hofmeister and Thomas share their research on using Virtual Literature Circles with third and fourth grade students. After reading a shared text, the students responded to the text on an Internet message board. They report on the cognitive complexity of the posted messages and the intellectual continuity of the threaded discussions. Broad and Labercane also used the computer to engage students in collaborative responses to text. The fifth grade students in their study used networked response-based reading and writing activities to extend their learning. They offer useful ideas for others who may be interested in conducting similar research on effective ways to use technology to enhance reading and language arts in the classroom.

Reynolds and Reynolds describe the Literacy Desktop Publishing course designed for high school students. This course offers students advanced opportunities to use technology to improve their reading, writing, listening, and speaking skills. The course content includes graphic arts communication skills required by local business and industry.

These papers examined the multiple literacies required in the classroom and in the workplace. They focused on a variety of ways that technology enhances literacy teaching and learning. A common thread throughout many of the papers is the importance of collaborative online learning.

Improving the Teaching of Reading, Language Arts and Literacy through WebCT: A Work in Progress

Linda Akanbi
Reading Institute
Kennesaw State University
United States
lakanbi@kennesaw.edu

Abstract: This paper is a description of how WebCT is being used to enhance the delivery of a graduate reading course -- Reading Strategies in the Content Fields -- that is part of a Reading Endorsement program for PreK-12 classroom teachers. The course is the third and final reading course in a program designed to address the need to improve reading instruction in pre-kindergarten through grade twelve in the State of Georgia. The course is being delivered online via WebCT, with some "face time" on campus.

Introduction

In 1999 the University System of Georgia, in conjunction with the Georgia Professional Standards Commission, formed the University System of Georgia Reading Consortium. The consortium was created in response to the state's need to improve reading instruction in PreK-12 schools. Toward this end, the consortium developed the Reading Endorsement to enhance professional development in literacy teaching and learning for practicing PreK-12 educators. Two models, the Reading Institute Model and the Teaching Reading Distance Learning Model, emphasize classroom application and address three strands: Understanding Readers and the Reading Process, Linking Literacy Assessment and Instruction, and Instructional Strategies in the Content Areas Across PreK-12. WebCT was chosen as the vehicle for the distance-learning model. In this model, each course is offered online. In the Summer Institute Model, the major content for all three strands of the program is presented in a three-week format.

Kennesaw State University utilizes a combined delivery model. The first two strands listed above are emphasized in a Summer Reading Institute, and the third strand is the focus of a separate course offered online in the fall. A Literacy Action Plan developed by the teachers at the end of Summer Reading Institute 2000, and tied to their schools' performance goals, serves as the foundation for the Fall semester course -- EDUC 7718: Reading Strategies for the Content Fields. The remainder of this paper will be devoted to a description of the design of this course, which is a work in progress even as it is being taught, and a discussion of how WebCT is being used to facilitate its delivery.

Course Design

This graduate reading course -- Reading Strategies for the Content Fields -- is a study of the concepts and specific processing strategies involved in reading and writing in the content areas. It emphasizes development and teaching strategies appropriate for the specific content area and grade level. The purpose of the course is to provide a learning-support network through readings, course seminars, online dialogue and supervised field experience, for reading professionals to examine their philosophies and beliefs, and to apply newly acquired conceptual knowledge as to what constitutes effective literacy instruction for their grade level and/or content area. Teachers are required to collect data to show evidence of student learning, analyze these data, reflect on their teaching and develop strategies for improving learning. These data will be included in a portfolio that teachers must submit at the end of the academic year, indicating that they have successfully met all the requirements for receiving a Reading Endorsement.

Course Participants

The teachers enrolled in the course represent elementary, middle and high school levels, as well as both public and private schools. One of the elementary practicing professionals is a reading teacher, and so are two of the middle school teachers. There is one male teacher in the group. Two of the teachers are also pursuing a Master of
Education degree in Early Childhood Education (P-5), and they will be able to add the Reading Endorsement to their certificate. The number of years of teaching experience of teachers enrolled in the program ranges from three to fifteen, with the average being five years. The diversity of grade and subject levels, school systems, teaching experience, advanced preparation, and gender represented in the class, lends itself well to the sharing of knowledge and perspectives on different classroom applications of reading and language arts instruction.

WebCT Course Delivery

Except for three initial class meetings where teachers were oriented to the requirements of the course, trained in the computer lab to use WebCT and Power Point, and two other campus meetings where they had to make class presentations, the teachers have been meeting online for class and to access the content of the course. The instructor utilizes the 3.1 version of WebCT, which includes the following tools: Course Content, Communications, Study Tools and Evaluation Tools. The Course Content tools used in this course consist of the syllabus, calendar, content module, and glossary. The Communications tools utilized include mail, chat and discussions. Study Tools is a feature accessible only to students. The only Evaluation tool currently used by the instructor is the assignment tool. In addition to the primary tools listed above, the instructor has added the following links to the course home page: Reading Online, which is the online journal of the International Reading Association, the International Reading Association organization, the Georgia Department of Education, and the Atlanta Journal Constitution’s News for Kids. The instructor has also added two pages to the discussions tool under Communications. One page is for teachers to post their teaching reflections, and the other page is for them to post literacy teaching tips that they discover, including useful web sites.

These tools have been used to create an online learning community. Through the WebCT communication tools, which are the most used tools in the course, teachers are able to share their teaching reflections with one another as they try to implement their Literacy Action Plans, learn what is occurring in literacy classrooms different from the level that they are teaching as well as in other classrooms at their own grade level, ask questions and offer one another support. Since all the reflections and responses are made public, by agreement, teachers are also able to read the instructor’s reply to each reflection. In addition to reflections, the WebCT communications tools are being used to post discussion questions and responses based on assigned readings, hold online class dialogues and send E-mail. WebCT content modules designed by the instructor, are used to supplement instruction. The other links added to the course home page provide extra resources for teaching; including children’s book lists, lesson plans and teaching strategies. In addition, teachers can keep up with the latest trends and research in the field, which helps them to further their professional development in the area of reading.

Conclusion

Glatthorn (1995) states that there are three groups of factors that seem to influence teacher development: those involving the teacher as a person, those relating to the context in which the teacher lives and works, and those involving specific interventions to foster teacher development (p. 42). The support that teachers receive from one another online and from the instructor makes them feel valued as individuals and helps give them the inner strength and confidence they need to pursue the attainment of their professional development goals. The teachers’ classrooms where they live and work provide the context for the online reflections, and finally, the content of the course provides specific interventions to enhance the teachers’ ability to teach literacy. Improved student achievement in reading will be the ultimate criterion measure for the success of this program.

Abstract This paper concerns computer software currently available in the market for bilingual children. The purpose is to survey the software options available to bilingual children, parents, and teachers. This paper will approach the topic from the following perspectives:

- Sources for Purchasing Software
- Bilingual Reading and Writing Software
- Bilingual Educational Games/Tutorial/Drill, and Practice

Introduction

During the last decade of the millennium, we have already witnessed a drastic increase in the number of bilingual students in the United States. To face this new change, many school districts are holding school-community activities such as Houston Independent School District's (HISD) Community Parade, featuring the theme, "Education: We Are All In This Together". The goal of these activities is to enhance, support, and encourage parent involvement with schools. Schools all recognize that parents are valued partners in the educational process, serving as the child's teacher in the home. Parents play an important role in reinforcing effective learning strategies and early intervention. Like many other immigrant parents, many Hispanic parents are eager to coach their children at home to adapt to the American culture and new school system, while keeping their cultural heritage.

Keeping their heritage alive and adapting and learning the ways of the American culture increase access to bilingual materials. Nearly 10% of children ages 5-17 nationwide speak Spanish at home, and as many as 22% in California and Texas. Teachers today face a challenge of ensuring that students are given a variety of opportunities to be successful in school settings. However, the interaction with new immigrant parents, student teachers in the bilingual education program, and teachers who are currently teaching bilingual students reveals that computer use is one of the topics which is in strong need of clarification and support for this special population. There are many misunderstandings regarding the use of computers in bilingual education. Proper use of computers, however, can not only help bilingual students to fit into their new community and become more productive citizens, but also is an effective tool to retain their cultural heritage.

This paper concerns computer software currently available in the market for bilingual children. The purpose is to survey the software options available to bilingual children, parents, and teachers. This paper will approach the topic from the following perspectives:
Sources for Purchasing Software

The first place to locate software titles for bilingual students is still the local computer software stores. The author found that in the Houston area, surprisingly, Office Depot carries far more children's titles than any other software store. Although Spanish software is hard to find in this kind of general computer software store, many educational titles can be "repurposed" to fit the needs of bilingual students. The term "repurpose" has been used widely in the educational multimedia field for identifying old video clips and reusing them in different settings. The same idea can also be used to turn a piece of software currently available in the market into useful instructional material for bilingual classrooms. Repurposing a popular software title in the current market to fit the special needs of bilingual students probably is the most efficient way for identifying software titles for bilingual classrooms: the price will be cheaper, the software will be more compatible with the existing bilingual classroom collection, the option is wider, and the software will be more up-to-date.

A pre-service teacher in the bilingual education program, for example, proposed a great idea of repurposing the software, the Explore Yellowstone program, by MECC. This software allows a student to take the role of a tourist in the 3,500 square miles national park and explore the mammals, birds, plants, earth science, reptiles, and other habitats in this area. The activities offered in the software include interactive virtual trip, field station, experiments, and visitor guidance. The pre-service teacher used Explore Yellowstone to plan a lesson. The objective for the lesson was to improve the reading and writing skills of 4th grade bilingual students and to expand vocabulary through reading, writing, and listening. According to the lesson plan, the teacher presents a poster board with animal drawings and the definitions or explanation about them. The teacher then directs the attention of students to the advantages they can have with technology by demonstrating the versatility and effectiveness of the software by projecting to the screen a colorful photo of a wild animal and its habitat. The teacher then models for students how this is achieved by clicking different animal names on the menu of the software. A new wild animal and its own characteristics then can be viewed on the screen. The teacher then repeats this step with two or three animals to be sure students understand what the software provides. The activities and procedures proposed in the lesson plan include several steps. The teacher divides the class into small groups of two to three students. Each group selects two to three animals to investigate using the software. The students then discuss several characteristics of each animal (i.e.) color, size, food they eat, weather, habitat peculiarities, etc. As a group they pick two characteristics of each animal and write a summary of their findings.

The use of "repurposing" existing software may be the best alternative for bilingual children, parents, and teachers. As this market has developed, more specialized traditional bookstores are carrying software titles that can be integrated with classroom instruction.

Another way to access software is through mail-order that is now popular among teachers. Mail-order from another country sometimes takes time and planning. Special-purposed software and many teacher-created materials can also be purchased either on-line or through catalogues. General online bookstores such as Amazon.com and Borders.com now also carry software titles along with book titles and music titles. Type in the keyword "Spanish" and a list of selection with detail description, user reviews, and screen shots of the software can be viewed. Educational titles online bookstore and software vendors such as Sunburst (at www.sunburst.com), Software World (at www sofware.com/spanish.htm), and Soleil (at www.soleil.com) have created web sites to offer information and take orders. Users can also purchase from the print-version of the educational software catalogues. However, the software products offered by these companies are mainly for learning the Spanish language. Only www.sofonic.com offers a few titles that have instructional application.

Bilingual Reading and Writing Software
For Hispanic families and bilingual educators, the most basic as well as the most widely used software suites probably is the international version of MS Office which includes word processor MS Word, spreadsheet program MS Excel, presentation program MS PowerPoint, and database maintenance system MS Access. If the whole set of the international version of MS Office is not available, the user can also pay approximately $75.00 to get a Spanish spell checker as an add-on to the English-standard MS Office suite. These add-on modules allow one to easily extend MS Word's proofing facilities to new languages. They are simple to install, and fully integrated with all of Word's normal proofing facilities; spelling and grammar are checked as a document is typed. Unknown words can be easily added to a customized dictionary. These are the same high quality proofing modules Microsoft includes with versions of Word that are sold outside the U.S.

Software has been developed also to support the Reading/Writing Workshop. This approach to teaching reading and writing has gained favor and fervor within the educational community in the last decade (Maddux, Johnson, Willis, 1997). Basically it is a way of teaching reading and language arts as an active, student-centered process. It gives students, individually and in groups, much of the responsibility for making decisions about what will be studied and why. It is also an approach that emphasizes the social and collaborative nature of learning. As with most methodological or pedagogical innovations, the reading/writing workshop has been redefined, realigned, and renamed on its journey toward widespread acceptance. Its early predecessor was perhaps the writing workshop in the 1970s. Reading workshops then developed to complement the writing workshops and the term "reading/writing workshop" is now used mainly because writing is an important aspect of learning to read. Also, because these workshops encompass reading, writing, speaking, and listening, they are also referred to as literacy workshops (Chen, 1998).

Collaboration in the workshop entails sharing responses, ideas, drafts, and finished written products through conferences with the teacher, conferences and journal exchanges with peers and the teacher, and with members of the student's wider, non-classroom, and community such as parents. Collaborating to make meaning, rather than summarizing or reiterating teacher-held interpretations, is the function of small-group discussion and whole-class discussion. The teacher in these classrooms takes many roles including that of a learner. The teacher collaborates with students in constructing meaning through reading, writing, speaking, and listening.

The examples of reading/writing workshop activities below illustrate the possibilities of this approach. Just Grandma and Me from the Living Books series published by MECC, is an example of a electronic book for the reading workshop. Children's electronic books often have detailed color illustrations on each screen along with text. But they can also be quite different as well. For example, some electronic children's books give readers the option of having the story read to them in any of several different languages. Some also give students the option of clicking a word or phrase they cannot read and both hearing it as well as hearing a definition or explanation. The colorful drawings on each screen of children's electronic books may contain many "hot spots," objects that react when they are clicked with the mouse cursor (Maddux, Johnson, Willis, 1997).

Electronic children's books are one of the most popular types of software today. The best known of this genre is MECC's the Living Books series including: Just Grandma and Me, Arthur's Teacher Trouble, The New Kid on the Block, Little Monster at School, Ruff's Bone, Arthur's Birthday. Each page contains detailed illustrations and some text. But electronic books like Grandma and Me can also be used in interactive ways. For example, the child can select to have the story read in English, Spanish, or Japanese (see Figure 1), and the drawings on each page contain many "hot spots" that react when they are clicked.
Story Weaver Deluxe from MECC is an example of the electronic writing workshop program currently available in the market. It also allows users to switch languages between English and Spanish (see Figure 2). From a blank page, the student have a wide selection of background pictures, sounds clips to add on as sound effects or background music, clip arts, objects, text to speech, and many other features as their building blocks to create their own "books".

Figure 2: A screen shot of the writing workshop program StoryBook Weaver Deluxe

Bilingual Games/Tutorial/Drill & Practice

Drills are software designed to allow the user to practice a skill that has already been acquired or taught (see Figure 3). A common type of drill and practice software involves practicing math skills such as multiplying two digit numbers. There are thousands of drill and practice programs that teach everything from math facts to sight vocabulary, parts of speech, names of the fifty states, and many other types of facts or basic skills.
Whereas drill and practice software is designed to provide a way to practice a skill that has already been learned, tutorial software is designed to teach the skill in the first place by direct instruction methods. While tutorial software may include elements of drill and practice and assessment, it is unique in that it presents new information and may be represented as providing an independent teaching environment. In its purest form, tutorial software is the embodiment of the teaching machine. The software takes the learner through a sequence of steps by first, present a new idea, concept, or task; present a query designed to assess the student's grasp of the new idea; provide feedback on the student's response; and finally branch the learner to a different sequence based on his or her performance. Computer games are a type of direct instruction program that can be adapted for use as a preparatory activity. Many types of interesting games are available. They generally involve a scenario such as saving a planet or discovering a treasure through knowledge and understanding some skill.

There are some collaborative efforts by scientists, educators, and professional video game and educational software developers who have come together to do research on and develop teaching materials that integrate games and computer-based explorations with learning (Chen, 1998). Their research activities focus on the human-computer interaction issues associated with learning in an electronic game environment. Specific topics include studying which game formats (fast-action, simulations, puzzles, etc.) can be used to carry math-science educational content, which formats are most attractive to students, and which formats are most conducive to learning. They are also investigating methods to integrate electronic games with more traditional classroom learning environments. The effect of collaborative play and how collaborative work can be incorporated into electronic games, and the role of mediation by teachers. Scholastic offers a great selection of software products (http://www.scholastic.com/kids/games.htm ) some of the products are: Royal Makeovers, Meet the first winners!, Animorphs Hawk Rescue, Captain Underpants Name, Goosebumps Sandwich Builder, Goosebumps Hare-Brainers, Scholastic's The Magic School Bus, and Maze Craze.

Conclusion

In conclusion, the availability of software products in Spanish is very limited. Bilingual teachers, parents, and children have very a few opportunities to read stories, play games, or have tutorials in Spanish. However, the need to have access to these materials is critical in the USA. Research indicates that children who come to the USA with a strong literacy level in the first language will achieve also higher literacy level in the second language quicker. Therefore, bilingual children need to have access to materials that will support their academic success in first language so that they can also achieve successful in their educational career.

Reader Response in the Information Age

Kelvin G. Broad, Department of Instructional Leadership, Center for Excellence in Education, Northern Arizona University, USA. kelvin.broad@nau.edu

George Labercane, Graduate Division of Educational Research, University of Calgary, Canada. labercane@ucalgary.ca

Abstract: This paper reports an investigation into the use of web-based, interactive computer technologies in the achievement of curricular outcomes in reader response-based literature instruction. The primary purpose of the study was to explore the use of computers as tools for implementing classroom reader response instruction. Rosenblatt's (1978) Transactional Theory of the Literary Work and pedagogical approaches developed from this theory were used as the basis for developing and implementing computer-based literature exploration. The study used a network-based software application called Zebu as a venue for conducting reader response-based instructional initiatives. A portrait of fifth grade student's reading, writing and responding in computer environments is presented. The nature of students' responses is discussed and key characteristics of effective web-based reader response environments are outlined. Findings suggest that computer environments represent one venue where students can engage in collaborative conversations about literature.

Introduction

The 1990s have seen computers and other digital technologies gradually pervading our schools and classrooms (Coley et al, 1997). Consequently, as we step into the new millennium, the use of technology has become an integral component of students' and teachers' lives. This focus upon technology raises important issues for teachers because they are being asked to find ways to effectively utilize computers in their day-to-day instructional programs.

Much of the educational thrust in the development of initiatives for using computers in classroom settings has focused upon integration of computer-based activities into existing curriculum (Alberta Education, 1997). The research discussed here embraces this integrative approach by exploring the integration of computer-assisted instruction within the boundaries of established pedagogical practice - namely reader response-based pedagogy.

Research Background

This study emerged from the researcher's interest two areas: reader response theory and practice; and, computer-assisted instruction, in particular computer applications that allow students to interact with one another in a discussion forum setting.

Reader response instruction has its roots in Louise Rosenblatt's (1978) Transactional Theory of the Literary Work. According to Rosenblatt, the act of reading is a transactional relationship between the reader and the text. "An element of the environment (marks on the page) becomes a text by virtue of its particular relationship with the reader, who in turn is a reader by virtue of his [her] relationship to the text. And at the same time the term transaction, as I use it, implies that the reader brings to the text a network of past experiences in literature and life" (Rosenblatt, 1985, p. 35). Thus, the transaction involves the feelings and images conjured up by the words in the mind of the reader. Literature instruction based upon reader
response theories attempts to encourage and nurture student’s articulation of the feelings and images that are evoked by the text – their aesthetic response.

Some reader response researchers (e.g. Leal, 1993; Eeds and Wells, 1989) have focused upon the role of literature discussion groups and how students collaborate in shared construction of meaning. Researchers contend that in such groups, students become involved in “a conscious weighing and discussing of one’s own and others’ responses” (Berg, 1987, p. 271) to text. Generative conversations like these are suggested to enhance and diversify student’s personal responses to text.

Research that connects computers and literature instruction is limited, with small pockets existing in particular areas (e.g. Shen, 1995). Much research to date has been conducted with university students (e.g. Evans and Pritchard, 1995). This may be due in part to greater availability of networked computers in higher education institutions. By comparison, school-based settings have only recently acquired the resources necessary to implement computer-based networked literature study. Previous studies have focused upon connecting historical, authorial, semantic, and stylistic information to literary texts (Smith, 1996, Landow, 1989). Evans and Pritchard (1995) suggest, “no single extended work examines the implications that such [reader response] theories have for teachers and students who work in a computer-assisted classroom” (p. 4).

The two research areas discussed above relate directly to what happens in today’s classrooms. Research in the area of reader response presents a vision of reading that sees the reader an active participant in negotiating their personal understanding about texts. Research relating to computer-based instruction uncovers the beginnings of investigation into use of computers in the implementation of reader response-based instruction.

The Research Context

This research was conducted at an elementary school in Alberta, Canada. The school opened in early 1997 and currently serves kindergarten to Grade 6 students. During the initial designing of the school, incorporating computers into the infrastructure of the school was considered an important factor. Being a new school allowed for the construction of a learning environment incorporating the latest in educational technology, rather than cobbling new infrastructure around the established superstructure of an older school. The student population of the school was socio-economically diverse while being ethnically homogeneous. The vast majority of students attending the school were Caucasian and spoke English as their first language. The participants for this research came from one fifth grade class. During the course of the research 12 students participated in the computer-based instructional events. The balance of the class completed similar events in traditional pencil and paper format. Thus, students’ participation in the research was considered an integral component of the classroom instructional program. The students selected to participate were considered by the teacher to be representative of the cross-section of abilities in the classroom.

Exploring the Possible Worlds of Computer Response

During the period of the research, the class was reading the novel The Sign of the Beaver (George Speare, 1983). Six instructional events were conducted that related to this novel. The global objective for these events was for students to develop literary understanding by "crafting it out of the raw material of their experiences, the text, and their discourse with other students, teachers, and writers" (Probst, 1990, p. 29). For this type of engagement to occur in the computer environment (and traditional environments for that matter) research suggests that teachers develop "tasks without single answers to encourage articulation, discussion and debate" (Oliver et al. 1997, p. 979). A computer application called Zebu was used as the venue for the students’ participation in computer-based literature exploration.
Zebu

In this research a computer application called Zebu was used to create and conduct the computer-based instructional events. Zebu was developed to enhance what the creators term "collaborative project-based learning" (Ward and Tiessen, 1997b, p. 22) in the computer environment. According to Ward and Tiessen (1997b), teachers can develop environments in Zebu where students engage in "social interactions aimed toward the development of understanding" (p. 22). Zebu is accessed via a web browser, either Netscape or Internet Explorer. "Technically the software is a set of CGI enhancements to a standard HTTP server, which allows users to construct and edit pages and other objects within a secure WWW site" (Ward and Tiessen, 1997a, p. 3). In Zebu, users can develop interactive web pages without the need to know HTML. The user is provided with a variety of page templates and editing tools to affect this process. A number of the features available in Zebu were particularly beneficial for this research:

- Information can be easily input, arranged and edited in the Zebu pages;
- Students' responses are easily tracked because responses are automatically labeled with the student's name; and,
- Discussion objects offer an interactive venue where students can read and respond one another's contributions.

Discussion Objects

Discussion objects are simply on-line discussion forums where students submit written information that is then posted on the page for the rest of the group to read and respond to. Once students make their response, they submit it using a button directly below the response area. The response is then posted for the rest of those working in the project to read. As students became comfortable with how the discussion forum worked, students' back and forth responses became conversational in nature. This domain also allowed all students to comment at once rather than waiting their turn, as is often the case in effective face-to-face group conversations. Often a number of strings of discussion unfolded simultaneously. The students' engagement with and conversations about a variety of text in discussion objects became the focus of this research.

Instructional Events

Instructional events in this project were designed to challenge students to revisit excerpts from the text and address open-ended questions and response starters. Revisiting allows students to develop a greater understanding of the text by re-engaging with the text. Hartman and Hartman (1993) recommend re-reading texts as a means of "expanding the role of the reader" (p. 202). The passages that were chosen to be re-read focused upon specific events or issues in the text that the teacher or students wish to explore more deeply. Then, questions and response starters were crafted to guide the students' exploration of the excerpts. Each instructional event was crafted to "encourage curiosity, activate prior experiences and feelings, [and] help students connect personally with characters, themes or issues" (Pritchard, 1993, p. 31).

Each instructional event was developed in such a way that students firstly made an initial response to a question or response starter that addressed the part of The Sign of the Beaver they were reading at that time. For example, in one instructional event, students were asked to explore the nature of the relationship that was developing between the two protagonists in the story. Students were asked to look at this relationship in light of which protagonist they thought was gaining or learning more from the relationship.

During each event, students engaged in two types of on-line response — initial responses and dialogic responses. Responses were contributed via discussion objects.

Initial Responses

Initial responses refer to the students written contributions that were made in response to their reading of excerpts and response starters. The nature of the initial responses varied across instructional events. As
students became more comfortable with the Zebu environment their responses increased in length and depth.

**Dialogic Responses**

Once students had made their initial responses to the response starter they would submit their response and update the page so they could then see the initial responses of their peers. Students would then read and make comments about the responses of their peers. In the initial events, these responses were rather cursory and many focused primarily upon grammar and spelling errors rather than the ideas and opinions that students were articulating. However, in the later events, students' focus shifted to center upon content. This was in spite of some student's responses containing numerous spelling errors. It appeared that with appropriate guidance in expectations for response and increased familiarity and confidence in the discussion group environment students engaged in generative conversations about text. The responding process became recursive in nature there was semantic contingency across strings of responses as one built upon another in conversational fashion. When this occurred students became engaged in collaborative knowledge building as each student's contribution added to the shared pool of understanding.

**Selected Findings**

This study indicates that networked computer environments like Zebu offer a setting where the boundaries of reading and writing blur. Reading and writing become coactive partners in the response process. In Zebu, the line between reading and writing merges in the response process along with the reader's thinking, which is woven across the response process. Thus, no one aspect can be viewed as a separate entity but rather each component (reading, writing and thinking) is coactive with the others. This coactive nature of the response process was demonstrated in Zebu as students moved seamlessly between reading, writing and thinking about texts and their personal experiences.

The impact of networked programs like Zebu is most noticeable when environments are created where a number of students can interact simultaneously. This allows students to access multiple perspectives by viewing and responding about the variety of responses contributed by their peers. Students in this research took an active role in constructing and negotiating literary understanding in the communal environment that Zebu offered. Students' literary engagement was characterized by their suspension of judgment in return for the opportunity to embark upon a generative journey of literary exploration. Students used the text and their peers as sounding boards for exploring ideas about the text.

Many similarities were recognized between the responses collected during this research and the nature of responses reported by previous researchers (e.g. Cox and Many 1992). The students' responses demonstrated that they:

- Use the text to support their assertions;
- Use one another's responses to support their assertions;
- Make connections with personal experiences;
- Empathize with characters in the text; and,
- Make tentative predictions about their understanding of the text.

The development and articulation of intertextual connections has been posited as an integral aspect of the aesthetic reading act (e.g. Beach, 1993). This study further demonstrated the importance of connection making in students' negotiation of literary understanding as students created responses that were interwoven with their autobiographical experiences. They played with the text, sometimes 'giving in' to what the text appeared to make obvious, then pulling away into statements of tentativeness as they balanced their experience of the text with their personal experiences of literature and life.

This study reaffirms the teacher's role in developing and delivering classroom reader-response pedagogy. In the computer, this role is particularly crucial because teachers must develop instructional events that
first, live out the goals of reader response and second, effectively utilize the tools computers have to offer to attain those goals.

During this study, students responded to a variety of questioning approaches. Observations made during this study provide further evidence as to the critical role that the nature and delivery of questions play in educational settings. Just as in the conventional instructional environment, articulation of aesthetic responses will only be realized if students' exploration of text is orchestrated in ways that encourage aesthetic engagement with text and provide avenues for effectively articulating response. In computer environments, reader response-based instructional events should be formulated in ways that constitute a "continuing reinforcement of habits of sensitive and responsible organization of literary experiences" (Rosenblatt, 1968, p. 344).

The use of computer technology in the classroom cannot be approached as a 'passing fancy.' In this study, as students became accustomed to engaging with text in Zebu, their "capacity for literary experiences of higher and higher quality and the capacity to reflect on these experiences with increasing insight and maturity" (Rosenblatt, 1968, p. 341) appeared to develop. To realize the computer's fullest potential, computers must be woven into the fabric of the daily classroom curriculum. Otherwise, teachers may not see the achievements students are capable of when they have the opportunity for ongoing experiences with the technology.

The development of computer-based initiatives in education should be a collaborative endeavor between educators and computer technologists. In the case of reader response-based initiatives, theories of how reading and writing unfold must form the basis for the development of reader-response-based computer initiatives. So, "instead of having technology shape the form and content of education, the educator has the responsibility of making education shape the form and content of technology" (Hazari, 1992, p. 145). Only when technology becomes advantageous should it be introduced into the reading and responding process.

"Educators need to be particularly careful about choosing when virtual environments are more appropriate than actual physical experiences" (Winslow, 1996, p. 817). This cautionary note was heeded in this study by having students read The Sign of the Beaver in traditional format. This allowed students to enjoy the physical experience of reading - curling up on a couch, lying on the floor or huddled under a desk or table.

Some researchers (e.g. Clifford et al, 1997) have lauded computers as providing an equitable environment where all students can experience success. Observations made during this study indicate that this is not always the case. In fact, some aspects of the on-line environment can have a deleterious effect upon some students' engagement in this environment. For example, some students' ability to type and navigate within the environment impacted upon their opportunity to participate in the instructional events. Also, the ability to read excerpts and instructions also presented a barrier for some students. In addition, online discussion spaces have been posited as presenting a democratizing discussion environment where all students have the opportunity to contribute to classroom conversations (e.g. Cooper and Selfe, 1990). Online discussions in programs like Zebu do appear to allow all students to contribute to discussions about text. However, the freedom to have all students contribute simultaneously may result in numerous parallel discussions where no clear synthesis of understanding evolves from the conversation. Furthermore, this study demonstrated that although students do have the opportunity to contribute, that does not mean that others will hear their 'voice' in the group.

Conclusions

In this project, the computer became a conduit for orchestrating conversations with and about text. Findings suggest that networked discussion forums present an environment where engagement with text using reader response approaches can be implemented. The study does not contend that programs like Zebu offer a panacea for implementing reader response pedagogy. Instead, the study indicates the possibilities that networked applications offer to augment instruction in this area. The collaborative venue created in Zebu opened up opportunities for students to read, write and respond about text in a shared context.
Overall, this study has proved to be a successful investigation of young readers' experience of reader response instruction in the comparatively new domain of the computer. As computer capabilities in schools continue to develop, there will be more opportunities to explore this growing area of educational research.

Abstract: An FL pedagogy, integrating reading and writing skills in foreign language teaching, associated with Web resources, may contribute to the development of those skills while producing collective texts. The EquiText, a collaborative writing tool, allows for innovations in text production either through teamwork or individually, mostly asynchronously. The readers/writers' participation in text construction may promote virtual interlocutions among the writers (FL learners), and their readers (the lecturer, the other fellow writers, researchers/observers). Another perspective of the current sole text reader, writer and evaluator is suggested. We propose to analyze the usefulness of the Equitext in significant written discourse as a result of the interactions in the tool. Three foreign language productions sustain our assumptions: texts produced by intermediate Brazilian college learners of French, English and Spanish as FLs, either individually, in paper, or in teams, using the EquiText, with significant results.

Introduction

The purpose of this work is to find new manners to teach reading and writing in a Foreign Language (FL) that may contribute to the development of abilities needed to construct more significant and discursive texts. Support was found in the software of collaborative writing text - the EquiText - developed in the Post-Graduate Program of Computer Sciences in the Education of the Universidade Federal do Rio Grande do Sul (UFRGS). It is a useful tool to aid FL teachers and learners to go beyond the traditional school pedagogy that, historically, has been treating reading and writing activities as exclusive classroom practices.
Our proposal is to look at text production as a collective and public act. Therefore, the text is open to insertions, alterations, substitutions even deletions as well as further comments. This environment may consequently contribute for collaborative text practices as it provides a virtual bond among the participants – the writers (learners) and their readers (other learners and teachers) – thus diluting the teacher's sole role as reader and evaluator. The text is discussed and built collectively on the Internet.

Linguistic and conceptual exchanges, experienced by more than one participant or collaborator, reduces the legitimated role of the teacher as the only source of knowledge, and enlarges the dialogic dimension in the discursive production, either in reading or in writing. For that reason the theoretical foundation is based on authors such as Mikhail Bakhtin (1999ed.), whose Marxism and Philosophy of Language stresses the collaborative experience and this reflection on such experiment. In addition, Possenti (1993), Foucambert (1994), Coracini (1995), Paulo Freire (1996), and others, guide the theoretical perspective of this analysis.

The idea of using the EquiText emerges from the possibility of rethinking the traditional teaching of reading and writing skills. Three (3) FL languages teachings were experimented with the following method. Intermediate level learners of an FL produced Three (3) texts individually and three (3) other texts were produced by collaborative construction on the EquiText, in French, English, and Spanish.

Three texts with the same topic were produced both individually and on the EquiText, in each of the selected foreign languages. Thus, “Likes and dislikes” were produced by students participating in an English course, coordinated by Janete Sander Costa; “Ce que j’aime et ce que je n’aime pas” were elaborated by the students of a French course, under the coordination of Joice Armani Galli; finally, “Hablando de gustos” were produced by students of a Spanish course, under the coordination of Lara Oleques de Almeida.

We present a more general and qualitative view that considers the formation of the reader/writer in the construction of the meaning of the text. We recognize the limitations of this first experience, whose results already point toward a different collaborative production that should provide easier access to writing and reviewing, not only for collaborators but also for the evaluator.

The reader/writer's formation in text construction

Relationship interaction between reading and writing

Classroom reading and writing teachers traditionally display a paternalistic attitude. However, current tendencies favor less passive imitation and more autonomic thinking by students. Any reading, including FL, is seen as an active process where the reader participates in turning the text into a meaningful proposition. So, writing I part of the reading process, making the reading class a special class of elaboration of meaning.

Justifying the present work, starting from the experience with students of French, English, and Spanish as FLs, we pondered on the practice of teaching reading and writing in FL. As described in (Foucambert 1994) the growing procession of the excluded ones proclaims the end of the literacy era. However, this certainly does not eliminate reading and writing. But freed by other media from the task of preserving the oral word, reading and writing were never so present, abundant, necessary, and decisive. In cultural, political, informative, and scientific fields, both reading and writing are the privileged means of exchanging, sharing, reflecting; of readiness, studying and option. In this sense, Foucambert, op cit, claims that if fifty years ago the percentage of the literates was a good indicator of industrial development, the readers' percentage reveals today, in the developed world, the real degree of democracy.

Under such perspective the text is conceived as an entrance to the reading act, a space of confluence and of divergence of ideas that are covered not simply by a certain linguistic code, but by a conception different from what originated in the mother tongue, or L1. Paraphrasing Foucambert, to read means to be questioned by the world and by self; it means that some answers can be found written; it means to have access to that writing and to create an answer that integrates with the existing text. To read is to interrogate the writing; therefore promoting an extra-curricular activity that allows solidifying the narrow relationship between reading and reading production, i.e., the writing, is meaningful.

Reading construction is an indispensable theoretical notion because it allows surpassing the challenges of most learners in an intermediate level in FL. At this point, the student seems to be "gagged" by the FL impediment. We can then compare reading construction and the moment of FL skill. Foucambert argues that literacy is over; it was necessary but the student is invited now to converse critically in an FL class. He no longer
comparar el alfabetado con el analfabeto, pero más bien al lector con el no-lector. La lectura no es la adquisición de un mecanismo, sino que nos esforzamos por enseñar el mecanismo de la palabra.

Desde el primero, o ascendente, el modelo de lectura que identificamos es un olvido del proceso de producción de sentido, ya que su práctica denuncia simplemente la decodificación del texto. También conocido como bottom-up, este modelo busca por gráficos que correspondan a unidades fonéticas que el profesor había solicitado, una mera reproducción del material escrito.

Así como lo anuncié anteriormente, consideramos que el espacio del aula de FL es un lugar especial de significado, ya que la lectura y la escritura son una actividad bidireccional que se acerca al conocimiento fruto de un proceso de producción de sentido.

Así como Foucambert sostiene que la lectura es un aprendizaje social similar al aprendizaje del lenguaje oral. Además, "la relación que el individuo establece con el ambiente, la percepción que tiene de él, la que se produce en él, la gama de conocimientos que desarrolla, el manejo de las personas que interacciona con, todo esto no es natural".

Por lo tanto, ofreceríamos un proyecto de lectura y escritura a un grupo de estudiantes de nivel intermedio, con el objetivo de participar en el proceso de construcción de sentido, permitiendo que el aprendiz anticipare el significado que va a producir el narrador. En este sentido, creemos que el lector es comprometido con el mundo que el escritor le propone, y no es por eso que se critica, porque el lector también se desvía de una unilateralidad.

El modelo de lectura interactivo, el tercero, presupone que aprender a leer no es recibir un conocimiento existente, sino transformar la situación desconocida en conocimiento adquirido. Un gran giro del aprendizaje ocurre en este modelo, minimizando la intensidad del intercambio que se presenta en el modelo anterior.

En el primer modelo de lectura ascendente, se identifica un desinterés por la formación de los lectores, porque siempre empieza desde lo que se entiende en la lectura, mientras que un proceso de integración colectivo permite que el lector participe en el proceso de construcción de sentido, permitiendo que el aprendiz anticipare el significado que va a producir el narrador.

Foucambert sostiene que la escritura es un medio de pensamiento y comunicación que (...) permite construir un modelo teórico a partir de la realidad y expresa la coherencia de este modelo inventando las relaciones entre los elementos. (...) La escritura, a través de la escritura oral o de la escritura, es un momento esencial y específico de cualquier elaboración de una idea de la realidad, un momento de desacopio y de teorización, que permite pasar de la conjunción,

Generado por el oral, para la estructural, expresado en el texto. Cada uno que intente tomar el poder en el mundo y la transformación de sí mismo.

El proyecto de lectura y escritura ha sido guiado considerando que la entrada en la experiencia de lectura es fundamental, ya que es desde la lectura que el escritor adquirió su significado de una manera de desacopio. Creemos que uno solo escribe a partir de lo que entiende en la lectura mientras se integra activamente con el proceso de escritura y vice-versa. De esta manera comenzamos a buscar para una educación crítica de los estudiantes de FL. En este sentido, la lectura y escritura se asocian: por el hecho de la comunicación y por el hecho de la escritura.

A través del EquiText se pudo practicar este proceso mediante un medio que permitió registrar los efectos en el lector/estudiante, a ser justamente el lugar de reconocimiento de unidades y estructuras lingüísticas cuya funcionalidad se debe sin el sujeto.

"La escritura es un medio de pensamiento y comunicación que le permite construir un modelo teórico a partir de la realidad y expresa la coherencia de este modelo inventando las relaciones entre los elementos. (...) La escritura, a través de la escritura oral o de la escritura, es un momento esencial y específico de cualquier elaboración de una idea de la realidad, un momento de desacopio y de teorización, que permite pasar de la conjunción, generada por el oral, para la estructural, expresada por el texto. Cada uno que intente tomar el poder en el mundo, debe entender que el pensamiento y la escritura."
Under such perspective, we summarize the impossibility of assuming the power of the language without understanding the social relationships that grants its power. It is in that sense that the conception of language in Possenti (1993) rebounds in a widest space than of the reading and writing abilities: Possenti suggests an entire social universe, individual and linguistic, that is put upon during the accomplishment of acts that demand a critical posture towards decision making. Inserted in that net of reflections, we establish a relationship between the formation of the reader/writer and the handling of a new way of dealing with thinking. To become a reader, it means to have access to the social writings. In other words, it means to be capable of dealing with collective tools.

And, as an echo to Foucambert's quotations, the proposal of our work with these three FLs brings new dynamics to the reader/writer's formation in the new communication circumstances, as described in the next part.

**Integrating or interacting reading and writing through a collective tool**

We should recognize at first on how this new writing procedure - with a connecting view in the reading and vice-versa - when interfering in a relatively recent arena, it causes strangeness, since other forms of organization of knowledge in a traditional classroom other than the textbook being still ignored. Then we consider pertinent to trace a short report regarding the experiment integrating reading and writing in a virtual environment which demands a new interaction mode.

The proposal initially launched to the groups, required that a text should be written about the learners' or the participants' likes and dislikes. The titles "Likes and dislikes", "Ce que j'aime et ce que je n'aime pas" and "Hablando de gustos" announced objectively what had to be developed. And from the very beginning, improvements promoted by the use of the EquiText - a collaborative writing tool in the Web - were evidenced.

During the elaboration of those individual texts, more than one of the participants looked for the mediator/FL teacher to explain how to write what h/she had in mind. The main orientation was to make it possible to promote as much autonomy for the search of the "good expression" structures in the FLs, emphasizing the fluency in detriment of the correction. In addition, we proposed to observe marks of rewritings, after the withdrawal of that material, like registrations accomplished possibly due to the (re) readings of their textual productions while interacting on the Equitext.

After having finished the individual works, compositions on the same topic "Likes and dislikes" in the three FLs, which took place in less than two weeks. The EquiText was then presented as a tool for the collective text production in the Web, a totally strange experience altogether. It was requested that each one of the students began his/her collaboration, elaborating and inserting their ideas in the paragraph format tool lay out, starting then a team text construction. It has been noticed that the sentences employed before, in the individual texts, were modified in the spaces offered by the EquiText, not only getting adapted to a new context, but also creating a new context. As Possenti points out, "The effect of meaning is not the same, because the game of images of the speaker gets explicit: it is a constant adjustment."

The first contact with the collaborative writing in the Web, being introduced initially as a participative writing, is worthy of comment, once relevant observations are made for reflection. Reflecting over the connected writing and reading processes evidenced by that first experiment with FLs students. "To produce a discourse is to continue acting with that language not only in relation to a speaker, but also in the language itself" (Possenti, 1993, p. 57). Language is not just seen as a tool to organize thought, nor as a means of communication. It is recognized as a form of action, a process of establishing relationships, of creating closeness among interlocutors. (See Guedes, 1999, 2000).
Unnecessary to register the resistance in handling a new writing environment, once it exposes the way of thinking added to the reading and writing style of the peer contributions in their FLs. The interacting itself in this new arena turns it even more visible to the fact that the text is in fact the individual's institutionalizer. The resistance can be identified in the 'historic' function, one of the resources of the EquiText, an important source of data collection; it allows nodal points to be identified in the production of each participant's paragraph. This historic function also shows evidences in the attempt of correcting each other's contributions or, otherwise, the mutual support as if they were in the old classroom context. An interesting point is that those moves cannot take place in the mother tongue (L1), forcing them to dive unavoidably in the form of thinking of that other LF.

In other words, during the writing process through the Web, the attitude of having to write "Comment on dit ça?" or "Correct my mistakes, please", registered in the 'Comments' function, next to a paragraph, for instance, are moves which take place clearly, visibly, and directly during the textual production, contrarily to the individual model. There, in the final text, or in its final product, it is presented without any possibility of recurrence to the difficult points expressed in that form of construction of meaning. "The interlocutors are neither slaves nor masters of their language. They are workers". (Possenti, p. 58).

As the experience ended, though it could have been extended for a longer period of time, it was requested that each participant presented his/her conclusions on the proposed tasks, comparing the individual and the collaborative productions, in order to compare some results in the use of the EquiText, once through him one had experienced a group of work with and on the language, in a space in which all the mechanisms worked in favor of a significance.

We recognized that at this time the participants felt more confident, an unfolding characteristic of exposing ideas different to the traditional, where it is possible to try the power of facing the world as a thinking being, active and, therefore, qualified to read and write as a free, autonomous citizen.

We equally identified that the status of each one of the students grew progressively in every moment of the negotiation of meaning. The explicit negotiations among them and their management as if in an intense game made possible through their exchanges towards the construction of their readings and writings. The two-way road imposed by the task proposal, resulted from the tension between the individual and the collective, in a demand of its sedimentation and a change or adaptation attempt as in Possenti's view of the double face of language. Also, the teaching/learning interrelation as the production of knowledge originated from the dialogical teacher/student relation, to "bring the other one closer to the movement to his/her thought". (Freire, 1996, p. 132).

We noticed that this type of activity employs an author/reader status to the learner from the beginning, matching Foucault's assertion that "The way of learning is what gives power, much more than what one learns. (p. 36). This is illustrated in paragraphs 10, 11, and 12, highlighting the peers' contributions. (Fig. 1)
the dissolving dicotomies in the teacher and student roles, reading and writing, teaching and learning, individual and collective.

According to Foucambert, the pedagogical rule, adapted here to FL teaching is the research-action, because we can only understand what we can transform; "an understanding that is built by the own transformation action and by the analysis of the processes and results of that transformation. (p.63). Because still the "access to the reading" of new social layers implies that reading and text production become tools of thought of a renewed social experience, since this presupposes the search of new points of view about a wider reality, that the writing, according to the author, helps to conceive and to change, through the simultaneous and reciprocal invention of new relationships, written and new readers.

We thought that the link with the reading, privileged in this space, deserves our work to conclude by now. The discussion on what one understands for reading in FL is, in fact, a fight for democracy, since it seeks the collective domain of the means of production of meaning. We will not just propose to increase the number of readers already existent, but to reflect on reading as a social change, a thought that rebounds unavoidably in the practices of teaching and learning of reading and writing in a FL. Writing and reading cannot lose their dynamic character, on the contrary, to look for alternatives that make possible the interactive/integrated writing of thinking and critical students in their FLs classes or groups.

In that way, reading classes and of textual production they should be the space to leave besides the information to the student, making possible them a more appropriate formation to your glance for the world, dinamizando the entrecruzamento of glances belongs to the writers, then, authors, belong to the readers, belong to the teacher inserted in this new reflection space and of action. According to the words of Coracini, the teacher should be a facilitator and not a simplificador of the compound process that is to teach one READS, propitiating spaces, be them virtual or real so that the student can be established how to be thinking - that is - in the construction of the sense. Like this, through EquiText, we saw him/it as the production conditions went decisive for the critical construction of the sense that each autor/escritor supplied your readers.

Japan
tami@dp.u-netsurf.ne.jp

In the countries except Japan, according to Japanese government investigation in 2000, learner of Japanese language are about 2,090,000 people. However, most of these learner are beginner grade. Middle grade learner are an extremely little.

In a beginner grade, they learn the character of kind of "Hiragana" of a phonogram. It is easy to understand this Hiragana which is the simple character. Other way, middle grade learner must learn the character of kind of "Kanji". "Kanji" is the ideograph character. And it is a hieroglyph of one kind of Chinese.

In Japan, the communication that we used only Hiragana for is difficult. In a field of Japanese business, people must use 2,000 kinds of Kanji characters. It is a big burden for the learner to memorize many complicated Kanji. In addition, Japanese language teacher oneself do not understand all Kanji characters, too.

So we developed the Kanji learning systems which worked with the PC. We were able to do "Memorizing by Writing" not to use handwriting input device in this learning system. This learning system is a system for self-study, we think that we let Japanese language teacher reduce the burden of education.

Introduction

At present, in 114 countries of the world, Japanese language is learned. In the countries except Japan, according to Japanese government investigation of this year, learner of Japanese language are about 2,090,000 people. As for the number of learner of Japanese language, 30% increase than the number of the learner of 1993.

However, most of these learner are beginner grade. Middle grade learner are an extremely little. In a beginner grade, they learn the character of kind of "Hiragana" of a phonogram. It is easy to understand this Hiragana which is the simple character.

However, middle grade learner must learn the character of kind of "Kanji". "Kanji" is the ideograph character. And it is a hieroglyph of one kind of Chinese. In Japan, the communication that we used only Hiragana for is difficult. In a field of Japanese business, people must use 2,000 kinds of Kanji characters.

It is a big burden for the learner to memorize many complicated Kanji. This big burden is the reason with a little middle grade learner. In addition, Japanese language teacher oneself do not understand all Kanji characters, too.

The system that the learner can learn Kanji by the high efficiency by oneself is necessary in order to increase the Japanese learner of middle grade. The system is to let you reduce a big burden of a Japanese language teacher.
Progress of Research

We have researched the efficiency method how we could take good care of learning of Kanji. First of this research, we have connected the handwriting input device to Macintosh first. And we set program to recognize a handwriting character and developed the system can execute "Memorizing by Handwriting".

In the next study stage, we shifted platform to the PDA to have a handwritten character recognition function from Macintosh. By this stage of research, we could develop the portable learning system.

We have used 4 kinds of platforms from Macintosh to PDA. It is to use a recognition function of handwriting character that these are common to in 4 kinds of development. However, PDA did not spread in the Japanese language school. Furthermore, there is not the possibility that PDA will spread in future either. We judged that it was not suitable to use PDA as a platform of the learning system in future.

So we considered learning environment in various countries and developed the learning systems which worked with the PC such as Windows or Macintosh. By developing this learning system, we gave up the connection of the handwriting input device and PC. Because, handwritten character recognition program in input device generate do freeze of the learning system frequently. Perhaps we think that the conflict between programs occurred in main memory.

So we were able to do "Memorizing by Writing" not to use this device in this learning system.

We developed this system by type of WBT(Web based Training System). Because, this system can work by any kinds of computer. And the operation of this learning system is possible with Internet.

Outline of the Learning System

There are 3 kinds of learning problems set by the learning system. They are "how to read of Kanji", "how to write of Kanji" and "listening". The learner chooses an answer to these problems(Reading, Writing) on the screen with the mouse.

![Flow Chart of Learning System](image)

Figure 1: Flow Chart of Learning System

Evaluation of result that the learner replied is totalized automatically. And, according to evaluation of answer of a learner, the next problem is displayed automatically.

When evaluation to the learner is equal to or more than 70%, the learning system displays a page of "problem of next unit."
When evaluation to the learner is range of 70% from 40%, learning system displays a page of "fundamental problem" that a degree of difficulty is low.

![Image of a page showing a fundamental problem]

**Figure 2: Memorizing by Writing**

And learning system displays a page of "Memorizing by Writing" if evaluation is less than 40%. In this page, multiple pieces are constituting one Kanji character is displayed. Furthermore, few wrong pieces mixes wittingly, too. We let the learner select right pieces in this page. By this learning method, the learner can learn the Kanji character that he seem to write.

In the page of "listening", conversations and questions of Japanese taped beforehand are played back. And the learner chooses an answer for the question that played back conversation. The learner chooses it among answer group in page.

**Conclusion**

We developed this learning system by "Front Page of Microsoft". By using this software, the Japanese teacher who did not know a lot about computer can maintenance of learning data comparatively easily. The learner can learn difficult Kanji by the situation that resembled handwriting learning. And, the learning system which we developed this time is a system for self-study, we think that we let Japanese language teacher reduce the burden of education. We hope that the Japanese language teacher use this learning system as the system to supplement their class.

This learning system can be used with either Internet or CD-R. As a plan of the duration, we distribute CD-R of the learning system to the university and the Japanese school of Asia / Pacific region where there are the middle grade learner. And we get evaluation of the learning system to us from Japanese language teacher and learner. We will make use of those evaluation in improvement of the learning system.
Literacy Junction: Exploring Narrative Theory and Books for Youth in a Cyberworld

Hiller A. Spires, Pru Cuper, & Cris Crissman
Department of Curriculum & Instruction
North Carolina State University
United States
Hiller_Spires@ncsu.edu, prucmc@aol.com, cris@writinglife.org

Abstract: This paper describes the development of Literacy Junction, which is an interactive web site for teachers and students in grades 5-8. Using an interdisciplinary approach to learning, Literacy Junction offers two distinct features: technology-enhanced experiences with outstanding young adult literature and cybercharacters who serve as both academic models and technology guides. A pilot study was conducted in which 8 students created their own cybercharacters after interacting with the site’s cybercharacters as well as text-based literary characters. Through qualitative analysis of students’ character drawings and oral and written discourse, several themes emerged depicting the role of cybercharacters in conjunction with students’ aesthetic responses to narrative texts. Based on these preliminary findings we anticipate that future studies will contribute to narrative transactional theory as it is recontextualized from print-based to web-based learning environments.

Introduction

Literacy Junction (www.ncsu.edu/literacyjunction) recently funded by BellSouth and the Kenan Institute, is an interactive web site for teachers and students in grades 5-8. Based on a ten-month iterative design process with input from a teacher advisory board, Literacy Junction’s purpose is to encourage teachers to accelerate the integration of new and emerging technologies into literacy instruction. By offering the opportunity for both face-to-face and virtual meetings, this networked professional community provides the mentoring and continued support that teachers need to initiate and sustain new teaching practices. Over time, we expect Literacy Junction to help teachers’ integrate technology, to increase students’ capacities to use technology as a learning tool, and to enhance student achievement.

What Are the Theoretical Underpinnings of Literacy Junction?

Using an interdisciplinary approach to learning, Literacy Junction offers two unique features. First, the site includes technology-enhanced experiences with outstanding children’s and young adult literature. For example, as students read Christopher Paul Curtis’s, Bud Not Buddy, they select from a variety of activities to explore the thematic layers of the book. They might then create a WebQuest, audio-documentary, or participate in a Socratic seminar. Tutorials created specifically for the site provide support for both teachers and students new to these technologies and strategies. A second feature of the site is the Cyber Heights Middle School. This fictional middle school offers an online community of cybercharacters who serve as both academic models and technology guides as teachers and students interact with the offerings on Literacy Junction. Cyberteacher Jan Rosenberg models online teaching strategies while students Anjoli, Garret, JC and Claire model participation in the reading-related activities on the site (see Fig. 1). All of the characters reflect real world personalities so students who visit the site can identify with both the character’s strengths and weaknesses. Students are also given the opportunity to examine and critique the academic work of the cybercharacters.

Figure 1: Cybercharacters in Literacy Junction
The creators of Literacy Junction endorse the time-honored pedagogy underlying Louise Rosenblatt's (1978) transactional theory as a platform for student engagement with narrative text. This theory suggests that within any reading experience, a reader's stance may fluctuate along a continuum between aesthetic and efferent. Readers taking an aesthetic stance bring their own personal meaning to the text, in effect "living through" the textual event. Rosenblatt argues that, to optimally experience narrative texts, students should take an aesthetic stance when reading. By extending Rosenblatt's theory to Literacy Junction's cyberworld, students are invited to engage aesthetically not only with the featured novels in a primary transaction but also with the site's cybercharacters and their cyberworld in a secondary transaction.

**Pilot Study**

Considerable research has been conducted on primary transactions with text (see Marshall, 2000) articulating spontaneous and idiosyncratic associations with personal experiences of the reader. However, extending transactional theory into cyberspace has yet to be fully explored (see Turkle, 1995; Tapscott, 1998 for a related discussion on parallel identities in virtual spaces). Our qualitative pilot study investigated the consequences for this type of secondary transaction, specifically examining the nature of students' relationships with the cybercharacters in the Literacy Junction environment. Guiding research questions included the following: How do students react to cyberpeers? How do they position these peers within the virtual/actual continuum? How do they identify with the personality traits of their cyberpeers? How are students' primary transactions with literature affected by their secondary transaction with cyberpeers reacting to the same literature? The participants consisted of eight 6th grade students (i.e., 2 African Americans and 6 Caucasians; 4 males and 4 females). Over a period of six weeks, the participants met with a researcher for six one-hour sessions as they read a sample novel and interacted with the primary characters from the novel, engaged with the site's cybercharacters through a series of oral and written activities, and finally created their own cybercharacters related to the novel.

**Preliminary Findings and Future Research Directions**

Through qualitative analysis of students' character drawings and oral and written discourse, the following themes emerged. First, the highest level of student engagement, interest, and motivation occurred when students were given the opportunity to create their own cybercharacters. Of particular interest to the students was the worldwide publishing capacity afforded by the Web. They wanted their actual peers to become familiar with the virtual characters they had generated. Second, students projected their personal idiosyncrasies and attributes onto the characters they created, signaling their capacity to objectify significant issues and experiences they face as adolescents. Third, the process of comparing and contrasting the cybercharacters' engagement with the actual characters from the novel (i.e., secondary transaction) appeared to entice students to revisit their initial aesthetic transaction with the text. Based on these preliminary findings, we anticipate that future studies using the unique features of Literacy Junction will amplify narrative transactional theory as it is recontextualized from print-based to web-based learning environments.

The Creation of a Nexus between Telelearning and Teleteaching

Marc S. Glassman
Faculty of Education
Memorial University of Newfoundland
Canada
glassman@mun.ca

Abstract: There is a group dynamic that occurs in a synchronous "face-to-face" university classroom environment (Johnson & Johnson, 1975). At times, this dynamic is an appropriate and authentic method of teaching. However, the prosaic nature of how we have viewed this sort of academic interaction up to the present time has both literally and virtually opened the door to the creation and implementation of dynamic computer-mediated web-based courses. This paper discusses the "links" between telelearning and teleteaching, and also recounts the "rites of passage", both intentional and unintentional, in the creation and implementation of seven university level Web-based courses.

Genesis

Many have questioned the validity of a university experience that has students learning via a direct lecture-based form of communication from a professor, AKA "the sage on the stage" (Hullfish & Smith, 1961; Moffett, 1968; Rogers, 1969; Hirst & Peters, 1970; Becker & Gersten, 1982; Weingand, D.E., 1984; Joyce and Calhoun, 1998). Personally, I have learned a great deal in just this sort of format, and have even utilized this pedagogy for part of my university teaching career. However, I have begun to question and rethink this form of instructional design and professional development, somewhat along the lines of thought presented by Roberts and Ferris (1994) and Boddy (1997), all of who dealt with the issues of time and knowledge acquisition/delivery.

During the 1980s, the Faculty of Education at Memorial University of Newfoundland (MUN) (http://www.mun.ca/educ/) became a leader in the utilization of distance education utilizing a province-wide teleconference system. I had the opportunity to develop three undergraduate courses for this teleconference system, which were offered collectively a total of twenty-one times during the period from 1981-1991. The synchronous nature of teleconferencing required that the students registered for one of these three courses be at one of the 38 teleconference sites located throughout the province of Newfoundland and Labrador. However, in a Canadian province three times the size of the state of California, this form of distance education was considered vital in enabling pre-service and in-service teachers opportunities to take university courses as a means of fulfilling degree requirements, or for professional development. The "seeds" of my understanding on the development and implementation of distance education courses was "sown" during this ten-year period. Yet it would not be until 1996 that these "seeds" would germinate into the early design for a computer-mediated web-based university course.

Serendipity

With encouragement from the Dean of the Faculty of Education, MUN, I undertook the task of creating my own web page (http://www.ucs.mun.ca/~glassman). I saw this form of communication as a means of providing my students with some insight into who I was as a professor and a person. Also, if the truth were known, I did not want to be considered an "Information Technology Luddite". This web site initially became the conduit for my course outlines.

One day, a student who was scheduled for surgery, asked me if I could put certain of my class notes and lectures onto my personal web site. It was at this point that I realized the potential for web-
supported course material. I created a dedicated web site for each of the undergraduate and graduate course I taught, with hyperlinked course outlines, class notes/lectures, diagrams/charts, writing guidelines for their assignments, along with other web sites of relevance to the course. Based on the immediate positive responses from my students, I discovered pedagogy appropriate to both the current technology and my personal style of teaching.

Exodus

I once saw a bumper sticker that read "Students need to help their teachers find the on ramp to the information highway." My students helped me "see" and understand the potential for web-supported course material, and now I was ready to "journey into cyberspace" with the creation of a self-contained, non-linear telelearning/teleteaching environment.

With the approval from the Dean of the Faculty of Education, MUN, and technical support from MUN's School of Continuing Studies (http://www.cc.mun.ca), I began the creation of a "mediacentric" classroom environment, which utilized the potential of multimedia and computer technology to "deliver my message".

Teleteaching

Specific pedagogical concerns were the focal points in the creation of my two initial web-based courses "Current Approaches to the Teaching of Reading in the Primary and Elementary Grades", Ed.3510 and Ed3520. The "transmissional" model of instruction, where content is the primary focus of all concerned, was a teaching strategy I was utilizing less and less in my on-campus courses. My web-supported courses had lecture notes uploaded onto our Faculty's server, where students could download these notes either prior to or after in-class discussions on their content. The "transactional" model of instruction, where interaction is the focus of the presentation of selective content, was a process that I was effectively utilizing in my on-campus teaching (Routman, 1991; Graves, Watts-Taffe & Graves, 1999). However, I saw the inherent need in the creation of these initial web-based courses to implement a "transformational" model of instruction, with its focus on a holistic, interdisciplinary curriculum and a social identity structure based on each student's own learning style. I did not want to create a telelearning environment that had a format founded on a sense of "Social Darwinism", where only the technologically "fittest" students survived. I wanted to develop a course where active involvement in the synthetic process of knowledge construction and the analytic process of understanding could be experienced by all, with each person enabled to achieve their personal potential (Lefrancois, 1991).

This teleteaching experience needed to become a guided discovery into learner-centered instruction. To accomplish this task of creating a self-contained, non-linear telelearning environment, I was forced to consider the paradox of "time/space binding". The asynchronous nature of this course required a format that enabled active on-line involvement from persons far removed from where I was located. Support services to assist any one learner had to be built into this system. These support services took the following forms:

- Detailed prerequisites were provided prior to any student registering for the course, as a "fail safe" measure to inform students of the technological necessities of the course (e.g., access to e-mail messages, an ISP account, a VCR, etc).
- Specific instructions were provided on-line as to how to access, register for and successfully log on to the Alta Vista Forum component of this course.
- Specific "finder-friendly" hyperlinked navigational icons were provided to assist each learner in their "journey" throughout the various components of this web-based course (e.g., a glossary was created for the various terms that were utilized throughout the on-line manual, with "hot spots" embedded within the on-line text to ease the navigation from the text, to the glossary and then back to the text).
- Direct e-mail contacts on a daily basis were established during the first week of this course, so as to ensure that any problems could be overcome immediately. Frustration on the part of students is the death of any distance educational format.

2395
At the core of this teleteaching experience was the necessity to create instructional content that had relational value when compared to traditional on-campus course. The traditional correspondence-genre of readings and worksheets/assignments is, in my opinion, not the best way to design web-based course material. The telelearner needs to feel a real sense of involvement and accomplishment from the onset to the conclusion of this experience. Such learners need to consider this form of learning "worth the effort". Thus, there had to be a relevant use of the on-line text materials, with on-going interactions between professor and student, and then among all students registered for the web-course.

**Telelearning**

I make a distinction between teleteaching and telelearning. Teleteaching requires the instructor to design experiences that will enhance a learner's knowledge and understanding via an analytical and critical engagement with various mediums. This cannot take the form of impositional teaching, which is the direct teaching of some form of knowledge without regard for the learner. The effective teleteacher needs to "think like a telelearner", envisioning as many potential sources of problems and frustrations as possible. As well, the teleteacher needs to consider what I call the "addendum factor". Classic lines from the Broadway play "Oliver" best sums up this addendum factor -- "Please, sir. I want some more." An efficient telelearning environment will contain components of what an instructor considers to be needed by a learner, along with components of what learners perceive as being relevant.

The telelearning experience, if designed well, provides for self-paced independent learning with remote feedback and assistance. However, telelearners need to fully understand their role in this new teaching/learning experience. Telelearners must assume some responsibility for their own learning. A sense of autonomous individuality and a unique form of self-affirmation need to be present in each learner. Such learners must work well alone, due to the flexible asynchronous schedule of this experience. The intrinsic motivation of these learners must be strong enough to overcome the sense of virtual abandonment. The teleteacher can provide "scaffolding", with clear-cut directions and electronic feedback (i.e., e-mail guidance), but the emphasis is on learner-centered experience.

**Convergence**

During the winter semester of 1997, Ed. 3510/3520 "Current Approaches to the Teaching of Reading in the Primary/Elementary Grades", the first totally web-based undergraduate course for the Faculty of Education, MUN, went on-line, with an initial enrollment of 29. This brought together (i.e., convergence) the various relevant elements of a traditional teaching/learning experience within a technology-based distance-learning environment.

The course combined an on-line textbook, which I authored, as well as a supplementary traditional textbook (Blount, 1994), along with a two-hour videotape, e-mail and an interactive discussion component utilizing the Alta Vista Forum.

The on-line textbook that I had written specifically for this distance education format provided the specific theoretical information and practical instructional techniques that I would share with these students if they were taking this as an on-campus course. This information was collated around the four "current approaches" of reading/writing instruction (e.g., the Literature-Based Curriculum, the Writing/Reading Connection, the Integrated Thematic Curriculum and Computer-Managed Instruction) that comprised the focal points for the course. This was to be a non-linear intertextual experience for the telelearners since they were required to relate this on-line material to teaching/learning in the "real world classroom".

The Alta Vista Forum (AVF) was the medium I utilized to assist me in my role as an instructional facilitator. I attempted to maximize student interactions with an asynchronous reflective format. I posed specific questions on the AVF that were to be answered by the telelearners. These questions were specific, but open-ended, to help create a "risk-taking" on-line environment where students felt that they were able to express their thought freely. Initially, I utilized a Socratic questioning technique, providing positive feedback with each of their responses and then posing additional questions for their reflection. In each of
these individual responses I made reference to the comments of other students, encouraging inter-student commentary and replies. Eventually, this interaction came about naturally, with students freely commenting on the replies made by each member of this virtual "cyber family". Students posed their own questions and this, in turn, added greatly to this interactive reflection. I provided a specific site on the AVF for exchanges of a non-academic nature. This site, the Café Chez Marc, was a "meeting place" where the participating students exchanged views on such diverse topics as the state of the Newfoundland economy, the trends in fashions found in today's schools, the weather, the Stanley Cup, et al.

I posted "E-mail Office Hours" when students could e-mail me a question and expect a fairly instantaneous reply. However, I found that students were e-mailing me their questions at almost every hour of the day. I attempted to access my e-mail from home each night at 8PM and midnight for those who posted their messages late at night, or for those who read my replies very early in the morning.

The videotape contained a visual collection of what I considered to be ten effective educational CD-ROMs. The videotape was professionally produced by the Center for Academic and Media Services (http://www.cc.mun.ca/cams/video.html) here at MUN. As I utilized each educational CD, the images and sounds on the screen of the computer monitor was fed directly into a video camera, along with a "voice-over" to describe what I considered to be the strengths and weaknesses of each CD, from an educational frame-of-reference.

Assignments, such as the WWW Learning Logs, the Interdisciplinary Literature-based Unit, a Reflective Final and the qualitative participation on the Alta Vista Forum, were submitted in a variety of ways. Other than the AVF interactions, the other three assignments could be submitted in hard-copy form via mail or hand delivered to my office, or on-line in the form of an attachment to a note sent via e-mail. Students submitted sample drafts of their writing on-line, and I commented, via e-mail attachments, on these on-line drafts the same day they were received. Thus, just as a student on-campus could come in and see me for specific guidance on an assignment, the web-based student could also access me and receive feedback on their assignment, albeit in a virtual format.

Eureka

At the conclusion of this initial WWW course, I realized that I had "discovered" a way to deliver university level courses utilizing the WWW in a pedagogically appropriate manner. From this experience came the impetus to create another five additional WWW courses. To supplement Ed.3510/3520, which is intended for undergraduate students enrolled in our primary/elementary grade education program, I set out to create three other undergraduate web-course intended for students enrolled in our primary/elementary and intermediate/secondary school program (e.g., Ed.3040 "The Assessment of Language Problems"; Ed.4350, "Content Area Reading in the Intermediate and Secondary Schools"; Ed.4920 "Literacy in the Rural School"). As a means of providing computer-mediated options for our graduate students, I created two web-based graduate courses in the area of literacy (e.g., Ed.6641, "Writing in the Primary, Elementary and Secondary Schools" and Ed.6647 "The Diagnosis and Assessment or Reading and Writing Difficulties"). By the conclusion of the fall semester, 2000, there will have been total enrolment of 255 students for the seven web courses I have created and implemented. In the four years I have been teaching web-based courses, I have had students from three US states, five Canadian provinces and two territories, and the United Kingdom.

While the five additional WWW courses have a structure that is similar to my initial course, taking into account a totally different content, there have been technologically significant additions to each of these courses. These additions were the use of PDF formatting for the on-line supplementary textbook, "streaming video", CD-ROMs, and the use of the SiteScape Forum, and enhanced version of the Alta Vista Forum.

PDF formatting, utilizing an "Adobe Reader", can provide a students with a "printer-friendly" format for downloading and printing off a personal copy of the on-line supplementary textbook for off-line reference. The main advantage of streaming video is that in many of my on-campus education courses I provide demonstrations and simulations that are best understood if they are seen and heard, rather than merely read about in text form. Thus, any student can "observe" these demonstrations and simulations (e.g., how to administer and analyze a miscue analysis form of oral reading proficiency) at any time. This form of "narrowccasting" is aimed at a telelearner with the lowest common denominator technology (e.g.,
28.8 modem, a Pentium or mid-range 486 PC with a soundboard and a good video card), so as to make the streamed video accessible to the vast majority of telelearners. An alternative to this streamed video is the creation of CD-ROMs containing the same content as would be presented in the streamed video.

Excelsior

Having been born and raised in New York City, I learned early on in public school that the motto of the State of New York was "Excelsior" (i.e., "Always Upward"). It is only now that I understand the complexity of that term. From my first teleconference course back in the Winter of 1981, to the e-mail note I received from a student I had never met, telling me how "great" it was to be able to take my course online, I now had a sense of the meaning of this continual upward momentum. What made that e-mail note so significant was that the student who wrote the note was located in Nain, Labrador. In relative terms, the distance between St. John's, where I was located, and Nain, Labrador, where she was taking the course, is comparable to the distance between New York City and Chicago.

When I consider the link between telelearning and teleteaching, I envision an environment with a revised paradigm of the teacher and learner. In this environment, the use of instructional technology "replaces" (as opposed to replacing) both the teacher and learner. In this zone of possibilities, both the teacher and learner are actively involved in a process of re-inventing their roles in the instructional/learning encounter.

Abstract: Many workplaces require individuals to collaborate electronically to solve on-the-job problems with others who may be down the hall, in a building close-by, or in another geographical place altogether. As a consequence, adult literacy programs need to be developed based on effective ways to teach individuals to use literacy skills in a technological context. This paper discusses the importance of integrating electronic writing into workplace literacy programs, describes an approach to instruction based on reciprocal teaching, situated learning and strategy instruction and offers some evaluative commentary on the effectiveness of the program.

Introduction

More and more workplace literacy skills involve electronic communication. Employees in a wide spectrum of contexts are expected to use computers efficiently and effectively to communicate with others and find information. As a consequence, adult literacy programs need to be developed based on the findings of research aimed at understanding effective ways to teach individuals to use literacy skills in a technological context. In this program we developed an instructional approach to teaching adults strategies for participating in electronic discussion groups.

Workplace skills that demand some knowledge of technology with regard to information processing are steadily increasing; in 1995, an Allstate Forum on Public Issues claimed that an estimate of 65 percent of all U.S. workers are affected by this increase of technology in the workplace and by the year 2000, this figure was estimated to increase to 95 per cent (Verville, 1995). The potential of electronic communication is unlimited. Conceptions of adult literacy education are undergoing rapid change (Dirkx, 1999) and with that, there is a need to understand changes in the knowledge and skills of practitioners that are necessary to provide effective adult literacy programs.

Currently, literacy programs and other forms of literacy support for adults are primarily based on traditional classroom practice and face-to-face tutorial-type programs (Malicky, 1990). While these programs have made an impact, obvious limitations exist within such frameworks of delivery including issues of accessibility and flexibility for learning. Geographical location, for example, may exclude one entirely from the opportunity to access literacy programs. It is no surprise that inadequate funding and understaffing has left some rural communities without literacy programs or with programs that are located too far away to serve the rural poor (Sparks, 1998). Further, the need to provide child-care in the home, one’s work schedule, or lack of transportation may prevent attendance at literacy support programs. Organizations and employers might be willing to provide opportunities to support literacy development if
more was understood about effective, flexible delivery of instruction. Additionally, many adults with low literacy skills may have had negative experiences with face-to-face instruction and continue to carry feelings of resentment, failure and poor academic motivation into their adulthood (Lavery, Townsend & Wilton, 1998) and therefore may welcome an alternative method of instruction. Moreover, computer-assisted instruction may in fact be especially well-suited for adult learners. It has been found that computer-assisted instruction “allows students to work at their own pace and level, which may be particularly effective for learners who exhibit great heterogeneity due to factors such as their wide age range (a common feature of adult programmes), varied levels of competence, and the time elapsed since their last formal instruction (Buckley & Rauch, 1981, Culclasure, 1982)” (Lavery et al., 1998).

Reciprocal teaching may be seen as an effective instructional strategy with adult learners in a computer-mediated learning context. Reciprocal teaching has been used previously in a study designed to teach students the cognitive strategy of generating questions about the material they had read. The results of this study showed that there were definite gains in comprehension, as measured by the tests given at the end of the intervention (Rosenshine, Meister, & Chapman, 1996). There are other instances where reciprocal teaching has been found to improve comprehension. In a study designed to explore the effects of a reciprocal teaching intervention created to enhance the lecture comprehension and comprehension monitoring skills of college students, the results of reciprocal teaching were encouraging (Spivey, 1995). The low-verbal ability subjects receiving the reciprocal teaching method significantly increased their lecture comprehension, as well as their detection of errors presented from text (Spivey, 1995). Based on previous research conducted on reciprocal teaching, it can be seen that it is an effective teaching strategy for learners of various levels. Reciprocal teaching provides an interactive link between student and instructor that may also involve teacher-led discussion, explanation, and modeling of strategy use to scaffolded attempts to use the strategy. However, reciprocal teaching may be even more effective if used specifically in a situated learning context, especially for adult learners who share a variety of diverse needs.

Today’s workers need reading, writing, and math skills; computer skills, including knowledge of different software; problem-solving skills; the ability to participate in meeting; report-writing skills; the ability to read blueprints; and other skills and knowledge (Askov & Gordon, 1999). However, it is also felt that these workplace skills are better learned in the context of the workplace, rather than in contexts unrelated to actual workplaces. Further, Askov and Gordon (1999) suggest that because situated learning involves contextual instruction, based on real-world knowledge and experiences, it encourages transfer of knowledge and skills from the classroom to the job. Askov and Gordon (1999) suggest that computer-assisted instruction is one approach that educators may take to customize instruction to suit the needs of adult learners. Specifically, Askov and Gordon (1999) offer e-mail as an effective mode of communication for adults in workplace literacy programs, suggesting that learners can further communicate with others and workplace literacy programs, as well as write about their jobs and workplaces. Situated learning provides learners with a context that is meaningful to them. A workplace literacy program based on situated learning may include group discussions, instruction, and practice that focus on interpersonal and communication skills, solving work-related problems, and other pertinent challenges found in the workplace. It is essential that workplace literacy instructors acknowledge the fact that adult learners bring already existing knowledge and skills to workplace literacy programs. Askov and Gordon (1999) suggest that the integration of work-related materials and instruction in basic skills builds on workers’ background of experience and knowledge while developing their abilities to use communication and computational skills more effectively in the workplace. Further, situated learning is an effective mode of instruction for adult learners enrolled in workplace literacy programs because it is directly applicable to their chances of finding and maintaining employment.

Overview of the Instructional Approach

There has been a proliferation in the use of electronic discussion groups (EDGs) in many forums (Bonk, Appelman & Hay, 1996, Hemming, 1999, Kuehn, 1994, MacKinnon & Hemming, 1998). EDGs require participants to use writing in online discussions, a potentially effective avenue for enhancing literacy. Electronic discussions can provide opportunities for participants to reflect, pose questions, and examine content (Brett, Woodruff & Nason, 1997). Electronic discussions were used during the instructional phase of the program that took place at the Annapolis Valley Work Centre (AVWC), a place that provides support to adults with attitudinal, social, and educational barriers.
To qualify for the various programs offered at the AVWC, participants must live in West Hants, Kings, or Annapolis County, be at least 18 years of age, have an identifiable barrier to employment, and be referred by either a community service organisation or a professional. The participants of this study were enrolled in various programs offered at the work centre to develop necessary skills that may lead to increased access to educational, vocational, and employment opportunities within the community. The AVWC provides its participants with instruction in real kitchens, offices, and shops so the participants receive actual on-the-job training. In addition to job skills training, the participants are required to attend classes on personal development and academic upgrading. The participants who took part in this program ranged in ages 18-48 years. Further, the participants of this program were experiencing difficulty finding and/or maintaining employment, due to various obstacles whether they may be academic, emotional, or behavioural. Regardless of their unique challenges, all of the participants have varying levels of difficulty with literacy skills. This is consistent with the fact that “adults who have a history of not being in paid employment represent a critical group for education in basic literacy skills” (Lavery et al., 1998). Thus, the adults at the AVWC could benefit from an effective literacy program that may improve their chances of finding and maintaining employment.

There were 22 participants from the Annapolis Valley Work Centre who were involved in this program. At the beginning of the program, each participant completed a computer usage survey to reveal the extent of his/her experience with computers, as well as his/her attitudes toward computers prior to the program. In addition, each participant was asked to complete a written sample based on the content of a selected case study, without the use of a computer. Then, the participants received basic computer instruction using IBM Thinkpads, which would be used throughout the program. After all of the participants were comfortable with using the laptop computers, they began the instructional phase of the program, when they participated in a reciprocal model of instruction involving eleven (40 minute) sessions that taught three writing strategies for making entries into electronic discussions.

During the instructional phase of the program, the participants received a protocol of direct instruction on three specific writing strategies: explaining/expressing a viewpoint, asking pertinent questions, and writing effective responses. The strategies focussed primarily on writing, since many jobs require employees to communicate in written language and difficulty expressing events, for example, in writing may lead to problems with regard to finding and/or maintaining employment (Gregg, Sigalas, Hoy, Wisenbaker, & McKinley, 1996). The participants worked in heterogeneous small-groups with a research assistant during their regular class hours at the Annapolis Valley Work Centre. In addition to using the laptop computers to make electronic discussion entries, they also provided the instructions for each strategy, as well as the case studies, which provided situated scenarios based on workplace preparation, that were used throughout the sessions. Each writing strategy involved three sessions: an introduction to the strategy where the strategy is modelled (the use of modelling as a teaching strategy is one of the approaches heavily promoted in the National Literacy Survey (Lewis & Wray, 1999)), an application A where the participants receive some guidance, and an application B where the participants use the strategy independently. Each of these sessions consisted of the use of worksheets and study guides followed by the entry of the participants' response into the electronic discussion group. After the participants completed the nine sessions, there were two additional sessions that required the participants to work through a case study using all three of the writing strategies. The first of those sessions included guidance and support from the research assistant while the second session required the participants to use all three strategies independently.

A reciprocal model of instruction allows participants to gradually gain independence with regard to strategy use. Based on previous research conducted on reciprocal teaching (Rosenshine, Meister, & Chapman, 1996, Spivey, 1995), it can be seen that it is an effective teaching strategy for learners of various levels. Reciprocal teaching provides an interactive link between student and instructor that may also involve teacher-led discussion, explanation, and modeling of strategy use to scaffolded attempts to use the strategy. Thus, reciprocal teaching seemed to be an appropriate instructional strategy for teaching in a situated learning context to adult learners, who share a variety of diverse needs. The three sessions on each writing strategy throughout the instructional phase explicitly depict a model of reciprocal instruction. During the first session, the research assistant provided an overview of the strategy, a rationale for learning the strategy, and a thorough modeling of the strategy. For example, after discussing the strategy in depth, the instructor read the case study aloud while the participants followed along on their laptop screens. Then, the questions at the end of the case study were addressed. Each step throughout the strategy was verbalized and discussed so the participants became increasingly aware of the various steps and procedures involved.
As the instructor talked through the steps, the worksheet was completed based on the open dialogue with the participants. Once the worksheet was complete, it was time to make an entry into the electronic discussion group. While this was being done, the instructor talked through all of the steps involved. The second session consisted of a review of the strategy before the participants were asked to work through a case study using the strategy with the guidance and support of the instructor. The third session included the participants using the strategy, independent of the instructor. These three sessions provided participants with the ability to gradually gain independence in using each of the three strategies, thus preparing them for the final two sessions where they were required to use all three of the writing strategies.

In addition to the reciprocal model of instruction used throughout this program, situated learning provided a strong foundation for the program. Each instructional session was based on specific case studies. These case studies involved real life scenarios situated in various workplace contexts, relevant to the participants involved in the program. Additionally, within the various workplace contexts of the case studies, there were other issues being addressed such as personal development, problem-solving, interview skills, anger management, and other pertinent skills that may be required in the participants' future workplaces. Thus, the design of this program enabled adult learners to use their already existing knowledge and experience throughout the instructional phase of the program, which was further based on content that was both relevant and meaningful to the participants involved.

Observations and Reflections

The computer usage surveys revealed that 68 percent of the participants had used e-mail and 41 percent of the participants had used chat groups prior to this program. Additionally, 14 percent of the participants considered themselves to be heavy computer users (many hours per day) whereas an additional 14 percent of the participants considered themselves to be light computer users (approximately once per week). After receiving the reciprocal model of instruction, 95 percent of the participants' online discussion entries showed evidence of using the worksheets and study guides. Further, after receiving this form of instruction, 55 percent of the participants showed a significant increase in electronic discussion entry length (number of words/number of sentences). Additionally, qualitative data was gathered based on observational information throughout the duration of the study, as well as interviews conducted by the research assistant after the participants' completion of the program.

Throughout the instructional phase, there were notable changes in many of the participants. With the initial introduction of the study, many participants showed enthusiasm with regard to using computers for discussion as opposed to face-to-face class discussion. One participant, after the introductory session of the first writing strategy, shared a personal story of his childhood memories of being ridiculed in front of the entire class for not knowing the answer to the teacher's question. He further added that since then, he did not like to participate in class discussions. Because of this, he was very interested in the alternative form of discussion through the use of computers. Also, personal thoughts and feelings may have been more readily offered through the less threatening form of electronic communication. Additionally, the content of the case studies used in this study was an important aspect of the program. The case studies used throughout the program were relevant to the lives of the participants. The case studies allowed the participants to build on their already existing knowledge and experience when working through the three writing strategies. Moreover, the participants gained useful practice in problem-solving, personal development in areas such as self-awareness, self-esteem, and anger management that are essential components of their own lives, both at home and in their future workplaces. Further, realising the various interests of the participants involved in this program, the case studies were situated in a variety of workplace contexts. Furthermore, the participants claimed to acknowledge the direct connection between the writing strategies being learned in the context of the case studies and their chances of successfully finding and maintaining employment. Since finding and maintaining employment is a common goal between all of the adult learners who participated in this program, this seemed to have been a driving force of motivation for many of the participants.

In addition to the increased amount of writing in many of the participants, it was also evident that there were other noticeable changes in some of the participants over the duration of the program. For example, one participant said on the first day that he "never liked writing, did not like writing, and never will like writing." When asked why he felt that way, he put his head down and muttered, "cause I'm no good at it." However, after receiving the reciprocal model of instruction in a situated context, this same
participant was heard telling another student about the program. He expressed with enthusiasm that he "gets to write lots using a cool computer so everyone else can read [his] stuff". In addition to this obvious change in attitude toward writing, he showed a particularly significant increase in the amount of writing he produced over the duration of the program.

On the last day of the program, after the participants had finished their final session, they were asked for their honest feedback regarding the program, whether or not they found it useful, and if they would be interested in participating in a similar program in the future. All of the participants responded positively to all three questions addressed. More specifically, when speaking about the reciprocal model of instruction on which the program was based, one woman added, "I liked that you didn't just throw us in there and expect us to know what to do right away - it was really straightforward" while the others agreed. With regard to the use of the case studies, many of the participants claimed that they were interesting and useful because, "you never know when something like that could happen to you" and participating in this program resulted in increased confidence in their abilities to problem-solve in their future workplaces. Although all of the participants stated that they felt comfortable using all three of the writing strategies on their own, many of them requested copies of the worksheets and study guides to show others and to use in the future.

Concluding comments

This program was designed to use a reciprocal model of instruction on the adult learners. We were interested in assessing the effectiveness of the program with regard to how they viewed themselves as literacy learners, as well as whether or not their electronic discussion entries were influenced by the instruction. Reciprocal teaching has been used extensively in the past in studies designed to examine the effectiveness of teaching cognitive strategies (Palinscar & Brown, 1984). Results in many studies suggest that reciprocal teaching has potential to be an effective instructional approach to teaching workplace literacy skills. In addition, this also examined the effectiveness of situated learning in workplace literacy programs. Gershwin (1996) documented workplace literacy instruction based on situated learning led to skills transfer among learners. It is also believed that these workplace skills are better learned in the context of the workplace, rather than in contexts unrelated to actual workplaces. Further, Askov and Gordon (1999) suggest that because situated learning involves contextual instruction, based on real-world knowledge and experiences, it encourages transfer of knowledge and skills from the classroom to the job. The adult learners who participated in this program benefited from using their already existing knowledge and experience while developing their abilities to use communication and computational skills more effectively in the workplace. Further, this program showed that the use of electronic communication in the instruction of writing strategies to adult literacy learners may be an effective means of customising instruction to suit the needs of adult learners.

Abstract: This paper reports current findings from an ongoing research project that is an offshoot of a three-year, $155,000 "Best Practices in the Use of Technology" grant awarded to one of the co-authors, 1998-2000. The portion of the study reported here focuses on the cognitive complexity of student written responses in Virtual Literature Circles or electronic message boards utilized according to the structure of more traditional classroom literature circles. The ex-post-facto research question examined was: Did the cognitive complexity of student responses increase with continued use of Virtual Literature Circles? The findings of this simple study suggest that this research question is best answered in the negative, and shed light on existing higher-order literacy theory and on the effectiveness of Virtual Literature Circles in their current pilot state. Additionally, knowledge was gained in this study regarding new instrumentation being developed to help with the unique challenges of assessing student message board responses.

Background

Message Boards: Elementary students find message boards to be unique web-based forums to engage in asynchronous discussions with other students. While current communication tools emphasize chat, instant messaging, and desktop video conferencing for real-time communication, message boards allow individual teachers to engage students from different schools on the same topic while maintaining autonomy in how each teacher schedules the day in individual classrooms. This connectivity along with individual flexibility provides teachers with the opportunity to integrate computer technology and the Internet within the reading program.

Literature Circles: The instructional process named "Literature Circles" by Harvey Daniels has produced significant improvements in various literacy outcomes (Daniels, 1994). Literature Circles are a combination of reading for interest, cooperative learning, and independent study. Teachers introduce Literature Circles by providing various literature sets of up to five books each. From this variety of books, students personally select the book of greatest interest. Based on the book selected, students form study groups to read and discuss various aspects of the literature. Once each student in the group reads a preset number of pages, the group members come together for discussion. Within the group, cooperative learning roles are assigned to each student. Within these roles, students engage each other in discussion, with the goal being to understand the literature as deeply and meaningfully as possible. During student discussions, the teacher remains engaged by facilitating the conversation. The teacher's role is to intervene only when students get off the subject, cannot settle a dispute, or seem stymied by the task.

Virtual Literature Circles: Combining message boards with the basic principles associated with Literature Circles created the phrase "Virtual Literature Circles," coined by one of the co-authors.
Challenges in Assessment: Assessment of cognitive complexity of student message board responses is important in determining the effectiveness of Virtual Literature Circles. However, this sort of assessment is difficult. There are few measures of cognitive complexity available for rating written responses in traditional writing environments, especially for the shorter responses common to many elementary-aged students. This challenge is magnified in Virtual Literature Circles where student written responses are rather like unique hybrids between short contributions to group conversations and traditional written responses. In order to help address this challenge in their on-going Virtual Literature Circles grant and research projects, the authors are developing a simple cognitive complexity rating scale that is hoped will continue to be refined, especially for use in the message-board environment. It is the earliest version of this rating scale that was used for the data analysis in this report, and will be explained in slightly more detail ahead.

Purpose of the Study, Research Question, Design, and Significance

This study was conducted to examine the depth of student reading and writing experiences in Virtual Literature Circles. An overall goal for the grant involved in this study was that students who participated in Virtual Literature Circles would be able to interact with other students at advanced (or at least advancing) levels of cognition and that message board response threads would maintain the intellectual continuity of the discussions, similar to a regular classroom discussion (or maybe even be enhanced by the asynchronous environment). This paper has been undertaken in order to begin to examine these issues and one research question was examined. This question was crafted ex-post-facto, but prior to formal data analysis and is as follows: “Did the cognitive complexity of the student responses increase with continued use of Virtual Literature Circles?”

This research question was examined by first dividing in half the multiple written responses chronologically posted by each student. Then the mean cognitive complexity of the first half of each student’s responses was compared with the second half, looking for mean score gains from the first half to the second half, in order to demonstrate that the cognitive complexity of student responses increased with continued use of the Virtual Literature Circles.

This study is small in scope, but may be significant because the findings provide educators with a clearer understanding of the potential educational outcomes that may result from the fusion of two seemingly complimentary and potent educational tools: Literature Circles and Internet message boards. This is an important step in continuing to delineate the results of combining traditional literacy instruction with the technological tools of 21st Century.

Method

Subjects: During a two-week study in the spring of 2000, 125 third and fourth grade students from five rural schools in central Missouri, USA, participated in reading and discussing Fig Pudding by R. Fletcher. All students listened to the reading of the story or personally read it. The text was discussed on a chapter-by-chapter basis in Virtual Literature Circles formed through message boards maintained by one of the authors. The discussions from a random sampling of 25 participants make up the population for this study. Students made different numbers of responses, but all responses were collected and analyzed per student in chronological order in order to evaluate possible gains due to continued use of the Virtual Literature Circles.

Data Analysis: The message board discussions were quantitatively examined for levels of cognitive complexity with a simple 4-point scale developed by one of the authors. See Table 1.

This Cognitive Complexity Rating Scale was an attempt by one of the authors to create an instrument useful to the particular needs of assessing message board responses. They attempted to create an elementary message board rating scale somewhat akin to aspects of the McDaniel's Cognitive Complexity Scale (McDaniel & Foss, 1992, unpublished, as reported and published in Foss & Stensvold, 1994) by creating a scale from the core dichotomy of the hierarchy of annotation types presented in the Read-Encode-Annotate-Ponder (Eanet & Manzo, 1976) reading, writing, and thinking strategy. The two authors independently rated the student responses according to this new rating scale, and the means from these two sets of ratings were used for the student cognitive complexity scores. The traditional psychometric interrater reliability in this pilot study was only .37, considerably lower than would be desired or perhaps even considered acceptable. However, according to Sax (1997), in some situations, especially where limited testing options are available, or the costs required to increase reliability may be prohibitive, even tests yielding low reliabilities may be useful, especially when they are used in exploratory or probative research with groups, rather than individuals. Additionally, when analyzing how often the rater mean scores for individual students were within 1 point (on the 4-point scale) of each other, there was an interrater agreement of 88%. For these reasons, it seemed reasonable to the authors to continue to report these findings, as probative as they may be.

Each student received two cognitive complexity scores: a mean of the first half of their message board responses and a mean of the second half of their message board responses. The scores were calculated according to the 4-point scale described above. Each student's score was the average of the two raters' assessments. The research question was analyzed by comparing the group means between the first and second half of the individual student responses, in order to see if cognitive complexity increased with continued use of Virtual Literature Circles.

Results

The absolute differences between the group means of the first and second half of the student responses were quite small (Half 1 = 2.23 and Half 2 = 2.38). A paired-samples T-test was calculated between the group means of the first half and the second half of the student responses and did not show statistical significance at the .05 level. Additionally, using the effect size measure of Cohen's d (Cohen, 1977), the difference between the means was relatively small (Cohen's d = .27).

Discussion

The results presented above suggest that the research question of this study should be answered in the negative. It seems reasonable to claim that the cognitive complexity of the student responses did not meaningfully increase with continued use of Virtual Literature Circles. Although this finding is small, it is not without importance. It bears upon existing theory about cognitive complexity and higher-order literacy, and it sheds light on what we may hope to find as valuable in using electronic message boards. Additionally, knowledge has been gained regarding the rating instrument used in this study, allowing for future refinements.

The results of this study support the descriptive theories of higher-order literacy of Manzo and Manzo (1995) and Thomas (in process), most notably the argument that higher-order responses to text are often dispositional, or driven by orientation and will. It is embedded in this theory that higher-order responses to text, or responses of higher cognitive complexity, seem to be highly related to one's desire, tendency, or will to respond in such a way, and that this response tendency is not often impacted by external factors. Some have a tendency to respond in higher-order ways, and others do not. In this study it is apparent that the cognitive complexity of student responses was predictable between halves; the response tendencies of the students at the beginning of their involvement in the Virtual Literature Circles was very similar to their response tendencies throughout their continued involvement in the project. Therefore this study suggests that the students' tendency toward cognitive complexity seems embedded in the students themselves, more than in a stimulus provided by the message board environment.

This then, sheds important light on some of the educational dynamics that may be (or may not be) inherent in Virtual Literature Circles and other similar uses of electronic message boards. Since observation reveals that elementary students find message boards to be stimulating forums to engage in asynchronous discussions with other students, it is reasonable to hope that this would have an impact on
helping to increase the cognitive complexity of written responses. It would be hoped that the more engaging and interactive the learning activity, the greater the increase in cognitive complexity. This, however, in these immediate findings, does not seem to be the case for Virtual Literature Circles, at least not in their present pilot-study form. It is possible that other, more finely tuned aspects of stimulating Virtual Literature Circle discussions are needed. It is possible, for instance, that focusing specifically on the types of question prompts used by the discussion board moderators may be the key to eliciting high-levels of cognitive complexity, as may be suggested by the “Just-Ask-For-It” hypothesis of Manzo and Manzo (2001). Future studies of Virtual Literature Circles should perhaps focus on intervention strategies, perhaps as simple as question prompts, in order to find ways to help Virtual Literature Circles increase student cognitive complexity.

Finally, this study has led to the initial stages of developing a much needed instrument for assessing student responses in message board environments. Although the interrater reliability of the author-created rating instrument was low, it at least provided a starting point for attempting to meaningfully assess and analyze the hybrid response forms unique to message board environments. Future studies using this instrument in Virtual Literature Circles should help refine this instrument, potentially providing an important tool for use in the inevitable merger of the Internet environment with traditional literacy practices.

Summary

This study is small in scope, but still may be seen as important because the findings provide educators with more information to help with understanding the potential from the fusion of two seemingly complimentary and potent educational tools: Literature Circles and Internet message boards. This is an important step in continuing to delineate the results of combining traditional literacy instruction with the technological tools of 21st Century.

Abstract

The VT ARTT Project (http://www.vtartt.org) is an online arts mentoring program now in its 5th year. Begun as an initiative of the WEB Project, ARTT has given Vermont art teachers and students access to training with state of the art web-based technology in order to improve student learning. It now continues beyond the Web Project's TICG funding as a non-profit with sister music project - VT MIDI (http://www.vtmidi.org) - serving students and teachers of Vermont through online arts mentoring, collaboration, and professional development in music composition and the visual arts.

Introduction

VT music teachers began sharing student work online in an effort to meet the new composition standards in the VT Frameworks and Standards. Those who had not been prepared to compose, or teach composition, felt that by enlisting the aid of professional composers they too could meet the new teaching standards. Vermont is a mountainous state, where severe weather can disrupt travel at any time during the school year. Teachers in districts unable to afford to bring composers into classes on a regular basis, or to take their students on out of school fieldtrips in order to visit the artists in their studios, looked to technology for a solution to these geographic and monetary barriers. Initially, student compositions from a few schools were shared via email with professional composers through a VT State seed grant. This trial met with success and in 1995 WEB Project support helped to redesign the process as a threaded discussion. Visual arts teachers receiving grants of multimedia equipment
from the WEB Project grant saw the promise that this online critique process held and so developed the ARTT Project connecting visual arts students with artist/mentors. Self-examination of ARTT practice reveals that the strength of the network lies in all participants - students, teachers, and mentors - learning and growing through conversations focused on student work in progress. Through ARTT a dynamic multi-generational, multi-media, and multi-cultural community has grown. A recent keynote address at our annual meeting of MIDI/ARTT given by Frank Watson, a state leader in technology, pointed out the 5 stages of technology integration identified by ACOT (Apple Classroom of Tomorrow http://www.apple.com/education/planning/profdev/index4.html) in their 10 year study of technology implementation. That study delineated the stages as entry, adoption, adaptation, appropriation, and invention. Our speaker pointed out that MIDI/ARTT has gone through those initial stages and is now focused on inventing new uses of the technology to advance the primary goals of teaching and learning for students and educators. This paper will explore the professional and technological growth that three members - mentor, teacher, and student - have personally experienced through their work with ARTT.

Backgrounds

Graciela Monteagudo is an Argentinian puppeteer and performer with Bread and Puppet Theater of Vermont, she creates her own shows incorporating both larger-than-life-size and hand puppet formats. She has done extensive work in Arts in Education, conducting residencies in schools that culminate in big puppet shows with over a hundred children on stage. Her puppets are made out of recycled materials, sticks, paper mache and found objets. Graciela has studied Photoshop and web design through ARTT programs, and has begun exploring photography and digital imaging.

Marty Leech teaches a broad spectrum of visual media at Missisquoi Union High School in Swanton, located in an underserved region of northwestern Vermont. Marty began her work with ARTT as a full time art teacher - as a result of pursuing her interests in technology through ARTT Marty is now also teaching technology courses both at MUHS and at the graduate level. She has actively involved the integration of technology into the artroom.

Majken began her work with ARTT as a junior at MVUHS. She was interested in digital imaging and website design, and shared her work online for school assignments as well as original pieces created on her own. She has graduated now, and will be participating online as a mentor to other students.

Online practice

Mentor: When Graciela logs on to the ARTT site, she first clicks on its 3D section. She tries to comment on every new piece that has been recently uploaded. When time allows, Graciela visits the Digital Image area and then the Traditional Arts section. Although her main area of expertise is not in those two media, she offers critique on composition and other design aspects of the students work that are universal. New messages posted on the threads she commented on are automatically emailed to her. This allows her to respond in a timely manner to any new developments in those threads.

Throughout the three years of Graciela's involvement with the project, she has attended a number of conferences and retreats in which the online community spends 'real time' together. Her focus during these meetings is not only to learn techniques for manipulating digital images, but specifically to develop a dialogue with the art teachers, students and administrators who make up the online community.
community. She has been interested in the process of learning how to ask the right questions and how to provide critique. She feels the ARTT site has improved greatly as students and teachers have learned how to ask for specific comments and feedback as opposed to asking general questions like: "Do you like my work." which are not conducive to in depth critique. The ARTT group has also learned that it is most helpful for a student to describe the process of their work as much as possible, clearly stating what they feel works and what they would like help with.

Teacher: Marty writes that one of the benefits for our rural student community is the wider view often offered online by artists, teachers, and students from all over the state.

Students initially learn the "language of art" (art terminology, elements and principles of design) in the classroom, then hear it again in the mentors comments on their work. This successfully reinforces what is being taught.

The online process offers another means of achieving specific Vt standards from the VT Frameworks of Standards, i.e.:
"Artistic Proficiency, 5.28 Students use art forms to communicate, showing the ability to define and solve artistic problems with insight, reason, and technical proficiency."

Student: Majken describes herself as an 'internet nut' - ARTT was her introduction to message boarding online, since starting she has expanded her experience and is now the administrator of her own message board. She adds, "I post my digital artwork on the internet all the time on a few different message boards as well, just for fun. ^_^"

Benefits of commenting online

Mentor: Graciela says that students who live in rural areas and have artistic interests feel isolated in their communities. The online critique experience opens up a world of peers for these art students. The attention paid by a professional artist to their work can enhance the real value of their artwork, for themselves and for the community, and even for their fellow students.

Teacher: Marty thinks that one of the most important and dramatic effects to participation is student validation. Often students are so used to their teacher's comments or encouragement concerning their work that it does not have the same effect that a new individual's insight may have. The mentors also give a more in-depth critique than is possible in the busy classroom. They may take an entirely different skew on a project and offer interesting facts that may not have been considered before, such as an historic perspective in terms of past artists or eras.

The online experience addresses the issue of literacy: as students articulate their intent online, they must communicate effectively. The ensuing dialogue encourages growth in written expression and also addresses Communication Standard 1.16 "Artistic Dimensions" which encompasses skill development, reflection and critique (students improve upon products and performances through self reflection and outside critique, using detailed comments that employ the technical vocabulary of the art form), and making connections.

Student: Majken feels that posting artwork online opens up the forum to a wide variety of people. The wonderful thing about the internet is that it is available to everyone, everywhere. Artists and students from all over the world can converge on a website and share ideas and techniques, all for free, and
without having to move from their chairs. It reminds her of the title of a CD by Jamiroquai, "Traveling Without Moving." She sees resources and personal connections as being a lot easier to come by now that the internet is in use.

**Drawbacks**

Mentor: Monteagudo feels that the online critique process works best when teachers in the schools have enough time to follow up on the students work and are able to post the images with the changes they have produced as a result of the dialogue with the mentors. However, it is a sad reality of the Vermont school system, that the art departments are under funded and teachers have on average 500 students visiting the art room for approximately 45 minutes of instruction each once a week. This makes it very difficult for students to actually post images of finished work. Without that final viewing of the student work, the mentors do not have a clear idea of how their feedback was received and processed by the student.

Teacher: Marty finds similarly, that the only drawback for her is lack of time, "I get so wrapped up in the day to day activities that time slips away and we don't get the cycle completed - a disappointment for all - the student, the teacher, and I think, mostly the mentor who has put a lot of time and thought into the response."

Student: Majken sees another failing in internet communication, especially through message boards, as lacking an ability to get across what you mean right on the spot. She explains that "when you talk with someone face to face, you can understand what they're saying a little better based from inflections in their voice and such... not available on the internet, in a text-based forum."

**Innovation**

Mentor: One of the formats that Graciela sees has been highly successful was created by art teacher Jan Danzinger. Her students take a two week Art Challenge class, and are free to create what they choose to, in any available medium, with the express purpose of posting it online while in progress for mentor critique. Because the process is geared toward offering their work for the professional artists, the students have the time and the interest to post their final projects as well as images of second or third drafts. In this way, the mentors can clearly see how their critique affected the creative process and learn from that for future reference.

Another innovative use of the ARTT project that incorporates both online and real time critique is the after school format developed by Rebecca Raymond at Manchester Middle School. Rebecca enlisted the aid of parents and mentors to provide students with a regularly scheduled after school ARTT activity, built on the models already in place for after school intramural programs.

Teacher: Marty's participation in ARTT has led her school board and administration to approve a new art/technology course - Digital Imaging in which her students not only create traditional art work, but have an additional focus on technology as they learn to digitize, scan, and manipulate their work. She is finding this to be a wonderful opportunity for students to expand their knowledge of technology while developing their artistic abilities and appreciation.

Student: Majken feels that the online ARTT program is especially beneficial to students like herself, either who have just started, or are already well-versed in digital media. She says online message boards are ideal to share graphic artwork, as one gets to see the original product, and not a scanned
Summary

VT ARTT's strengths are multiple. The technology has developed which allows us to easily share student artwork online through password protected discussion forums with attached files. In the early days of ARTT a two day training with follow-up instruction was needed just for participants to learn how to capture a still digital image from video using Premier. With the invention of the Sony Mavica camera - using a floppy disk to take stills that are immediately readable and uploadable - teachers were able to immediately move their ARTT time away from learning to use the technology toward teaching their students how to take effective images using the Mavica, and how to manipulate images using Photoshop.

The network has also grown stronger through action research conducted by WEB Project, VT MIDI, and ARTT participants has lead to practices that include new ideas about how to critique and receive critique online. ARTT recently added the prompt, "What Works Well?" in addition to a general request for description of the student work - this in response to mentors finding they were inadvertently hurting the students feelings by suggesting changes to parts of their work that the students actually felt were the most successful. The 'safe' environment, where students are able to post artwork and ask for help without fear of getting "dis-ed" is highly prized by the ARTT community, which self-monitors postings of questions and responses.

The Post-Respond-Reply cycle, first developed in VT MIDI under the WEB Project, is another key to making ARTT an effective tool for teachers and students. Original art is Posted while in progress, mentors Respond, and students Reply to the mentors' suggestions - posting new versions of their work as it progresses. When students have real questions that concern them about the art, mentors respond in a timely fashion and with specific suggestions, and students reply to let the mentors know how their advice was incorporated - or why it was not - the cycle is complete.

Of the original seven participants in ARTT, five are now trainers who provide workshops and assistance to the newest members of the network. Students like Majken have grown up with the project and continue to participate even after graduation or college takes them away from their community. Mentors such as Graciela have developed expertise in the new areas of digital imaging and web design which serve to enrich their personal art and provide new interests which they can share with their students.

Although the active work onsite is password protected, an example of an ARTT discussion can be seen at http://www.vtartt.org/jellyfish.html. Please contact Penny Nolte, ARTT Coordinator, for additional information.

Abstract: In order to meet a documented need for more advanced ELA (English Language Arts) electives, the secondary ELA teacher in an isolated rural school in southeastern Wyoming integrated graphic arts technology in a new course, Literary Desktop Publishing, to meet advanced students' needs. Students acquired graphic arts communication skills that are currently used in local businesses and met district ELA standards and benchmarks as well. The course is taught to motivate students to think for themselves, to solve problems, and to read, interpret and apply complex operations in computer applications. Other secondary schools in the district have adopted the course, as well.

Introduction

Prior to the inception of Literary Desktop Publishing as a district-approved ELA (English Language Arts) class in Albany County School District #1, many students at Rock River High School, one of three high schools in the district, would complete their required English courses by their junior year. Because of mandated Carnegie units, 8 semesters of attendance, these students would face 2-3 study halls in a row, then at least one "teacher's assistant" period to follow while they finished their required courses and electives their senior year. Their time was not being used prudently.

Also, it was not possible to hire additional staff to offer more electives, because of Rock River School's unique position of being a K-12 facility under one roof. There is neither room nor time in the secondary and elementary schedules to add sections of secondary courses or specialized electives. Consequently, many of the students were asking to come to the ELA classroom during study halls to work on computers, since no other electives were available in the small, isolated rural school that explains the configuration of RRS. Various classes go as a group to the school's computer lab, which is comprised of one Mac Quadra and 16 Mac LC II's, but students are not allowed to go independently, because there is no on-going supervision in the lab. Additional staffing for on-going care, maintenance, and supervision in the lab is not a probable alternative.

The school serves as an "option" school for students in the district. For a variety of reasons, students can elect to attend Rock River School as a matter of choice. The end result is that RRS has a unique population of students with barely enough classes and services to accommodate the need created by the option of attendance. As one example, RRS has neither the facilities, equipment, nor staff to accommodate a football team. The real bottom line is that the student population of RRS is 40% identified as needing special services, and .06% as qualifying for National Honor Society membership.

The students are introduced to computer applications in their earlier ELA classes (20 percent of instructional time allotted to computer applications, at the discretion of the ELA teacher). As a result of the exposure in earlier ELA classes, students were looking for electives where they could learn more computer applications and find places to use what they had learned. Over a period of several years, the
English teacher had spent any and all available resources to enhance the technology available in the English room. Because of a recent in-depth study of English language arts in the district, when additional monies are made available for the acquisition of texts, as well as the purchase of new technology, the English classroom is now equipped with a Macintosh G3, a G4, as well as an iMac. Because of the computers being housed in the classroom, a closer scrutiny can be maintained over the student use and (potential) abuse of the equipment. Therefore, supervision is not usually a problem.

Rationale

The impetus for developing, securing approval, and then teaching Literary Desktop Publishing at Rock River School for the last two years came from many sources. First of all, because of a close association with the University of Wyoming’s Instructional Technology faculty and facility, the ELA teacher has had some first-hand experience with what is possible in an e-classroom that is run the way it should be run. Further, because of personal experiences at SITE 1999 and SITE 2000, it has become clear to the ELA teacher that a constructivist approach to applied communications skills might be just what is needed to breathe some new life into the common core of skills taught at RRS, especially considering the school’s diverse, identified population.

The school is undergoing massive school-improvement reconstruction, due to district-wide and state-wide school reform initiatives. The Literary Desktop Publishing class was designed to be a part of those initiatives in a substantive way. The same old way of doing “things” simply does not work, any longer. According to the Sept., 1996 report of the National Commission on Teaching and American’s future, What Matters Most: Teaching for America’s Future, points to the close relationship between students’ achievement and the knowledge, skills, and practices of the teacher. According to this report, what teachers know and can do is crucial to what students learn.

Policy implication #3 from that text says: “School reform cannot succeed unless it focuses on creating the conditions—including the curriculum contexts—in which teachers can teach well.” From student feedback obtained in the first two semesters that the Literary Desktop Publishing class has been offered, it seems as though students themselves feel that allowing self-paced progress through the various applications, to read what is necessary to make the applications work, is an extremely successful way of enabling students to learn. To teach the class requires a new definition for the term “teaching.” The teacher allows the students to discover the secrets of the applications, and then apply those secrets to various projects.

Further, as Richmond said, “Effective use of technology to support teaching and learning across the curriculum has the potential to transform the learning environment.” He points out that there is much experimental use of technology in classroom learning and many attempts to implement change are locally conceived. (Richmond, 2000, p.2) While some caution in new approaches is warranted, the ELA instructor felt inclined to follow the advice of Lee Iacocca who said, “Either lead, follow, or get out of my way.” The adoption of the class by the other, larger high school in the district this year, is some validation for the course’s approach to literary desktop publishing, meeting standards, and teaching the common core of skills and competencies in English/Language Arts.

Richmond stated, “Just as the industrial revolution created tools that served to off-load the physical labor previously carried by both ‘man and beast,’ the information revolution is creating tools that promise assistance with the intellectual dimensions of our lives. While the technologies of the industrial revolution were at times misused and misapplied, so, too, the technologies of the computer-generation must find their appropriate place within our communities and our schools.” (Richmond, 2000, pg.3) One of the most rewarding assessments of the class this year has been their articles on their perceptions of the utilization of all of the skills that they have learned. One student, who plans to be a lawyer, said that at first she couldn’t think of how a lawyer might use the various applications. Then she thought some more, and the ideas for use of the applications by a lawyer just jumped into her head.

In his book Business at the Speed of Thought, Bill Gates, Microsoft CEO said, “The old saying ‘knowledge is power’ sometimes makes people hoard knowledge. They believe that knowledge hoarding makes them indispensable. Power comes not from knowledge kept but from knowledge shared. A company’s values and reward system should reflect this idea.” Another remarkable result of the introduction of Literary Desktop Publishing as a class for two years at RRS is the amount of sharing, collaboration, and actual
talking among students that I have observed. If one student figures out one little quirk in a particular application, all I have to say to one struggling with the same piece is “Talk to Justin. I believe he got that piece figured out.” Then the two students will talk to each other, even if they might not have under other circumstances. The magic works.

Background

The ELA teacher had tried for years to systematically incorporate technology integration in her classroom, and English students still felt as though they were not getting enough exposure to various applications of computer expertise. Even though in the regular ELA classes, 20% of the total instructional time was devoted to technology utilization and application, it became obvious that additional exposure was needed. However, as students advanced through Rock River High School, they had to be aware of the need to accumulate “English credits” for graduation. As they got older, they could not have periods allocated to classes that did not count toward graduation.

The idea and motivation for developing the course occurred from a “Schools-to-Careers” job-exploration externship experience in the summer of 2000, that the ELA instructor had. This experience enabled the instructor to explore the expectations of local businesses and industry for entry-level employees in graphic arts communication. Time was devoted to working at the local newspaper, observing a “high tech” graphic communications firm that does business world-wide, a local photo processing business, and a local printing firm.

The instructor discovered that the skills and competencies expected of newly-employed persons in the Laramie area are similar to those being taught in the Literary Desktop Publishing class. Although Laramie is certainly the largest population area close to RRS, and Laramie is the location of most available jobs for RRS graduates, it must be noted that “the Laramie area” is a small version of what is available in larger, metropolitan areas, such as Denver and the front range. But it was a start.

The course was taught one semester in 1999, and the second enrollment was finalized in the fall of 2000. For both sessions, students seemed eager to “get into” the class, and underclassmen frequently asked when they would be allowed in.

Because of the “Schools-to-Careers” initiative, and because of additional materials that were procured through a “Schools-to-Careers” mini-grant opportunity, the applied language arts class offered at RRS materialized. It hadn’t been done before. The ELA curriculum in the district and certainly in RRS was the very traditional English 7, English 8, English 9, English 10 sequence, with Publications being offered as “junior” English and alternating electives being offered as “senior” English. The electives were standard: Drama as Literature, English literature, Research Writing, Play Productions, and Writer’s Workshop. The concept of offering a new English class was pretty much unheard of. In the fall of 1999, 6 students enrolled in the new class, even given the possibility that the class would not be approved by all the various committees and supervisors who would have the opportunity to turn down the initiative. The first six enrolled, knowing that the class may turn into Research Writing, pending the decision of the approval process.

Implementation

In getting the course approved, the instructor related the computer technology components as well as the language arts components of the class to the district and state ELA standards of Reading, Writing, Listening, Speaking and Integration. It should be noted, that in Wyoming the implementation of standards-based instruction and assessment began, state-wide, with English language arts. For that reason, all new curriculum offerings for any school, need to be explicitly aligned to state and district standards. For Literary Desktop Publishing, that job was not difficult.
For example, the students are asked to read and comprehend what ever is necessary to make their particular computer application work. No chapters are assigned, but students are asked to read necessary directions to aid in their use of the computer applications. They are also asked to read trade magazines about current technologies and career opportunities involving computer technologies. They then give speeches about what they have discovered. They listen to demonstration CD's that teach the direct instruction of the applications. They listen to each other's speeches. They write a term paper and weekly reports based on their exploration of "techno-trends." They give a major speech to the entire school about their conception of current "techno-trends" They create an original piece of literature, and then they create the graphic to go with the original piece of literature. All of the language arts standards are covered.

After the course was written to align to district and state standards, the approval process was initiated. There were many hurdles to overcome.

It didn't take much convincing to get the principal on the side of the new course. He had to deal with the disciplinary situations that are a natural consequence of students having three study halls in a row. He supported the new class as a solution to a problem that he had to face. Also, the local Site-based council had first-hand experience, through interviews, about the students’ views of three study halls in a row. The senior students told the Site-council members that three study halls in a row is a waste of time. Then, the council asked the question, “Why can’t there be more electives offered for upper-level, advanced students.”

On the district level, the going was not as easy. The business/computer department felt as though the course infringed on their “turf” of teaching computer applications. The ELA instructor was told she would get "no support" for a class that was out of the ELA domain, that she attempted to get approved out of the traditional time sequence, and that students had registered for before it was approved. Those concerns were answered in time. Once in district committee, the course again hit a roadblock. Concern was raised as to how to count it for English credit. The person who raised the concern had not seen the alignment document that specifically answers how it is an English course that meets English standards. The small concession of calling the course Literary Desktop Publishing was one solution to those concerns. If the title of the course included an ELA reference, then perhaps it would not be challenged by a college as not having sufficient rigor and relevance as an English course.

Design

Examples of computer applications used by the students in the class included Adobe PageMaker, PhotoShop, Premier, Bryce (a 3-D landscape application), Claris Home Page, and QuickTime VR. Other computer applications that the students were introduced to in the second year of the course included Painter 6, Design Your Own Home, After Effects, KPT 6 (a Photoshop plug-in), Typestyler 3, Textissimo and iMovie 2.

The specific utilization of these applications have included, but are not limited to: design of the cover of the 2001 Longhorn yearbook, design of the 2000 graduation multi-media event, design of the multi-media visual aid that was used to accompany on of the 2000 graduation speeches, design of the school web page, design of the school's first literary magazine, design of the 2000 graduation program.

Students also used multi-media applications such as Hyperstudio to incorporate text, images, and sound as part of the communication process. These tools challenged the students well beyond the usual word-processing and "word art" software used in most classes.

Students are given one week (4 days) to learn the application that they are assigned to. By Thursday of the week in question, they are expected to have a sample project to share with the class. On each Friday of the first quarter of the class, the students are asked to read a trade magazine article and then give a speech discussing the article’s presentation of a technology innovation as well as their thoughts about the subject. During the second quarter, students are given time to work on the school’s web page, updating what is necessary, securing permission for the addition of pictures of students, creating the next addition to the literary magazine on-line, and then they are given time to work on their term paper. The assignment is based on the predictions in the Daniel Burris book, Technotrends.
Conclusion

The Literary Desktop Publishing class now being taught at other high schools in the district, as well as at RRS, offers students advanced experiences with complicated computer technologies. It meets district and state ELA standards, and it offers the language arts curriculum in an attractive package that the students actually like. The class proves that English skills and competencies can be taught by using something other than college-prep, literary material. The college-prep literature is taught in the other electives, but for the diverse population of RRS, it seemed important to offer a class with an "applied" approach. Enrollment in the class is high, and students are giving up study hall after study hall to "buy more time" on the machines. Future adaptations to the curriculum might include the construction of professional level advertising for the yearbook, construction of professional level advertising for the newspaper, and the addition of graphic arts projects for the school, whenever possible. The magic works.

Use of Telecollaboration to Develop Authentic Learning Experiences for Teacher Candidates

Regina Royer
Education Department
Salisbury State University
United States
Rdroyer@ssu.edu

Abstract: Participation in a telecollaborative project with K-12 students can provide authentic learning experiences for teacher candidates that connect theory with practice. This paper discusses how teacher candidates in a preservice teacher education class moderated a K-12 global telecollaborative writing project. As a result of the candidates' participation as moderators, the candidates gained an understanding of how to integrate technology into the classroom to achieve curricular objectives and became motivated to use technology in their own teaching.

The Redesign of Teacher Education in the state of Maryland as well as the new National Council for the Accreditation of Teacher Education (NCATE) 2000 standards include expectations for increased field experiences for teacher candidates. These organizations, along with educational reformers, believe that teacher education currently lacks sufficient connection with practice. (Lampert & Ball, 1998). Teacher candidates need to connect theory with practice and the consensus is that this is best done in the K-12 classroom. There are difficulties, however, associated with increasing the number and length of field experiences for teacher candidates. It is often difficult to find a sufficient quantity of placements in schools to accommodate methods students as well as student interns. Likewise, it is difficult to find quality placements with teachers who practice new approaches to teaching (Lampert & Ball, 1998). Finally, in education program coursework it is often difficult to discuss field experiences with students who may not share common field experiences. For this reason, many educators are using technology to bring the K-12 classroom to teacher candidates via electronic case studies, in which students examine videos of K-12 classroom instruction. Education, like business, law, and medicine, is realizing the benefits of a case method approach. Electronic cases allow students to examine, reflect, and discuss mutual observations in a time-independent manner (Bonk & King, 1998).

Another approach to creating authentic experiences that connect theory and practice is to use technology to take teacher candidates into K-12 classrooms. With the use of email, listservs, digital cameras, and the World Wide Web, candidates can converse with K-12 teachers and can mentor K-12 students, providing teacher candidates with teaching and learning opportunities without their ever leaving the higher education classroom.

As more and more K-12 schools have become wired for access to the Internet and as their teachers have become more familiar with email, the number of telecollaborative projects which bring together K-12 classrooms from around the world for collaborative study has greatly increased. Teachers are recognizing that telecollaboration is an effective way to create authentic learning experiences for K-12 students as well as increase their motivation. Numerous studies have documented the positive impact of participation in telecollaborative projects on student achievement (Allen & Thompson, 1994; Bagley & Hunter, 1995; Cohen & Riel, 1989; Petko, 1991). Harris (1998) categorized the wide variety of online projects, encouraging K-12 teachers to match classroom objectives with the appropriate type of online project. Web sites such as I*EARN (www.iearn.org), Lightspan’s Global School House (www.lightspan.com), and Kidlink (www.kidlink.org/KIDPROJ) offer hundreds of collaborative online projects from which to choose.

The Telecollaborative Study

This study used telecollaboration tools to connect teacher candidates, K-12 teachers, and K-12 students in a global writing project. The university students participated in the online project as moderators and in doing so learned about teaching writing as well as participating in telecollaborative projects. Activities such as the one in this study provide authentic learning experiences and teach candidates not only pedagogy but also technology.
skills. The intent of integrating technology into the curriculum is to promote the acquisition of technology skills as a secondary rather than a primary instructional objective (Kent & McNerney, 1999). Using technology as a tool for accomplishing other classroom goals gives the technology a purpose. This study examined the use of teacher candidates to moderate a K-12 telecollaborative project. The study posed two questions:

1. Does participation in a telecollaborative project yield understandings on the part of teacher candidates concerning how to integrate technology into the classroom?
2. Does participation in a telecollaborative project result in high levels of motivation on the part of teacher candidates concerning integrating technology into teaching?

Method

Background

Through Our Eyes (TOE) is a telecollaborative writing project run annually on the Kidproj listserv and moderated by the author of this study. Its purpose is to involve K-12 students in the descriptive writing process. K-12 classes register to participate via an email registration that is distributed through various listservs and websites. In the project, K-12 classes choose a location in their area to describe, plan a field trip, complete pre-writing on location, and write collaboratively to create one final descriptive essay. Final essays are submitted to all participants via a listserv and posted on the TOE web site for all to see. The results of each year’s project can be seen on the TOE web site (www.kidlink.org/kidproj/eyes00). During the Fall 1999 project, 28 classes from 7 countries participated in the project.

Subjects

This study was conducted by the author in the capacity of instructor to nineteen teacher candidates in the EDUC 471 Computers in Education class at Salisbury State University. Some candidates in the class had not yet taken methods courses, while others had already completed their student teaching. Everyone, however, was a beginner in understanding how to integrate technology into teaching and learning. For the past four years, the instructor had moderated the TOE project, sharing the results with candidates as an example of a telecollaborative project. During the Fall 1999 semester, however, the instructor turned the project over to the candidates to moderate, guiding the students through the necessary steps.

Data Collection and Analysis

Prior to the beginning of the course, the instructor posted the call for participation in the TOE project on two listservs and one web site and began to accept registrations. The project design, required activities, timeline, and web site were already established before the first day of the class. When the Computers in Education course began, each student in the university class was assigned two K-12 classes to monitor through the project. The candidates sent letters of introduction, announced assignments and due dates, monitored their assigned class’ progress through the project, and responded to work submitted by K-12 students with praise and reflection. Communication was maintained through a listserv and email. In addition, all work was posted on web pages along with photos of participants and places for all to see. During the study, classroom discussions at the university identified concerns and techniques for communicating with K-12 participants and maintaining K-12 student enthusiasm for the project. In addition, the instructor monitored the messages sent from preservice moderators to their assigned K-12 schools as they appeared on the listserv. Teacher candidates maintained journals, documenting correspondence sent and received and their reflections on the project.
Moderation of the project

Whenever someone moderates a telecollaborative project, one of the primary objectives is to facilitate the project in such a way that all participants who register to participate go on to successfully complete the project. This is particularly important for the K-12 students who are registered for the project. It can be very disappointing for K-12 students to begin a project with classes from another country, build classroom enthusiasm, begin activities for sharing with participants, and then never hear from them again. While the instructor had been moderating the project for several years, there was some concern that candidates, who were themselves novices in use of technology, could not successfully maintain communication and encourage participants to remain throughout the four months of the project. However, the candidates moderated the project quite successfully. They embraced their roles as moderators and sent directions and encouragement along the way enabling their classes to complete the project. Several of the teacher candidates’ comments appear below and serve to document their role as successful moderators of the TOE project. After teacher candidates and K-12 classes introduced themselves, the K-12 students were required to select a place to describe. Teacher candidate moderators sent messages to encourage them to select a place. One candidate wrote to a class in Italy:

I was wondering if your class has chosen a site for your descriptive essay yet? Since I am of Italian heritage, I am very interested in learning more about Italy and your culture. Many of my family members have been to Italy and have told me how beautiful everything is. They have even shown me pictures of all the beautiful places and sites. I am very excited to find out what site you are going to write about. I look forward to hearing from you soon.

After selecting a place to describe, K-12 students were encouraged to take a field trip to the site for the purpose of completing prewriting activities. In reminding a class in North Dakota to share their prewriting, one candidate wrote:

I was so happy to see your introduction on TOE this weekend. You sound as if you are very active in many different subjects. I look forward to reading about the place you have picked out for the project. Your prewriting on that place can be in the form of brainstorming a list of descriptive words, a paragraph, a few sentences to get your started, etc… I look forward to seeing your work on TOE soon.

Another student, also encouraging the class in Iowa to complete prewriting activities, wrote:

It was great to hear from you guys. I’ve never seen a real prairie before so I can’t wait to hear more details about your topic. … If you haven’t taken time to go outdoors and write about the prairie you may want to. It’s amazing what you notice when you sit there and focus on something more than usual. You may find more details about it you would want to include in your brainstorming and prewriting. Hope to hear from you soon.

Yet another candidate wrote to encourage students in New York to take a field trip to complete prewriting activities:

You are all ahead of the game since you have a place picked out to describe. I’m sure the pizza place will be lots of fun to visit as a class and describe. Sometime this month you should visit the place and write a list of descriptive words, nouns, verbs and adjectives. I will be waiting to read your list. I have a feeling it will make me hungry. Remember to write if you have any questions. Have fun.

The teacher candidates saw their role as that of teacher and easily transformed that into email messages. They guided their assigned classes through the project enabling them to complete the project. Of the 36 K-12 classes initially registered to participate in the project, 28 remained in the project and submitted a final descriptive essay. When a school did drop out of the project, the university students were very disappointed and voiced their disappointment in their reflective journals. One student wrote:
I was very disappointed that my class from Spain did not complete the project. They were off to such a wonderful start and then they just lost touch.

The candidates not only successfully moderated the project but also wanted more responsibility. Once K-12 classes registered for the project and were given the timetable for activities, there was not much to do as moderators except send weekly reminders of activities due (class introductions, location to describe, prewriting, final essay) and responses of encouragement for work sent. The candidates, however, wanted much larger roles as moderators and more opportunities for exchange of ideas. One student wrote:

I was most interested in communicating with the students and teachers, which I didn’t get to do enough. I realize that everyone is busy, but I would have liked to be a little more personal with my schools.

Along the same lines, another candidate wrote:

The only thing that disappointed me was that my classes needed very little guidance. I was sort of hoping that I would have more communication with them, but I think that this was a false impression I had of what my job would be from the start. Overall I would love to do this again, and maybe when I start teaching in a year or so I could even participate in TOE.

Findings
Research Question #1

As a result of participating in the TOE project, these teacher candidates understood how to integrate technology into the classroom to accomplish a variety of curricular objectives in core content areas. This understanding was voiced in their reflective journals. One student wrote:

Through Our Eyes is a great way to get students interested in writing, which is definitely hard to do in many classes. Descriptive writing can also prove to be challenging for many children, and this encourages descriptions of places and then using those descriptions to form an essay. A terrific way to put all the steps together is in this manner.

Another candidate wrote:

I wish I had the opportunity to learn about places all around the world from telecollaboration rather than from a textbook. I know my learning would have been a lot more meaningful for me if I had the opportunity for telecollaboration in grade school.

Another teacher candidate wrote:

The students benefit by using their critical thinking, cooperative, language and writing skills. They also see the world around them through the eyes of others. By sharing their vision with each other, each is given the opportunity to magically travel the globe to near and distant places. Places that were simply a picture in a book or a graphic on a web site suddenly come alive as if you were right there. The ability to learn from others is a benefit worth wonders.

Another candidate wrote:

I would want to use a telecollaboration such as TOE because TOE can be used across the curriculum. In Math class the students could calculate how far away the collaborating schools are from our school, the ratio of boys to girls, or ratio of students to our students. In Science we may compare the collaborating schools’ climate or landscape to our climate or landscape. In the Social Studies class I would discuss with my students the different events that have shaped the area where our participating school is located. I could also have my students plan a make believe trip to the area where our participating school is located. Finally, in English we could use our
information to create a very descriptive essay. This is why I feel that telecollaboration can be used across a wide range of subject areas.

These candidates linked technology use in the classroom to achieving curricular objectives using constructivist approaches, demonstrating an understanding of how technology can be used in the classroom to support student achievement.

Research Question #2:

As a result of participating in the TOE project, teacher candidates expressed motivation to integrate technology into the classroom. The goal of including the TOE project in the Computers in Education course was not only to teach candidates how to use technology but also to motivate them to want to use technology. Fortunately, the teacher candidates' comments in their journals revealed a desire to participate in telecollaboration with their own classrooms. One candidate's comments are typical of those voiced by the class:

I really enjoyed every aspect of this project. When I have my own class I will be sure to incorporate some use of telecommunication in the curriculum.

Conclusions

From the success of the TOE project itself and the comments from teacher candidate moderators, it is clear that candidates benefit from moderating a telecollaborative project. The results of the TOE project can be seen on the project web site, which includes K-12 participant introductions, pre-writing, final essays, and numerous graphics of K-12 students on location. Participation in the TOE project immersed the candidates in an authentic project and provided them with first hand experiences, which integrated technology into the classroom. This experience enabled them to develop an understanding of how technology can be integrated into the curriculum to accomplish curricular objectives. Finally, the experience left the candidates wanting a more active role in the project and fostered motivation to use technology in their own future classrooms. These teacher candidates are likely to be tomorrow's K-12 teacher participants in telecollaborative projects.

Implications for Practice

The purpose of this study was not only to determine if teacher candidates benefit from moderating a telecollaborative project but also to provide guidance for those who may be interested in trying telecollaboration. In their journals and in classroom discussion of the project, candidates offered a number of observations about ways to improve the telecollaborative experience. The following suggestions discuss the practical implications of the study.

First, teacher candidates seek a greater role as moderators. For the purposes of this project, which provides four months for the participants to complete the project, it is important that the participants be registered to participate prior to the beginning of class. For shorter projects, the instructor could allow the candidates to be involved in designing the project and announcing the project on several lists.

Second, the candidates need guidance concerning their roles as moderators. Initial discussion should occur regarding the tone of messages sent and instructors are advised to read correspondence prior to being sent to K-12 classes. In reading one student's journal which included messages sent, it was discovered that the student seemed to be reprimanding a teacher for being tardy in submitting assignments. Needless to say, the teacher dropped out of the project.

Next, moderators need a way to track progress of their assigned schools. This can be accomplished in several ways. First, to keep everyone in the communication loop, subscribe all participants and moderators to a listserv. There are several free services available on the web. One that has been used successfully at Salisbury State University is Nicenet (www.nicenet.org). Next, provide student moderators with a list of activities that K-
12 schools need to accomplish. Then create a table so that the preservice moderators check off each activity as their assigned schools complete it. This will facilitate class discussion regarding where all schools are in the project.

Finally, the instructor needs to maintain contact with the K-12 teachers to discuss their needs and the success of student moderators.

Suggestions for Further Research

Schools of teacher education are encouraged to explore the use of telecollaboration as a way to provide teacher candidates with authentic field experiences. While this study has explored the possibility of using telecollaboration, other researchers will hopefully identify additional ways to allow candidates to be even more involved in the design and implementation of telecollaborative projects. Further research could explore the impact of this tool in the higher education classroom.

Abstract:

Introduction

In the age of information, a university graduate has to be competent not only in his major field. The world business community, traditionally communicating in English as lingua franca and well advanced in using modern technologies to manipulate relevant information, requires both language proficiency and technology skills as mandatory for a business executive from outside the English-speaking world. This implies the broad-scale integration of modern information technologies in all courses of any university program. ESP (English for Specific Purposes) courses should, therefore, be based on the wide use of language-learning technologies as well as operational software employed in the field. Using the English-based operational software at Business English classes is the efficient way to develop the students' command of the language as well as that of technology, thus raising the quality of higher education.

The paper presents the basic ideas for integrating operational technology in the Business English course and discusses the necessary competencies of an ESP (English for Specific Purposes) practitioner.

Content-based ESP Teaching and Technology in ESP Courses

Apart from the language-based approach in Teaching English for Specific Purposes (TESP), the content-based approach (Dudley-Evans & StJohn 1998) has been widely spread. It appears to be more efficient than the language-based approach: instead of dismembering the language structure for no obvious reason, students are encouraged and motivated to use the language for manipulating professionally valid and valuable information. Thus, the conditions are produced for engaging students in "in experiencing, creating, and solving real problems" (Lieberman 1995), motivating the use of professionally oriented language which is vital for its internalization (Berryman & Bailey 1992; Zahorik 1995).

Obviously, content-based TESP requires that an ESP practitioner have some specific competencies. These include the knowledge of the specialty basics (Master 1997), specific language, and field routine: "Text comprehension, a necessary precondition for the use of the text in the LSP [Language for Specific Purposes – T.S.] classroom, is facilitated by specialist knowledge and hindered by its absence" (Ferguson 1997). The field routine includes also the information technologies involved in handling information. Thus, an ESP instructor has to know, among other things, what technologies are used in the profession taught to his/her students. The use of operational technologies for professionally relevant problem solving offers the unlimited reserves for better ESP courses and, finally, quality education on the university level.

Technology in ESP Courses
P. Delcloque (1997) pointed out that foreign language teaching had always been on the forefront of using technologies. Ironically, as technologies become more sophisticated, they are less used in language teaching (op. cit.) - partly on the account of their inaccessibility, but mostly because of ESP practitioners' technofear (op. cit.) and their lack of specific competencies: having no idea of the specialty basics, they can - and are not scared to - use only the simplest of educational technologies (e.g., computer drills). Only a few technologically advanced instructors use multimedia in their language courses.

However, there is another class of technologies used in specialist training and thus considered educational. If instructional technologies are used for language learning facilitation, operational technologies, employed for information handling in the field, should be involved in ESP courses on the stage of communication practice. Their enormous educational potential is completely ignored by the Humanities faculty, though, if creatively used, they can significantly add up to instructional technologies' educational impact.

Operational Technologies in Business English Courses

Operational technologies can be integrated in Business English courses as the tools for manipulating professionally relevant information (obtaining, organizing, generating, and disseminating various data) that serves as the information base of further communication. "Requiring the learner to generate materials is a powerful technique" (Hammond 1989); using the learner-generated materials for further communication is another successful practice for facilitating language acquisition. This provides learners with the information to communicate and motivates the communication that helps internalize the knowledge of the language structure (declarative knowledge) and the skills of using it in professional settings (procedural knowledge).

The integration of operational technologies into Business English (BE) courses implies the use of software and hardware utilized in the business realm for solving professional problems. The software used can be classified as document-makers, information managers, information sources, presentations, and communication programs. The first include business card makers, business planners, marketing campaign builders, resume makers, etc. Information managers are the tools for manipulating various types of information; they comprise daily organizers, financial managers, project managers, etc. Finally, on top of the Internet, there are such information sources as small business packs, Incorporate™, Infobusiness Information USA & Government Giveaways™, and others. Business presentations in the format of computer slide shows are made with Microsoft PowerPoint™ or Corel Presentations™; this group also embraces Web page makers. Communication software includes e-mail, listserv, electronic billboards, etc. The types of operational technologies to be used in Business English courses are presented on Fig. 1:

**Figure 1.** Operational technologies in Business English courses.

Integrated into Business English courses, operational software is used in class as well as out of class, e.g., for students' projects and for preparing materials and handouts for role play, thus making the courses, in general, more functional and the classes, in particular, more authentic. "Requiring the learner to generate materials is a powerful technique" (Hammond 1989); using the learner-generated materials for further communication is another successful practice for facilitating language acquisition. This provides learners with the information to communicate and motivates the communication that helps internalize the knowledge of the language structure (declarative knowledge) and the skills of using it in professional settings (procedural knowledge).

Office equipment can also be integrated in BE courses for modeling business communication. It includes the tools for processing and multiplying documents to be used as handouts as well as the means of communication, e.g., telephone, fax machine, and modem. In some cases, video and audio can be involved in preparing presentations as well as multimedia.
In the original ESP course developed by the author for students of Economics, Management, and Finance at Northern International University, modern technologies are used as the integral part of the program:

Table 1. Educational Technologies at ESP classes.

This broad use of various technologies in the BE course not only improves the classes, bringing them closer to life, but also requires some specific skills from the ESP instructor.

Course-specified Competencies of a Business English Instructor

On top of the general competencies that include the language command, the knowledge of teaching methodology, cross-cultural techniques, the skills of classroom management (Johnstone 1997; Master 1997), and educational technologies, an ESP practitioner delivering a particular course, e.g. Business English, has to develop some specific competencies, based on the knowledge which is necessary for successfully arranging and managing classes in the professionally situated discourse. Educators (e.g. Ferguson 1997) define this knowledge as specialist knowledge, or «knowledge of the subject matter or profession of the students taught» (op. cit.).

However, this definition is not complete because it implies only the declarative part of specialist knowledge, completely ignoring its procedural part. The latter includes the routines of the profession and tools/technologies used for solving professional problems. So the course-specified competencies of an ESP practitioner comprise not only the basics of the specialty theory, but also their practical implementation through the use of operational technologies. Therefore, a Business English instructor should be competent in both business basics and technologies used in everyday business practice. Only then he/she can be reasonable and responsible in selecting the operational technologies to supplement his/her course and make it professionally relevant.

Operational Technologies in ESP Courses: Implementation Experiences

The framework used for successful implementation of operational technologies in professionally oriented language courses is presented below:
Starting with some basics ("Basic Business Concepts," "All About Companies," etc.), the author’s Business English course is structured according to five principal activities within the sphere of business:

1. Management
2. Marketing
3. Accounting
4. Finance
5. Computer and Data Processing.

Each theme comprises several topics, including various situations that are typical for professionally set communication. Considering the formats of information presented as the communication base, the instructor selects the technologies that facilitate manipulating this information. For instance, the “All About Companies” unit includes such topics as:

1. Company structure
2. Company profile
3. Jobs and responsibilities
4. Company hierarchy
5. Formal introductions, etc.

Considering the most typical situations and developing relevant tasks, the instructor comes to the following:

<table>
<thead>
<tr>
<th>Topic</th>
<th>Situation</th>
<th>Task</th>
<th>Technology</th>
</tr>
</thead>
<tbody>
<tr>
<td>Company structure</td>
<td>Telling a new employee about the company</td>
<td>Compile the organization chart presenting the company structure / the board</td>
<td>Corel WordPerfect™, Microsoft Office™, Adobe PageMaker™, ResuMail It!™</td>
</tr>
<tr>
<td>Company profile</td>
<td>Company presentation at an international business conference</td>
<td>Produce a computer slide presentation about the company</td>
<td>Corel Presentations™, Microsoft PowerPoint™</td>
</tr>
<tr>
<td>Jobs and responsibilities; company hierarchy</td>
<td>Recruiting new employees</td>
<td>Compile a Wanted ad</td>
<td>Corel WordPerfect™, Microsoft Office™, Adobe PageMaker™</td>
</tr>
<tr>
<td></td>
<td>Job interview</td>
<td>Generate a job application form</td>
<td>Corel WordPerfect™, Microsoft Office™, Adobe PageMaker™, ResuMail It!™</td>
</tr>
<tr>
<td></td>
<td>Meeting a business partner</td>
<td>Prepare a business card</td>
<td>Corel WordPerfect™</td>
</tr>
</tbody>
</table>

| Formal introductions                 | Meeting people at an international business conference | Prepare a business card                                             | Various business card makers                                              |

Table 2. Technology-enhanced Business English course: contents and operational technologies.

This framework, based on the Six T’s approach (see Master 1997), helps integrate renowned technologies and technological innovations on any stage of any ESP course.

Conclusion

Integrating operational technologies into Business English courses is best performed through using the Six T’s approach postulated by Stoller and Grabe (Master 1997). It implies structuring the course content from themes and topics.
to communicative situations and tasks as the assignments to be done by students. These should apparently include the seventh T - technology, both instructional and operational. The use of operational technology in BE courses would make them more authentic and successful and, finally, would help improve the quality of higher education, in general, which is vital in the age of information.

Abstract:
The quality education today is associated with the operational command of English as the vehicular language of the world business community. Successful teaching English for Specific Purposes (ESP) involves the use of technology-enhanced language-learning materials that present the authentic model of discourse as well as its genuine professionally determined background. Video as inexpensive and widely spread presentation technology has both advantages and drawbacks; an ESP practitioner has to employ the former so that they compensate the latter. The paper introduces an original video-based ESP material and the framework for its implementation in a university-level Business English course.

Introduction

Being instrumental within the global business community, English has become an integral part of quality education in the post-industrial society. In the format of English for Specific Purposes (ESP), it has taken a firm position in the university curricula outside the English-speaking world: «...Throughout the world there are similar trends towards increasing academic and professional stability and expanding markets, with the consequent need for specialized language skills» (Howard & Brown 1997). Consequently, «Special-purpose courses geared towards students' professional interests have become popular» (Scinicariello 1997). However, the ESP practitioners encounter the problem of teaching/learning materials scarcity or imperfection: the materials available either do not meet the needs of a specific ESP course or appear too general for it and thus can be used in fragments only on the early stages of specialized language learning. The observed trend to the greater variety of ESP courses is followed by their greater specialization. So, what we need today is the set of linguistically authentic, professionally relevant ESP course materials with the enormous matemagenic (Rothkopf 1979; Laurillard 1993) potential, to be used in class and in self-studies.

The increasing demand for constructivist ESP-learning materials, both informative and motivating, has only been partly satisfied. Obviously, the technology-based learning materials used in teaching Business English are rather scarce and limited to a few computer programs on top of numerous audio and several video courses. This reflects the troublesome tendency in teaching English as a Second Language in general, pointed out by P.Delcroque (1997): “Linguists... have made full use of audio, little use of video, and have been very slow to adapt to the computer revolution.”

Thus, only a small portion of the immense potential of video has been employed in language learning. The paper presents the work that aims in increasing the use of video in TESL/TESP and is an example of incorporating video materials in Business English university-level courses.

Video in TESP

Whatever a course is, technology is engaged in language learning to serve the general purpose of raising the language learning quality. The reasonable and well-grounded use of technology on the constant basis enhances the cognitive power of the course. However, it is vital to realize that «it is not the technology itself but rather the way in which teachers use the technology that has the potential to change education» (Carr et al. 1998).

Considered basically as a presentation technology modeling the language discourse (Dudley-Evans & StJohn 1998), video presents the language use patterns as well as the genuine communication background. Its undoubtful advantages are its affordability and accessibility: there hardly is a school where a video class would be impossible. Besides, video allows multiple repetitions of the presentation in a user-friendly mode, which also adds to its educational value, as well as its self-studying capacity. However, in terms of ESP teaching, it suffers several major drawbacks, such
as weak feedback, which certainly has to be compensated by the teacher in class.

According to M. Bush (1997), when trying to implement any technologically enhanced material in language teaching and learning, an ESP practitioner should consider the language model used in it, and develop the appropriate instructional design and system implementation strategies. In an ESP course based on the 'technology-as-a-supplement' model, the instructor has to consider both real and carrying content (Dudley-Evans & St John 1998), i.e. the language used and professionally valid context, presented in videos.

In the specially prepared language-learning video courses, the language used is carefully selected and to some extent simplified; therefore, the discourse presented there is but a blueprint of real-life communication. This makes it applicable on the primary stage of the learning process, as an introduction of the language material and a model of its use. Mastering the language command with time, students gradually come to need more authentic examples, containing more sophisticated language, and more life-like communicative situations. These can be found in movies.

Movies in TESP

As a source of the real-life discourse, movies are characterized by the authenticity of discourse and communication background. However, the general fault of all video materials, their weakened feedback, requires the additional efforts from the instructor aimed in stimulating the students' cognition and in motivating communication in class. The format of video implementation is of primary importance here.

In ESP courses, such as Business English, movies can be used in the following formats:

1) complete movie presentation (e.g., Take A Letter, Darling and Wall Street) with the proper introduction and feedback
2) movie fragment (e.g. job interview in The Firm), actively elaborated at the class
3) original video program, containing several movie fragments, comments, and feedback, and
4) a part of language-learning multimedia software, supplied with interactive assignments.

The first two formats are no news for an ESP practitioner and have been widely used, though the fault of the complete movie presentation is the feedback limited to classroom discussions and essay writing. The second two are less common because they involve more creativity, time, and technological competence from a teacher. However, when developed by a practicing educator in the context of a certain ESP course, they may be more successful than the renowned professionally prepared language-learning materials.

When producing an original language-learning movie-based video program, the instructor has to keep in mind the following faults of video as a teaching aid:

1) technically complicated and time-consuming revisions of the fragment;
2) background noises, e.g. city transport in the street, etc.
3) zero interactivity of the material.

Considering these drawbacks realistically, the ESP practitioner has to find a counterbalance for each. To waste no time for rewinding in class, he/she should copy the clip on the same cassette as many times as it is implied by the lesson format. Careful selection of episodes practically eliminates the background noise interference which can also be reduced technically or, much easier, through the use of the printed script in the workbook. But the zero interactivity problem appears the most difficult because it requires specifically designed language-learning materials; otherwise it takes a lot of creativity, time, and effort from the instructor to compensate it.

Each unit of professionally developed video courses contains the special feedback section. For instance, in the world-renowned Family Album, U.S.A. video course, an Activities section closes each of the three acts making an episode. However, the tasks offered are hardly interactive in terms of language learning, where interactivity implies the collaboration between the communicants and the context of situation. «Students achieve facility in using a language when their attention is focused on conveying and receiving authentic messages (that is, messages that contain information of interest to speaker and listener in a situation of importance to both). That is interaction...» (Rivers 1987). When using a movie as a basic discourse pattern for an ESL/ESP class, the instructor has to arrange the interaction part.

So, a quality video-based language-learning material would be linguistically and culturally authentic, informative, motivating, and interactive. Movies present the real-life communication in genuine settings; they supply language learners with valuable and veritable information on language and culture; they are intrinsically motivating because of the intricate; and, like any video they possess the zero interactivity potential. This determines the need to involve additional technologies that can provide the needed interactivity. One of these technologies is multimedia that combines the video and audio input with interactive feedback.
**Mergers and Acquisitions: Video-based Business English Materials**

The original video-based materials developed by the author for her Business English course taught at the Northern International University include:
1) the *Mergers and Acquisitions* video program
2) a corresponding module of the *Wiser Educator™* multimedia software.

The *Mergers and Acquisitions* video program is based on seven fragments of the 1987 20th Century Fox movie, *The Working Girl*. The fragments present an acquisition project from the idea to the completion and thus go with Unit 2 («Forms of Business Organization») of the content-based Business English course. Each fragment has been preceded with the video introduction, including comments on language and culture. The program was compiled and edited by the author with the use of the *Avid Cinema™* video editing software and is used as the presentation of both real (language) and carrying (professionally determined communication context) content.

The *Mergers and Acquisitions* multimedia module has been produced on the author’s platform of the *Wiser Educator™* multimedia authoring software, which allows to import video and audio clips and smart-link them with the text. It also helps generate exercises in five basic formats, thus providing multiple repetitions and revisions of each clip. The module is designed as the additional language training set.

**The Mergers and Acquisitions Video**

The *Mergers and Acquisitions* program is supplied with the workbook that, on top of the video fragment scripts and comments, contains the extensive reading material and assignments, thus providing the necessary feedback which has always been the Achilles’ heel of any language-learning video course.

The workbook is opened with the Introductory Reading that contains the basic information about mergers and acquisitions in business. It is followed by seven units, each presenting an episode in the strictly observed format, including the episode script, comments, and several stages of elaboration.

After the Preparation that implies reading and discussing the episode script and comments, each episode is supposed to be presented several times. First comes the Preview aiming in the general understanding of the situation; it is checked by questions about it. Next, the students move on to the View stage: they watch the movie fragment again and fill in the blanks in the script. After the Review, they have to do some writing assignments (prepare either reviews or essays on the given topics). Finally comes the Interaction, including role play and presentations. An important feature of this part of the unit is the outreach that implies the search for additional information to be used in role play and students’ presentations.

The workbook is completed with the Summing Up unit built around two groups of issues, Language and Business: while Language Issues aim in checking the mastery of the language material, both general and specific, Business Issues comprise more presentations, information search, and projects based on the material learned.

**The Mergers and Acquisitions Multimedia**

The multimedia module is based on the same episodes and the *Wiser Educator™* authoring system that allows compile five types of activities:
1) Matching, that implies finding the text of the phrase presented in a video fragment;
2) Sequencing, i.e. arranging the sentences in the correct order of the dialog presented in the video clip;
3) Gap Filling, that checks the knowledge of the unit vocabulary through filling the gaps in the text of the dialog;
4) True or False, testing the student’s knowledge of the whole situation; and
5) Multiple Choice, used to estimate the student’s knowledge of the communication background details, e.g. business etiquette, etc.

The smart-linking technique ties each of the activities with the video episode fragments. The activities allow develop both real (language) and carrying (professional) content. Since they do not coincide with those submitted in the video workbook, this module can be used independently as well as in the format of a training supplement to the video.
Software Selection

Software selection was based on the following qualities of the former:

1) its relevance to the task and material format. An ESP practitioner has to develop an accurate idea of the material he/she is planning to design. A movie-based language-learning program based on the theory of constructivism implies multiple presentations of the discourse patterns on the video, accomplished through several stages of watching the video and practicing the language structures, and extensive interaction, including role playing and various projects completed by students;

2) its user-friendliness, which is one of the most important technology characteristics for Humanities faculty, with their comparatively low level of technological proficiency and even technofear (Delcloque 1977). The author had a terrifying experience with several professional multimedia authoring systems and found that the Wiser Educator™ is surprisingly easy to use;

3) its time- and effort-saving capacity directly results from user-friendliness. It is vitally important for instructors involved with, so to speak, condensed courses that comprise long and frequent classes (e.g. intensive ESP programs).

Framework for Implementation

The Mergers and Acquisitions program is designed as the supplement to the corresponding unit of the Business English course. As such, it can be employed in parts as successfully as in the whole. In any case, the work starts with the Introductory Reading section to be completed before the first video presentation class. Practice shows that the most successful classes are conducted in the mixed format (general video presentation of each episode followed by its individual multimedia elaboration and completed with the interaction). Thus, the multimedia has to be included in the video presentation between the Preview and View stages. This significantly increases the number of motivated multiple revisions of each episode, which adds up to the successful accommodation of the language and background information. Thus, the acquisition of the professionally valuable language content and the cultural component of the discourse occurs within the constructivist paradigm that implies active learning, encouragement of deeper understanding through multiple responses to the unfamiliar stimuli, and learning in context (Berryman & Bailey 1992).

Movies in Business English: Entertainment in Education or Education in Entertainment?

The use of movies in ESP classes differs significantly from that of language-learning videos. Sharing such
characteristics as the enforced discourse presentation due to combining video with sound and the weak feedback, movies, however, are noted for their greater motivating capacity and emotional appeal. Successful integration of movies in ESP, e.g. Business English, courses requires that the instructor assess realistically all their technological advantages and drawbacks as well as the learning potential.

</tbody>
</table>

**Table 2. Language-learning video vs. specially selected movies in TESP**

The creative use of movies for knowledge construction in ESP courses is one way to realize the idea of easy, relaxed learning (Kitaygorodskaya 1986) that is known to facilitate language acquisition. A recently coined term, *edutainment*, finds another meaning here: this is not just learning with fun, it is using the educational potential of entertainment.

**Conclusion**

The language and background potential contained in some movies can be successfully used in ESP teaching and learning. An ESP practitioner can easily develop original audio and video programs as well as the multimedia learning modules that are highly authentic and close to his/her course. The synthesis of video and multimedia classes has proved highly successful at advanced Business English classes based on the authentic linguistic and extra-linguistic information presented in some movies. The author plans to continue the project, adding more interactive video programs and multimedia modules.

Technology, Language Arts, and Teacher Preparation: Stacking the Odds of Classroom Use

Rod Winters
Winona State University
Winona, Minnesota
United States
Rwinters@vax2.winona.msus.edu

Abstract: This paper presents the results of a university project funded by a Rural Integration of Technology in Education Grant from the U.S. Dept. of Education. The project, entitled "Tech Bridging for Literacy Development", involved collaborative use of communication technology across five sites involving preservice teachers, elementary pupils and university teaching methods faculty. Feedback results from participant groups indicated positive benefit from the project with regard to extended computer competencies and an increased likelihood of using technology in future classroom instruction. The preliminary findings support the perceived benefit of change efforts aimed at simultaneous involvement of multiple constituents in the infusion of technology-enhanced instruction. The report concludes with several recommendations aimed at overcoming some of the difficulties inherent in multi-site technology collaboration.

Introduction

During the past decade, universities have been repeatedly criticized for failing to equip future teachers to implement technology enhanced instruction. In particular, the 1993 report from the Office of Technology Assessment stated, "...Teacher education students are exposed to very few educators who use technology as a teaching tool in their preservice program and see very little technology use in their student teaching placements." (p. 4). Continuing study of classroom teachers in the 90s has confirmed that teachers are using computers far more frequently for administrative functions than for purposes associated with instruction (McCannon & Crews, 2000). As we turn the corner of the new century, a new sense of urgency for infusing technology into teacher education has been created, driven largely by competition and impending standards from professional accreditation organizations (Rogers, 2000).

Given the calls for change, it would appear that higher education personnel involved in teacher preparation need to simultaneously answer questions concerning two different components of preparedness: a) How can we increase the instruction-related technological capabilities of future teachers, and b) How can we change future teachers' plans for incorporating technology in their classrooms? This paper reports on the implementation and results of a project intended to address both questions.

Description of the project

During the spring of 2000, preservice teachers in reading and language arts methods courses at Winona State University participated in a semester-long project aimed at showcasing technology infusion possibilities for elementary language arts classrooms. The project, titled Tech Bridging for Literacy Development, sought to model two different approaches to classroom technology use, both of which allow teachers to sustain interactive communication around explorations of children's literature.

The first phase of the project involved preservice teachers from Winona State University and two other universities in the collaborative building of an interactive children's literature web site. Each preservice teacher enrolled in selected language arts methods courses at the universities read and reviewed a book from each of five different genres for the intermediate elementary grades (4-8). After creating the reviews in basic word processing software and utilizing spell checking tools, the preservice teachers were told to open a web-based version of File Maker Pro and search for the reviewed title. Students then made a new entry or continued an existing entry as they copied their reviews into the database.

The general structure of the reviews was prescribed to include the fulfillment of expectations, comments on author craft, and perceived connections to other books. Each review ended with a question for subsequent reviewers of the book.
The second phase of the project involved WSU preservice teachers in creating and sustaining a literacy conversation centered around a children's novel and carried on through a series of email exchanges with distant fifth grade partners. Students from WSU were partnered with students from two different elementary classrooms, one from a very diverse metropolitan area, and one from a rural town, population 2300.

Implementation: Anticipated and Realized Difficulties

The design of the project anticipated difficulties with coordination between the three university faculty as each person attempted to implement the project in different locales with varying technology access, varying computer platforms and applications. Voice and email conversations in the weeks prior to the project were scheduled to talk through foreseen difficulties. Similar early contact with elementary instructors attempted to address planning and computer access issues. At launch day, all parties appeared to have worked out logistics for initiation of the project.

Phase One, the database project, was initiated with WSU students by introducing the WSU students to a sample review along with modeled oral and written directions for accessing the database in the education computer lab. The first review of children's literature was assigned to be completed by February 15. Following instructor feedback on the initial review, students were given the rest of the semester to complete the remaining three reviews for the project, with a suggestion that they pace their reviews equally across the semester in roughly two to three week intervals. All students completed the required total of four reviews.

Unexpected difficulties arose in the intended collaboration between universities. Instructors from similar methods courses at a private institution in Minnesota and at a state institution in Georgia had agreed to have their students join the WSU students online in the collaborative development of the children's literature database. Repeated technology difficulties arose at the Georgia institution and scheduling issues made it difficult to anticipate participation from the private university in Minnesota. Although follow-up phone calls and email to Georgia were received positively, participation by the Georgia students was not apparent in the database by semester's end. In spite of this, the instructor did indicate interest in pursuing the project in the upcoming school year. Although the private university students from Minnesota did not providing identification coding, based upon a noticeably different structure in the reviews it was estimated that they made approximately 23 entries to the collaborative database. Project evaluation forms were not returned from either institution.

Phase Two, the literacy letter exchange was scheduled to coincide with an on-campus visit by one of the two fifth grade classes. The students from the metropolitan elementary made the 110-mile trip to visit the WSU campus in April 2000. In order to establish a leading relationship, the email exchange was scheduled to take place the two weeks prior to their arrival. The same email schedule was used to establish the email exchange with students from the rural elementary in hopes that they also would be able to make an on-campus visit. This proved to be an unfounded assumption as the field trip of 20 miles was subsequently denied. Nonetheless, the classroom teachers and the university instructor had agreed upon stopping points within the novels being read, and asked students to read up to a given stopping point by the date of each of the three email exchanges.

Difficulties arose almost immediately with the commencement of the first email exchange. Classes at the metropolitan school had never used email before. However, the media specialist there set up Hot Mail accounts for each student. However, after each scheduled email exchange, the WSU instructor typically received five to eight reports of problems where students had either not gotten email or had not responded back before time for the next exchange. The situation was complicated by the inability of the WSU instructor to schedule class time into the computer lab so that all emails would be sent at a given point in time. Also, the lab time at the metropolitan elementary was scheduled earlier in the day than the WSU course. Thus sometimes messages from WSU were sent on a specified day, but elementary students had already left the lab and could not return until their schedule permitted later in the following week.

Initial correspondence with the rural elementary also met with confusion. Students at the rural elementary had completed a computer unit earlier in the year and already had Hot Mail accounts established, so their teacher assumed that everything was in place. Upon the initiation of the email exchange from WSU however, it was discovered that several St. Charles students had been "kicked off" their Hot mail accounts because they had not been using them regularly. This led to delays in responses to emails as well. Eventually, the WSU college instructor tired of serving as the central clearinghouse for complaints and provided emails for all participants to the college students and classroom teachers. This appeared to help resolve issues more quickly, although a few students continued to report difficulty establishing and maintaining contact.

College students were asked to submit a printed copy of their email exchanges for instructor review. All college students completed at least three email messages by the end of the planned time. A culminating activity was planned for the face-to-face meeting with the students. College students were placed into groups of three or four, and were asked to design a game board using the theme of the shared novel. Students then developed questions at three different levels of comprehension and used the questions as question cards in the playing of the game. The games provided a comfortable structure for interaction when the students from the metropolitan elementary came to meet their key pal on campus. The group working with the rural elementary ended their exchange with a final email telling the students that their games were going to be delivered to the school for the fifth graders to use in class time.
Results of Phase I: Collaborative Database

Both projects were completed by May 1, 2000. At the conclusion of the database project, WSU students were asked to complete a one-page project evaluation form, which incorporated both Likert scale items and open ended sentence completion items.

The Likert Scale items asked students to respond to four statements: a) I think the database project is more enjoyable than index card reviews of children's literature for future teachers, b) I think the database project is more effective than index card reviews of children's literature for future teachers, c) This project extended my ability to use technology, and d) This project increased the likelihood that I would consider using technology in my classroom in the future. Data collection for the database phase of the project resulted in eight sets of usable preservice teacher feedback data from WSU students. This report will focus on the data sets from preservice teachers.

From the Likert Scale items, a majority of students reported that the database project was more enjoyable (87% agree or strongly agree) and that the database project was more effective than traditional index card reviews of children's literature (87% agree or strongly agree). A majority indicated that the project had extended their ability to use technology (75% agree), while 100% of the respondents felt the project increased the likelihood of using technology in their classroom in the future (12% strongly agree; 88% agree). The latter finding goes directly to a guiding question for the project: Can technology-based projects in preservice literacy methods change future teachers' plans for incorporating technology in their classrooms? The limited results of this project would indicate a positive answer to this question.

From the sentence completion portion of the project evaluation, it appears that students felt the project developed their capability for teaching by its focus on different genres of children's literature, and appreciated it most for providing access to their peers' reviews of books. The aspects of the project that students appreciated least were clustered around issues with technology. However student suggestions for refinement of the project were decidedly not technology improvements, but rather a variety of shifts in directions, genres, and sharing of reviews.

Results of Phase II: Email

Similar to the database project, students were asked to complete a one-page project evaluation form, which incorporated both Likert scale items and open ended sentence completion items. Data collection for the email phase of the project resulted in forty-seven sets of usable elementary student feedback data, two sets of usable elementary teacher feedback data, and sixteen sets of usable preservice teacher feedback data from WSU students. This report will focus on the data sets from preservice teachers.

Similar to the database project, Likert Scale items indicated strong support for the project in general. Students were in general agreement that the email project was more enjoyable than traditional index card reviews of children's literature (88% agreed or strongly agreed). A similar majority felt that the project extended their capability to engage in informal but meaningful book talks. The group split evenly over whether the project extended their ability to use technology (50% disagreed or strongly disagreed). It was somewhat surprising to the author that 50% of the students thought it did extend their tech capability, given that the email technology under consideration is relatively common at the university level.

As in the database evaluation, the last item went directly to the guiding question for the project: Can technology-based projects in preservice literacy methods change future teachers' plans for incorporating technology in their classrooms? Once again, the responses were strongly affirmative (100% of students agreeing or strongly agreeing).

When students were asked what they appreciated most about the project in the sentence completion portion of the project evaluation, students felt the project developed their capability for teaching: the project focus on informal interaction and understanding of elementary student views as well as realistic technology utilization. When asked about the aspect of the project they least appreciated, several students stated they had no problems with the project. However, others indicated concern that the email was too structured both in terms of a given number of exchanges and the content of the exchanges. Student suggestions for refinement of the project focussed on procedural improvements to ensure that students had more regular and frequent exchanges.

Conclusion & Recommendations

Any results or conclusions drawn from the two-phase project should be considered as tentative at this point. The difficulties with technology access, the constrained timeline for email exchange, the less than full participation of collaborating institutions, and the limitations of the data gathering system employed would each need to be addressed
before drawing firm conclusions from such a study. Nonetheless there are possible insights to be gained from the project's implementation and findings.

Insights and recommendations from the implementation of the database project are threefold. First, future projects might explore providing extended time for "silent mentoring" of would-be instructor participants. The time necessary for mentoring would allow the technical issues to be addressed prior to beginning the project. Secondly, it is recommended that future project investigate the establishment of a "scouting team" of would-be college student collaborators. The scouting team would allow clarification of project requirements and create on-site champions of the project to encourage subsequent participants in the project. Finally, it is recommended that project originators gain advance agreements from would-be college instructor participants. Such agreements would involve a commitment to joint ownership of the completion of the project as well as completion and return of project evaluation forms.

Several specific recommendations pertaining to subsequent email collaboration projects are also made. First, a less restricted schedule of email exchanges should be utilized. The fixed schedule of three exchanges was utilized in the current project to insure no student was left out. However, such limitations seem to run counter to the ever-present nature of email communication. An unlimited number of exchanges across a longer duration of time should be explored to allow individual student participants to tailor the project to their own needs and all participants should have needed contact information to re-establish contact in the likely event of missed exchanges.

Lastly, the technical difficulties of distant collaboration for technology should not overshadow the benefit of such projects. In spite of the frustrations which accompanied the logistics of such networks, all participants involved expressed a desire for continuation of such projects.

Innovative Software-based Strategies for Reading/Listening Comprehension:  
how Information Technology is Reforming Foreign Language Acquisition

Zhang Senquan  
Faculty of Education  
University of Ottawa  
Canada  
senquanzhang@hotmail.com

Abstract: This paper presents supporting background information for the interactive session where the actual hands-on use of reading/listening comprehension software has taken place. To provide the larger context for using IT (Information Technology) software, the methodological and theoretical framework of IT is discussed, from the viewpoint of SLA (Second Language Acquisition) theory and practice. By training SLA teachers to delegate the more mechanical "programmable" linguistic skills to CALL (Computer Assisted Language Learning) software, more emphasis can be placed on the practical aspects of language use and language socialization, and acquisition of cross-cultural interaction skills. Emphasized is the role of IT-based reading and listening comprehension tools that enable the learner to work independently with authentic foreign language texts from the Internet.

Introduction

In my work as a teacher of the English language in China and a teacher of the Chinese language in Canada, I have witnessed a wide spectrum of phenomena in language teaching, methodology and foreign language didactics, ranging from the rote learning of vocabulary from word lists to computer-based courseware. No doubt, computer-based instructional technology and educational media have gone a long way during the past decade, since the outlook given by Last (1992) on computers and language learning. In my Master's thesis (Zhang, 1997) I emphasized the importance of a needs analysis for IT-based language instruction, while in my present doctoral research I lay stress on the cross-cultural component of communicative competence, and on the communicative aspects of language socialization (Lazaraton, 1995). Employing IT in language teaching benefits teachers and students, because more time and effort can be devoted to issues of language use in a naturalistic environment (Tesch, 1990), in particular to the issue of cross-cultural understanding in real life settings. Thus, my message to language teachers and students alike can be summarized: making full use of interactive multimedia computer technology, both in the authoring of teaching materials, in language teaching and learning itself and - the special concern of this paper - in using analytic software tools for the acquisition of reading/listening comprehension skills, allows teachers and students to focus their attention on issues of the students' language socialization.

The Dichotomy in SLA

For a brief background overview, let us for the moment disregard instructional technology and other IT aspects and look at the area of SLA. In the theory and practice of SLA we are confronted with a deep-rooted dichotomy: on the one hand, there is an understanding of language as closed system of formal knowledge (Chomsky, 1965) that allows the learner to generate grammatically correct sentences; on the other hand, Hymes (1970) and his followers view language as social behaviour, thus including the cultural aspects of language communication. Both interpretations of language have their advocates among the practitioners of language teaching, and both views are reflected in the design of language courseware that has been published during the past decade, as will be discussed in the next chapters.
Within a theory discussion of the background in SLA, another dichotomy must be mentioned: the polarization in research methodology, resulting in the diametrically opposed quantitative and qualitative approaches. Although the boundaries are not always sharp and clearly cut, in general the linguistically oriented researchers favour quantitative research methods, and they outnumber the qualitative researchers who have an ethnographic orientation. In her discussion of applied linguistics, Davis (1995) points out that the social and cultural aspects of language acquisition have been considered less important than the mental processes involved in language acquisition. SLA studies usually do not have a sociological orientation, and many sociolinguists use methods from psychology, and have a positivist perspective, collecting data through experimental techniques or surveys, and analyzing the data through statistical methods. In the SLA discussion among these different schools, the opinion of Lazaraton (1995) stands out: she advocates the principle of Language Socialization, which is defined as language use in non-instructional, real-life settings – the opposite of language acquisition in a controlled, pre-programmed environment that is based on the quantitative testing of linguistic skills. This reflects the concern of the functionalists’ view of language “what is language for?” instead of the formalists’ concern “how is language learned?”

Firth & Wagner (1997) point out that in traditionally oriented language SLA research the social factors of emic relevance are neglected, and that most socially and contextually oriented studies relating to language research tend to take the formal learning environment, typically the second and foreign language classroom, as the point of departure. They further lament that although second and foreign language interactions occurring in non-instructional settings, such as in the workplace, are everyday occurrences, but they have not yet attracted the attention of SLA researchers. Such views are motivating language teachers and educational experts to rethink and renovate existing SLA syllabi that are built on traditional designs and traditional methods; courseware that is technology-based may sometimes be merely a presentation of old contents in a new-looking hi-tech wrapping.

From Courseware to IT Language Learning Tools

The concept of “Information Technology” (IT) as it is used in this paper within the SLA context, particularly for the acquisition of reading and listening comprehension in the foreign language, does not necessarily include all computer-based courseware. In order to call itself IT-based, a learning program has to take advantage of certain capabilities that are inherent in computer technology, especially computer software, such as electronic search functions and interactive multimedia features that allow learners to dynamically interact with the foreign language text they are trying to understand. For example, a CD-ROM-based program that presents text in static format, using the same linear programming as in a book, would not be included in this concept of “IT”, because it would miss the dynamic factor.

In order to illustrate the general focus of discussions in CALL (Computer Assisted Language Learning) literature, we take a look at a few samples of such discussions. A relatively early (1992) overview of the area of CALL covers the time since the first experiments with simple tutorials in the mid-1970s, commenting in great detail on the simple linear interaction in tutorial mode between the learner and the computer. “This simple tutorial mode of interaction formed the basis of the first generation of CALL software, although the ingenuity of the software writers caused it to extend far beyond the question-and-answer mode ... the issue rapidly broadened into a recognition of the importance of the user interface as a whole in promoting good CALL practice and encouraging the learner to treat the computer as a reliable and non-threatening tutor” (Last 1992). Describing the desirable and undesirable features of a CALL software package, a higher degree of flexibility in the course design is then suggested. “... there should be a feeling of flexibility in the package as a whole; in other words, many packages have an extremely limited form of interaction. A word is flashed on the screen and you have to offer up the Spanish or French or German for that word. Nothing else is on parade - no contextualization, no tests of the gender, no listing of synonyms, no help panels, and in such circumstances the poverty of the learning environment soon causes the learner to tire of what ought to be recognized as a highly intensive interactive mode” (Last 1992). A further concept which considered to be a successful computer application is the field of clozentropy (gap testing), with the goal of improving the learner’s inferencing ability, or guessing strategy. The author concludes the article by stating that CALL has still not achieved the critical mass of a mature and universally supported discipline, and there are still many in the profession “who are frankly suspicious that the computer is being applied to teaching the wrong things in the wrong way” (Last 1992, pp. 227-245).
An article by Zekulin (1993) about instructional computer technology was published in a collection of papers from the International Colloquium on the Teaching and Learning of Modern Languages held at the University of Ottawa in 1993. The author draws from his experience with the computer language lab at the University of Calgary. Since 1991 when the lab was established, students of first and second year Russian and Japanese use the computer lab as a part of the regular course requirement; starting in 1992, computer exercises for first and second year Chinese were introduced. Students also use the lab on a drop-in basis for self-study. The article warns against the numerous pitfalls the course designer of a language course might encounter. CALL is described as a highly labor-intensive approach to learning a language, the importance of efficient courseware is stressed, and the difficulties are mentioned for using a cognitive approach to L2 learning on the computer. “A number of people originally welcomed CALL because they saw it as a means of relegating repetitive and therefore boring tasks to the computer. This ignores the fact that if the task is boring for the instructor, it is likely to be boring for the student and is therefore unlikely to be pedagogically effective. Computer exercises are excellent for pattern customization, but rather more tricky for assisting with intellectual understanding. This problem can be exacerbated by the fact that students often ignore instructions and explanatory screens that precede the exercise in their eagerness to ‘get on with the exercise itself’, and, furthermore, in doing computer exercises, some students are primarily interested in right and wrong answers, less in why a particular answer is right or wrong.” (Zekulin 1993). Guidelines for courseware design are: the screen should not just be treated as an electronic book; attempts to emulate computer games in CALL courseware are “doomed to failure (we cannot match the arcade), while in fact disguising the seriousness of what we are doing”, and “careful design regarding the length of one exercise; dividing long exercises into several shorter ones has proven effective” (Zekulin 1993, pp. 230-238).

In their recent quantitative study, Herron et al. (2000) measure whether and to what extent a video language course can teach overall cultural knowledge, and their results support that video is an effective technological tool for presenting culture in the FL classroom. However, after mention of several references corroborating this view, we find a warning about possible interferences between the visual component of the video and the learner’s comprehension. “However, this positive view of using video to teach culture is not unanimously shared. It could be that the first time students watch a video, the processing of syntactic information could place such a high cognitive demand on the students that they are unable to process any other kind of information (e.g. cultural information). This processign problem is one of the major tenets of the capacity theory of text comprehension (Just & Carpenter, 1992). According to this theory, it may be overly optimistic to think that first semester French students will be able simultaneously to process both the linguistic and the cultural information from an authentic video” (Herron et al. 2000, p. 397).

All these discussions are about designing learning programs, and writing and handling content. It is the goal of my presentation to add to the discussion with the concept of a analytic instrument in form of an IT-based “Comprehension and Learning Tool”, which I perceive to be the application of the future in IT-oriented SLA operations. Undoubtedly courseware may have its purpose at an introductory level, but at the same time a universally applicable reading comprehension tool should be given to the language learners as early as possible, enabling them to learn reading foreign language texts of their choice in an independent manner, from the largest pool of electronic text available: the Internet. “Software selection is one of the first tasks in establishing a CALL program. A considerable literature exists which offers advice to teachers on how to choose software that will be suitable for their students, syllabus and curriculum. On the other hand, the actual dynamics of software acquisition, while mentioned occasionally in the literature, has not, to our knowledge, been studied in detail” (Robb & Susser 2000, p. 41). Regarding IT in SLA, we have to think beyond electronic courseware, by using analytic, text-exploratory comprehension learning tools, for an independent, student-centered CALL approach, as an important supplement to the existing courseware.

**IT in SLA: Comprehension Learning Tools**

We now investigate the ultimate concept of “IT in SLA” which I demonstrated in my interactive session and which is in the focus of this paper: combining the principle of language use in naturalistic, real-world settings with the analytic power of computer software. In addition to the courseware with its predetermined content, the language student should be given a “content-free” language comprehension and language leaning tool that is universally applicable to any foreign language text in electronic format. The main
intention here is to lead the students to an authentic real-world context. I demonstrated this principle in my interactive session through the KEY software (detailed instructions for computer-assisted text analysis see on the “Multimedia” page of www.cjkware.com), as an example of an IT tool for learning to read and comprehend foreign language text. Such software tools enable even beginners to independently develop a reading and listening comprehension of foreign language texts. The interactive session demonstrated how an analytic software tool can benefit teachers and students through

- Opening the door to information that is written in a foreign language
- Acting as the key to reading foreign language content on the Internet
- Allowing language learners to independently acquire reading and listening comprehension skills in a foreign language, at an early level
- Doing away with rote learning of vocabulary: whether using the software tool to read Chinese (as demonstrated in the interactive session) or English (within ESL) or any other language, students can devote more time and effort to reading about their subjects of interest in the second language
- In the case of Chinese, automatically bridging the gap that exists in the written Chinese language between traditional characters (used in Hong Kong, Taiwan and the overseas Chinese communities) and simplified characters (used in China and Singapore)
- Enabling non-English readers to read English newspapers, magazines and other publications.

Conclusions

Based on the principle of language socialization, IT in foreign language learning that combines content-oriented courseware with multimedia comprehension tools is ideal for language learners to achieve reading/listening comprehension skills. Having powerful analytic software tools at hand helps students apply confidently the knowledge and skills they acquired in content-based language courses, when they encounter real-world authentic text environments, which would otherwise intimidate them. For the reader who ventures out into the ocean of the foreign-language Internet, such tools are a reliable floating aid.

References

The importance of technology in the teaching and learning process has gained considerable support from educational institutions at all levels. As technology is increasingly incorporated into teaching and learning, researchers are answering the call for a better understanding of technology’s role in education. This year’s SITE conference papers reflect many issues that contribute to this understanding. The authors of these contributions highlighted students’, teachers’, and administrators’ perceptions of technology and technology use, differences in competence and use of Instructional Technology (IT), evaluation of technology use in practice, and methodological issues in the use of IT.

Perceptions of technology and technology use

Many articles fell into the category of perceptions of technology and technology use. Askar & Umay related self-efficacy, attitudes, and perceptions to computer use by preservice elementary mathematics teachers in Turkey in their research. Askar & Usluel interviewed teachers and administrators in Turkey regarding an IT innovation and content analyses revealed two different diffusion processes: as an instructional tool, and as a management tool. Berson & Armstrong study technology beliefs and practices among graduating teacher education majors focusing on the International Society for Teacher Education’s (SITE) National Educational Technology Standards (NETS). Chambers, Smith, Hardy & Sienty used the Myers-Briggs Type Indicator (MBTI) to identify personality types of teachers, which were then related to teachers’ willingness to use technology. deMontigny, Cloutier, Ouellet, Courville & Rondeau studied teachers’ information and communication technology (ICT) self-efficacy preliminary to introducing ICT components into a Nursing Master’s Program in Quebec. Heafner & McCoy reported on a survey of computer use and attitudes towards computers of seniors at a computer intensive liberal arts college that supplies each student with a personal laptop. Janz reported a survey study to determine how the use of a notebook computer will impact a student’s computer experience, confidence, and attitudes when compared to those of a traditional university student. Kemker, Harmes, Kalaydjian & Barron focused on a survey of over two thousand teachers targeting their attitudes toward and use of computers in instruction, with specific emphasis on classroom uses consistent with the proposed National Educational Standards (NETS) for teachers and students. Litton reports a study addressing how the use of technology impacts teacher education programs by exploring what teacher education students learn besides content knowledge when using technology in the classroom. Owens & Magoun conducted a study of junior high girls to encourage enthusiasm for computer science and applications through an intensive summer program. Prater & MacNeil compare perceptions of instructional use of technology by teachers and principals. Results found that principals perceived students were using technology for higher level skills such as desktop publishing whereas teachers perceived student use for more drill and practice activities. Wang studied the redefined role of the teacher as technology is incorporated into teaching and learning. The focus of Wang’s research centered on preservice teachers’ perceptions when teaching with or without computers.

Differences in competence and use of Instructional Technology

Several articles came under the category of differences in competence and use of IT. Ang, Edwards, Kim, Little, Matuszak, Simmons, Stinson & Pierson reviewed constructivist-oriented practices supporting technology, cost-effectiveness of technology use, the effectiveness of virtual field trips, instructional courseware, online discussion tools, and computerized tests. Borthwick, Handler & McGrath, in seeking to determine the features of outstanding doctoral programs through survey and interview techniques, point out that the field lacks clear consistent definitions of terms such as IT, Instructional Design and Educational Technology. Heath, Burns, Dimock & Ravitz
focused on answering three questions: (1) What do constructivist learning environments (CLEs) supported by technology look like in practice? (2) How can teachers be assisted in developing CLEs supported by technology? (3) How does technology facilitate the development of a CLE? Hughes seeks to characterize some uses of web page data and the most common experiences of researchers who are new to the experience of working with large amounts of information in a theoretical paper. Leh & Ogata’s work focused on how teachers use technology to better address the needs of diverse populations. Liu & Cheeks found that the nature of assessing technology-assisted use of information was to assess a learning process as well as specific skills. Pastore addressed how the effect of multimedia software training can be used to move from a teacher centered classroom to a more student centered environment. Reehm, Long & Dickey used performance criteria established by the Kentucky Department of Education technology standards to compare confidence among undergraduate and graduate education majors to non-education majors. Schmertzing & Schmertzing studied graduate education students’ adaptation from traditional instruction to a technologically mediated classroom. Sherry & Billig presented findings from a five year Technology Innovation Challenge Grant purposing to infuse technology into multimedia, digital art, music composition and online discourse into the curricula of Vermont’s schools.

Evaluation of technology use in practice

In the category of evaluation of technology use in practice, Sangrà & Bellot examined the use of information and communication technologies (ICT) in non-university settings in Spain using a survey, interviews, round tables and discussions. Bornas & Llabrés found that dynamic helping software combined with teacher assistance was more effective than software providing static help. Civiletti, Santos & Santoro used a longitudinal case-study method with genetic text analysis to focus on teacher effects during situations involving cooperative learning and autonomy. Dean provided a quasi-experimental program evaluation of a teacher preparation program designed to help teachers integrate technology into their teaching in the state of Washington. Elliott examined student teachers’ ICT experiences in Australia with an eye to improving teacher preparation programs. Flowers, Jordan, Algozzine, Spooner & Fisher reported on a quasi-experimental study of student evaluations of the effectiveness of distance education courses and instructors. Guimaraes described a program in which teachers are introduced to and learn to evaluate educational software programs before leading students in educational activities. Juliana describe qualitative research focusing on 3rd and 4th grade students’ understanding of science concepts before and after a technology rich learning experience in order to answer the question: How does technology support higher order thinking goals about science concepts? Kamb & Niederhauser examined self-efficacy and peer status as factors that influence interactions between students working in learning groups on a computer-centered activity. Kilbane examined the effects of CaseNET, a professional development course using case methods and web-assisted technology, on pre-service teachers’ classroom problem solving skills. Leh & Keeler present case studies and action research to illustrate technology use in today’s English as a Second Language (ESL) classrooms. Loveless, Taylor and Millwood addressed the progression in practice of visual literacy and information and communication technology (ICT) through a series of projects in a five year period. Lucking, Rovai & Ireland studied the impact of classroom community in a higher education classroom. This complex study looked at multiple factors including distance versus traditional instruction, type of school, level of schooling and gender. Preservice teachers were studied to help determine if technology activities encouraged higher cognitive levels using an adaptation of Bloom’s taxonomy and ACOT scales in Murphy and McFarland’s research. Nail, Hare, Davidson, Ferguson & Leman used a qualitative study to determine if an educational technologist was helpful in facilitating technology integration in the K-12 classroom. Rhodes reports that students from impoverished areas have too little access to IT; teachers have insufficient time to learn to use programs; and staff development on effective use of technology is not emphasized. Stuckey, Hedberg and Lockyer examined the role of an on-line professional development strategy and teacher implementation of a software application for the performing arts program in K-12 schools. Weber & Sabine present experiences from the HALUBO Project dealing with the relation between intercultural competence and the Internet. Willis, Tucker, Rowland, Wong & LeCrone studied the effectiveness of K-12 schools and universities in preparing a literate workforce. Methodological issues in the use of Instructional Technology

The final category was methodological issues in the study of IT. Christensen & Knezek described the Technology in Education Competency Survey (TECS) related to NCATE standards. Balioan, Ochoa & Fuller presented a model for designing courses based on the authors’ experiences designing and redesigning a software engineering course. Hughes & Walker provided a meta-analysis of text and documents in the public domain to characterize and evaluate the methodology adopted during IT course evaluation in the United Kingdom and the USA. Major suggests distance education courses should contain
multiple communication methods including threaded online discussions, video conferencing as well as printed materials for optimal effectiveness. Shotsberger extended research from an earlier SITE paper to encompass synchronous dialogue generated from a Web based inservice program using a qualitative analysis software package. Thomas, Wilkinson, Marr, Thomas & Buboltz studied measures to decrease the attrition rate in engineering programs through the instructional technique precision teaching in a web based approach.

Dr. Reagan Curtis completed his Ph.D. in Education at the University of California at Santa Barbara and is currently an assistant professor in educational psychology at Northwestern State University. He currently teaches courses in human development, research methods, and statistics. His research focuses on the development of quantitative knowledge from infancy and cross-cultural mathematical development.

Concerns Of Administrators And Teachers In The Diffusion Of IT In Schools: A Case Study From Turkey

Petek Askar
Department of Computer Education and Instructional Technology
Hacettepe University
Turkiye
paskar@hacettepe.edu.tr

Yasemin (Kocak) Usluel
Department of Computer Education and Instructional Technology
Hacettepe University
Turkiye
kocak@hacettepe.edu.tr

Abstract: In this study 27 teachers and 6 administrators from three primary schools in Ankara were interviewed about the characteristics of IT: relative advantage, compatibility, complexity, triability and observability. In addition, the stages of concerns (awareness, informational, personal, management, consequence, collaboration and refocusing) of the teachers were assessed. Overall %30 of the teachers showed no interest in using computers. %40 of the teachers are between at awareness and personal stages. 30% the teachers are at the management stage.

Introduction

Use of information technology in schools for the purpose of teaching and learning is a kind of diffusion process in which IT is an innovation which is defined by Rogers (1995, p.11) as "any idea, practice or object that is perceived as new by an individual or other unit of adoption". In fact, IT as a relatively new building block in the educational system, causes innovations which ranges from way of communications, and interactions to teaching methods, and materials.

Information technology were first introduced to schools in Turkey in 1984. Since then, computer literacy courses have been offered as elective courses in the primary and secondary schools. On the other hand Ministry of National Education has allocated considerable about of budget for the diffusion of computers in the teaching and learning process. For the diffusion of IT into schools, so many efforts have been undertaken like inservice training of teachers and administrators, courseware and educational material development and training of computer coordinators. The type of innovation-decisions in the educational system in Turkey are authority innovation-decisions which is explained by Rogers as the choices to adopt or reject an innovation that are made by a relatively few individuals in a system who possess power, status or technical expertise. The body of authority is the key policy makers in the Ministry of National Education for all levels of schools. However the implementation of any innovation, including IT is under the responsibility of the schools. Therefore the adoption rate varies due to the administrators and teachers. To install a computer lab or to get a trained teacher (computer coordinator) do not imply that adoption is successful even it is an authority innovation-decision.

The evaluation of one of the World Bank supported experimental study showed that: those schools with laboratories that were not yet in full operation often lacked computer formator teachers or computer teachers. On the other hand not all subject teachers are interested in training. One school reported that only 15% of the teachers attended in-school training (Askar, Rehbein, Noel, 1996).

The theoretical framework of this research is based on these four elements defined by Rogers (1995, p.10-35). As stated by Hall & Hord (1987), the diffusion of an innovation process strongly depends on the experiences, concerns, skills and knowledge of the individuals and groups involved in the innovation. In addition according to Hall, George and Rutherhord, (1998), concerns will vary depending on the amount of one's knowledge about and experience with the innovation. Therefore concerns of the teachers and administrators play an important role in the diffusion of IT in the schools (Dooley, Metcalf, Martinez, 1999).
Study

In this study 37 teachers and 6 administrators (three of them are principals, the others are deputies) from three schools A, B and C were interviewed. School A, a private school, has been using computers for about seven years. School B, a public school, is a curriculum laboratory school which has received computers three years ago. School C, another public school, has started to use computers in this semester. The data were analyzed qualitatively. Content analyses was used and coding categories were created. It seems that there are two different diffusion processes: IT as an instructional tool and IT as a management tool.

Findings and Conclusions

Relative Advantage: One of the characteristics of an innovation as stated by Rogers (1995) is the relative advantage which is the degree to which an innovation is perceived as advantageous. Over all, this study has presented the advantage of using computers as a management tool. The perceived advantage is higher in School A which is using computers for at least seven years. However, many questions were raised when the computers are taken as instructional tools. The reasons for the concerns are related to crowded classrooms, curricula and the age of teachers. One classroom teacher stated that “computers are for younger teachers.” Compatibility: Compatibility is the degree to which an innovation is perceived as being consistent with the existing applications in the schools. The results showed that in School A, teachers rated the degree of compatibility of computers as near to high where in the other schools they are rated as near to low. Complexity: In this study complexity is taken as the degree to which computer is perceived as difficult to understand and use. The results showed that teachers could be categorized in two groups. One group perceived computers as a very complex device, the others perceived as an easy tool to handle. These groups differ according to their ages. As age increases, the number of teachers regarding computers as complex devices getting higher. Triability: Triability is the degree to which computer as a tool experimented with on a limited basis in schools. As a management tool, it is perceived as triable. In fact as an instructional tool the rate of triability is very low. Observability: Observability is the degree to which the results of using computers in the schools are visible to others. As a management tool, preparing lesson plans, giving the test results or developing presentation materials are visible at some degree. However, teachers haven’t seen enough examples for using computers as instructional tools.

Most of the teachers in the study showed their willingness to use computers for various reasons. One dominating reason is that, to know how to use computers is a necessary skill for information age. Another reason for using computers is its storage capability in which lesson and unit plans could be used several times with little changes, without making extra effort. Surprisingly, only one teacher out of 33 mentioned its impact on students’ learning by stating its capabilities.

The stages of concerns by Hall was stated as: awareness, informational, personal, management, consequence, collaboration, refocusing. Overall 30% of teachers in the study has no concern about computers as a management tool. We can not regard them even in the awareness stages. Most of these teachers are in School C in which a computer laboratory has been recently installed. Overall 40% of the teachers are between awareness and management stages. They have general awareness of the use of computer in their daily routines, they are uncertain of their inadequacy to meet all their needs. 30% the teachers (Most of them are at school A) are at the management stage. Their attention is focused on the processes and tasks of using computers and the best use of information and resources. Only one teacher is at the consequence stage. She mentioned the impact of computers on students and focused on the relevance of computers for students.

Preservice Elementary Mathematics Teachers' Computer Self-Efficacy, Attitudes towards Computers, and their Perceptions of Computer-Enriched Learning Environments

Petek Askar
Department of Computer Education and Instructional Technology
Hacettepe University
Turkiye
paskar@hacettepe.edu.tr

Aysun Umay
Department of Primary Education
Hacettepe University
Turkiye
aumay@hacettepe.edu.tr

Abstract: In this study 155 preservice elementary mathematics teachers responses were taken on Computer Self-Efficacy (CSE), Attitudes toward Computers (ATC), Perception of Computer-Enriched Teaching Environment (PCETE). The study showed that preservice elementary mathematics teachers have positive attitudes toward using computers, and learning and teaching with computers. They believe that CAI is better and more comfortable way of learning than are conventional methods. On the other hand their self efficacy in using computers is low.

Introduction

Increasingly, the schools are focusing their attention on the use of computer as a management and teaching-learning tool. The computer not only demands changes in the school environment, but also requires new roles for the teachers. In fact, majority of the teachers have concerns in adopting computer as a tool to use in their daily applications. Lack of or inadequate training is one of the reason why teachers are not using computers for their courses. Moreover, studies stating that, students, in general, are far more knowledgeable than their teachers. It is obvious that unless teachers feel comfortable with the new technologies they will be unwilling or unable to use them meaningfully. On the other hand, research studies showed that most of the time in-service training programs are not effective and efficient for many reasons. Therefore preservice teacher training is getting more important.

The efforts for using computers in Turkey are growing exponentially. This leads to changes in preservice teacher training programs. One of the differences is the computer courses added in the preservice mathematics teachers training programs. Preservice mathematics teachers enrolled in the School of Education at the Hacettepe University in Ankara are required to take three courses related to computers: Computer Literacy, Instructional Technology and Material Development and Computer-Based Mathematics Instruction. The reason for these courses is to prepare the teacher candidates to be confident and competent in using computers in the schools.

In addition to the organizational implementations, individual differences in using computers is another critical issue to be taken into consideration. One of the concept that can explain individual differences in computer acceptance and utilization is computer self-efficacy which is defined as a judgement of one's capability to use a computer (Yi, M.Y., & Venkatesh, V. 1996). Expectations of personal mastery affect both initiation and persistence of coping behavior (Bandura, 1977). One of the sources for efficacy expectation is performance accomplishment. The effects of failure on personal efficacy partly depend on timing and the total pattern of experiences in which failures occur. Another source of information is seeing others perform threatening activities. If others can do it, they should be able to achieve at least some improvement in performance. (Bandura, 1977). A study done in Turkey showed that a course on computer literacy for preservice teachers increased their self-efficacy in application tools (Cakiroglu & others, 1999). Another issue might be related to the acceptance of computer usage in educational setting is its perceived characteristics in terms of usefulness and difficulty as a management and teaching-learning tool.
The purpose of the study is to address the following questions:
1. What is the computer self-efficacy (CSE) of preservice elementary mathematics teachers?
2. What is the attitude of students towards computers (ATC) in terms of usefulness and difficulty?
3. What are students' perceptions of the difference between computer-enriched teaching environment (PCET) and regular classroom environment?
4. What is the relationship between CSE with experience, accessibility and frequency of using computers?

Study

The subjects in this study are 155 pre-service elementary mathematics teachers. The students were assessed on three scales: Computer Self-Efficacy (CSE), Attitudes toward Computers (ATC), Perception of Computer-Enriched Teaching Environment (PCETE). In addition, a questionnaire was administered to the students in order to get an information about: the frequency of using computers, accessibility and experience. The reliability estimates of CSE is 0.71, ATC is 0.85 and PCETE is 0.65.

Findings and Conclusions

The first analysis was conducted to identify the preservice elementary teachers' responses, as a group, to the items on the computer self-efficacy scale. Results indicated that students' computer self-efficacy is relatively low. For example, the mean of the item “I believe in my abilities to use computers” is 2.73 out of 5. One of the reasons for low self efficacy is limited experience on computers.

The responses of preservice teachers to computer-enriched teaching environment scale concerned with the differences between the regular classroom and CAI environment is in favor of CAI. Overall, preservice teachers believed that interest, attention and success would be increased and the level of understanding the material presented on computers could be higher. In addition, they stated that fear and anxiety would be decreased. On the other hand, they saw no difference between these two environments with respect to interaction between student and teacher and class participation. The responses to one of the item related to self-confidence is high, indicated that experience with computers improve beliefs about their self.

Preservice elementary mathematics teachers felt positive attitudes toward computers since they believe that computers play an important role in their lives. They thought computers are useful and essential tools. However, since their experience is limited, the responses to the items in the affective domain showed uncertainty about the degree of attitudes.

The correlation coefficients between the computer self-efficacy scores and experience, frequency of using computers and access to computers are, 0.42, 0.37, and 0.18 which are significant at 0.05. The positive and significant correlation coefficients indicated that self efficacy on computers is increased with experience and usage.

The study showed that preservice elementary mathematics teachers have positive attitudes toward using computers, and learning and teaching with computers. They believe that CAI is better and more comfortable way of learning than are conventional methods. On the other hand, their self efficacy in using computers is low which means that recently added computer courses are not enough to improve their confidence. Nonetheless, computers are now available in most schools. If the role of teacher preparation programs is to produce teachers able and confident to use computers, there is a need to re-analysis the courses and activities.

THE OBSERVATORY OF THE ICT IN HIGH SCHOOL CENTRES

Albert Sangrà,
Edu Lab director (Universitat Oberta de Catalunya)
asangra@campus.uoc.es
Spain

Andreu Bellot,
Head of Edu Lab projects (Universitat Oberta de Catalunya)
abellot@campus.uoc.es
Spain

What is it?
The observatory of ICT in non-university schools is a project implemented by Jaume Bofill Foundation and the Edu Lab of the Universitat Oberta de Catalunya, whose purpose is to analyse the use of information and communication technologies (ICT) in the non university education.

Main goals
Measuring the evolution of real use of ICT in non-university schools
Comparing the use of ICT in different communities and countries
Detecting useful ideas for the centres to act with a future view
Creating topics for discussion around the pedagogical use of ICT

Who is participating?
Around 33 centres in Catalonia with different characteristics according to their ownership, population and technologies resources are taking part of a proof to examine (from survey, interviews, round tables and discussions) the situation of the use of ICT.

An assessment council integrated by experts who undertake the use of ICT in non-university school from different fields (trainer of trainers, teachers association, educational administration, etc) are establishing the principles of the project from the analysis of the sample centres work.

A technical team undertakes the communication with the sample centres, from the data collecting and analysis, the research diffusion, and the main conclusions reached every time.

Main aspects subject to study by the observatory
There are many aspects to consider with regard to the ICT use in the non university school. The study of the following list of questions adduce a pedagogical enrichment in the use of ICT in the non university centres. We will formulate hypothesis for each aspect and the study will be orientated attending two criteria:

Possibility of having conclusions more or less immediate and useful to make better the use of ICT.
Interest demonstrated from the centres and educational institutions involved in the project.

Work Methodology
The use of ICT by teaching staff: Knowing how teachers use the ICT can help us to answer questions like: Is it a priority? Is another resource for the teacher? Is a qualitative improvement? What is the contribution of ICT to the educational process?
Strategies the use of the ICT are responding to. It is worth to detect the motivation that teaching staff has to implement ICT in the centre. Is it a new pedagogical resource? Is it just a motivation tool?...

The presence in the centres of interschool projects as a result of the use of ICT. Detecting new experiences can help the Observatory to evaluate changes in the methodology, in the standard of learning and the motivation of the pupils as well as detecting which changes the curricular design is making (basically focussed on the interdisciplinary) comparing co-operative projects with other individual projects focussed in the school without the participation of the ICT.

Changes in the pedagogical exposition of the centre according to the use of ICT. Knowing if the use of ICT raise the co-operative work or reinforce the individual one either the pupils or the teachers, if teachers are forced to expose the subject in a different way. How do work teachers with pupils? And with the rest of the teaching staff?

The interdisciplinary: Although the curricular design is made to be interdisciplinary most of the times the credits proposed become insulated from the rest of the curriculum. Can the use of ICT promote a learning planning more interdisciplinary?

Strategies of the teaching staff to re-establish curricular projects according to the use of ICT. Knowing if planning are re-established according to the use of ICT. It is very important to detect the consideration of the teaching staff face to ICT. Is the new technologies another resource or an essential tool of work that helps to articulate a credit.

Departments (credits, subjects...) with more affinity to the use of ICT. Are there any areas that have tendency towards the use of ICT?

The integration of ICT in the curricular project. Has any influence the use of ICT to the curricular project of the centre?

The capacity of innovation of the teaching staff in the centres which use ICT. Do teaching staff work as usual when using ICT or this use allows teachers to make innovations affording a qualitative improvement? How do teaching staff value the changes made when using ICT?

Teaching staff

- The use done by teaching staff of ICT We do believe knowing what are the uses made by teaching staff of the new technologies. The point is knowing if teachers have a priority in the use of ICT. Do teaching staff consider ICT as a pedagogical resource or it is only another tool else to develop their job?

- The re-defining of the curricular project according to the use of ICT. We value the necessity of knowing if the curricular project has been modified because of the use ICT. Do the modifications in the curriculum make better its understanding, and its adaptability to the different levels of pupils making better and wider the subject to course?

- The innovation in the centres through teachers that use ICT: The point is knowing if the use of the ICT produce innovation in the pedagogical field, new ways of work organisation, increasing of the interdisciplinary work and increasing of co-operation among different centres.

- Changes in the role of teaching staff. Traditionally, the teacher assumed the role of knowledge transmitting. How do modify ICT this change of mentality? We have to value if the following aspects affects in the work of the teaching staff: research through Internet, teachers on-line and changes of the pedagogical exposition when using computers.

Attitude of the teaching staff face ICT: The complicity of teaching staff is essential to implement ICT in the centres. This is the raison why it is necessary to know the attitude of teachers. Knowing the grade of implication will help us to know the consensus in the cluster about the use of ICT. Moreover, detecting how teachers see the use of ICT become essential to suppose how difficult, or easy, will be the penetration of ICT in these centres. Mistrust for not knowing how to use them? Uncertainty for the changes implied for using usually ICT? Or, contrariwise, we are talking about been enthusiastic for been able to innovate?

Pupils

2455
How to manage the information received by pupils through Internet. Are there any filters established by teachers? Does the quantity, and sometimes the lack of quality, of the information going round by Internet enable a correct evaluation of its possibility of use? How do pupils use this information?

The use of ICT as a possible generator of inequality. Can a new borderline born between pupils with more initiative and some others passive face the use of the computers. Is it possible to have pupils passing the subjects successfully in the traditional educational but not motivated at using the ICT in the new model of learning? On the other hand, economic inequality among pupils can be widely increased because of the use of ICT in educational centres? Or, contrariwise, the use of ICT become an element which democratize the access and improvement of learning?

The abilities related with the reading and writing of pupils. Which use do pupils of ICT and how are they affected? Are these abilities condition for been useful at using ICT? Do the use of ICT make worse these traditional abilities?

The motivation of the pupil Is a real motivation the use of ICT that brings improvement in the capacity of learning?

The variation of the relation of ICT with pupils. How do the learning of ICT (either the formal one in the school or the intuitive at home) is integrated by pupils? How do they front the learning of a new environment or a new program?

Educational centres and its organisation

The consensus in the cluster about the use of ICT. The use of the ICT as a pedagogical tool of the centre is an aspect to discuss in the cluster, it would exist different inclinations among teaching staff (People against and for). Observing the vision that each cluster has about the use of ICT can help us to detect inclinations and difficulties of each centre.

The appearance of new private educational services through Internet (teachers on-line, new educational software) The thing is to check if the proliferation of these services make evident the limitations of the own centres to reply for the pedagogical necessities of their pupils modifying, in a certain way, the role of the teacher in the classroom.

The performance organisational in the centre. Technology serve to the professionals that use it. From this point of view we think is worth to know if the infrastructure of communication has been modified among the members of the educational community of the centre for the application of the new technologies. It would be important to know also if the bureaucratic process has been modified and the administrative management (making them shorter and quicker) before and after using ICT. Is the communication process with parents and pupils better than before?

The reports of the observatory

Every three months the observatory will make a thematic report reflecting all the study conclusions and the exchange of information with the centres.

The objective of the report is to gather in a systematic way the reality and the work made by the centres with the new technologies in order to obtain a dynamic image about the activities, the expositions and the problems the centres find when implementing new technologies.

The reports are directly linked with those aspects that we pretend to study in the observatory. Three reports will be published in 2000:

First report - April 2000: the reality of the centres will be analysed according to their software and number of PCs, the activities usually made which are based on pedagogic expositions.

Second report - July 2000: the teaching staff role will be analysed in the setting up of ICT, changes in the teaching staff role and their attitude towards the ICT.

Third report - November 2000: First of all, we will study the relationship between pupils and new technologies, the way to manage the information obtained by the pupils from Internet, to know if ICT generates differences, pupils reading and writing improvement with the use of ICT, and their motivation.
The observatory web

The observatory web page is, mainly, an informative reference based on what is done and offered:

Framework for non-university professionals who use ICT, exchange of experiences
Framework for the exchange of experiences in innovation projects
Innovation initiatives as a way to implement achievements in the dialogue between ICT and the educational community members
Knowledge viewed as a way to improve in the ICT use in educational centres
Discussions for enriching all the opinions about this subject

Examining Technology Education and Practices of Preservice Teachers: Lessons Learned from a Large, Urban College of Education

Michael J. Berson, Department of Secondary Education, University of South Florida, Tampa, FL, USA
berson@tempest.coedu.usf.edu

Roberta Armstrong, Department of Educational Measurement and Research, University of South Florida, Tampa, FL, USA
raristroro@tempest.coedu.usf.edu

Abstract: This paper describes the results of a study of the technology beliefs and practices among graduating teacher education majors. The purpose of the study was an exploratory effort to examine the University’s compliance with The International Society for Teacher Education’s (ISTE) National Educational Technology Standards (NETS): Standards for Students and state graduation skill requirements in the area of Technology education. Additionally, application of technology skills during the students’ internships was evaluated. Participants (N=175) were proportionately representative of the enrollment by major and demographics of the college. Recommendations for technology integration and curriculum modifications are proposed.

Purpose

In order to assess the degree to which the University was in compliance with The International Society for Teacher Education’s (ISTE) National Educational Technology Standards (NETS): Standards for Students (International Society for Technology in Education, 2000) and the state graduation skill requirements (Accomplished Practices) in the area of Technology Education (Florida Education Standards Commission, 1996) an exploratory study was conducted.

Resources allocated to increasing classroom access to technology have resulted in 96% of all public schools and 75% of all classrooms having computers (NRP Online, 2000); and 90% of schools have Internet connections (Becker, 1999). When schools are given access to technology, the emphasis shifts from the number of computers to how technology is used in the schools (CEO Forum, 2000). However, the U.S Department of Education reports that only 20% of the 2.5 million teachers currently working in our public schools feel comfortable using these technologies in their classrooms (U.S. Department of Education, 1999). A 2000 study by the Center for Educational Statistics reported that: only 24% of the teachers with access to computers make assignments involving the production of multimedia reports; only 30% assigned research using the Internet; and only 19% percent required graphical presentations (Rowland, 2000). The need for teachers adequately prepared to use technology in the classroom is evident and the focus for this study.

Results and recommendations are intended to provide the basis for development and implementation of policy and the identification of future efforts in the area of Technology Education. Education majors are currently required to complete one basic course in computer applications prior to acceptance, however, the generalizability of the skills students gained in this course to the classroom setting was unknown.

Areas of interest assessed in the survey include: technology skills and knowledge students had obtained as well as the sources of these skills and knowledge, student confidence in applying technology skills in the classroom for both teaching and lesson preparation, and the amount of exposure to technology uses in the classroom gained by students during their semester long internships.

Methods

Participants

At the completion of their final semester-Spring 2000, graduating Education majors were administered the survey ‘on-line’ during their final internship seminars. One hundred and seventy five students participated in the survey. Seventy-six percent of the respondents were female, and 24% were male. Eight-two percent identified themselves as Caucasian, 7 percent African-American, 8 percent Hispanic, 2.5 percent Native American, and .5 percent as Asian.
Sixty-three percent of the group were under 25 years of age, 23 percent between the ages of 26 and 35, 10 percent between 36 and 45 years, and 4 percent were over age 46. Respondents were representatively distributed across majors within the College of Education: 38% Elementary Childhood Education, 14% Early Childhood Education, 11% Social Science Education, 9% Special Education, 7% English Education, 6% Physical Education, 6% Mathematics Education, 4% Science Education, and 2% or less from Foreign Language Education, Teachers for All Students and Business Education.

Instrumentation

The International Society for Teacher Education’s (ISTE) National Educational Technology Standards (NETS): Standards for Students, served as the foundation for development of the survey. College of Education Faculty members provided expert review in the construction, modification, and development of the survey items and format.

In addition to demographic data, students were requested to complete three sections of the survey and make recommendations for current and future technology training for teachers. Section I – Computer Instruction and Frequency of Use was composed of two parts. The first part asked students to indicate the primary way in which they had learned various computer skills and applications by selecting one of the following categories: Not learned, On-the-job, Self-taught, In a workshop, or In a required course. In the second part, students were asked to indicate the frequency with which they used the skill or application by indicating use as daily, weekly, monthly or never.

Section II – Confidence using Technology for Instruction and Experience with Technology applications during Internship was also composed of two parts. The first part asked the respondents to describe their level of confidence in using technology for instruction in the areas of a) lesson planning, b) lesson development, and c) lesson delivery. Responses were indicated on a three-point scale: none, somewhat or very confident. In the second part students were requested to indicate the amount of experience they had applying technology during their internship. Students responded on a five-point scale: 1) I have not observed or performed this skill, 2) I have observed but not performed this skill, 3) I have performed this skill under direct supervision, 4) I have performed this skill independently once or twice, and 5) I perform this skill routinely in my work.

Section III – Confidence in Teaching Technology Content assessed students’ confidence in transferring technology content through teaching. Students were asked to rate their level of confidence in teaching various content areas to students on a four-point scale: 1) Not confident, 2) Somewhat, 3) Usually, or 4) Very Confident.

Students were asked to provide information regarding the technology availability and accessibility at their internship sites and information regarding the number and type of technology courses taken.

Results

Table 1 displays the responses to the survey items in Section I – Computer Instruction and Frequency of Use. Technology Information was categorized by Technology Use: Telecommunications, Program Applications, Advanced Applications and Equipment Based Uses. In part A of the following section, students were requested to indicate the primary way in which they learned the listed computer skills/applications. In part B, to indicate the frequency with which they use the skill or application. Tabled values represent the percent of respondents selecting each response choice. Category averages are shaded. With the exception of Advanced Applications (Hyperstudio, C++), students report being self-taught as the most frequent learning method. Knowledge gained in required courses was the next most identified source of technology training. On-the-job training and workshops were not significant sources of acquiring technology skills.

Seventy percent of respondents indicated daily computer use for Telecommunications purposes (E-mail, Web-browsing). A similar number of students are using word processing programs on a daily basis, however, other program applications are used with much less frequency, with at least 40% of all respondents indicating they never use other computer-based program applications. Over 85% of the respondents indicated that they never used Advanced Applications or Equipment Based Uses of Technology tools such as scanners and digital cameras.

Table 2 provides student responses indicating their level of confidence in using technology during instruction and the experience students had applying technology during their internships. Technology tasks are grouped into lesson planning, lesson development and lesson delivery applications. In part A, students were asked to rate their confidence in using the listed technology during lesson planning, development and delivery. In Section B, students indicated the amount of experience in applying technology they had received during their internships. Tabled values represent the percent of respondents selecting each response choice. Category averages are shaded. Students felt most confident using technology for lesson planning and delivery, with over 80% of students indicating...
they were very confident or at least somewhat confident in their ability to access technology for these tasks. Students were less confident in their ability to use technology for lesson development—over 25% of the students indicated no confidence in this area.

Responses to Internship opportunities to apply technology in the areas of lesson planning, lesson development and lesson delivery indicated that students frequently did not encounter the opportunity to apply technology in the internship setting. Over 50% of the respondents indicated they had not witnessed technology use nor did they have the opportunity to use technology during their internships in the areas of lesson delivery and development. Students did indicate more exposure to technology use in lesson planning and that they had self-initiated the incorporation of technology into lesson planning during their internships. Lesson Planning responses indicated that students were also working more independently in this area than in the areas of development or delivery.

In response to a related question regarding internship site technology availability, students reported that the technology they wanted to use for instruction was available at their internship sites always (40%), sometimes available (48%) or not available (12%). Students reported that 83% of the schools where they completed their internships were equipped with adequate technology and that 17% of the schools were below average or not equipped.

Table 3 summarizes student confidence in transferring technology through teaching. Survey items were categorized as either Theoretical Bases for Technology Use or Applications of Technology. Students were asked to rate their personal confidence in teaching their students the computer knowledge and skills listed. In general, students felt more confident teaching students to use different Technology Applications than with the Theoretical Bases for.
Technology Use. As noted in Sections I and II, students were most confident in the Telecommunications areas of email and web-surfing.

Student suggestions for enhancing technology training in the College of Education were requested. Students were asked to respond to the following question: "What suggestions do you have for enhancing future technology training and instruction in the College of Education? What would have been useful to you?" Responses were categorized as either Comments on Current Courses or Further Technology Training. The number of student responses precedes each subcategory.

Comments on Current Courses
9- Courses not useful as technology not currently used in school classrooms
6- Classes too large
6- Technology information is not relevant to program, information is not applicable
5- Inadequate support, TA’s not helpful, more one-on-one assistance needed

Suggestions for Future Technology Training
14- More real life applications-develop actual lessons-hands on experience
13- More technology courses are needed
10- Incorporate technology more into current courses
5- Specific training in PowerPoint & Web Page Development
4- More open access labs with more educational software available to review
4- Training on Macintosh/ Apple-IBM not used in schools.

Summary and Recommendations
Although the incorporation of technology into education has grown at a massive rate, the lack of teacher preparedness has necessitated development of standards and graduation requirements to facilitate the seamless integration of technology into instruction. Enhancing the efficacy of technology for transformation of schools is a strong basis for reform; however, the focus of educational development and design needs to be informed by a
conceptual framework which explicitly addresses the challenges and potential of technology innovation in education. We are at a crossroads with tremendous potential, and the following recommendations are suggested to direct the use of technology implementation.

- Faculty technology leaders within COE departments are encouraged to develop content specific examples of technology integrated into lesson plans. For example, Social Studies Faculty may use the CITE Forum web site to gain ideas for integration: http:\www.citeforum.org
- Reexamine and restructure undergraduate technology course.
- Consider more content focused courses by major area of study. For example, technology in Science Education.
- Work with area school districts to ensure students are exposed to technology applications in the classroom by selecting good model teachers and technologically equipped schools.
- Offer individual (one-on-one) training for faculty on the seamless integration of technology into courses.
- Consider reward systems for faculty who integrate technology into courses in the areas of classroom assignments and tenure-promotion.
- Develop college-wide grant writing initiatives for technology development.
- Provide students and faculty better access to and training on technology equipment such as scanners, digital cameras and teleconferencing.
- Create a supportive environment within the College of Education that provides risk-free opportunities for the practice of using various forms of technology.

Multimedia Tools and Case-Method Pedagogy for Teaching and Learning

Clare Ryan Kilbane
University of Massachusetts, Amherst, Massachusetts
The United States of America

Teacher educators face the challenge of preparing teachers to recognize and respond to educational problems as they arise in highly variable, often unpredictable contexts. Two recent innovations in teacher education offer promising possibilities for doing so: case-method pedagogy and multimedia tools for teaching and learning. The purpose of this research was to explore how these innovations interacted in CaseNET to help preservice teachers learn to address problems as they emerge in K-12 classrooms.

CaseNET is a set of Web-assisted professional development courses for educators that combines the use of case methods and Web-based technologies. CaseNET provides preservice and inservice teachers at approximately 20 universities in four countries and 15 school districts in the United States and three other countries opportunities to improve their professional problem-solving skills. Participants in CaseNET use a variety of technologies including videoconferencing, electronic journals, and online discussion groups to learn to analyze multimedia cases. Throughout a fourteen-week academic semester, participants learn to analyze cases using a specific five-step problem-solving strategy (McNergney, Herbert, & Ford, 1994; Herbert & McNergney, 1995, McNergney & Herbert, 1995) and practice this strategy when analyzing a set of multimedia teaching case studies.

Teaching case studies might be described as stories, vignettes, or “slices of real life.” These cases present predicaments from practice that demand some kind of action (Gideonse, 1999). They illustrate reality in its intricate complexity and often include important contextual evidence. Although based on reality, cases condense facts or elaborate on real events to create succinct analytic puzzles. Cases illustrate life in the classroom as it is, not necessarily as it should be. Learning with cases provides preservice and inservice teachers with opportunities to practice problem identification (Merseth, 1996). The skills developed through case methods are useful in a variety of settings. Experience with various types of cases also helps professionals develop a repertoire of defensible solutions for commonly occurring problems (Kleinfeld, 1992; Merseth & Lacey, 1993).

This study investigated the efficacy of a particular problem-solving method on participants’ experiences with a multimedia case. The sample consisted of 33 preservice teachers participating in CaseNET at two institutions of higher education (Group One), 26 preservice teachers from these institutions of higher education not participating in CaseNET (Group Two), and 34 other students enrolled in arts and sciences from these institutions of higher education who were neither CaseNET participants nor preservice teachers (Group Three). Problem-solving proficiency, as demonstrated by participants’ three-page written case analyses, was determined by a panel of professional educators, or judges, who were prepared to use an instrument measuring participants’ abilities to: (1) identify educational issues, (ISSUES); (2) consider events in the case from different points of view, (PERSPECTIVES); (3) identify professional knowledge (personal, empirical, theoretical) relevant to issues in the case and raise questions about other potentially useful knowledge, (KNOWLEDGE); (4) propose actions for addressing a variety of issues, (ACTIONS); and (5) speculate about the consequences of such actions, (CONSEQUENCES).

Participants in the study assembled in groups of about 15 in computer labs where they were asked to read and analyze a case presented in hypertext and multimedia format called “Here to Serve.” The case tells the story of a middle school technology coordinator who is challenged to address the needs of mainstreamed students with special needs, attend to the professional development of teachers under her authority, and deal with the many other tasks her position demands. Information useful for analyzing the case was embedded in descriptions of the characters and events occurring in the case and in ancillary materials contained in a resource area linked to the case. After reading the case, participants submitted a three-page analysis that was then rated by a panel of judges.
In examining the generalizability of the judges' ratings, analyses were considered the objects of measurement. Judges were considered random facets and subscale scores were considered fixed facets. The design of the study was participants' written analyses (p) crossed with judges, (j) who were nested within subscales (i), p x (j : i). Using GENOVA, the generalizability coefficient was sufficient to propose adequate dependability (g=.77).

Scores indicating participants' problem-solving performance were calculated and a comparison of these sub-scale scores and a total scores was performed. Participants' subscale scores were calculated by summing the points participants received from both judges on each of the subscales on the judges' rating instrument (issues, perspectives, knowledge, actions, and consequences). The subscales reflected each participant's performance on the individual steps of the five-step method.

Judges' ratings were summed to yield the total score. A direct discriminate function analysis was performed using the five variables as predictors of membership in the groups. Variables were ISSUES, PERSPECTIVES, KNOWLEDGE, ACTION, and CONSEQUENCES. One discriminant function was significant. With a combined x²(10) = .81, p<.01. After removal of the first function, there was no strong association between group and predictors. The loading matrix of correlations between predictors and discriminant functions suggests that the best predictors for distinguishing between CaseNET participants and those in the other two groups was the rating participants' analyses received on the subscale KNOWLEDGE, ISSUES, and CONSEQUENCES. Group One had higher scores on this variable (M=17.79) than Group Two (M=14.73) and Group Three (M=14.26). Variables loading less than .50 were not interpreted.

The total scores reflected participants' performance on all the subscale items combined. Group scores obtained for participants' total scores were significantly different among groups (F(2, 90) = 57.91, p<.01). A Tukey post hoc test revealed that there were differences between Group One (M=71.06, s=4.37), and Group Two (M=63.54, s=3.01) and Group Three (M=62.24, s=3.07), but not between Groups Two and Three.

Results suggest that preservice teachers in CaseNET were able to learn the problem-solving strategy and apply it when analyzing a multimedia case study. Participants in this group identified problems, applied professional knowledge, and anticipated consequences more proficiently than did the participants in the other groups.

At least since John Dewey (1910) promoted the joining of education and real life, teacher educators have tried to help preservice teachers develop reflexive teaching strategies that are adaptable to many learners. Teacher educators have provided opportunities for preservice teachers to learn from one another in college and university classrooms and from more experienced colleagues in K-12 schools. Now, multimedia technology offers teacher educators new ways to provide realistic educational experiences for teachers.

Abstract: The aim of our study was to evaluate the instructional effectiveness of a curriculum based software for low achieving children students (LA). In order to test the importance of the type of help, two versions of the same software were developed (static vs dynamic help). Furthermore, the dynamical version was used in two ways (computer alone vs computer and psychologist's support). Sixty students participated in the research. The results of our study clearly suggest that computer technology can help teachers to attend the LA students, at least when the instructional software has been developed regarding the school curriculum and the teaching style of the regular teacher. However, LA students working with the computer alone used less advanced strategies than those used by the LA students who got psychologist's support. Therefore, our results recommend to put computers into the regular classroom so that teachers can "be there" if the student needs help.

Introduction

Although low achieving students (LA) usually do not cause serious problems in the school, they need an individualized instruction to learn what high achievers learn in the classroom through regular teaching (Bornas, Servera, & Llabrés 1997). Teachers have too many students in the classroom, so they could not attend their LA students individually. Computers can deliver such instruction if an appropriate software is used (Bender & Bender 1996). This software has to be based on the specific school curriculum. In addition, the software teaching style has to be in accordance with the regular teacher's style. Despite we know that, generally speaking, instructional software with those characteristics can be useful, several specific questions remain unclear. One of these questions is related to the type of help the software must provide when the student does not understand a concept or when he or she is not using the correct strategy to solve a specific task. Static help is provided when the computer just reminds the student "to be careful", "to pay attention", "to try again", and so on. However, computers can provide dynamic help too. Dynamic help is provided by showing the student the process of solving a specific task (Shute & Miksad 1997). For example, to teach how to solve the addition of 1/4 and 1/2, the computer could show several tanks with water and how water flows from small tanks to a big tank with 1/4 and 1/2 marks. Dynamic help is provided also when the computer teaches a specific strategy. Using criteria to group words (e.g. "red" and "blue" are names of colors) may be a good strategy to remember a list of words. Moreover, dynamic help can be provided by the computer as the only instruction tool or by the computer and the teacher together. Traditional curriculum materials (textbooks) only provide static help. Dynamic help is usually provided by teachers when they draw on the blackboard, play with blocks or other things, build some apparatus in the classroom, etc. (Bornas, Servera & Llabrés 1996).

The aim of our study was to evaluate the instructional effectiveness of a curriculum based software for LA students. In order to test the importance of the type of help, two versions of the same software were developed. One of them provided static help, and the other one provided dynamic help. Furthermore, this dynamical version was used in two ways: with the computer alone and with the computer and a psychologist who gave help to the students if they needed it.
Method

Subjects

Sixty low achieving (LA) students from four third-grade classrooms of a private school in Palma (Spain) participated in the research. They were selected because of their low achievement in the school as well as in the Math and reading specific tests that were administered before they start using the software. The students' teachers also gave their opinion about the achievement level of every student. LA students were randomly assigned to one of four conditions: Attentional Instruction (AI), Computer Driven Instruction (CDI), Computer Assisted Instruction (CAI) or control. Each group was made up of fifteen students.

Educators

There were two psychology students in each group who had been trained to be educators, both in the knowledge of the software and the purely educational aspects. One of them only had the function of observer but could substitute the other when necessary (which did not happen). These students participated both in the pre-intervention assessment and in the post-intervention assessment.

Variables and measures

Academic achievement in math and reading was measured using curriculum based tests before and after the instructional period. In addition, a measure concerning the process of doing the instructional tasks was used for the three experimental groups (see below). Standard attention and impulsivity tests were administered as additional selection criteria.

Procedure

Regular teachers contributed to select the academic contents (reading and math) the software should include as well as the strategies they were teaching in the classroom to solve specific tasks (e.g. dividing). Even some figures that appeared in the students textbooks were reproduced in the software to make it more familiar to the students. In other words, what the software was going to teach and how was going to do it was determined by the school teachers and the school curriculum and materials. The software was developed using the Toolbook® authoring package and it took three months. When the software was almost completed, it was installed on the school computers, and the ten-weeks instruction period started. Some more exercises were added later, during this period, because some students did the programmed tasks very quickly. The AI group worked with the software that provided only static help, and the educator could only refer to this software for help. The CDI group used the same software but it provided dynamic help and the educator did not help students. In the CAI group, dynamic help was also available and the educator helped students if they needed it. Students in the control condition did not work with the software and they followed the regular instruction in the classroom, while the other three groups went out of the classroom to go to the technology classroom to use the software when they had reading or math tasks with their regular teachers. It is worth to note that the software replaced, and it was not added to, the regular instruction during the ten weeks research period.

Sixteen computers were located in the school's technology classroom, and the instructional software was installed on all of them. LA students went to this classroom two times a week during ten weeks. Every instructional session lasted 45 minutes, so the total time they could use the software was 15 hours. During each session students had a sheet of paper where they could write or draw whatever they want. These sheets of paper were collected at the end of each session to have some knowledge about the strategies students were using to solve the tasks, but no comment about them was made to the students. At the end of the instruction period, LA students were administered Math and reading performance tests. These tests were designed in accordance with what the regular teachers said they have taught in the classroom during that period.

Results

In general, as to the achievement in the math and reading tests used, there were no statistically significant differences between the four experimental groups. In other words, the children in the control group, who continued to attend regular classes, had the same achievement at the end of the intervention as those who had worked with the computer. As far as the reading comprehension is concerned, by making an analysis of the main effects we obtained a
"group" factor score of F=0.90. Neither was the interaction between the two design factors significant (F=0.38), which is why we analyzed the "test" factor (F=51.87; p<.001) uni-factorially, but none of the groups showed any significant difference between the two assessment points. With respect to the math scores, the same pattern of lack of differences between groups is maintained. The study of the main effects of the different factors indicates there is no significant "group x test" effect (F=1.92) although significant "test" factor differences can be seen (F=67.37; p<.001). The analysis of this factor shows how despite the fact that the four groups improve significantly from the statistical point of view, the three intervention groups are the ones that show the greatest difference after treatment (see table 1).

Table 1: Calculation Score Before and After Intervention

The analysis of the strategies employed by the children in solving the intervention tasks has been carried out with the information obtained from the sheets of paper handed out to the children involved in the three experimental groups during the intervention sessions. We do not have the strategies of the control group because if we had handed out a sheet of paper while they were in class with their regular teacher we would have distorted the study. The sheets collected during the math lessons did not show any particularly interesting strategy given the fact that the children only made use of them to do the necessary calculations in order to solve the math problems set by the computer. In the case of reading, the sheets showed more varied, interesting strategies. The strategies used were independently assessed by two experts, who only had a list of all the strategies used without knowing at any moment in time the subjects who had carried them out or which group they belonged to. Each expert categorized each strategy as rudimentary, normal or advanced and gave it a score of between 1 and 10. For instance, copying the full list of new words to be remembered was considered a less advanced strategy than grouping words according to certain criteria (e.g. arm, leg, and foot, or red, green, yellow, and white). Afterwards, the value of each strategy was defined as the mean of the two scores appointed by each observer whenever they were placed in the same category and there was a difference of no more than two points between the two scores (otherwise the strategy was not taken into account in the analysis).

According to the ANOVA carried out (see table 2), the CAI group used significantly more strategies than the AI group, and the strategies they used were more advanced than those used by the other two groups.

Discussion

The results of our study clearly suggest that computer technology can help teachers to attend the low achieving students they have in the classroom, at least when the instructional software has been developed regarding the school curriculum and the teaching style of the regular teacher. It is worth noting that the children in the control group continued learning in class the same as what the other groups learned with the computers. Therefore, the computers have been just as efficient as the teachers as far as academic achievement is concerned.

The results obtained as to the strategies are the most important point. Unfortunately, we did not find a good way of assessing the strategies used in math and this would need more research in the future. In addition, it should be said that the procedure we used to know the students' strategies has a clear limitation: A blank sheet does not mean that the student has not used any strategy. However, we chose the blank sheet procedure because it is less reactive than directly asking students what strategies they had been using. Further research is needed to develop better strategies'
assessment procedures. Despite this limitation, which recommends caution when reading the following discussion, we think that the results on the strategies in reading deserve close consideration.

Statistically speaking, only the CAI group used strategies which were more advanced than the other groups working with computers. Below, we will comment on this result, but it would now be worth noting the differences between the three groups. The AI group worked with software offering static help and the value of the strategies employed was 7.80. When the software offered dynamic help (CDI) the corresponding group used rather more advanced strategies (13.14). And when, in addition to the software’s dynamic help, the educator provided further assistance (CAI) we find much more advanced strategies (21.42). The progression, at first glance, is curious: the value of the CDI group strategies practically doubles the value of those used by group AI, and the value of those used by group CAI practically triples this value. The fact that this was not reflected in the academic achievement could be simply a question of time. It could be supposed that on a more long term basis, the children who acquire advanced strategies will have higher achievement.

Let us now focus on the CAI group which statistically used more advanced strategies than the others. This group, like the CDI group, worked with the computers that offered dynamic helps. The difference between the CDI and CAI groups was not in the software employed but rather in the additional help provided by the educator. Whereas in the CDI group it was minimal or non-existent (the whole responsibility was the software’s), in the CAI group the educator actively helped the children who asked for it. Hence, the human factor seems to have been decisive.

If we analyse this factor a bit more we see that the scaffolding provided is meta-cognitive, whereas the scaffolding provided by the software is cognitive. The software with dynamic helps provides cognitive strategies but does not deal with (at least not intentionally or explicitly) the meta-cognitive aspects. For instance, knowing when it is convenient to use a particular strategy, which makes it possible to generalise its use in different tasks or activities is not provided by the designed software. On the other hand the educator, despite having instructions not to teach cognitive strategies directly, could suggest or remind the child of a previously learned strategy. Thus, he was putting himself in a meta-cognitive scaffolding level and this could then explain how this CAI group used statistically more advanced strategies than the others.

To close, specific meta-cognitive aspects could probably be introduced without too much difficulty, and this is a challenge for research into educational software in the near future, but meta-cognition also involves flexibility and speed in adapting to children’s needs. Therefore, computers by themselves can be useful instructors to consolidate the students’ knowledge, but they have limitations to teach advanced strategies to solve specific tasks. If this is the teacher’s goal then the teacher must be there.

Our Own Tower of Babel: Describing Instructional Technology or Educational Technology Doctoral Programs

Arlene Borthwick, National-Louis University, USA, abor@wheeling1.nl.edu
Marianne Handler, National-Louis University, USA, mhandler@nl.edu
Diane McGrath, Kansas State University, USA, dmegrath@ksu.edu

Abstract: Many of us who teach those who will become tomorrow's professors have not found a way to clearly share what we do and find out what others are doing in their doctoral programs. Information the authors gathered about a variety of educational/instructional technology programs demonstrated the complexity and richness of doctoral programs in this area. This appears to be the right time for discussion of how we are alike and different and for the possible development of additional doctoral programs in the area. A better understanding of our missions, visions and language within this community will assist us in our conversations. Further, clarity in our program foci is reflected in program goals, university/grant-funded research opportunities for graduate students, employment options for graduates, and the hiring of appropriate faculty. This round table will discuss a project that aims to help build a common vocabulary and common understandings to encourage the conversation.
Abstract: As a result of innovative technologies designed to enhance learning, today's teachers must learn to incorporate the newer technologies into instructional strategies. The present study examined the impact of certain personality types of Emergency Permit secondary teachers' inclination to use technology. A selected sample of 200 Emergency Permit teachers was surveyed using the Myers-Briggs Type Indicator and a questionnaire designed to determine the subjects' willingness to use technology. The Kruskal-Wallis one-way analysis of variance test was applied to each of the 20 items contained in the survey. Findings indicate that Intuitive-Thinking types of personalities were more likely to utilize technology in teaching while the Sensory/Feeling types were the least likely.

Introduction

The quality of public school education has been of grave concern since the Nation at Risk report in 1983 (National commission of Excellence in Education, 1983; Schlechty and Vance, 1981, 1983; Doyle and Hartle, 1985; Seely, 1990). Commission reports--The Twentieth Century Fund Task force on Federal Education Policy (Making the Grade), the Task Force for Economic Growth (Action for Excellence), and the National Science Board Commission (Educating Americans for the 21st Century) supported the growing alarm and called for changes in public education and reform in the preparation of teachers. Major concern in the U.S. today focuses on public education and teachers' ability to educate students for the 21st Century. One major challenge is the use or disuse of newer technologies available. The importance of a technology-based, integrated learning environment for students cannot be over emphasized since technological transformation is occurring.
As early as 1989, Dezell stated, "We must work together to ensure that technology becomes a constructive force in children's lives." Technology is an instructional tool that can lure students to engage actively in the learning process. Public schools must incorporate and transfer the use of technology into teaching methodology to successfully educate students for tomorrow's generation.

In addition to the use or disuse of technology in teaching, there has been an interest highlighting the types of personalities that tend to use or not use technology. Erdle, Murray, and Rushton (1985) found that specific personality traits of teachers are reflected in classroom instruction, especially through the teacher's use of various instructional strategies and material. They also found that a positive relationship existed between individual personality constructs and learning styles. Meisgeier and Richardson (1996) concluded that all personality types and learning styles of children in the classroom would receive direct benefits from teacher education and preparation programs that used the Myers-Briggs Type Indicator (MBTI) in preparing future educators. One of their more supportive findings stated that teachers and pre-service teachers knowing the implications of their MBTI, as well as their students' MBTI, may have a more global understanding of a useful framework for modeling instructional technology. In addition, they will more likely to include it as a tool to focus on integrating the curriculum both vertically and horizontally. Research results support the use of the Myers-Briggs Type Indicator (MBTI) as a valid means of identifying the different types of cognitive styles and how individuals process information and make decisions. Once identified, the MBTI also describes how individual types make needed adaptations through self-reflection and personal growth (Lyons, 1984; Thompson and Borrello, 1986; McNickle and Velman, 1986; Clark and Peterson, 1986).

Griddler and Stratton (1990) found that the MBTI results could be used to help teachers develop different teaching methods and more readily accept materials and technology. Studies indicate that extroverted, stable, and tough-minded personalities were more receptive to the use of the computer (Grant and Cambre, 1990; Katz, 1992). Knupfer (1989), in a study with elementary education majors concluded that a "sensing" individual directed access to technology but that a "intuitive" type was cautious and needed some prior training before initiating multimedia procedures. "Intuitive/thinking" types of intermediate/secondary teachers or those educators who are creative, analytical, logical, and imaginative are more receptive to the use of technology than the "sensory" types who are practical, realistic, and sociable (Sudol, 1991; Katz, 1992; Smith, Munday and Windham, 1993). "Sensory/feeling" types of teachers are interested in examining meanings and relationships and are least likely to be comfortable with technology that other personality types (Grindler & Stratton, 1990; Smith, Munday and Windham, 1993).

The 1995 NCATE standards have raised expectations for colleges of education for candidate and faculty use of technology in instruction and assessment. Wise, Leibbrand, and Williams (1997) state, "The challenge is how to change the situation so that teacher candidates are provided with a solid foundation in technology skills which they can use in the classroom. The accreditation standards will continue to have higher expectations for educators to utilize technology for teaching and assessment.

Instrumentation

The Myers-Briggs Type Indicator (MBTI), used to identify personality types, and a questionnaire designed to describe teachers' willingness to use technology were administered to collect data for the present investigation. C. G. Jung created and tested the MBTI model in his clinical practices, and Isabel Myers furthered the model through the development of the Indicator to make it possible to test and use Jung's theory with nonclinical populations. The instrument, developed through clinical experiences and supported by research, was created in the 1940's and revalidated in 1977 (Myers and McCaulley, 1985). In order to make practical applications of the instrument possible for research, the MBTI was published by the Educational Testing Service (ETS).

The MBTI is a widely used personality inventory with positive evidence of its construct validity (Thompson and Borrello, 1994). Mendelsohn (1965, p. 321) reported that "an unusually large body of reliability and validity data" has been completed on the MBTI. Test-retest correlation of approximately 0.70 were obtained for three of the indices and 0.48 for the fourth. Further, Mendelshon reported the internal consistency reliabilities (split-half) for the indices ranged from 0.70 to 0.80 (1965).
The MBTI, form G, is a self-administering questionnaire that has a 96 item in forced-choice self-scoring format. Scores generate eight basic personality preferences that assist individuals in understanding themselves and their behavior. Of these eight, this study used the following four: Sensory/Feeling (SF), Sensory/Thinking (ST), Intuitive/Feeling (IF), and Intuitive/Thinking (NT).

Background literature and similar studies guided the selection of questionnaire items for the technology questionnaire (Dezell, 1989; Calister & Burbules, 1990; Cicchelli & Baecher, 1989). A panel of six professional educators with expertise in the field of educational technology and who met criteria established by the researchers established content validity for the survey. The questionnaire contained 20 statements, with eleven of the 20 statements considered to elicit positive responses concerning the respondent's perception of his or her willingness to use technology. Nine items were considered to elicit negative responses on similar issues. A Likert-type scale was used to indicate the relative importance of each item. Number "6" on the scale indicated the lowest degree of acceptance, strongly disagree; and number "1" revealed the highest degree of acceptance, strongly agree.

Methodology

During the spring semester, 2000, a selected sample of 200 Emergency Permit teachers enrolled in university courses, SHED 515 and Reading 515 and who are currently teaching on an emergency permit contract in grades 7 -12, were invited to participate in the study. These teachers were employed in school districts on emergency permit teaching certificates in the Northeast Texas area. Data for this study was acquired from scores on a technology questionnaire and the Myers-Briggs Type Indicator (Form G). Demographic data was obtained from personal reports included in the questionnaire. Instruments were administered in a regularly scheduled class period by the researchers. Of the 200 teachers contacted, 149 returned both instruments with their responses.

Treatment

To assess the impact of teacher's personality types their willingness to use technology, the Kruskal-Wallis one-way analysis of variance test was applied each of the 20 items contained in the technology survey. For ten out of the twenty items, a significance difference between ranks were obtained \( p<.05 \). For each of the ten significant items, a Mann-Whitney U test was applied to assess the impact of specific personality types – Intuitive/Thinking (NT), Intuitive/Feeling (NF), Sensory/Thinking (ST), and Sensory/Feeling (SF). Tables 1. and 2. provide a listing of the significant \( p<.05 \) personality type pair-wise comparisons within each item.

Conclusions

Alternative certification program participants classified as Intuitive (N) were more receptive to the use of technology than Sensory (S) types. Pair-wise comparisons of personality types within ten of the technology survey items found significant differences between Intuitive associated and Sensory associated types. This conclusion is congruent with cumulated research on type-indicators and their relationship to teaching and learning styles (Grindler & Stratton, 1990). Smith, Munday & Windom (1993) found that Intuitive/Thinking (N) types of secondary teachers, those educators who are creative, analytical, logical, and imaginative, are more receptive to the use of technology than the Sensory (S) types who are practical, realistic, and sociable. They also discovered that Sensory/Feeling types of educators who are interested in investigating meanings and relationships are also least likely to be comfortable with technology other than personality types.

Within Intuitive types, a significant difference was found between Thinking (T) and Feeling (F) types on two technology survey items. Within Sensory (S) types, no differences were noted between Thinking (T) and Feeling (F) types.

Implications for Practice

Because of the emerging demand for teachers to use technology, the research data may add to the body of knowledge on professional development and be used by educators to modify and adapt programs and curriculum through the identification and individualization of the different personality types. This study suggests that those who are charged with educating preservice and novice teachers need to be aware of specific types of personalities that tend to use or not use technology as an instructional tool and their tendency to incorporate and transfer this information into a practical teaching methodology. Therefore, educators must support the call for change and reform in the preparation of teachers in order to successfully reduce anxieties often experienced by some novice teachers when challenged with the task of supporting alternate ways to align materials and their teaching styles with new technology-related projects and curriculum packages.

Teachers who are aware of their own and others' type profiles can develop different attitudes and teaching methods that will empower them to accept materials and technologies as well as help to facilitate the learning process of diverse student populations. In return, they will be able to provide a more solid foundation in educational technology which will improve the potential for each individual to develop those global technology skills needed to survive in a high-technological society. For effective training educators need to design programs for pre and in-service teachers that include descriptions of how different personalities can best use technology in the classroom with diverse students. Those individuals more inclined to use technology may be identified to work in interdisciplinary teams with others who are less successful using the newer technologies in the instructional process. Building on the ability of those personality types more inclined to use technology, provide models that could enhance the use of technology of others in schools.

The Technology in Education Competency Survey (TECS): A Self-Appraisal Instrument for NCATE Standards

Rhonda Christensen
Gerald Knezek
Institute for the Integration of Technology in Teaching and Learning (IITTL)
University of North Texas
Denton, Texas USA
rhondac@unt.edu

Abstract: The Technology in Education Competency Survey (TECS v1.1) is a self-assessment rating form covering teacher competencies in major areas addressed by the National Council for the Accreditation of Teacher Education (NCATE) standards for the USA. It is intended for preservice educators interested in measuring the level of technology competency in their students. Preservice programs may wish to use this instrument as a posttest to determine if students, upon exiting, feel competent to use information technology in their future classrooms. TECS v1.1 may also be useful as a tool to assess pre-post changes in classes that intend to teach integration techniques.

Introduction

TECS v1.1 is a self-report measure for use in assessing teacher education graduates' technology competency in six major areas: Professional Productivity, Project-based Learning, Problem Solving, Assisting Students with Special Needs, Teaching about Technology, and Ability to Use a Range of IT Learning Environments. The instrument was constructed using the ISTE guidelines contained in "Preparedness of Graduates" (ISTE, 1999) as a blueprint. Nine items were written to represent the areas listed in Table 1. Five-choice Likert rating categories (1 = strongly disagree to 5 = strongly agree) were selected as the means of gathering responses. Normal completion time is less than 5 minutes.

TECS Content and Construct Validity

A factor analysis (ULS, Oblimin rotation) was carried out on data gathered from 188 preservice teachers and 44 university faculty in Texas during 1999-2000 in order to explore the underlying construct(s) of the scale. A scree plot of the eigen values produced by factor analysis indicated that either 1 or 2 factors existed in the data. Successive interval scaling (T-scale, Dunn-Rankin, 1983) performed on the same data indicated that the 9 items form a reasonable unidimensional scale. These analysis outcomes were judged to be sufficient evidence that the TECS has high content and construct validity.

Internal Consistency Reliability

This direct appraisal, 9-item form has yielded an internal consistency reliability estimate of .92 across 188 preservice educators and 40 university faculty (Christensen & Knezek, 2000). The instrument appears to consistently yield reliability estimates in the range that instrumentation authorities such as DeVellis (1991) would label "very good."

Contemplated Refinements

Psychometricians have suggested that removal of compound item components in items 1, 5, and 6 may further improve the scale. Future research is planned to determine if selecting just one descriptor of skill level for a given NCATE competency, rather than listing the several examples included in the specification, is sufficient. For example, deletion of the phrase "and implementing" from item #5, "I feel competent constructing and implementing..." may improve its measurement characteristics. TECS v1.1 is
currently available in the book, *Instruments for Assessing Educator Progress in Technology Integration* (Knezek, Christensen, Miyashita, & Ropp, 2000). It can also be found online at http://www.iittl.org.

**Table 1. Items on the Technology in Education Competency Survey (TECS) v1.1**

1. I feel competent using a word processor and graphics to develop lesson plans.
2. I feel competent using e-mail to communicate with colleagues.
3. I feel competent using the World Wide Web to find educational resources.
5. I feel competent constructing and implementing project-based learning lessons in which students use a range of information technologies.
6. I feel competent to help students learn to solve problems, accomplish complex tasks, and use higher-order thinking skills in an information technology environment.
7. I feel competent in recognizing when a student with special needs may benefit significantly by the use of adaptive technology.
8. I feel competent about teaching K-12 students age-appropriate information-technology skills and knowledge.
9. I feel competent working with students in various IT environments (such as standalone and networked computers, on-computer classrooms, labs, etc.).

Abstract: This research aims to investigate the role of teacher’s mediation in the development of cooperative learning and autonomy. It was based on the constructivist and social interactionist teaching conception. In order to do that, we accomplished a longitudinal case study with genetic analysis of the occurrence of situations involving cooperation and autonomy among 8-10 year old children in the course of a work project using Microworld software. A field journal was organized by the teacher and four categories were used in its analysis: “Cooperative learning”, “Autonomy”, “Non-existent cooperative learning” and “Heteronomy”. The increase of the two first categories and the extinction of the last ones were verified during the intervention, demonstrating the importance of teacher’s intervention in the development of those characteristics.

Introduction

The current study, based on a constructivist and social/interactional concept of the teaching-learning process, aimed to investigate how teacher’s mediation in the construction of hypertext projects benefit the cooperative learning and autonomy development. In order to do so, a longitudinal case study was accomplished. It lasted five months, during which a genetic analysis about the rising of situations involving cooperation and autonomy among children engaged in the construction of a work project using Micromundos software (Logo language) took place.

We can consider the pedagogic approach adopted by the teacher as a guide to his/her work, either towards reproduction or construction of knowledge. Coll (1994), based on Deutsch’s studies (1973), states that some investigations succeeded in demonstrating how cooperative learning experiences provide the establishment of more positive relationships among students than competitive ones. The students’ connections became more friendly, attentive, respectful and helping.

Seidl de Moura and Oliva (1996) point out some of the cooperative working traits: it is a long term activity with a longitudinal evaluation of the student who should be able to overcome a plausible stipulated stage; it is a group with a common goal and co-helping elements; it is an active, dynamic search for knowledge through individual reading and sharing; the teacher should suggest about the task division; there should be a division of the material to be studied making everyone responsible for the knowledge to be collectively acquired; it should promote critical evaluation by presenting a topic, a subject to the students.

Socializing has been Vygotsky’s study subject (1984). He affirms that social interaction has an essential role in cognitive development and identifies two child development levels that can be extended to any other
The real development level, determined by one's capacity to accomplish the proposed task by him/herself and the potential development level which is determined through proposed activities achieved with help or cooperation of a more skilled person.

The gap between the real development level and the potential development level is known as the 'Proximal Development Zone' and that is where the learning process should be taking place. "Already consolidated processed do not require outside interference to get started; on the other hand, processes yet to be structured do not benefit from this sort of interference" (Oliveira, 1997, p.61).

According to Vygotsky (1984, p.60), "(...) other people's interference really affects the results of an individual action", therefore social interaction is considered very important in the building of human psychological functions, promoting one's development. "Other people" could be their own classmates, more capable or not, or even the teacher. Seidl de Moura and Oliva (1997) say that his/her classmates help the student's development during a cooperative activity, which does not depend on spontaneous formation but on "a person who coordinates these interactions by distributing the prompting tasks. The teacher establishes certain objectives that should be accomplished by the group" (p.3). However the partners for promoting the Proximal Development Zones are not always the more experienced ones: classmates with similar development level can be actors throughout this process for the significant amount of time they spend together.

As you can see, the child is considered an actor in the scenery and not a mere receiver of social interference. For that reason, he/she can assume multiple roles, having the opportunity to live meaningful experiences and interact with others, promoting the development of superior mental functions.

Newman, Griffin and Cole (1989) bring about the concept of construction zone, which amplifies the conception of proximal development zone. The construction zones are development-promoting spaces, where signification is traded, shared and interchanged. In these sites, the growth of the partners engaged in the trading and acquirement of a wide range of signification is very likely to occur.

Tudge (1996) calls our attention to certain studies, which could suggest that children learn meanings, behaviors and adult technology during a process of collaboration (p.152). As a result, the development of appropriated cultural forms happens because of the cooperation with grown ups or an advanced classmate. Beyond its social aspect, partner collaboration is an effective way of stimulating cognitive growth, and, to researchers based on Piaget, the social cognitive conflict would be its promoting agent. Nevertheless, the ones based on Vygotsky, have concluded, "for interaction to be effective, children should work as a group towards a common goal" (p.164).

Forman (1981, in Tudge, 1996) describes a research involving fourth grade children in which it was verified that during a certain age the individual does not think about coordinating his/her activities with the other classmates. Still, many of these children gradually grew more able of working in groups and even subordinating their own individual roles to a partner's, willing to accomplish a common objective.

Many studies have proved that children learn more historical concepts when working in groups than in individual activities, confirming that active participation towards a collective aim is a necessary element for collaboration and critical evaluation (Tudge, 1996).

Piaget (1977) deals with autonomy and heteronomy as he presents a study about the game rules in the book "The moral judgment of the child". According to it, two group of phenomena are connected to these rules: a) rule practice, or how they are applied and b) the consciousness of these laws, and either autonomy or heteronomy, which are inherent to the rules.

Through his studies of moral realism, Piaget (1977) concluded "it seems like there are two distinct morals for the child" (p. 170), as a result of experienced processes: adult moral enforcement and cooperation. The first one promotes heteronomy and moral realism while the second generates autonomy.

The last one begins to develop when the child discovers that veracity is essential to friendly relations and mutual respect. "There is moral autonomy when the consciousness longs for an ideal independent from any external pressure. Without relationship there is no moral necessity" (Piaget, 1977, p.172). In every connection to another person with unilateral respect, heteronomy can be found. Autonomy rises with reciprocity, mutual respect and necessity to treat others, as they would like to be treated.

To this author, cooperation and autonomy are always together what can be easily noticed by the statement that there are two types of respect, and consequently two morals: one is heteronymous and the other, autonomous or cooperative: "Heteronomy provides objective responsibility as well as autonomy; natural to mutual respect, leads to subjective responsibility" (1977, p.290).

Kamii (1988) defines autonomy, as being governed by one's self in opposition to heteronomy, that implies to be guided by another person.
According to her, children are gradually able to become more autonomous and thus more independent, being less guided by others. However, it happens only if adults adopt an attitude that promotes the development of autonomy. Any how, as she reviewed Piaget's theory, Kamii (1988) stated that adults reinforce children's natural heteronomy by using rewards and punishments.

The punishment has three different consequences: repetition of the act but this time the child worries about not being caught, obedience, which assures safety and respect, or reaction, which can lead to criminal behavior. Therefore, punishment strengthens children's heteronomy, stopping the development of autonomy.

According to Kamii (1988), Piaget has developed a new theory on how children learn moral values. While traditional conception believes that children assimilate such values from their environment, Piaget defends that, in order to acquire these principles, children must first construct them inwardly, by interacting with their environment. The outside does not absorb the values.

Autonomy is also developed intellectually and not only on the moral field, by using the same principle: knowledge construction should come from the inside instead of an outside insertion. Children acquire knowledge by creating and coordinating connections. This is what we call constructivism.

We believe that reporting this sort of educational proposal, which uses work projects and computers to promote an appropriated environment for developing a more cooperative and autonomous subjectivity, is a pertinent contribution to teachers because: "A well-succeeded school performance would be the one that agreed to the student's potentials and demands, promoting their growth and creative production, motivating the assimilation of new knowledge and learning attitudes, comprehending life in its modern complexity" (Novaes, 1999, p.105).

Method

Twenty-three students, ranging from 8 to 10 years old (third grade of elementary school), took part in the project. A longitudinal case study with a genetic analysis of the rising of situations involving cooperative learning and autonomy was adopted as the research model. It happened throughout a pedagogic intervention consisting of an interdisciplinary project with hypertext production. The theme, object of the interdisciplinary work, was included in the Social Studies program: "Rio de Janeiro at different times (Colony, Empire and Republic)." Other subjects were involved in the study, such as Geography, Science, Math and Portuguese Language, allowing the knowledge to be expanded and inter-related.

Fourteen topics on the yet to be researched subject matter were selected by the students (occupation of space, fauna, flora, water supply, illumination system, clothing, communication means, economic activities, sewerage, transportation means, alimentation, and significant historical and scientific facts.

During the entire project, there were various communication sources available to the students (videos, magazines, newspaper, CD-ROM, books, songs, suggestions of field trips), stimulating the group and bringing up interest and curiosity towards the subject. Besides there was a field trip to downtown Rio de Janeiro, in order to verify some researched aspects. The book adopted by the school was also very useful through written exercises, which helped to organize and register the data.

The activities were divided in seventeen steps, distributed along the weeks from August to December. First of all, an initial study was done with the whole group, then a series of researches about the selected topics of each historical period, a data assemblage, discussion, organization of the texts, seminars, and finally, a test and computer implementation (through Micromundos software, based on Logo language).

During the initial study, some activities were used in order to prepare and stimulate the group, bringing up interest and curiosity towards the subject. Regarding the research, data assemblage, discussion and text organization, the students worked in randomly chosen pairs, trading places with each other every time the focused historical period changed. After organizing the reports on each period, the pairs presented seminars sharing the gathered information with the rest of the group, which was then able to evaluate their work, make suggestions and select the words to go in the glossary. The computer implementation occurred, throughout the three periods, right after the seminar analysis. During the first week of December, by the end of the experience, the class determined what links should be used to connect the "knots" (information islands) developed by Micromundos. This moment of wrapping up the hypermedia was considered the climax of the entire process.

In its final form, the hypermedia presents a summarizing scene in the opening page with the elements referring to the three historical periods. Each aspect, including the ones not represented with drawings, has an icon, which enables the user to move on to the next page, holds an index of the included matters and presents the chosen subject in the historical periods.
On the next page there are three icons with the aspect name and the numbers 1, 2 and 3 that illustrate
the following time periods: Colony, Empire and Republic. There is also another icon called “Voice” through
which the user can hear the students’ explanations on how to proceed when getting information about the
selected matter. As one of the three icons is chosen, it moves on to the next page and a new topic is explained in
the same way. The page contains information about the selected aspect and more icons leading to other pages
with drawings, games and other topics.

In order to collect data, the teacher elaborated a field journal. The analysis was done through four
different categories: ‘Cooperative learning’, ‘Non-existent cooperative learning’, ‘Autonomy’ and
‘Heteronomy’. ‘Cooperative learning’ situations involved: interaction; shared action; sharing of information;
respect to individual differences; negotiation practice; collective responsibility. Situations with opposite qualities were identified as ‘Non-existent cooperative learning’. A situation of ‘Autonomy’ presented the following items: information search through different sources; ability to question, evaluate, gather and organize the most relevant information and capacity to take decisions alone. On the other hand, a situation of ‘Heteronomy’ was recognized by passive demand of information; acceptance of a transmitted knowledge or situation without questioning; incapability to take decisions.

Results and Discussion

The category frequency was grouped in three time periods. Teacher’s mediation throughout the project
allowed the rising of certain categories: ‘Cooperative learning’ (5 times during the first period, 20 during the
second and 21 in the third) and ‘Autonomy’ (27 times during the first period, 39 during the second and 41 in the
third); as well as the extinction of others such as ‘Non-existent cooperative learning’ (5 times in the first, 4 in the
second and none in the third) and ‘Heteronomy’ (10 times in the first, 3 in the second and none in the third).

Table 1: Evolution of the frequency of the categories throughout each period

Data analysis verified that the students had learned to work in groups, becoming more autonomous and
cooperative during the project implementation.

Cooperative work resulted from the teacher’s planning and could be easily identified through some
parts of the field journal, as can be seen in the following examples.

Group elements engaged in mutual support aiming to overcome difficulties:

*Some pairs (three), which had finished their part before the others, offered help by giving tips of how to
complete the implementation and explaining the right procedure to accomplish it.* (Santos, 1999, p. 119)

Active search for knowledge, through individual reading and group sharing:

*After using the books and marking some pages considered relevant to the seminar, they offered the same material to other classmates.* (Santos, 1999, p.163)

Task division suggested by the teacher:

*Each group organized the task division. Each student, from the three teams, was responsible for bringing a poster or drawing of a certain time period.* (Santos, 1999, p.111)

Division of the topics to be studied, making each member responsible for a piece of the whole:

*The class was divided into five groups that had to look up more information about the Republican period using books and magazines. One of the students suggested that each group had a different theme in order to avoid gathering similar data.*

(Santos, 1999, p.186)

Presenting a topic to the group, allowing critical evaluation:

*The teacher explained about the procedures during the seminar (intervention if necessary to ask
anything or suggest any change in the explanations and choosing of the words that should go to the glossary and let the children decide which group should be the first one. (...) Every child stood up in front of the class; some held posters, others just stood aside and a student explained the topic. (Santos, 1999, p.112)

There was still another relevant topic, promoter of cooperative learning and that considers the act of 'explaining a certain subject that has been elaborated to somebody else', as one of the most efficient ways to attain cognitive restructuring. In the first group (republicans), two classmates talked about the system of government and architecture, while the others explained the drawings, representing what had been said before.

According to the analyzed authors, interactions of this nature allow the students, both the explainers and the listeners, to learn in a much more successful way.

Collective responsibility was also identified during the project:
During the video, one of the student's grandfather made an interruption and asked his grandson to leave the room for a moment. A few minutes later, the child returned with a smile and told the teacher that he would only leave after the video exhibition. The day after, the teacher found out that the student had explained to his relative that the video was very important for what he was doing, his group work and that it would be unfair with his partner not to stay. The little boy then asked his grandfather to wait by the school gate for he would meet him right after the end of the class.
(Santos, 1999, p.134)

During the discussions about the project, "concept controversies" (Coll, 1994) were verified, or in other words, "a disagreement of ideas, information, opinions, believes, conclusions or theories among the members of a group, and a desire to reach common ground" (p.89). These situations may also be described as social-cognitive conflict, in which the group members have different opinions but need to reach a common conclusion, generating intellectual progress:

During the presentation of the group about 'Water supply', there was a real mess and misunderstanding because they also talked about 'sewerage'. When the student started this part of the explanation, a girl said, 'that again? Thierry's group have already talked about it?' Another child replied: 'Let them finish and then we talk'. After the group was done... 'There is water in the sewerage, that's why we decided to talk about it.' But another element of the group said: 'No, that wasn't the reason. The thing was that Ariene gave us this material and we figured we could add it to our topic...' There was still another one that tried to explain...'It's ok, there is water in the sewerage, but it's dirty, it's not the same water they used to drink, take a bath, make food, and that was what your seminar should be about'. After a lot of discussion, the class decided to take this part out of their seminar and keep only the one about the water supply. (Santos, 1999, pp.145-146)

The occurrence of cooperative learning and autonomy was possible, mainly as a result of the attitude adopted by the teacher, based on the constructivist theory.

In a changing world, where things are gradually becoming more uncertain and unpredictable, it is necessary to prepare individuals to be agent of this transformation. Beyond adapting subjects, these individuals must be able to think by themselves and question any sort of proposal, either from work or society in general. In order to accomplish that, the school ought to focus on the development of cooperation, autonomy and critical thought, which are fundamental features to a citizen to be a critical and questioning agent.

Unfortunately there are few elementary school projects like the one analyzed through this research. Generally, the schools emphasize activities involving competition or non-cooperative exercises.

Conclusion

We concluded that two aspects were essential for the work to succeed: teacher's mediation and its hypertext feature.

The teacher's mediation promoted a complete interaction among the students. They really learned to work as a group, respecting the classmate opinion and sharing their information and discovers.

In this context, the teacher did not adopt an attitude of merely transmitting information, going from simple to more complex concepts and stimulating the students to absorb the knowledge just to express it during a test. She acted as a mediator between the student and the information to be learned.

Therefore, the teacher promoted the student's contact with different subjects and sources, stimulating a critical analysis: "learner and information emerged with new meanings after each contact, reflecting new knots, links of the extraordinary web of human knowledge" (Civiletti & Araujo, 1997, p.244).

A hypertext project was possible by the use of Micromundos, authorship software that allows the
construction of multimedia pages (text, pictures, photos, music, moving images, etc.), which may be interlinked in a non-linear way: "hypermedia production from authorship software may be considered a very useful pedagogic strategy because it is able to integrate different subjects, promoting a web-like knowledge construction" (Civiletti & Araujo, 1997, p.245).

However, choosing 'constructivist' software did not guarantee a pedagogic use based on the same principle. It was viable because of the project context. Being constructivist is not an abstract conception. It is a responsibility of the educator. The teacher provided a propitious environment to the students, through which they could be active during the exercises, in a cooperative, autonomous and critical way.

The lack of linearity was presupposed in the project organization. Knowledge construction was not meant to be focused on "the master" but fragmented in multiple intersections among the students, in a collective search of information about some common interest. It happened when the different subject matters included in the project started to establish internal links, relating the groups and demanding discussions and analysis in order to effectively achieve these connections.

Actually, two hypertexts were developed. The first one involved the children themselves, who cheerfully collected data to produce knowledge and feed the knots and links yet to be negotiated. It represented unique moments, filled with friendship and learning. The second, a virtual reflection of the other, is also its recorded memory. Besides a rich source for future users, it proves that transformation is a perennial possibility.

Infusing Technology in K-12 Classrooms: A Study of One Method Used to Evaluate the Impact of a Teacher-Focused Technology Integration Program

David E. Dean, Ph.D.
Information Resources
Eastern Washington University
Cheney, Washington USA
Dave.Dean@mail.ewu.edu

Abstract: This paper describes one method used to evaluate a program designed to prepare teachers to integrate technology into the classroom so that children will become capable and confident users of technology. The method observed involved in-depth training conducted outside of teachers' school districts via the Teacher Leadership Program sponsored by the Bill and Melinda Gates Foundation in Washington state. A quasi-experimental evaluation method was used. Results showed significant improvements in teachers' computer attitudes, self-efficacy, and experience measured on a pre to post test basis. Responses on post-test only factors indicated that: (a) school districts did not contribute significantly to participant's technology infusion efforts; (b) teachers described themselves as collaborative, mentoring, confident integrators of technology, and (c) teachers perceived that student learning was being positively impacted.

Introduction

This paper examines the author's recent evaluation of a statewide technology infusion effort in Washington state. What evaluation method was used? Why? How was the evaluation implemented? What were the results of the evaluation? The focus of this paper is on HOW and WHY the specific evaluation method was used and administered. Results from the study are included in this paper in order to illustrate the kinds of findings which can be achieved by the evaluation method used. The research described in this paper took place in the context of the authors' Doctoral dissertation study. This paper provides an extremely abbreviated description of the study.

In the state of Washington, school administrators and teachers are being pressured to improve student performance on standardized exams and they are being asked to integrate technology into their curriculum. Factors supporting the development of exemplary computer-using teachers should be studied to determine their relative cost effectiveness and to demonstrate to administrators that teaching practices will change given time and an appropriate technology environment for teachers (Becker, 1994, p. 319). Research was conducted on 210 teacher participants of the 1999-2000 school year Teacher Leadership Project (TLP), sponsored by the Bill and Melinda Gates Foundation (the "Foundation") in Washington state. The training method observed involved seventy hours of in-depth training conducted outside of teachers' school districts. Participants received technology training, a laptop, and funding for technology for their classroom.

Conceptually, the research project consisted of six distinct steps: (1) Conduct research to build a scholarly foundation, (2) Identify research questions, (3) Determine methodology and develop or locate a research instrument, (4) Execute the study, (5) Analyze data, and (6) Present findings in context with the research questions. A discussion of the evaluation of the Teacher Leadership Project (TLP) follows. The TLP study is described in the context of these six research steps.
Case Study - Teacher Leadership Project

Conduct Research to Build a Scholarly Foundation

It is critical to take time to perform background research before executing a study. This step is the equivalent to scraping and priming a house before it is painted. The more thorough job that is done in preparation of the house (or in building the foundation for your evaluation effort) the better and more long-standing will be the results when the actual task – painting the house (or administering your study) – is performed. Take time to gather background materials and to discover how previous researchers have tackled evaluation projects similar to the one you face.

For the TLP study, a review of the literature regarding integration of technology into the classroom revealed that teachers will be much more likely to infuse technology into their curriculum if the following items are true: (a) training is available on the use of computers; (b) training is available on integration of computers into the curriculum; (c) the teacher has a sense of self-confidence; (d) the teacher believes that computers are, or can be, relevant to their role as a teacher; (e) the teacher is innovative; (f) the district has conveyed an expectation to the teacher supporting the importance of computers in the classroom; (g) technical support is available to the teacher; and (h) the teacher has peers to collaborate with regarding instructional uses of information technologies (Becker, 1994; Chiero, 1997; Evans-Andris, 1995; Koons, 1992; Marcinkiewicz, 1994-1995).

The study of the TLP incorporated research from 51 recent studies, the majority of which involve research conducted within the past three years. These studies focused on identifying: (a) differences between exemplary computer-using teachers and "typical" computer-using teachers (e.g. Becker, 1994; Evans-Andris, 1995); (b) differences in technology infusion skills between pre-service and practicing teachers (e.g., Marcinkiewicz, 1994-1995; Rosenthal, 1999; Trilling & Hood, 1999); (c) specific hypothetical "causal factors" such as gender, age, classroom environment, and percentage of budget spent on technology where the researcher seeks to determine the significance of such factors in teachers' technology infusion practices (e.g. Busch, 1995; Loyd & Gressard, 1984a); (d) the current level of teacher technology infusion skills and "best practice" factors which lead to technology infusion excellence (e.g. Peck, 1998; Smith, 1995); (e) the relationship between positive classroom experiences and self-efficacy (e.g. Ertmer, et al., 1994; National Science Foundation, 1984-1989); and (f) the relationships among computer self-efficacy, attitudes toward computers and the desirability of learning computer skills (e.g. Bandura, 1997; Zhang & Espinoza, 1998).

Identify Research Questions

As the saying goes, "If you don't know where you are going, how will you know when you've arrived?" Properly designed research questions provide a study with direction. In a sense, when designing the study you "reverse engineer" the study to identify what you want to know at the conclusion of the study. Design research questions with the conclusion of the study in mind. The research questions also allow the researcher to narrow the focus of the study so that a methodology and a research instrument can be identified.

In the case of the TLP, the following research questions were identified at the beginning of the study and were answered by the study:

1. Is there a significant change in the level of computer attitudes, self-efficacy, experience, and frequency of use of computers among the participants following the 10 month treatment?
2. What level of support have participants received, from their school districts, for technology infusion?
3. What are participants' perceptions of the impact technology has had on their role as teacher?
4. What are participants' perceptions of the impact of technology infusion on their students' learning experiences?
5. What impact do demographic variables (number of years of experience teaching, age, gender, and grade level taught) have on CASE scores, teacher perceptions of district role, teacher perceptions of their own role, and teacher perceptions of the impact the training has had on student learning?

Develop or Locate Research Instrument

Instrument Design: A Computer Attitudes, Self-Efficacy, and Experience (CASE) assessment instrument was designed by the researcher for this study. The CASE was modeled after three instruments - the Bath County Computer Attitudes Scale (BCCAS) by Bear, Richards, and Lancaster (1987), the Computer Self-Efficacy Scale (CSE), developed by Murphy, Coover, and Owen (1988), and a measurement of Computer Experience as described by Moroz and Nash (1997a).
The instrument consisted of four parts. Part One contained attitude items modeled after the BCCAS. Part Two included items of computer self-efficacy modeled after the CSE. Part Three asked computer experience questions in a format similar to that described by Moroz and Nash. Part Four asked demographic questions. The CASE pre-program questionnaire included 21 questions pertaining to attitudes about computers, 18 questions regarding computer self-efficacy (perceived computer skills), and 13 questions that measured computer experience. A six-point scale was used to measure attitudes and self-efficacy. Teachers were asked to rate the extent to which they agreed or disagreed with each statement, on a scale where 1 = strongly disagree and 6 = strongly agree. Computer experience was measured on a five-point scale, where 1 = never use and 5 = use daily. In addition to these questions, four demographic questions were asked regarding (a) the number of years of teaching experience, (b) participant age group, (c) participant gender, and (d) grade level taught.

Computer Attitudes: The BCCAS was selected as the model for the attitudinal component of the CASE because it has been used with several large groups of elementary grade level students as well as with adult populations, and it has been found to effectively measure overall attitude towards computers (Francis & Evans, 1995; Katz, Evans & Francis, 1995; Moroz & Nash, 1997b). Developed by Bear, Richards, and Lancaster (1987), the original BCCAS questionnaire included thirty-eight Likert items designed to assess attitudes toward computer use. Some items were worded positively (e.g., “I enjoy learning about how computers are used in our daily lives”), others were worded negatively (e.g., “Reading and talking about how computers might be used in the future is boring”).

Self-Efficacy: A variety of studies have examined the relationship between computer self-efficacy and other attributes. Miura (1986) suggested that self-efficacy may play an important role in a person's acquisition of computing skills. Self-efficacy is defined as an estimation of one's ability to successfully perform target behaviors to produce outcomes (Bandura, 1986). Self-efficacy theory proposes that individuals who judge themselves as capable (efficacious) to perform certain tasks or activities will tend to attempt and successfully execute them (Murphy, Coover, & Owen, 1988).

Busch (1995) defined self efficacy as “the belief in one's ability to execute successfully a certain course of behaviors” (p. 174). Miura (1986) found that self-efficacy impacted a person's understanding of the importance of computers in the future and she found that self-efficacy could be used to help predict an individual's intention to learn about computers. Woodrow (1991) asserted that students' attitudes toward computers played a key role in their success with computer classes and with self-paced computer materials.

Bandura (1997) encouraged the development of an instrument designed to measure teacher self-efficacy for a specific domain, such as computer self-efficacy. “Teacher's sense of instructional efficacy is not necessarily uniform across different subjects. Thus, teachers who judge themselves highly efficacious in mathematical or science instruction may be much less assured of their efficacy in language instruction and vice versa. Therefore, teacher efficacy scales should be linked to the various knowledge domains” (p. 243).

The Computer Self-Efficacy Scale (CSE) was chosen as the model for the self-efficacy component in the CASE instrument. The CSE scale was developed by Murphy, Coover and Owen (1988) to measure perceptions of respondent's capabilities regarding specific computer-related skills and knowledge. The scale employs a 5-point Likert-style response format, with each question preceded by “I feel confident.” A high score indicates that the person has a high level of confidence in his/her ability to use computers. The CSE has been found to have a high level of validity when administered to groups of adults and students.

Computer Experience: Research has shown that the amount of experience a person has with computers will significantly impact that person's assessment of their computer self-efficacy (Ertmer, Evenbeck, Cennamo, & Lehman, 1994; Loyd & Gressard, 1984a; Loyd & Gressard, 1984b). It has also been shown that computer experience and computer anxiety are interrelated (Loyd & Gressard, 1984b) and studies have found a link between computer experience and attitudes about computers (Bear, Richards, & Lancaster, 1987; Delcourt & Kinzie, 1993; Loyd & Loyd, 1985; Moroz & Nash, 1997a; Zhang & Espinoza, 1998).

Exemplary computer-using teachers have been found to spend more than twice as many hours personally working on computers at school than do “typical” computer-using teachers. Only a small difference has been found in computer use at home between typical and exemplary computer-using teachers (Becker, 1994, p. 307). Computer experience questions in the CASE, were developed to collect data pertaining to the respondents' computer-related activities — distinguishing between computing activities performed at work and those performed at home. Questions ask the respondent to select appropriate indicators of computer usage that describe the intensity and consistency of activity rather than asking for indicators that would measure the length of time they spend on that activity. This method of measuring computer experience based on frequency of activity rather than temporality (time on task) has been employed in a variety of studies (Chiero, 1997; Hudiburg, 1990; Mitra, 1998; Nash & Moroz, 1997; Zhang & Espinoza, 1998).
Demographics: Demographic questions on the CASE include: (a) number of years the respondent has taught, (b) respondent age range, (c) respondent gender, and (d) grade level of students the respondent teaches. Research indicates that exemplary computer-using teachers have more years of teaching experience and more years of exposure to computers than the typical computer using teacher—exemplary computer-using teachers had taught their subject for three years longer than other computer users, and they had used computers for about one year longer (4.0 years versus 3.2 years) (Becker, 1994, p. 309).

Post-Program Questions: The post-test instrument was enhanced by the addition of questions arising from the literature and geared to provide insights in the areas of: (a) school district role in participant’s technology infusion efforts, (b) teachers’ perception of their teaching role upon exit of the TLP, and (c) teachers’ perception of the impact their technology infusion efforts are having on student learning.

Execute the Study
Pre-test data collection took place at the start of the first week of training for each participant (July and August, 1999). Two-hundred and twenty-five surveys were collected during administration of the pre-test. At each (of seven) initial training sessions, attendees were given a copy of the CASE (Computer Attitudes, Self-Efficacy, and Experience) instrument and were asked to randomly select a small manila envelope from a collection of similar envelopes. Each envelope contained two adhesive mailing labels, each label displaying a printed control number unique from other participants’ number. This control number, adhered to pre and post assessments, guaranteed respondent anonymity while providing a mechanism to correlate pre and post program data for each participant.

Post-test data collection took place at eight locations across Washington State on April 29, 2000, the last day of the final TLP-sponsored training session attended by the 1999-2000 school year’s participants. In early April, participants were instructed by the Foundation to reserve their place with the appropriate regional coordinator for the location at which they planned to attend. The Foundation provided the researcher with a list of participants by location. Sealed envelopes containing the matching control number were sorted by region and forwarded, along with surveys, survey instructions, and post-paid return envelopes to the regional coordinators. Regional coordinators administered the surveys the morning of the last day of the last TLP training session for this group. Completed surveys were returned to the researcher.

Gather and Analyze Data
Initially, all of the data were analyzed using descriptive statistics. Frequency scores, mean scores, and standard deviation scores were computed for all Likert scale responses for all response items—both pre and post treatment. A total CASE score for each individual was calculated to measure TLP impact pre and post test. In order to answer research question number one, which asks whether there were significant differences in teacher responses pre to post treatment, t-tests for correlated samples were calculated for each of the 62 CASE factors. Research questions number two, three, and four were answered based exclusively on the results of descriptive statistics calculated on post-treatment data (questions 61-74, which were used to answer research questions number two, three, and four, appeared only on the post-instrument). Two statistical routines were utilized to answer research question number five, which asks whether there was a significant relationship between CASE factors and demographic factors. A Pearson correlation score was calculated to determine if a significant relationship existed between the first demographic factor (number of years teaching) and CASE scores pre, post, and case-change (post minus pre score). One-way Analysis of Variance (ANOVA) statistics were calculated to determine if a significant relationship existed between the three other demographic factors (age range, gender, and teaching grade level) and CASE scores pre, post, and case-change.

Present Findings in Context with the Research Questions
Results of this study led to seven conclusions:
1. Teacher’s computer attitudes are significantly higher following the TLP.
2. Teacher’s computer self-efficacy is significantly higher following the TLP.
3. Teacher’s computer experience is significantly higher following the TLP.
4. Teachers perceive that school districts provide little support for TLP participants’ technology infusion efforts.
5. TLP participants’ perceive their role as a teacher to be dramatically different from the classical role of the teacher as the “sage on the stage.”
6. Teachers perceive that students benefit from technology infusion efforts.
7. Participants' age, gender, number of years teaching experience, and grade level taught do not significantly relate to CASE scores.

Summary

Research can be exciting, rewarding, and enlightening. Take the time to do the "scraping and priming." Reverse engineer your study and determine ahead of time what you want to know when the study is completed. Avoid creating your own instrument – get permission to utilize existing instruments if possible. Make sure you are gathering data that will allow you to answer the research questions. Carefully analyze the data and report your findings in the context of the original research questions.

The Teacher Leadership Project (TLP), has concluded its third year and has reached more than 400 teachers. Interestingly, the focus of the TLP training model is not on computer use (the "which button do I push" kind of class), but rather the focus is on helping teachers learn how to adopt a mentoring, collaborative teaching style. Training emphasizes use of discovery learning lessons with the appropriate use of technology as a tool to improve student achievement. Sixty of seventy hours of training focus on: discovery learning, technology infusion, and teacher collaboration. About 10 hours of traditional computer application training is provided, nevertheless, the minimum computer experience score doubled on a pre to post test basis indicating a substantial increase in the frequency of use of computers by even the least experienced respondent.

A new environment is emerging in the classrooms of TLP participants. Students often become teachers, and teachers learners. Students are engaged, curious and interested in active inquiry. They have begun collaborating with each other and serving as peer mentors. Teachers have adopted a mentoring, collaborating style of interacting. And through regular meetings and workshops, teachers had the opportunity to share and learn from their peers' new strategies.

Research conducted by the National Center for Educational Statistics (NCES) found that only 20% of the 2.5 million teachers who currently work in public schools feel comfortable using information technologies in their classrooms (Rosenthal, 1999). In contrast with the NCES finding, the majority of participants in the 1999-2000 Teacher Leadership Project indicated overwhelmingly that they are comfortable using information technologies in the classroom. Participants reported that they enjoy using computers (99% positive response), they feel school is a better place with computers (100% positive response), they indicate a positive self-efficacy score on a variety of computing tasks, and they uniformly believe (99% agreement) that student learning is being positively impacted due to participants' technology infusion efforts.

The author hopes this abbreviated description of the Teacher Leadership Project evaluation will provide one more example of an evaluation effort that future studies will build upon.

Abstract: The aim of this three-year project is to develop information and communications technology (ICT) competencies in both nursing students and teaching staff by means of, implementing technologies into a graduate nursing program offered throughout the province of Quebec, (Canada). Through reviews of the literature and experience from other colleagues, we have learned that actors’ motivation is essential for the success of such a project. Our first step was the identification of teachers’ perceptions of efficacy and beliefs. These two concepts were then examined in an exploratory research with a mixed research design. In all, twenty-four nursing professors participated, and findings indicate that they perceive themselves as being more efficient in basic level ICT, and less so in advanced ICT. Nevertheless, the research sample in general expressed their belief in the importance of integrating ICT in graduate students’ curriculum.

Introduction

During the past four years, nursing professors have been involved in initiating a master’s degree in nursing, which has become effective since September 2000 in five universities throughout the province of Quebec, (Canada). These five universities work together as networked learning environments (Chute, Sayers, Gardner, 1997) to ensure that graduate studies are accessible to nurses in all Quebec regions. We anticipated that this geographic layout would represent a big challenge in terms of allowing a specific teacher’s expertise to be available to students from all institutions; however, we feared that both actors, students and teachers, would eventually feel isolated.

Integrating information and communication technology (ICT) in the program offers interesting possibilities in terms of enhancing access to knowledge and promoting networking activities. We wanted to create a learning community on the web, that is, a community of practice, which could stimulate energy exchange between the program’s partners. We feel that the use of video-conferencing, e-mailing, and the creation of a technological learning environment, etc, seem to provide interesting answers to the needs of both teachers and students. Referring to experiences in the United States, we observe that since 1995, one third of all superior education institutions offer distance-learning opportunities (Cravener, 1999). Amongst them, nursing teaching experiences can be found (Milstead & Nelson, 1998; Cravener, 1999). In Europe, the Open University in England is a leader in distance education. Closer to home, in Quebec, a growing number of experiences have been attempted by colleagues, but never to the extent of offering a full graduate program. Cloutier, (1999) deMontigny & al, (1997, 1999) agree that appropriating information technology is a major challenge for all actors involved. For most of these projects, the conclusions appear quite similar; for one thing, the leaders are thrilled with the existing possibilities however, at some point, they doubt that their colleague teachers and students involved have the intention or the capabilities of really integrating the technologies into their everyday work. Many of these projects have their grounds in the leader’s will but do not proceed from the actors’ wishes.
In order to implement technologies into our master degree program, we developed a three-year project called MISTIC, (Maitrise en Sciences infirmieres integrant les Technologies de l'Information et de la Communication). The purpose of MISTIC is to develop competencies in both students and teaching staff, thus facilitating integration of information and communications technology. Knowing, (from our colleague’s experience and upon reviewing the literature) that the actor’s “intention” is a fundamental aspect in the success of such a project, we first attempted to consult around us. We were in fact, unable to make a description of teachers’ knowledge or abilities pertaining to information technologies, although we were aware that there were variations and disparities. It was obvious that our first step had to be the proper identification of teachers’ perceptions of efficacy, learning needs, beliefs and motivation (Cloutier & al, 2000). This paper presents nursing teachers’ self-efficacy perceptions and beliefs relating to information and communications technology.

The study

This study’s objectives are to identify nursing teachers’ self-efficacy perceptions and beliefs. This exploratory research has a mixed research design, and the instruments combine both quantitative and qualitative items. A self-efficacy perception questionnaire was devised for this research, based on Bandura’s definition of personal self-efficacy, in which he states that beliefs are built by an individual regarding his abilities to mobilize his motivation, his cognitive resources and the behaviours necessary to meet the demands of a given situation (Bandura, 1991; Ozer & Bandura, 1990; Bandura, 1996). The twenty items questionnaire was constructed by a team of three professors and was submitted to two expert judges for content validity. Qualitative data concerning beliefs relating to obstacles and facilitating factors in the use of information and communication technology were gathered. Beliefs were defined as: “the conviction that a subjective reality is the truth” (Wright, Watson & Bell, 1996, p.41). According to these authors, constraining beliefs decrease solution options to problems, whereas facilitating beliefs increase solution options. ICT was defined as usually accepted technologies of communication and information, such as cyberspace, e-mail, discussion groups, chat, video-conferencing, etc. For this study, we distinguished between basic techniques and advanced techniques; the former referring to daily teaching and research activities (for example, e-mailing) and the latter referring to more specialized activities requiring mastery of basic techniques (for example, creating a web page).

Participation was anonymous and on a voluntary basis. Twenty-four nursing professors participated by filling in an online questionnaire, which was available on a web site for a ten-day period. This questionnaire, which the creation in itself was a technological innovation, is presently being used in an independent study carried on by Pothier (2000). It allows data to be compiled into descriptive statistics, which are automatically transferred into a data base.

Participation rate was 73%, which is considered acceptable. According to Polit and Hungler (1999), a response rate greater than 60% is sufficient for most purposes. Among the participants, 50% (12) were in the 40-49 year age group, as illustrated in tab.1. Of the twenty-four participants, 83% (20) were women and 17% (4) were men.

Data Analysis

Data were recorded using Microsoft Excel and Oracle and content analysis was performed with the qualitative data.
Findings

Nursing teachers' self-efficacy perceptions of ICT

Analysis of self-efficacy perceptions revealed that nursing teachers perceive themselves as mastering all basic information and communication techniques, except for participating in group discussions, and using and upgrading anti-virus software. Nursing teachers perceive themselves as being limited in terms of their efficacy in using their university's library web site (tab. 2).

Table 3. Nursing teachers self-efficacy perceptions of advanced ICT.

Nursing teachers' beliefs in ICT

Facilitating beliefs

As for beliefs, we found that the majority of nursing teachers (85%) believe that ICT should be used in nursing graduate studies (tab. 4). They are also convinced that ICT could improve their way of teaching and the students' learning. We observed that the motivation to use ICT was high in this group (84%). The nursing teachers felt they were supported in their experiences with ICT with sufficient equipment (84%) and available expertise (74%).
Constraining beliefs

Nursing teachers hold some beliefs that can be seen as obstacles when using ICT in teaching-learning experiences. For example, 60% of the participants mentioned that the lack of time was an important restraint, and 50% felt the cost of the equipment was a limitation factor. Several of the teachers consulted believe that the development of such activities needs further recognition from their peers.

Interestingly, although nursing teachers perceive themselves as being competent with ICT, a large proportion doubt (75%) that their students have the abilities to work with ICT.

Table 4. Nursing teachers' beliefs in integrating ICT in education

Conclusion

When new elements are introduced into teaching-learning situations, it can be expected that teachers will perceive these as important stressors, especially when these changes are imposed from the outside and when the time required to learn how to use technologies is time taken away from course content development (Akerlind & Trevitt, 1999). In this context, the study sample's positive attitude about ICT integration in teaching stands out. This may be attributed to the fact that most nursing teachers in these institutions are mature professionals who have experienced a variety of instructional methods in their career, and are thus more able to adapt to novelty. According to Bandura & Wood (1989), an individual's history of success and failure and his past experiences are his most significant sources of information to evaluate his abilities and limits.

In the end, our findings are not unusual. For instance, Roblyer's (1993) reports that usually, teachers quickly recognise the importance of using technology in teaching situations. Self-efficacy theory stipulates that an individual's self-efficacy perceptions will influence the quantity of effort he is likely to put into an activity and the length of time he will maintain his effort in spite of obstacles and failures met (Stretcher, de Vellis, Becker & Rosenstock, 1986). Considering this study's results, we are lead to believe that the participants will be persistent in integrating ICT in their teaching experiences.

Even though most teachers realize the importance of integrating ICT in their curriculum, different obstacles encountered often hinder their efforts, such as: difficulties working with a new software or the fear of negatively affecting their teaching performance (Ertmer, 1999). These apprehensions can be found in the qualitative data,
despite the overall positive comments. It is clear that both pedagogical and technical supports are important aspects of integrating technology in the curricula. This leads us to recommend: an investigation of nursing professors’ learning needs regarding ICT, training sessions to meet those needs, and finally, a re-evaluation of self-efficacy perceptions following the training sessions.

Academic Product Assessment: A tool for graduate action research assessment

Charles Elliott & Florence Elliott, Gannon University, USA

This research project examines a systematic assessment process as part of the Educational System Design (ESD) model, derived from work at Vanderbilt University by the Cognition Research Team and by Charles Reigeluth at Indiana University at Bloomington. The ESD model outlines four principles of effective learning environments: Problem-Based Learning, Scaffolding, Deepening Learning, and Collaboration. The research will explore the use of a formative assessment tool within this educational model. As part of Gannon University's M.Ed. Cohort program, academic portfolios are required as a final synthesizing activity. A part of this portfolio is the Applied Master's Project (AMP), an ongoing action research project. Students in the cohort program are to design, construct, and implement a research project over the course of the 18 months of cohort coursework. The AMP project is to be incorporated as a component of each of the six core courses, advancing the project from design and construction, through implementation and culmination. Research indicates that feedback, provided at key stages in the portfolio development process, results in improved final products. Providing effective feedback during this course should contribute to product improvement. Questions are raised however, about the type of feedback provided and the mechanism for providing this feedback.

The use of portfolios has emerged in recent years as a mechanism for students to demonstrate their subject knowledge and skill proficiency. In the area of fine arts and English, portfolios have a documented history and specific purpose. In these curricula, students assemble a collection of their best work to present for final evaluation. Each element of the portfolio has undergone a process of design, construction, and revision. Inherent in portfolios is the understanding that these collections represent the student's best work. It is understood that each product has undergone the design, construction, and revision process. Portfolios are a work in progress and feedback is an important part of the portfolio's development. How the feedback is gathered and used plays a significant factor in the quality of the final product(s). When the final portfolio is presented, reviewers expect to see the highest quality work possible from the student. At the time of the final portfolio submission, reviewers use some criteria to evaluate the portfolio products. The assessment instruments are typically rubrics, which the student may have been using to guide and direct the portfolio's design and construction. There may be a separate rubric for each item in the student's academic portfolio, making evaluation a maze of rubrics. More often, one standard assessment instrument is applied to each portfolio product or applied to the portfolio as a whole, focusing on global learning goals.

The review process is the focus of this research initiative. In this project, a standard assessment tool (Academic Product Assessment Form – APAF) was used to provide direction and guidance in the design and construction of portfolio products, through its use in providing feedback to students. This assessment tool was derived from the work of Reigeluth and Reis. Feedback was provided through assessment by peers and contemporaries. There appear to be a number of unique features in this research project, which address some of the criticisms of portfolio use and academic product assessment. It was the goal of the research initiative to address the following objectives: determine the utility of the Academic Product Assessment Form (APAF) in evaluating components of a Master's degree Applied Master's Project and Portfolio; examine the use of this assessment tool as an integral part of a comprehensive assessment program; establish reliability and validity of the Academic Product Assessment Form (APAF).

The Academic Product Assessment Form (APAF) is a modified version of the Student Product Assessment Form (SPAF) designed and constructed by Drs. Joseph Renzulli and Sally Reis at the University of Connecticut. The original assessment form was designed to be used as a formative assessment tool used by younger students in enrichment programs. The form used in this study incorporated the same nine categories used in the original format. These included eight (8) individual dimensions: Statement of Purpose; Problem Focusing; Level of Resources; Diversity of Resources; Appropriateness of Resources; Logic, Sequence and Transition; Action Orientation; Audience. A ninth category incorporated seven (7) descriptors used for the
Overall Assessment of the product. These included: Originality of the idea; Achieved objectives stated in plan; Reflects familiarity with subject matter; Reflects a level of quality beyond what is normally expected; Reflects care, attention to detail, and overall pride on the part of the student; Reflects commitment of time, effort and energy; Reflects an original contribution. The category descriptors were revised only to eliminate the use of terms referent to younger students, school, or age. The item descriptions were modified to reflect the project at hand and the adult students engaged in the project. Four additional items were included in the assessment form. These came from the Gannon Cohort Applied Master’s Program Manual, detailing the current evaluation criteria for the program.

As part of Gannon University’s M.Ed. Cohort Program, academic portfolios are required as a final synthesizing activity. A part of this portfolio is the Applied Master’s Project (AMP), an ongoing action research project. Students in the cohort program are to design, construct, and implement a research project over the course of the 18-month program of study. The AMP project is to be incorporated as a component of each of the six core courses, advancing the project from design and construction, through implementation and culmination.

Students enrolled in Technology as a Change Agent (GC 654) were to advance their AMP project as part of the course. Students electronically posted an abstract of their project. Learning teams were formed and these teams evaluated each other’s projects and assisted in resource building throughout the course. Each cohort member presented their project at the last class meeting for the course. This session was set up using a conference format, where students presented either during a poster session or oral presentation. At this class meeting, colleagues provided input to presenters of each poster and presentation. The daylong conference was intended to provide each cohort student an opportunity to develop and present what may become a part of a final portfolio presentation for the M.Ed program. Graduate students enrolled in the Cohort Master’s Program offered through Gannon University’s School of Education were recruited to participate in the study as part of a course within the core program of study. Data from the APAF is currently being collected and reviewed.

Students were asked to complete the Academic Product Assessment Form for each of the poster and oral presentations, scheduled to take place during the last day of class. Confidentiality of student information was assured through a process of random coding. The instructor and research assistant’s assessment forms were not included in the research data. A copy of each completed assessment form was returned to the each student in the course for his/her project. Students used this input as they continued to develop their projects and prepare for their final portfolio presentation. A second collection point is being planned at the final portfolio presentation of each student, where evaluators will be solicited to complete the APAF on a voluntary basis. The forms will not be used for grading, but may be copied and given to the research participants. All evaluator names will be eliminated from the APAF in all cases.

At the current time, this research project has implemented the phase one collection process. This has generated over 500 assessments on 48 projects and presentations. These have been completed by cohort peers. Some general observations have been included in this stage of research progress. The use of one standard assessment device for the variety of portfolio projects and presentations has benefits and limitations. Although a customized form for each individual project would be preferred, this would require that the device be conceived at each project’s initial creation and then would have to be modified throughout the project life. An alternative form might be constructed around each of the eight core courses in the program of study, with the hope that students would integrate something from each of these courses. This creates another series of issues due to the diversity of projects in which students are engaged. Students have found the form easy to use with minimal orientation to the item descriptions. The ranking scale (1 to 5) has not discriminated adequately the projects on any particular scale. In effect, cohort peers are being rather generous in rating each others’ projects.

As students in the cohort program undergo their final portfolio presentations, faculty reviewers will be asked to complete the APAF for specific portfolio products. These reviews will be examined for internal consistency and inter-rater reliability, and then compared with peer assessment reliability data and previous studies using this instrument. Additionally, assessments conducted by M. Ed. Students and cohort faculty reviewers will be compared on specific products and students to examine variations between peer and contemporary assessments. This study is expected to continue through the academic year 2001-2002, initially focusing on the establishment of the instrument’s reliability and face validity. As cohort student complete their portfolio presentations, additional reviews will be conducted as sufficient data becomes available.
Student teachers' information technology experiences in schools

Alison Elliott

Step into many elementary classrooms and it's like stepping into a time warp. Classrooms look, feel and operate much the same as they did in the 1970s. While many teachers use computers to support children's learning in meaningful ways, most in-class use of computers is minimal and has changed little from the drill and practice and story writing models of the 1980s (Marcinkiewicz, 1994-95, Elliott, 1998). With information and communication technologies (ICTs) now so widely available in schools and the community, the possibilities for classroom adoption are ripe. Yet, few elementary school students' experiences of ICT, and especially in the early years of schooling, encapsulate the potential of the technology to enliven, enrich and individualise learning.

The reasons for teachers' limited adoption of ICTs, even in schools that are well resourced, have perplexed researchers and policy makers. Further, limited classroom use of computers has implications for pre-service teacher educators who rely on partnerships with schools to provide student teachers with experiences of contemporary pedagogies, curriculum content and classroom management. As teacher educators, we expect that during school professional experiences (practicum and internships) students will be involved in a range of first hand, authentic teaching experiences that complement university-based teaching, including ICT experiences.

At the same time, policies and practices in teacher education affect students' engagement with information and communications technologies and are important in shaping pre-service teachers' attitudes to adoption and integration. In Australia, the document Computer Proficiency for Teachers (1997) represented an attempt to ensure greater awareness of contemporary computer needs in schools, to specify the ICT competencies required by beginning teachers, and to remind teacher educators of their responsibilities to prepare students for teaching in an information and knowledge oriented society (DET, 1997). Clearly, teacher educators must continually strengthen applications of information and communications technologies across their programs if student teachers are to gain relevant pedagogical understandings, attitudes and skills. Explicating ways of using the technologies in an integrated manner must be a cornerstone of teacher education curricula. Concomitantly, student teachers must have opportunities to work with children in classrooms as they use information and communications technologies, including the internet.

In NSW, almost all schools have good access to technology, infrastructure, and teacher support, but many have done little to adapt instructional processes to capitalise on ICT access, strengths and flexibility. While schools are known as inherently conservative entities (Rizvi, 1993), reluctance to embrace ICT to focus on improving educational outcomes is of concern to education policy makers, and to teacher educators.

There is considerable evidence showing that student teachers have only limited opportunities to experience computer use in classrooms (Bosch & Cardinale, 1993; Downes, 1993; Elliott, 1996; 1998; Hunt, 1995; Yang & Holthaus, 1997). From a teacher education perspective, cooperating teachers' limited modelling of computer use in teaching and their seemingly negative or ambivalent attitudes to ICT, are not conducive to developing student teachers' ICT competencies.
Translating information and communication technology from the policy documents and marketing brochures into classroom practice has been an elusive goal over past decade. Clearly though, developing future teachers’ expertise in harnessing ICT to provide meaningful learning opportunities in classrooms is important for current teacher education programs.

The aim of this paper is to report student teachers’ ICT experiences in some 60 early childhood classrooms (Kindergarten to Year 2) during recent pre-service professional teaching periods in greater Western Sydney. Drawing on both quantitative and qualitative data I document student teachers’ perceptions of children’s in-class information technology activities and identify some characteristics students associated with computer-using teachers. The purpose of highlighting student teachers ICT experiences and their perceptions of computer-using teachers is to articulate some of the qualities that might be capitalised on or complemented in building programs to support teachers’ ICT competence. In particular, a clearer understanding of characteristics of computer-using-teachers might ensure that teacher education programs can better prepare students to deal with realities of classroom situations where computers are not widely used because teachers are not particularly committed to improving practice through adoption of relevant ICT support. Student teachers may also be better prepared for the more hostile situation where specific strategies are needed to counter teacher pressures, often subtle, to adjust to the way things are and maintain the status quo (Britzman, 1991). Finally, greater knowledge of the classroom situation may help us better prepare student teachers who find themselves having to persuade well meaning, but technologically novice classroom teachers to “allow” them to observe and use computers in class.

Finally, reference is made to the computer enactment model for teacher education proposed previously (Elliott, 1999b) and its role in helping teacher educators develop partnerships with schools to support student teachers’ ICT experiences during professional experience programs.

**Method**

After completing a 4 week block teaching practice on K-2 classrooms in elementary schools in the western suburbs of Sydney, NSW, 60 student teachers completed a short questionnaire probing the nature of the computer experiences encountered in schools and participated in focus group discussions about characteristics of teachers who embraced ICT in their classrooms.

**Results and Discussion**

Consistent with previous studies (Elliott, 1996, 1998, 1999b), results from the present research showed that most students had limited opportunities to observe computer use in day-to-day classroom practice. All students reported that teachers had access to computers in their classroom or adjacent space, in a dedicated computer room, or in the library. A few had access to computers on multiple sites. Over the four week period, nearly half the student teachers (43%) estimated that each child in their class used computers for less than 15 minutes per week. Two students reported children did not engage in any computer-based learning activities while at school. A further 25% estimated that each child had 20-30 minutes of computer use per week and 16% estimated that children spent about 35-45 minutes engaged in computer activities. Only 5 students reported that children in their classrooms had over one hour of computer use per week.
Again, as noted in earlier studies of student teachers’ experiences in schools (Elliott, 1996, 1998, 1999b), the main types of activities observed in the classroom were word processing for story writing, some directed maths activities (number recognition, counting, shapes), reading electronic books and some word recognition and spelling. Only five students saw children using the internet; in each case activities related mainly to the Olympic games; emailing athletes, tracing the journey of the torch, and other Olympic-related activities. Internet use occurred only in classrooms where children averaged over 35 minutes of computer use per week.

There were a number of cases where children went to a dedicated “computer room” for “computer lessons” with a “specialist teacher” on a weekly basis. In several cases “computer lessons” were held in the library. In five cases, the only computer-based activities for children were those provided by the student teacher as part of the practical requirements of the professional experience. Two students claimed that children in their classes had no computer use of any sort during the 4 weeks and that they were “not allowed” or “not able” to complete the university required computer tasks with children.

In classes where student teachers reported that children averaged 20 minutes of more computer use per week, and computer activities were initiated by the regular classroom teacher rather than a “specialist computer teacher”, terms such as “motivated”, “creative” and “involved” were often used to describe the cooperating teachers. The main distinction though, between descriptors of teachers in these more “computer-active classrooms”, as opposed to classrooms where computer use was less evident, was teachers’ apparent strong “communication” with parents, their “excitement” about teaching, their positive attitudes, motivation, and enthusiasm, and their “confidence”, and expertise in teaching. In some cases, the teacher described as “fantastic” or “excellent”.

Focus group discussions with student teachers based in classrooms where children averaged in excess of 35 minutes computer use per week suggested that cooperating teachers articulated a strong commitment to ICT use in learning, were good classroom managers, and tended, generally, to be involved in a wider than normal range of school activities. One teacher, for example, was the school’s “computer coordinator”, another the head of the junior school, and another the “choir leader”. Indeed, good classroom management strategies have long been regarded as a cornerstone to effective teaching (Stannard, 1995) and in most cases students commented that their cooperating teacher was a “great organiser” and always “very busy”.

That only 10 students claimed that each child in their class had in excess of 35 minutes of computer use per week, and 5 reported experiences in excess of one hour per week, hardly points to a major classroom adoption of ICT. Nor is there any indication that children are having too much computer use. Further, data do not show that computer-based activities were particularly innovative. Indeed, even in the high-use classes, most children engaged in the standard word processing, and basic skill-type activities associated with reading and math. There were no apparent differences between the types of activities in high-use and low-use classes, except for internet use.
As discussed elsewhere (Elliott, 1996; 1998; 1999b), that student teachers had few opportunities to observe teachers and children using ICT in every-day classroom situations is not surprising given the limited integration of computers in the enactment of curriculum. And, as also mentioned previously, the situation is affected not so much lack of appropriate technology, but rather lack of teacher commitment to changing pedagogy to facilitate enactment and integration of technologies (Elliott, 1999a).

In the light of the present findings, it seems teachers are not confronting the main tasks that must be addressed before change of any type, and in this case, adoption of ICTs can be effected. A major tenet of organisational theory is that effective organisational structures and directions can be shaped around tasks (Bolman & Deal, 1997; Scott, 1998) and, in turn, that tasks are pivotal for shaping teachers' work (Rogoff, 1990). In the case of ICT, three main tasks confront schools—fostering new understandings of ways teaching and learning processes can be supported through use of ICT; promoting and supporting use of ICT in classrooms; and building partnerships between school and community through the use of ICT.

As shown previously (Elliott, 1999a) individual teachers must be prepared to reconstruct their conceptions of pedagogy to embody less teacher-centred notions about learning and embrace more fundamentally democratic understandings, beliefs and values about classroom practice. Further, major changes to classroom structures and pedagogies needed to adopt ICT will not occur until teachers both understand and commit to change. Change occurs only when participants construct new understandings of the tasks and processes, not simply when technical innovations are introduced.

From a teacher education perspective, it is important that cooperating teachers are able to support student teachers' development of ICT competencies. Part of teachers' professional role is inducting new teachers to the culture and practice of teaching in all its complexities. Thus, efforts to enhance beginning teachers' ICT skills must involve partnerships between teacher educators and classroom teachers. Using computers to enhance classrooms learning should be as important as guiding learning and practice in more traditional aspects of pedagogy and curriculum.

Explicating ways of using and managing information technology to complement and support children's learning must be an integral part of teacher education curricula. Importantly, student teachers must have authentic opportunities to work with children as they use information technologies, including the Internet, to complement and support their learning. Adoption of an ICT enactment model (Elliott, 1999b) can assist in developing partnerships between teacher educators and schools. Significantly, such a model proposes joint ownership and collaboration between teacher educators, student teachers and teachers. In such partnerships teachers must work as co-creators of new pedagogies that embody ICT, because for changes to be lasting they must be accompanied by new values and understandings.

Abstract: This study examined differences in student perceptions of course and instructor effectiveness in distance education and traditional courses. The type of distance education examined was a two-way interactive TV. Three different modes of course delivery were studied: (1) distance education off-campus, (2) distance education on-campus, and (3) traditional on-campus. Eight instructors taught a course using each method of delivery. On-campus students in traditional courses perceived the course and the instructor as being more effective than their off-campus peers in distance education courses. The magnitude of difference between the means was large.

Introduction

The term “distance learning” describes any instructional arrangement where the teacher and learner are geographically separated (Moore & Thompson 1997). Distance learning, sometimes described as distance education (DE), home study, correspondence study, independent study, or external studies, has been an alternative method for delivering university-level courses for almost 300 years. Correspondence education was invented in the late 19th century to enable learners to receive instruction when they could not attend traditional classes (Moore & Thompson 1997). Today, the more popular term for this type of learning at a distance is distance education.

Moore and Thompson (1997) describe effective distance education as requiring communication between the instructor and learners through media and a new approach to instruction. Currently, distance education incorporates many alternative education opportunities, a significant number that involve emerging technologies such as two-way interactive TV, video, and web-based or web-enhanced instruction.

Keegan (1988) suggests that there are six defining characteristics of distance learning. First, there is separation of the teacher and the student (i.e., separation vs. face-to-face in the same classroom). Next, there is a
component not typically found in most on-campus courses, the influence of an educational organization (e.g., department or college) in the planning, preparation or delivery of material (vs. a stand alone instructor responsible for content generation and delivery of course information). Third, there is the use of technical media. Historically, this technical media has been print, but as technology advances, electronic media (computers, TV studio delivery, computer software presentation packages) will be added to a list of technical options. The fourth defining characteristic is the provision for two-way communication. This could be via a telephone conference with a single student, or a group of students at a central location at a prescribed time. Another defining characteristic is the possibility of an occasional seminar. This would be the opportunity for students working independently, to assemble as a group in the presence of the instructor.

The last defining characteristic as illustrated by Keegan is participation of the most industrialized form of education. Simply said, the industrialized form of education means a division of labor. Basically, there would be a team of individuals involved in the preparation and delivery of course content. Members of the team could be a content expert (e.g., a faculty member in elementary education, for a course offered from that program), graphic illustrators, who for all practical purposes, have no knowledge of the content, but, take the content and bring it to life with related illustrations, and a "TV personality," an individual trained to work in the presence of the camera and a TV or radio announcer's voice to deliver the content.

Although distance education has been viewed to be effective by some, in the eyes of others it has been seen as something less than education typically received on a university or college campus. In studies of various types of distance education, comfort and convenience were repeatedly cited as positive elements of the distance experience (Moore & Thompson 1997). Essentially, students in these studies like the convenience of distance education, but if given the choice to be in the same room with the instructor, most students will choose the personal contact.

Research on the effectiveness of distance learning is sparse. For example, a comprehensive historical review of technology research in special education does not mention distance learning (Woodward & Reith 1997). Moore and Thompson (1997) reviewed research on learning outcomes and attitudes for students in higher education. The studies included in their review reflected no differences in cognitive factors (amount of learning, academic performance, achievement, and exam and assignment grades) between the distance classes and traditional classes.

Other factors (e.g., student satisfaction with the course, comfort, convenience, communication with instructor, interaction and collaboration between students, independence, and perceptions of effectiveness) had more mixed results in the Moore and Thompson review. In the majority of the studies where interaction was studied, the distance condition seemed to negatively affect opportunities for interaction between students and with the instructor. In contrast, distance condition was found to positively affect collaboration and interdependence among students, in addition to support for independent learning activities.

Comfort and convenience were repeatedly cited as positive elements of the distance condition. However, a promising characteristic of one of the studies described distance education as "an acquired taste." Students reported that the more experience that they had with distance education technology and conditions, the more comfortable they became with the course and mode of interaction (Jones 1992). Perhaps the lessening of "distance tension" would allow students to enjoy the benefits of distance education (e.g., comfort, convenience) to a greater extent. Spooner, Spooner, Algozzine, and Jordan (1998) assert that learning, attending classes, and obtaining information should be enhanced via distance learning.

Initial support for the "no difference phenomenon" in higher education was provided by Spooner, Jordan, Algozzine, and Spooner (1999) who compared student ratings in two special education courses in a masters-level curriculum sequence for students in the area of severe disabilities when each was offered on campus and off campus. Additionally, student ratings were compared when distance classes via two-way interactive TV were taught at local and remote facilities. Student evaluations suggested no differences for overall course means. Organizational ratings were similar for a methods course taught on campus and at a distance, but were different for a curriculum course. When outcome measures for on-campus students vs. off-campus students were examined no differences were found in the overall ratings. Ratings for course, instructor, and communication were similar across settings and courses. Ratings for organization were similar for a curriculum course taught on campus, but were different for a methods course.

The purpose of this study was to empirically compare students’ perceptions of (a) course effectiveness, (b) instructor effectiveness, and (c) overall effectiveness of the instruction in distance education (DE) courses, both off- and on-campus locations, and traditional on-campus courses. The courses included in this study are part of a graduate program in special education in learning disabilities.
Method

A quasi-experimental study was conducted to examine differences between DE courses, both off- and on-campus, and traditional on-campus courses. The independent variable was mode of course delivery - DE off-campus, DE on-campus, and traditional on-campus. To control for the effects of instructor and course topic, the same instructor and same class were taught under all 3 conditions; that is, each instructor taught the same course under the DE off-campus, DE on-campus, and traditional on-campus conditions. Students self-selected into the type of class they would attend. A questionnaire was administered to students at the end of the course to evaluate their perception concerning course effectiveness, instructor effectiveness, and overall effectiveness of instruction. The instructor was not present when the questionnaires were administered and all responses were anonymous.

Participants

All participants were graduate students enrolled at a large university in the southeast United States. Most students were white (89%) females (91%) and worked full-time (83%). All courses were required for graduation by all participants.

Treatment

This study examined three modes of course delivery - DE off-campus, DE on-campus, and traditional on-campus. All the DE courses were delivered using a two-way interactive TV that allowed for real-time interaction between the instructor and students. The only difference between the DE off-campus and DE on-campus was the location of the instructor. Typically the instructor taught the class from the on-campus location. Students in the DE off-campus viewed the lesson from the two-way interactive TV screen. Students enrolled in DE off-campus classes met in a community college classroom fully equipped with video and audio communication equipment. The traditional on-campus classes were taught with the instructor and students in the same classroom.

Instrumentation

The questionnaire consisted of 23 items that examined course effectiveness (e.g., This course had clearly stated objectives), instructor effectiveness (e.g., Instructor was able to simplify difficult materials), and overall satisfaction with the course. Each item was answered on a 5-point scale ranging from strongly disagree (1) to strongly agree (5). The questionnaire consisted of three domains, (1) course effectiveness (items 1-11), (2) instructor effectiveness (items 12-18), and (3) overall course effectiveness (items 19-23). The domain scores were calculated by averaging all the items within the domain with scores ranging from 1 to 5. Coefficient alpha internal consistency reliability estimates were 0.98 for all 23 items, 0.95 for the scale that evaluated the course effectiveness (items 1 to 11), 0.95 for the scale that evaluated the instructor's effectiveness (items 12 to 18), and 0.94 for the overall course evaluation (items 19-23).

Results

Eight instructors teaching eight different courses that were required in a graduate degree program were examined in this study. A total of 261 DE off-campus, 106 DE on-campus, and 176 traditional on-campus students completed and returned the questionnaires. Student results were aggregated to the class level and used in the analyses; that is, the mean class scores were used in the analyses.

A series of repeated measures ANOVAs was conducted with one within factor (i.e., mode of course delivery) to determine differences between the three modes of instruction. The means, standard deviations, F-values, and effect sizes (partial $\eta^2$) for each domain (course effectiveness, instructor effectiveness, and overall course effectiveness) are reported in Table 1. The means for the DE off-campus were lower than those of the on-campus courses in all the domains. The DE on-campus courses had lower means than the traditional on-campus courses. In addition, there was greater variability in scores for the DE off-campus courses.

There was a statistically significant difference between the mode of course delivery for all three domains. The mode of course delivery accounted for a large part of the explained variance ($\eta^2$), ranging from .33 to .41. Follow-up analysis (dependent t-tests) indicated that there were statistically significant differences between the DE off-campus courses and the traditional on-campus courses; large effect sizes (Hedges, 1981) were found for (a)
course effectiveness (g=1.16), (b) instructor rating (g=1.14), and (c) overall course effectiveness (g=1.10). There were no statistically significant differences between the DE off-campus courses and the DE on-campus. In addition, there were no differences detected between the DE on-campus and traditional on-campus domain scores.

To better understand the differences between the mode of delivery, each item was examined. Examining the course effectiveness items (Tab. 2), there were statistically significant differences for items 3, 4, 5, 8, and 9. Follow-up analyses indicated that the mean differences were between the DE off-campus and the traditional on-campus courses. The magnitude of differences between the means was large, ranging from .97 to 1.34. There were no differences between the DE off-campus and DE on-campus or the DE on-campus and the traditional on-campus course means.

Table 4: Descriptive Statistics, Repeated Measures ANOVAs, and Effect Sizes for the Overall Course Effectiveness Items

Summary

The results suggest that on-campus students perceive their courses and instructors as being more effective than the off-campus DE students. Students in the off-campus sections consistently rated the course and instructor lower than both on-campus groups. The students in the DE off-campus courses reported (a) not being as challenged...
and motivated to learn, (b) lower opinions about the extent to which the class meetings helped them see other points of view, (c) lower opinions about the course building understanding of concepts and principles, (d) less feeling of respect, and (e) lower opinions of the contribution of the course to their professional growth. In addition, the DE off-campus students rated the instructor lower in (a) displaying clear understanding of topics, (b) being prepared for class, (c) stimulating interest in the course, (d) applying theory to solve problems, (e) evaluating often and providing help when needed, and (f) adjusting to fit individuals abilities and interests.

Universities that base instructors’ performance on student evaluations should be aware that teaching DE courses might present disadvantages to overcome. What can be done to address the potential hazards? Spooner, Algozzine, Flowers, Gretes, and Jordan. (1998) suggest seven strategies that can be used to facilitate faculty/student interaction at a distance, so that the students at the remote sites believe that they are connected to their peers and the instructor in the studio classroom on campus. These techniques include: (a) establishing weekly agenda that goes beyond the syllabus, (b) facilitating a weekly student share to encourage class participation, (c) establishing off-line small group discussion with reporting, (d) tapping sites and individuals at remote sites for questions, (e) encouraging across site questioning by students, (f) traveling to remote sites for broadcast (each site one per semester), and (g) playing off of your local audience.

Other variables which will likely impact on the instructor’s ability to reach students at remote sites, in addition to altering presentation style might be the overall size of the class. The instructor will likely have to work harder at making ALL students feel included as part of the group when the collective numbers approach 50, as opposed to as smaller number of students. A second important variable, and one that could potentially affect the evaluation outcomes is the number of times that the instructor delivers a course at a distance. The more practice the instructor has and the more times that s/he is “on the air” will also likely impact that individual’s ability to be effective at reaching those students at remote sites. The type of presentation equipment (e.g., white board “on the fly” writing, or prepared overhead material, or material developed with electronic presentation software with appropriate images to illustrate content) that the instructor uses to deliver the content is another variable that could likely affect the outcome of student evaluation of instruction as well. Regardless of the approach taken to address potential problems and difficulties when teaching at a distance, there is a clear need for additional research evaluating implementations of improvement strategies and their effects in distance education courses.

Abstract: Today's educational requirements have forced the traditional institutions to introduce technology in the education and modify the teaching-learning process in order to maintain curricula updated and cope with the constant changes. Although this is a costly and time consuming task there is still not a proper methodology which would help authors to carry out this task. The model proposed in this paper (MCD) is a systematized way for designing/redesigning computer technology-based courses (coursewares), based on their learning goals. This model is a formalization of a set of successful strategies applied by the authors, in the design/redesign courses in the computer science area.

Introduction

Most of the existing courseware development tools have a very poor support for the course design and redesign, especially for curriculum design if any. This may be a serious drawback of them, because the evolution of technology and knowledge is demanding courseware authors to continuously update and/or redesign their courses. This task is difficult, slowly and costly, so we think it is important to define one which can be easily embedded in a courseware development tool or used for complementing the work did by these tools, in order to support a clear and systematic methodology for designing courseware. We introduce here such a methodology, based on the hierarchical definition of the course's pedagogical goals. This methodology called "MCD".

The proposed model (MCD) arises as a formalization of the authors' experience in the process of design and redesign of a courseware in order to improve the achievement of its learning goals. The course is called "Software Engineering Workshop" and it is part of the curriculum of the Computer Engineer of the Catholic University of Chile. Many design principles of the software engineering were used for defining MCD, adapting them to the courseware design (Jackson, 1999). We also used some ideas taken from the Artificial Intelligence area, especially those used for designing curriculum in Intelligent Tutoring Systems (ITS). In the next section we present the proposed model, and finally, the conclusions of this work.

A Model for Courseware Development (MCD)

The proposed model offers a guide, step by step, to design a course and then to build a courseware based on this design. The model is based on the prototype development model used for software engineering (see figure 1), which is very easy to adapt it to the design/redesign of a course.

The model has three stages: The first stage called the "course design" consists in the hierarchical definition of the specific goals and restrictions of a course. The second stage consists of the development of the curriculum which will be used to implement the courseware. We understand the curriculum as the selection and logical sequencing of the learning material in order to achieve the learning goals. Finally, this implementation is tested to find errors or weaknesses. In order to do the reengineering of the course, it is important to implement feedback mechanisms about teaching/learning process, in order to identify each wrong or weak strategy to replace it, and each successful strategy to repeat it and maybe to extend it.

In the design phase we have defined three steps. The first step is called "goals design" in which a hierarchical goals tree is defined. The root of this tree is represented by the overall goal of the course. The nodes of the second level of the tree will define the chapters goals, and the nodes on the third level will be the sections goals. Several cycles can be employed to get a final goals design and it can involve people such as lecturers, assistants, students, and experts in the course domain. The reason for organising the goals in a hierarchical way (tree) and with this organizing the whole courseware in this way is because it is the most natural way for human beings to organize things in their mind (Novak, 1998). Beside the nodes that represent the goals this tree has another type of nodes called "means". Goals are intermediate objectives that contribute to achieve the main goal, means are the activities that should be executed, to reach the designed goals. These are the leaves of the tree.
The second step of the design phase is called "means design". In this step, the activities/contents (means) to reach each goal are selected and designed. The combination of one activity and the computer-based learning material, which will support this activity (content), is called a mean. For example, a mean to satisfy a certain goal could be "the expositive presentation of the topic 1". The activity associated to the mean is the "expositive presentation", and the content associated is the "topic 1". In this stage, the duration of the mean (activity) should also be designed. These means can be student's means or teaching means, and both have different graphical representation on the tree. A student's mean is an activity for which the student is the main responsible to carry out.

On the other hand, the teaching means are the activities whose main responsible is an instructor (lecturer or assistant). An activity node is graphically represented as a rectangle while a goal node with a circle. The third step is called "means sequence design" and its goal is to organize the means as a sequence of activities which will implement the teaching-learning process to reach the goals. Once step 2 is concluded, it may be necessary to establish the implementation constraints among means of different branches, in order to achieve the goals. Normally there will be many possible means sequence, while keeping the constraints specified in by the tree. For that reason, the goal of this phase is to design the most appropriate sequence of activities. To carry out this task, it is necessary to sequence the teaching and student's means in two separate sequences. After that, both sequences should be joined to get the final course means sequence. Once this sequence is defined, it is possible to establish the course schedule. The sequence of the teaching means allows lecturer and assistant to fin out wether the time to be spent in each one is the appropriated, as well as whether the mean sequence is correct. In the "implementation" phase, all activities and course contents are created and linked together to get a courseware. This courseware will help the lecturer to carry out the teaching-learning process, and to get the course's goals. To build a courseware we use a framework of educational software components that permits to implementers to create a course assembling and adapting this predefined components. Thus, this is a way to reuse existent learning material.

Conclusions

With the proposed model we want to define a methodology that will systematize the design process of a course which will take place in the context of a normal high education institution in a simple way. As it was mentioned in the introduction, the proposed model is a formalization of a design and redesign process used by the authors on a software engineering course. This process has been carried out five times for three years. The student's performance in the course has improved notably with every redesign, indicating that this strategy may be correct. Recently the same methodology has been used to redesign the "Groupware Workshop" course also with good results. Part of the course design can be validated before its implementation, which it can reduce the product's development time and cost (Jacobson, 1999). Besides the courseware, a very important product that can be obtained applying the model is the course's activity plan (or course's schedule). This activity plan is generated automatically based on the course's final design. The construction of the courseware itself is carried out assembling the software components. Therefore, this model also promotes the reuse of the content and knowledge structures (like chapters, sections, etc.) of a courseware content in other courseware, thus reducing the efforts in the generation of future courses and improving the quality of the final product (Boehm, 1999).

Degree: Doctor of Philosophy Major Subject: Instructional Leadership

Name of Candidate: Jenka Keizer

Title of Dissertation: A Study of Social and Academic Uses of the Internet by High School Students

This research studies how ninth-grade students in a fully computerized, K-12, affluent school use computers for educational purposes and in their personal lives. The target population for the study was the student body from the American School Foundation of Mexico City (ASF), a K to 12 American-type school with an American curriculum for over 100 years, and 2,400 students. The survey also included parents and teachers.

The qualitative and quantitative surveys revealed that students use the Internet from one to three hours daily, and the predominant use is as a personal communications tool. Students are knowledgeable about precautionary measures that are required in conversations with strangers in the Internet social space.

Parents believe computers and the Internet help their children with school assignments, and that the lack of Internet connection at home would put their teenagers at a disadvantage with their peers. The students' use of computers and the Internet at the ASF is meeting their parents' expectations. Most teachers give daily assignments to be done on the computer and require Internet searches for their assignments. The majority of the students say they use the Internet for research.

Gender and nationality are not differentiating factors with respect to the use of computers and the Internet by high school students at the ASF for school-related work.
However, there are some variations in other applications. For example, male students use the Internet more than females for games and for accessing sexually explicit images.

The study sheds some light about the potential benefits of the introduction of computers and the Internet into U.S. classrooms. However, it also reveals that full integration of the technology into the curriculum is an elusive goal. Fundamental transformation in education, as in any major social change, certainly requires clear vision, hard work, and time.

Analysis, Design, Implementation and Evaluation of Instructional Software by Computer Science Students and Public School Teachers

Mario A.M. Guimaraes, mguiama@kennesaw.edu
Kennesaw State University, Department of Computer Science and Information Science

Abstract: This paper describes how computer science students of Texas A&M-CC (TAMUCC) and public school teachers benefited from an Eisenhower Funded Project "Training k-3 teachers on how to best use educational technology in the classroom" and were able to evaluate and construct educational software. During the first phase, teachers were exposed to educational technology. The next step was to evaluate educational software to teach science and rank the top software. They used a tool constructed by a computer science graduate student. In a third phase, they designed storyboards for computer science students from a Visual Programming Language Course to implement the software.

I) Introducing Educational Technology

During the first phase of our project, teachers became familiar with Educational Technology. After brief history of Computer Science & Computer Uses in Education, teachers became acquainted with the Web by searching for articles in educational technology (mainly from Northwestern and MIT) and wrote an essay analyzing Roger Schank and Seymour Papert's educational point of view. Many of the participants learned to search the web and use a word processor for the first time. MS-Powerpoint (in order to prepare their class presentations), MS-Excel (to grade their students) and Hyperstudio (to gain ideas concerning what an Educational Software may do) were also presented. Finally, teachers created their own web-pages.

II) Evaluating Educational Software

The primary reason that Educational Software is not widely used is not due to the difficulty of constructing good tools, but disseminating and incorporating them into the curriculum. It is frequently said that a limited software tool well applied to the curriculum is of much more value than a very good tool that is applied inappropriately [LAJO93]. Furthermore, there is reluctance on the part of instructors to incorporate these tools into their classrooms [STAS97].

Some authors [B0R097] believe that as the World Wide Web becomes the universal medium for disseminating information, all educational software will be platform independent, thus solving the dissemination problem. Although Educational Software is being made web compatible and this will increase its use, there are other barriers that keep instructors from using it.

This reluctance is in great part due to: faculty not knowing that the tools exist, difficulties in obtaining the tool, not knowing which tools to use, not knowing how to incorporate the tool into the curriculum, and fearing that the tool will increase their course load. What is needed is a mechanism for searching what Educational Software for a specific domain as well as a uniform location for students and teachers to discuss classroom experiences with the tool.

To solve this problem, we created an Interactive Repository for Educational Software (IRES) prototype that may be accessed from our project's home page (http://www2.tamucc.edu/ecdc/eisenhower.html). The functions of this software are to: 1) search for and add an educational software, 2) Evaluate, read evaluations, edit and/or delete evaluation(s), 3) Search for an educational web site, and add information about an educational web site.

Besides lacking security features (users could update or delete others' evaluation), we also received feedback concerning the unfriendly user interface. The feedback included too many fields to fill in
(separate the mandatory and the optional fields), some fields had to be more intuitive, an easy help system informing the objectives of the software and a tool to summarize the evaluation (example: if 20 evaluators rated the tool, obtain the avg. rating). We also found a necessity for a form to specify teachers' request for new software (Describe educational software that the user would like developed).

The software not only catalogs all the educational software available, but also allows the participants to view each other's evaluations. For each, software there are several evaluations (one for each participant).

III) Constructing Educational Software

After the teachers became familiar with Educational Technology and Evaluated the Software, they tested the softwares with experimental classes of K-3 grade children. Following this phase, each teacher chose the software they wanted to purchase and also used storyboards to specify what softwares they would like developed. This served as input to a Visual Programming Class held at TAMUCC. The students of the Programming class interacted with the teachers, providing them hands on experience with a real world scenario. At the end, a web page was produced where the prototypes can be downloadable http://www.sci.tamucc.edu/~mariog/vpproj/vp.html. Some of these prototypes are already being used in public schools.

Abstract: As colleges and universities consider various options for wide scale "computerization," one southern liberal arts university has instituted a technology program that insures that all students have equal access to laptop computers. At this university each student is issued his or her own IBM ThinkPad, and activities involving this computer are infused throughout the academic and social life of the campus. Students use the computer extensively in class activities and projects and also in social communication and entertainment. This study sought to examine the computer attitudes of students who had experienced a technology-rich environment for four years.

Introduction

Much has been written about the infusion of technology into academic life. While colleges are moving at different paces in its integration, we all recognize that technology is an integral part of education in the 21st century (Brown, 1999). Research studies describe an exhaustive computing environment as a positive influence on academics (Corwin & Marcinkiewicz, 1998; Geissler & Horridge, 1998; Walters & Necessary 1996). Papert (1987) implies that integrating technology involves a systematic change. Systematic change refers to systematic evolution of a university’s political and social climate. "Potential computer networking may hold for creating, nourishing, and sustaining the genuine learning communities so desperately needed if we are to confront the social, cultural, economic, and ecological challenges of the coming years" (Sayers, 1995, p. 773). It is these communities that foster academic and social growth of university students immersed in a culturally rich learning environment.

Intensive implementation of computers transforms an academic institution’s climate, culture and atmosphere. With increased experience with technology, students’ academic and social lives are significantly impacted and student attitudes toward computers become more positive (Mitra & Steffensmeier, 2000). Through forced familiarity, students develop an appreciation for computers and readily accept the evolution of the university into a completely wired educational and cultural environment.

Methodology

Yahoo has identified the university where this study took place as one of the "most wired" campuses in the country. Upon initial registration, each first-year student at this university was given his or her own personal IBM ThinkPad computer and printer. At the beginning of the junior year, students traded in the initial computer for a new ThinkPad. A computer support system included professional and peer assistance. Each dormitory room was equipped with network connections and everyone on the campus had the same standard computer and standard software load. Professors regularly integrated the computer into instruction, and students also used it for personal and social tasks. At the end of the fourth year of this program, the senior class had lived and worked in this environment of ubiquitous computing for their entire
college career. Approximately 800 students were surveyed near the end of their senior year to obtain their self-reports of computer use and computer attitudes. This study reports the analysis of the attitude items and narrative comments from the student surveys.

A survey was constructed to obtain use and attitude data. The survey was posted online (with a CGI script to encode responses in a text file) and an email message was sent to all 800 seniors encouraging them to follow the included link and complete the survey. After one week, a reminder email was sent. Then after another week, a paper version of the survey was sent to all students who had not responded. After two more weeks, a random sample of the remaining nonresponders were interviewed by phone and asked the survey questions. To check for representativeness, Computer Expertise scores were compared for the three groups (web (n=274), paper (n=35), phone interview (n=10)) and there were no significant differences (F (2, 316)= 0.391, p=0.67).

Results

Campus Culture

Students reported, “Constant exposure to technology is great.” On the attitude items, 73% of students reported that they "loved" computers, while 23% "liked" them, 4% "disliked" them, and 1% "hated" them. See Table 1.

Table 1. Students' Attitudes toward Computers.

Many students developed an affinity toward technology, because it was such an integral part of their campus life. The integration of computers forced significant changes in the campus climate. Computer use, email, and web surfing are major components of everyday campus activities. Given the fact that all students unquestionably had the computer availability, there was forced familiarity with many different computer applications, which resulted in increased computer expertise. Self-ratings of computer expertise revealed that 80% of the students rated their abilities average or above. See Table 2. In a cyclical manner, students used the computer more, became more computer savvy, and found increasingly more needs for using the computer. 83% of the seniors felt that the ThinkPad had significantly impacted the campus culture. Students feel that “Technology pervades every aspect of college life in one way or another.”
Table 2. Students' Self-reported Computer Expertise

Increased communication was another result of computer accessibility. Students used online technology tools to interact frequently with friends, family, and faculty. A student commented that "Email and IM are more accepted forms of communication here than on other campuses." Because of the widespread availability, email has become the preferred method of communication. This is true in both academic and social settings. It is common to hear students remark "email me" instead of "call me." In addition to regular email, students participate in list serves and news groups that keep them informed of academic and social information. Many students commented that email had enabled them to do more projects collaboratively. They also stated that they were more informed of university activities and functions. Many campus student groups, including social and service organizations, use email for routine communication. Other "real-time" communication, which is common includes chat rooms and Instant Messenger. A final means of computer communication is Internet phone, where a computer is used to make free long distance voice calls. 48% of the students surveyed felt that the ThinkPad had helped in their overall social life.

Many students emphasized the exclusivity of campus life as a result of the ThinkPad Initiative. Exposure to technology provides Wake students with invaluable skills and an intimate social experience. One student stated, "I believe that the ThinkPads have made Wake Forest a unique community/campus. It allows the students on this campus to experience something that students on other campuses do not have." In a question relating to job marketability, many students reported that in job interviews their computer expertise had given them an edge. It appears that future employers recognize Wake Forest University as a leading source of technical-savvy employees.

Academic Life

75% of the respondents felt that the ThinkPad had helped in their overall educational life. The accessibility to computers has decreased preconceived inequities among sexes and socioeconomic groups that infiltrate other universities. Because the ThinkPad is included in tuition fees, it is "covered" by financial aid packages. A further source of standardization is the fact that each student has the same computer and the same software. At many universities, even if a computer is required or recommended, there is wide variety in the hardware and consequently in the software. With the standard hardware and software, much time and effort is saved on the part of faculty and students in sharing resources and collaborating on assignments. A student commented, "Everyone is on equal footing. Everyone has the same access to resources, presentation, etc." As a result, students develop a familiarity with computer applications. Students use computers extensively; consequently, using computers becomes second nature. See Table 3. Students' views are summarized by one student's statement about ThinkPads, "It has redefined how we learn by adding an enormous new resource in information receiving."
increased accessibility of computers, students are forced to become technologically literate. A representative student comment suggests, “The ThinkPad has overall improved the education on this campus.”

A few Times each Month 0%
Several Times Weekly 53%
Several Times Daily 36%
Daily 11%

Table 3. Students' Self-Reported ThinkPad Use

Consistency of technical resources offers a commonality among students, which provokes conversation that in turn promotes collaborative learning. One students feels that “Whether it is just a topic of conversation, an article in the newspaper, or knowing that everyone had a computer when doing a project, the ThinkPad has been a major focus of energy in many areas.” Many students stressed that with the ease of access to email, they were more able to collaborate on projects, discuss assignments with their classmates, and clarify professors' expectations through constant contact. A student remarked “Everyone I know uses the ThinkPad every day, to communicate, to do research, or just to goof around. We all discuss things we can do with our computers. Sometimes, we complain about what they can’t do. But everyone knows that if they talk about the computer, every other student will understand what they mean.”

Overall, 82% of the students felt that ThinkPads saved them time, but they recognized distractions and problems from having the computers. One student commented that “The convenience factor is a huge time-saver, however, I also wasted a lot of time goofing off. But overall, I feel like the time I have saved with the ThinkPad outweighs the time wasted.” Arguments for time saved include convenience, accessibility, improved communication, and standardization. On the time-wasted side, students identified higher academic expectations, time-consuming tasks such as scanning, and distractions like games, chat rooms, and web surfing, which resulted in procrastination of academic work.

A student pointed out that “It (the ThinkPad) has saved me a significant amount of time due to the accessibility and the availability of the Internet.” Many students recognized the limitations of computer labs and the advantage that they had in ease of access. A student remarked “Everyone has equal access to the internet, email, and word processors without having to wait in long lines in computer labs.” It is common for students to research topics for major academic papers on the Internet. Even those who use the Library used the online card catalog and other online indices to locate materials. One student commented that “Being able to access the library catalog from my room was awesomely helpful. I could get abstracts even articles in the comfort of my pajamas.” Efforts have been made to educate students on critical analysis of online sources, so that they select Internet references that are of the same quality as printed works.

A student stated, "I spent a lot of extra time surfing the web and emailing, just because I could." Because of the accessibility to the Internet, students were enticed by the entertainment features of the Web. Many students spend an inordinate amount of time with email and several students have become addicted to music and gaming on the Internet. Students commented that it was very convenient to use their computers in the comfort of their own rooms. One student reported that “If students still had to walk to a lab to check e-mail, surf the web, etc. They (myself included) wouldn't be so willing to spend time on the
web, etc. However, since we have easy access to the Internet, chat programs, and e-mail, it is much easier to fall into surfing around the web or chatting with friends and family on a chat program. The ease of access and availability of the Internet provides an easy distraction and causes students to procrastinate in completion of academic assignments. A student acknowledged that "Web-surfing has enslaved me."

One student remarked, "Although I love the computer, and while in some ways, it has saved me time, overall it has cost me time. For example, doing presentations on PowerPoint, scanning pictures, etc, takes more time than the old-style presentations." Students commented that the standardization of computer access had increased the professors demands for assignments; consequently, increasing the preparation time for assignments. Some students felt that they had learned many computer skills through trial and error, with no guidance or instruction. Just because students had a computer, professors assumed that they knew how to operate it. Students reported that "There are many times when professors think you know how to do stuff and you do not. We had basic computer training and that is all." This issue was addressed in more detail with a section for other comments. The students' consensus was that a course should be designed to familiarize students with their ThinkPad, to train them in the standard software load, and to develop computer expertise. It was recommend that this course be required early in each student's freshman year. There is not a direct link between computer access and computer understanding. Because of having a personal computer, many students did however recognize that through forced familiarity that they had developed a computer expertise that most college graduates do not have.

Implications

Students emphasized changes in the academic and social atmosphere at Wake Forest as a result of the computer initiative. Results of this study verify that these changes were positive toward technology. An overwhelming 95 percent of the students reported that they either "loved" or "liked" computers. It is important to note that this is a liberal arts university, which typically does not attract the "techie" type. Similarly, 88 percent of students rated themselves as average or better in computer expertise. The students incorporated the technology into all aspects of their lives, including academics as well as communication and entertainment. It became an integral part of their day-to-day activities.

Students recognized the benefits of equal access to technology, improved technical skills due to forced familiarity, and the cultural evolution of the new technological community. This new environment fostered academic success by establishing a comforting and supportive network between faculty and students. Rather than becoming a tool of isolation, as feared by many detractors, the ThinkPads have opened new channels for communication. Students are able to be in constant direct contact, both synchronous and asynchronous, with faculty. This contact and resulting improved conversation offer a more personal educational system. Students expressed appreciation of the ability of the ThinkPad to allow involvement and individual feedback from professors on a regular basis.

This new learning environment also promotes communication among students, as they share ideas and provide support. Because of standardization, students are able to rely on their peers' expertise to solve problems. Through collaboration, shared experiences, and problem solving, students develop closer relationships. Students' computer expertise and cooperative skills make Wake Forest University students highly marketable.

Overall the integration of the ThinkPads was very positive in many aspects. It saved students time and enabled them to create a higher quality of academic work. Students did recognize that with all the electronic diversions available like entertainment, games, music, and web browsing, students must develop self-discipline to stay focused on educational objectives. Balancing these issues is a problem that all youth face as our society evolves, as this campus has, into a techno-focused environment. Wake Forest students are better equipped to manage computer distractions, because they have experienced its easy accessibility and have developed a comfort level and balanced attitude.

As implemented at this university, wide scale "computerization" changes the social and educational climate and has a positive impact on campus life. This cultural evolution in not just limited to academic universities. Technology infiltrates all aspects of our lives. One student commented that "The world is becoming more and more wired. Computers and the Internet are a huge part of life now, and they will continue to allow a greater level of efficiency in life, and will play a pretty major role in most people's lives, regardless of if they have computers or not. I don't think that we could avoid this change if we wanted."

Abstract: The Applying Technology to Restructuring and Learning (ATRL) study was carried out over a two year period to document and assist 150 teachers in six schools during the process of creating constructivist learning environments (CLEs) supported by technology. The research component of this project involved an intervention study with a two-tiered research design. Tier One was a collective case study of the approximately 150 classrooms, located across six school sites, whose teachers participated in 72 hours of ATRL professional development. Tier Two consisted of six detailed case studies of individual teachers whose experiences represented the process and the practices they employed in creating a constructivist learning environment within their classrooms. This paper will summarize the findings from the Teaching, Learning, and Computing (Becker & Anderson, 1998) teacher survey regarding the impact of the professional development intervention that was provided for the teachers in the project.

The Intervention

Design and delivery of 36 hours of professional development each year (72 hours total) was carried out over the two years of the Applying Technology to Restructuring and Learning project. Sessions were designed to be highly interactive and to model the application of constructivist learning theory. Major emphasis was devoted to teachers’ own prior knowledge about how students learn. Instructional strategies included inquiry, project-based teaching, authentic learning and problem-based learning. Sessions used various types of software that supported student-centered learning and focused on teachers’ ideas for other ways of using these software applications. The design and development of the professional development sessions for the ATRL project evolved over a period of several months and strove to accommodate the unique characteristics of the teachers as well as their individual schools, a variety of computer skill levels, different learning styles, curriculum interests, and varying available hardware and software.
The Teaching, Learning, and Computing Teachers Survey was given to all of the participating teachers at the end of year two. It provided a comparison of the ATRL teachers to a national probability sample. As the participating teachers received professional development designed to assist them in creating constructivist learning environments, one might hypothesize that rankings on constructivist practice and use of technology would be higher than for the national sample.

Effectiveness of professional development

Several measures were used to assess the impact of the professional development however, the effectiveness of professional development was most evident in results of the Teaching, Learning, and Computing Teachers' Survey. Analysis of this comparison of these 102 teachers to the national sample regarding the effect of professional development is reported in Table 1 below.

Table 1: Effects of Professional Development

Conclusions

As the above data show, professional development that modeled technology-integrated, constructivist practices appeared to have assisted teachers as they shifted from traditional to more constructivist approaches. Results are consistent with the findings of other researchers (Education Week, 1999) who report that up to sixty percent of teachers who had eleven hours or more of basic technology skills training and curriculum-integration training say they feel "much better" prepared to use technology. This is but a brief snapshot of what took place in this two year study. Results from the this two year study also showed that professional development needs to be combined with other internal and external support structures to bring about effective integration of technology use and constructivism in classrooms. A complete report of this study can be obtained from any of the authors.

Abstract In response to a perceived increase in the amount of course evaluations being presented at conferences and appearing in the journals, this short paper seeks to characterise the methodology adopted during the evaluation of information technology courses forming part of teacher pre-service education. An attempt is made to discover the strengths and weaknesses of the most common procedures by the review of course evaluations readily available in the public domain. Elements of course evaluation are described in a short taxonomy under the main headings of curriculum effectiveness, learning effectiveness and cost effectiveness.

Too Many Course Evaluations

“It’s all very well coming to these conferences but all you get is session after session of people presenting the results of student evaluations of their ICT courses. Is that all course leaders can do – ask the students? I think we should have one enormous ‘poster’ session where we can lock all the students’ evaluations in one room and provide a key if anybody is remotely interested.”

This is not perhaps a verbatim recollection of a colleague’s sense of frustration at finding conference proceedings dominated by course evaluations, but it does serve to illustrate the potential threat to a balanced approach to course evaluation. Is there an over-reliance on gathering participants’ perceptions in this context and if so, does it matter? Is the customer always right? This paper sets out to illustrate and characterise the most common sources of data for course evaluation in ICT, the methods of analysis applied to the data and the kinds of conclusions drawn from the work.

Gathering the Data

A straightforward method was used for gathering literature. Both the Eric and British Education Index databases were searched for references using criteria related to course evaluation, education technology and teacher pre-service education. Abstracts were searched for any indication that the title of the paper bore some relevance to the content and the most promising complete papers were then gathered. Analysis was made using the conceptualising, formulating and verifying elements of a methodology for using the Internet as a source for qualitative research (see Hughes, 2000).

The most striking characteristic of the evaluation of ICT (technology) courses in teacher education, is a reliance on students’ self reported attitudes. Attitudinal surveys, with and without contextual information appear to have been and to remain the first and only recourse for course evaluation.

An Emphasis on Student Evaluation

Most published reports are concerned with a post-course evaluation (Boylan et al, 1994; Bauer, 1998) and student satisfaction (Bechtelheimer and Tamashiro, 1987). Some analyses provide information which looks to co-relate factors taken from pre and post-course questionnaires (McDermott, 1985; Savenye, 1993) and these examples look to find shifts in student self-esteem, confidence, professional self-perception and attitudes to using technology in the classroom (Cannon, 1996; Bauer, 1998; Brush, 1998).

Student evaluations are used to help reconstruct courses (van Rennes and Collis, 1998) or to assist in the development of guidelines for the development of distance learning courses (Cochenour and Reynolds, 1998). It is not always clear from the literature accessed during the present study what is the purpose of the evaluation. Neither is it clear what use was to be made of any conclusions that were drawn. Whatever use is made of the evaluation the use of students’ perceptions provides a very reassuring picture. Evaluations are almost invariably positive and in some cases glowing.
The reliance upon students' self-reported perceptions and reactions may extend to the comparatively unstructured context of the trainee's or learners' diaries and journals (Badley, 1986). Diary data may potentially be perception-rich and less open to the charge that questionnaires are likely to pre-position possible responses and so 'miss out' on some interesting and valuable information. However, there are concerns about the use of journals. Information from diaries is usually in a format that is difficult to analyse. On balance, although such instruments as diaries and journals are useful examples of contextual information, by themselves they are unlikely to capture elements of course evaluation that we need to address.

Some further clue as to what those elements should be are provided by Fucaloro and Russikof (1998) in their study to develop an assessment model for an on-line course. The model was applied to examine the effects of on-line instruction on teaching and learning by examining factors of faculty-student contact, speed and type of tutor feedback, student time on task and the range of learning styles offered. A second set of factors was centred around observable characteristics of the participants: the shift of technological skills, the chosen preferences of participants, and the extent to which students were actively involved in their learning. Finally, the evaluation looked at the demands on the faculty: staff workload, the technical support required for participants, and the demands of a reflective teaching approach.

The present study has examined an apparent over-reliance on students' own perceptions of the value and impact of ICT courses leading to professional qualifications. The following taxonomy seeks to indicate what the present author considers to be the purposes and aims of course evaluation. At this stage no further discussion of appropriate methodologies is offered. However, subsequent papers will consider how these elements of course evaluation are best achieved.

**Elements of Evaluation**

- **Achievement of Expected Outcomes – Curriculum Effectiveness**
  - Shift of technological skill
  - Ability to apply principles of course into practice
  - Changes in students' confidence to be appropriately critical of their own and others' practice.

- **Effect upon Students Experience – Learning Effectiveness**
  - Availability of a range of learning styles
  - Opportunities for and outcomes of tutor/student contact and feedback
  - Student outcomes as a positive function of time on task

- **Effect upon the work of the Faculty – Cost Effectiveness**
  - The workload of the Faculty: in-service training and an erosion of other scholastic activity
  - Course demands on IT provision
  - Impact upon the delivery of other courses offered by the Faculty

Creating a Methodology for Using the Internet as a Source of Data for Qualitative Research in the Social Sciences

Malcolm Hughes University of the West of England, Bristol, UK. Malcolm.Hughes@uwe.ac.uk

Abstract: At a time of much increased use of the Internet as a source of data for research, there is concern about how best to do this. This short theoretical paper seeks to characterise some uses of web page data. Can the Internet deliver what we are looking for and how will we know when we have found it? A methodology is suggested, drawing heavily upon 'Grounded Theory', and some principles of good practice are recommended.

The Nature of Qualitative Research and Documentary Analysis

Researchers in the social sciences are more and more attempting to make use of the vast amount of information available on the Internet. This short paper is an early attempt to re-configure the way we think of conventional concepts of validity, authorship and the representation of reality. The Internet offers a resource with its own ethical and moral properties formed by a multitude of authors publishing in unstructured and unregulated ways. This attempt to explore how we 'move around' in the ethical space created by the Internet will necessarily be constrained by the fact that we are trying to invent a new language to uncover 'standards', i.e. agreements on how to manage information and interaction on the web.

The qualitative researcher is often concerned with finding patterns of meaning, perception and reaction evidenced in the language used by actors within either a 'live' social setting or the more deliberative context of the written word. Documentary analysis is generally non-intrusive, particularly in contrast to ethnographic approaches and may be considered strength of documentary analysis: the researcher is demonstrably not having any effect upon the social setting she is observing. Yet it may also be considered a weakness, in that the researcher is distanced from the reality of the setting, only gaining access through the report of others. Any methodology in this area must take into account the possibility of authorship being open to similar criticisms as with any unquestioning reliance upon oral history (Seldon and Peppworth, 1983).

By analysis of the content and nature of the language used, an attempt is made to reveal the significance and meaning of what is observed. Notions of validity and bias in the data are important in documentary analysis, particularly where the content is considered as an attempt at persuasion (Sparks, 1992). So if it is the case that researchers will be increasingly accessing the many millions of pages stored on web sites and applying documentary analysis to that data, what should that form of analysis look like? How will it differ from the methodology most usually applied to text, images and the analysis of their meaning?

Why Create a Methodology?

What if we were to simply not bother with the Internet? By adopting research methods that preclude the collection of data of this sort, the researcher is doing more than simply excluding vital evidence from their study. They are also assuming a particular view of social activity and of provenance, one moreover that argues that as researchers we cannot grasp the nettle of sorting data in compelling and powerful ways. We would thus be assuming a way of thinking that reduces our human interaction with the information highways to the role of 'unwitting dupes' of ideas and attitudes beyond our comprehension and influence, and this will not do.

The creation of a supportable methodology in the context of the Internet is dependent in some way upon an acceptance of the limitations of our ability to generalise findings and create proven principles. Qualitative studies based upon access to large amounts of data are particularly vulnerable, when it comes to managing the data. Nevertheless, it is appropriate to set down a way of working that can support researchers in their planning. The procedures and principles of a methodology for qualitative research using the Internet are summarised in Figure 1. They are based upon the application of Grounded Theory in a context where selection and exclusion of material are primary procedures.
Figure 1. Summary of the Procedures of a Grounded Methodology when using the Internet for Research

</tbody>
</table>

In conclusion, an argument has been put forward that a development of grounded theory in the context of searching the Internet, provides a potent and robust method for constructing theory. It enables researchers to generate ideas that are true to the data and, because of its emphasis on inductive logic, closes the theory-data gap. Working with the Internet is time-consuming, complex and potentially frustrating. However, the advantages to the researcher of accessing such huge amounts of 'free' data, can do much to make more inviting the prospect of overcoming these impediments.

Computer Confidence and Attitudes of College Students Attending a Notebook or Traditional University

Kenneth Janz
Instructional and Information Technology Services
Indiana State University
United States
kjanz@indstate.edu

Abstract: This study attempts to determine how the use of a notebook computer impacts a student's computer confidence and attitude when compared to those of a traditional university student. This descriptive study used a survey research instrument to gather quantitative data concerning computer confidence and attitudes. Forty-six students at a notebook university and 64 students at a traditional university were surveyed during the summer semester of 1999. Data were collected on computer attitudes to determine students' perceptions of computer usefulness, and comfort or anxiety. The study found that notebook university students had significantly higher levels of computer usage, confidence, and positive attitudes than did students at a traditional university.

Introduction

Colleges and universities are studying ways to integrate technology and instruction. Administrators at two North Dakota higher education institutions feel that the prevailing technology model for higher education is no longer working. Brown (1997), Executive Director of the Associated Colleges of Central Kansas, and former Vice President of Mayville State University and Valley City State University, believes knowledge of current technology is a basic tool for learning and success in the workforce; therefore, every student needs access to the hardware and software. Notebook universities share this same goal.

In order to be competitive, students should have equal access to computers both at home and school. Many students already have home computers, but some others do not. Providing each student with a notebook computer is the most equitable solution for problems of access. Giving computers to every student levels the field for all students at the university. In addition, since universities are finding it difficult to provide access to the computer labs faculty members want to use, notebook computers alleviate scheduling problems for courses involving required computer use.

Notebook universities are looking at not only new methods of teaching but also new methods of enhancing student learning (Chaffee, 1995). Information resources are becoming fundamental in daily classroom activities. The notebook computer can be used in the classroom as a conduit to information. Students are able to examine the information they have collected and to synthesize the data; they can then evaluate both the value of the information they have gathered and the technique used to gather it. Students who collect their own data partake in active learning. Active learning increases knowledge retention and synthesis. When a student has a notebook computer available twenty-four hours a day, active learning is facilitated.

Four recent studies measure attitudes toward computer notebook use. Brown (in press) found that 20 to 25 percent of university classes across the nation use e-mail, and 10 to 15 percent use presentation software. At two notebook universities in North Dakota, 54 percent of the faculty used technology in their courses. In 1993, 48 percent of the faculty of these two universities rated themselves high in utilization of information technology. By 1996 two-thirds of the faculty reported high utilization for instructional purposes.

In 1997, Holleque, Professor of Education and Psychology at Valley City State University, determined that a notebook computer environment had a positive effect on students' perceptions of computers. By the end of one semester, 92 percent of the students surveyed reported a mostly positive attitude toward having a notebook computer. In addition, 91 percent of the students were at least somewhat
confident about using their computers. Finally, 97 percent of the students reported using their computers on a daily basis.

A survey at the University of Minnesota-Crookston (UM-C) found students used the notebooks for much more than writing papers and taking notes. In 1996, 90 percent of the students at UM-C said they used the notebook computer for e-mail; 80 percent used notebook computers to do research on the Internet; 75 percent of the students used the notebook computer to communicate with their professors and to work with other students on projects; and almost 50 percent used the notebooks for graphics and presentations. In the same survey, 75 percent of the students said the notebooks increased "the amount and quality of learning" at UM-C. Ninety percent of the students stated that the notebook computer helped them build the technology skills they needed in their careers (Osborne, 1997).

In a fourth study, conducted by Rockman et al. (1997), an independent research organization, for the "Anytime Anywhere Learning by Microsoft Corporation" and the "Notebooks for Schools by Toshiba America Information Systems," found teachers', parents', and students' positive attitudes for the notebook computers used in the schools had a direct effect on students' motivation and engagement, time on task, and sharing of work. The study showed that 70 percent of the teachers involved in the notebook computer project had a high degree of enthusiasm for the notebook computers in the classroom. Ninety percent of the teachers used the notebook computers for word processing, 74 percent for presentations, 61 percent for Internet, 46 percent for spreadsheets, 35 percent for skill remediation, and 29 percent for databases and record keeping.

The purpose of this study is to attempt to determine how the use of a notebook computer will impact a student's computer confidence and attitudes when compared to those of a traditional university student. It is a descriptive study using a survey research instrument to gather quantitative data on experience and confidence. The survey will cover areas of computer expertise including word processing, Internet and communication applications, spreadsheet, and data management software. In addition, data were collected concerning computer attitudes to determine students' perceptions of computer usefulness, and comfort or anxiety levels.

For the purpose of this study, the following terms have been defined: Notebook Computer: A portable computer that has a flat screen usually weighing less than six pounds which is small enough to fit into a briefcase. In terms of computing power, notebook computers are equivalent to desktop computers. Notebook computers come with batteries enabling them to run without the need of an external electrical power source. Notebook University: A campus where all students and faculty are issued a notebook computer (as defined before). Students and faculty have 24-hour access to a computer. Classrooms feature student tables with electrical and network connections. Computer labs at these institutions have become obsolete because any classroom on campus is, in essence, a computer lab. Traditional University: A campus that does not issue notebook computers to students and where class-related computer activities take place in a computer lab.

This study was undertaken to determine how computer confidence, and attitudes are affected when comparing notebook campuses and traditional universities. The data in this study will be of interest to individuals who are exploring the idea of implementing a notebook campus. The results are intended to add to the total knowledge about notebook campus implementation and its effect on students.

The Study

The objectives of the study were to answer the following questions: (1) Do notebook university students have higher computer confidence and attitudes when compared to students from a traditional university? (2) Do students who own a home computer at a traditional university have computer confidence and attitudes equivalent to students from a notebook university? A survey was used to measure student's experience, confidence, and attitudes to answer the above research questions.

The participants were students from two state universities sharing similar foundations as normal schools that developed into more comprehensive universities. One is located in the upper Midwest and follows the notebook model; the other is located in the lower Midwest and follows a traditional model.

A survey was used to measure students' computer confidence, and attitudes. The survey was based on existing surveys. The survey contains the following categories: Background Information, Computer Experience, Computer Confidence, and Computer Attitudes.
The students were given the survey in various courses during the summer semester. The questionnaire was constructed so that the students would need no longer than 10 minutes to complete it. The students were informed about the goals of the study. The participants were assured that their responses were voluntary and would be anonymous. The students were also informed that their names would not be associated with any individual scores nor would their names be identified with any results of the study.

All of the replies for computer confidence and attitude questions used a 4-point Likert scale (strongly disagree = 1; strongly agree = 4). T-tests were performed to compare means in computer experience, confidence, and attitudes between students at notebook and traditional universities. The t-tests were then repeated to compare experience, confidence, and attitudes between students attending a traditional university who owned a home computer and notebook university students. A final set of t-tests was carried out to compare experience, confidence, and attitudes between students enrolled in computer classes at a traditional university and the entire notebook university sample student population.

**Findings**

A total of 108 students completed the survey. Among this total, 46 students attended a notebook university, and 62 students attended a traditional university. The sample populations were represented by students from two fields, business and education. At the notebook university, 76% of the students declared an education-related major, while 24% of the student population declared a business-related major. Within the traditional university, 84% of the students surveyed listed education as a major, while 16% of the students declared business. Of the sample population at the notebook campus, 78% were female, and 22% were male. Sixty-three percent of the sample population of the traditional university were female, and 37% were male. The grade levels of participants at the notebook university included 43% seniors, 40% juniors, 13% sophomores, and 4% freshmen. In the traditional university, the sample population reported 40% seniors, 39% juniors, and 21% sophomores. Employment of the students at the notebook university was 78%. This rate was comparable to the 73% of the students holding employment in the traditional university.

The purpose of the present study was to determine how the use of a notebook computer would impact a student's computer experience, confidence, and attitudes when compared to a traditional university student. The analysis is organized according to the individual research objectives.

Does the average notebook university student have higher computer experience, confidence, and attitudes when compared to a student from a traditional university? T-tests were used to compare means in computer experience, confidence, and attitudes between students at a notebook university and those at a traditional university. A t-test compared computer confidence between students at a notebook and a traditional university. This analysis showed that in three areas of confidence--word processing software, Internet and communications software, and spreadsheet software--notebook computer students had significantly higher scores. There was no significant difference between notebook and university students with respect to database management software.

Table 1. Computer Confidence (Traditional University-Notebook University)

A second t-test was used to compare a notebook and traditional university student's computer attitudes. Computer attitudes were divided into the categories of usefulness and comfort/anxiety. The analysis showed that a notebook university student had significantly higher scores in computer usefulness and comfort (Table 2).
Do students who own home computers at the traditional university have equivalent computer experience, confidence, and attitudes when compared to students from a notebook university? As in the previous section, t-tests were used to compare means. Thirty-nine students in the sample population of the traditional university, or 63%, owned a home computer. The analysis of computer confidence between notebook university students and computer owners at a traditional university showed three areas of significance. Notebook university students have higher confidence in word processing software, Internet and communication applications, and spreadsheet software. There was not a significant difference with respect to database management software (Table 3).

A second t-test in the second research objective compared computer attitudes between notebook university students and computer owners at a traditional university. The notebook university student had significantly higher attitudes toward computers, including both the areas of computer usefulness and comfort (Table 4).

The study found that notebook university students had significantly higher computer usage in all areas than students at a traditional university or than students who owned computers at a traditional university. Computer use was also significantly higher for notebook university students in the areas of word processing and spreadsheet software when compared to students who were currently taking computer classes at a traditional university.

Whether comparing notebook university students to the traditional university population as a whole, to traditional students who are currently taking a computer class, or to traditional students who own their own computers, notebook university students display higher confidence in word processing software, Internet and communication applications, and spreadsheet software. Figure 1 provides a graphic representation of computer confidence with regard to notebook and traditional universities.
When comparing computer attitudes, this study showed that students who attended a notebook university have significantly higher scores in the areas of computer usefulness and comfort in using computer technologies than traditional university students, computer owners at a traditional university, or students who were currently attending a computer class at a traditional university (Figure 2).
Recommendations

Several recommendations are made for future research.

1. The effects of experience and its relationship to confidence and attitudes should be studied in the context of the notebook university and the traditional university.
2. The scope of a future study should be enlarged to examine if notebook university students use the computer to be more productive in their educational pursuits.
3. In future research efforts, the survey instrument for computer experience should collect data beyond the use of computers for word processing, Internet and communication applications, spreadsheet software, and database management software.
4. In future research efforts, the survey instrument for computer confidence should include an additional category for presentation software.
5. In future research efforts, a larger sample size including multiple institutions should be used to allow for generalizations.
6. Future research should examine the modeling of computer use by faculty at notebook and traditional universities to determine its relationship to computer use, confidence, and attitudes of the respective student populations.
7. Future research should explore why computer use is significantly higher for notebook students than for traditional university students.
8. A study should focus on the different training methods used by universities that may contribute to computer experience, confidence, and attitudes.
9. Computer performance between notebook and traditional university students should be studied.
10. Additional research should be done to explore and identify other factors that contribute to the implementation of the notebook computer model.

Science Concepts, Technology, and Higher Order Thinking Skills- What's the Connection?

Margarete Juliana, Research Center for Educational Technology, USA

Abstract: Using the scientific process involves ample opportunity for complex higher-level thinking. Integrating technology into the unit can support and enhance these same critical thinking skills. This qualitative study was designed to examine students’ understanding of a science problem involving human habitation of wetlands, woodlands, and grasslands. Four fourth grade students and their teacher were observed during a six-week period in which they spent two hours a day in a technology immersed classroom. Researchers observed how students used technology to proceed through defining, investigating, and drawing conclusions about the problem. Student interviews revealed how useful they felt technology had been for completing each stage of the process. Teacher interviews revealed how she believed technology was supporting and enhancing students’ complex thinking. For the purposes of this study, the scientific process has been limited to the following four main stages: identify the problem; collect information; analyze information; and draw/present conclusions.
Peer-Status and Self-Efficacy: Effects on Technology-Based Small Group Interactions

Rachel Kamb

Rachek@xmission.com

Dale Niederhauser
Department of Teaching and Learning
University of Utah
United States
niederhauser@gse.utah.edu

Abstract: Computers use in many U.S. schools is shifting from individual to group-based learning environments. This development is forcing a reevaluation of traditional uses of computers as tools for tutoring individual students. Teachers are beginning to recognize the potential for computers to serve as a medium for group-learning situations. This study examined some of the factors that influence interactions as students work in learning groups on a computer-centered activity. Twelve groups of three high school students each worked together around one computer to solve a mystery presented in a problem-based learning program. Prior to the activity, participants' self-efficacy was assessed and their peer-status was determined relative to the other members in their group. The preliminary results of this study indicate that high self-efficacy and high peer-status positively influenced individual participation. These results suggest that these teachers should attend to these individual student characteristics when forming student groups for technology-based learning situations.

Introduction

As the use of computers in our society increases, so does the need for research on effective ways to incorporate uses of computers into classroom learning. Teachers have typically used computers to present individual learning activities in lab settings. However, as more computers are integrated into classrooms, this dynamic is changing. Teachers are starting to view computers not just as tools for tutoring individual students, but as a potential medium for cooperative learning activities. When using computers in small-group learning situations, teachers must not assume that cooperative learning will automatically occur. The environment must be structured to promote cooperation and interpersonal interaction among group members and stimulate cognitive growth (Johnson, Johnson & Stanne, 1985). Examining the factors that influence the effectiveness of the interactions that occur in a cooperative-learning group will help teachers understand how to create a more effective cooperative learning environment. Some of these factors include a) how the group functions, b) the task structure, and c) individual characteristics of students (Hooper, 1992; Webb & Palincsar 1996). This study examines how two individual student characteristics (self-efficacy and peer status) influence group functioning in a computer-centered task that is structured to promote cooperative interaction.

Several features are important in developing tasks that support cooperative interaction. One important factor that affects cooperation in small groups is whether members share a common goal (Webb & Palincsar, 1996). It may prove more effective for group members to function independently or competitively when the goals of individuals within the group differ. The goals that are established for the group, and thus whether the group functions cooperatively, are largely determined by the task structure. Ill-structured tasks tend to elicit cooperative interaction (Cohen, 1994). Ill-structured tasks are less clearly defined than well-structured tasks. Where well-structured tasks tend to have one “right” answer, ill-structured tasks require group members to reiteratively process the task or problem definition, to generate
several problem-solving approaches, and to analyze all the viable solutions (Gallagher, Stepien & Rosenthal, 1992). These processes force group members to interact at a highly mutual level, that is, cooperatively.

One model of cooperative group learning that provides an ill-structured task with common group goals is problem-based learning (PBL). PBL is a student-centered pedagogical strategy in which students try to solve ill-structured problems set in authentic contexts by reflecting on their experiences and sharing experiences with others (Hmelo & Ferrari, 1997). A key component of PBL activities is the opportunity for participants to engage in cooperative small group problem solving.

The characteristics of individuals within a small learning group may have a powerful influence on the nature of the group interactions. Social status is one characteristic that teachers consider when grouping students. Social status may be influenced by several factors including ethnicity, socio-economics, and gender (Cohen, 1982). Less obvious status characteristics that should also be considered include academic status and self-efficacy (Cohen, 1997; Busch, 1996). However, it is not clear how these characteristics influence group interactions. More effective grouping strategies could be used if teachers had a better understanding of the effects of status and self-efficacy on technology-based small group interactions. This study was an examination of the influence of self-efficacy and peer status on small group interactions during a computer-centered PBL activity.

Methodology
Setting and Participants

Participants were students in a private high school in a medium-sized western city. Thirty-six students with 3.0 or higher grade point average were randomly selected from one section of a ninth grade Spanish class and one section of an eleventh grade Spanish class. Eighteen of the participants were male; the other 18 were female. All participants were in the middle- to upper-middle class socioeconomic status. The 36 participants were randomly assigned to one of 12 same-gender or mixed-gender working groups of three students each. Three groups were all females, three groups were all males, three groups were two females and one male, and three groups were one female and two males to counterbalance gender across the groups.

Materials
Computer Software

The PBL activity involved developing a solution to The Mystery of Machu Picchu, a problem-based hypertext program developed by the lead author. Each group of students worked at a laptop computer with an external mouse. The objective of the program was to have the students choose a theory to explain the demise of the culture that built Machu Picchu. Students were required to use supporting evidence (gathered from informational resources in the program) to support their choice. Thus, students were assigned a common goal and the program provided an ill-structured problem—several viable theories that could be supported through information in the program were provided for the students.

The main screen of the program introduced the mystery of Machu Picchu to the students and indicated that there were several possible theories as to why Machu Picchu was built and what happened to it. Students were asked to determine which of the possible theories was most likely after exploring several different paths along the Inca Trail on their way to Machu Picchu. Different paths provided information that supported different theories. Hyperlinks to the Theories screen and to the Inca Trail screen were on the main screen. The Theories screen listed five possible theories. From there, students could link back to the main screen or to the Inca Trail screen.

The Inca Trail screen contained a graphic image map linking to five different sections: (a) Location of Machu Picchu, (b) Inca Customs, (c) Inca Construction Techniques, (d) Inca Artifacts, and (e) Tour of Machu Picchu. All sections contained from two to eight related subsections. Each of these subsections contained graphic maps and textual descriptions. Students could link back to review the information on the main screen or the Theories screen from any section or subsection screen.
Case sheet

Two column case sheets and pencils were provided for note taking. The first column of the case sheet was divided into five sections (one for each theory) with space to write supportive evidence found in the program and to note the section and subsection of the Inca trail where the evidence was found. The second column provided space to make notes about how the evidence in the first column supported a selected theory.

Self-efficacy test

A self-efficacy measure was adapted from the English version of the General Perceived Self-Efficacy Scale (Schwarzer & Jerusalem, 1995) and the Computer Self-Efficacy Scale (Eachus & Cassidy, 1998). This assessment was used to determine general self-efficacy toward learning and self-efficacy toward using computers. A series of 23 statements regarding how students handled difficult situations, their feelings about learning and school, and their feelings about computers were presented. Participants rated each statement on a scale from one to four (1 = not at all true, 2 = hardly true, 3 = mostly true, and 4 = exactly true). Higher scores correspond to higher self-efficacy. The highest possible score was 88.

Peer-status ranking

Peer-status ranking was assessed using a sociometric instrument developed by Cohen, Lotan and Catanzarite (1990). A series of 20 descriptive questions regarding the academic and social status of each groups’ members were presented. Next to each question were all the names of the individuals in the respondent’s group. The participants were then asked to circle the name of the group member who most accurately fit each descriptive question. Respondents had the option of selecting him or herself as well as the other two members of the group.

Video equipment

A video camera was mounted on a tripod approximately 10 feet from the group to record interactions during the activity.

Procedures

The research was conducted in two sessions. During the first session students took the self-efficacy test and rated themselves and the other students in their group in terms of academic and social status. This session took approximately 20-40 minutes.

The second session was conducted with one three-person group at a time. Each group worked on The Mystery of Machu Picchu PBL computer program in an empty classroom. Before starting, the researcher gave the students instructions that they were to work together to solve the problem presented in the program, and to take notes on their case sheets as they progressed through the program. The problem and instructions as to how the users of the program were to go about solving the problem were presented in the program. Each group of students worked through the program with little intervention from the researcher. While students worked they took notes on their case sheets when they found supporting evidence. The groups were free to talk among themselves. Each group was given approximately 35 minutes to work through the program. These sessions were videotaped to record the group interactions during the process of completing the task. The researcher also recorded general and task-specific observations made during the activity. Participation, attentiveness to the task, the types of questions and responses, the amount of both task and non-task verbalizing, and mouse control were recorded and later categorized.
Analysis

To investigate the effect of an individual group member's self-efficacy and peer-status on group interactions, the participants' pre-activity questionnaire results were compared to the videotaped interactions during the activity. Each participant's score on the self-efficacy scale was totaled and individuals were given a self-efficacy rank within the group relative to other group members' scores.

The second part of the pre-activity questionnaire asked the participants to circle the name of the group member (including him or herself) who most accurately fit each of 20 descriptive statements regarding academic and social status. The number of times each name appeared on any of the three lists was totaled for each group. The individual whose name appeared most frequently received the highest peer-status ranking; second and third place rankings were assigned accordingly.

Videotapes of group interactions were analyzed to categorize each group member's actions and interactions during the activity. Transcriptions from the videotapes of each of the group's interactions were qualitatively coded into the following categories: 1) questions, 2) responses, 3) initiation of concepts, 4) elaboration, 5) building on elaboration, 6) directing, and 7) disagreements. All on-topic questions were coded as questions. All responses to on-topic questions were coded as responses. When an individual came up with a new idea without prompting from other members of the group, that statement was coded as initiation of a new concept. Statements that elaborated on (a) something that was read or (b) their own idea were coded as elaboration. Statements that elaborated on another group member's idea or statement were coded as building on elaboration. Giving instruction or directing other members in how to act or think was coded as directing. When a group member disagreed with another group member's idea, the statement was coded as disagreement.

Preliminary results from these data suggest that both self-efficacy and peer-status positively influence an individual group member's participation in group interactions. 50% of the time, the individual asking the questions in the group had the highest self-efficacy score and peer-status ranking of the group. Concepts were initiated 57% of the time by the individual with the highest self-efficacy score and 50% of the time by the individual with the highest peer-status ranking. Building on elaboration, the most frequently coded type of statement, came from the individual with the highest peer-status ranking 58% of the time and from the individual with the highest self-efficacy score 50% of the time. These findings suggest that students who are confident in their abilities and hold higher social status within a group show more willingness to present new ideas and build on and develop their peers' ideas in PBL computer-based learning group-environments.

These data also suggest that self-efficacy may have more influence on an individual's confidence to disagree with another group member than peer-status. Fully 75% of the disagreements with another group member's ideas came from the individual with the highest self-efficacy score. However, the student who disagreed never had the highest peer-status ranking. Perhaps those individuals with a high peer-status ranking were afraid to openly disagree with the other members of their group for fear of disrupting the group dynamic and potentially losing their peer-status. Students with high self-efficacy scores who disagreed consistently had lower peer-status ranking. These students may have had the self-confidence to express their disagreements without the fear of losing peer-status.

Finally, in each of the three groups with the greatest within-group difference between self-efficacy scores the individuals with low self-efficacy scores had the least total participation of all students in the study. This suggests that when there is a large disparity in self-efficacy, individuals with low self-efficacy may be intimidated when paired with individuals with much higher self-efficacy and hesitate to fully participate in group discussions.

Conclusions

The preliminary findings from this study suggest individual characteristics such as self-efficacy and peer-status may play an important role in how PBL-based cooperative learning groups interact. Self-efficacy and peer-status were found to influence student involvement relative to initiating new ideas and elaborating on others' ideas, while challenging ideas through disagreement appears to be positively related to self-efficacy and negatively related to peer-status. The findings also suggest that the characteristics of each of the individuals in a group may influence each other's participation. Pairing very low self-efficacy
students with very high self-efficacy students may have a negative influence on low self-efficacy students' participation.

As teachers begin to move beyond traditional drill-and-practice implementations of computers, these results can provide helpful information for teachers who want to use computers as a context for problem-based cooperative learning activities. Self-efficacy and peer-status appear to be important factors in shaping the interactions that take place in group learning contexts. It appears that including a student with high self-efficacy and peer-status would increase the likelihood that new ideas would be presented and elaborated. Further, including a student with high self-efficacy who does not hold the highest peer-status may increase the chances of disagreement—fostering a more critical and lively discussion. However, the range of self-efficacy and peer-status within a group should be limited so that all group members feel comfortable participating and interacting to complete the task.

In this study, we have begun to examine some of the factors that effect student interactions when using computers in PBL-based cooperative learning groups. Other topics that deserve attention include the influence of gender, socio-economic status, ethnicity, computer skills and prior knowledge. Issues of group dynamics are central to teachers' adoption of new ways of integrating technology into their instruction through cooperative project-based classroom instruction.

References

Abstract: Technology, when properly implemented, can bring a new dimension to education. In addition to automating some applications, it can be used "to help us do things in education that were heretofore impossible" (Thornburg, 1999, p.1). This paper focuses on the results of a survey of almost two thousand teachers. The survey focuses on the teachers' attitudes toward and use of computers in instruction, with specific emphasis on classroom uses. The study investigated the extent to which classroom teachers are prepared for meeting national standards through their use of technology for educational applications and instruction.

Introduction

In recent years, states and districts have increased expenditures to equip schools with computers and related technology (Quality Education Data, 1998). As a result of the significant investments being made in hardware, software, and infrastructure, there is a call for evidence regarding the effectiveness and appropriate use of technology in K-12 schools (Panel on Educational Technology, 1997). Many researchers have "realized that technology cannot be treated as a single independent variable, and that student achievement is gauged not only by how well students perform on standardized tests but also by students' ability to use higher-order thinking skills" (North Central Regional Educational Laboratory, 1999, p1). It also became apparent that with the acceleration in the pace of technological innovation, skills, such as problem solving with appropriate tools for learning, synthesizing information, and communicating are essential for today's students (Panel on Educational Technology, 1997).

Although technology cannot solve all of the issues facing education, there is substantial evidence that, when used effectively, it can promote an improvement in student achievement, including higher-order thinking skills (CEO Forum, 2000; Means, Blando, Olson, Middleton, Morocco, Remz & Zorfass, 1993). In an attempt to provide guidelines and expectations of technology use in education, several states have instituted standards related to competencies in the use of technology. One of the first national movements toward establishing standards for technology was initiated by the International Society for Technology in Education (ISTE). Through their leadership, a consortium of organizations representing major professional education groups, government entities, foundations, and corporations was formed to create a national set of standards to govern the use of computers in schools.

The first set of standards, the National Educational Technology Standards (NETS) for Students was published in 1998. It categorizes technology competencies into six areas: (a) basic operations and concepts, (b) social, ethical, and human issues, (c) technology productivity tools, (d) technology communication tools, (e) technology research tools, and (f) technology problem-solving and decision-making tools. Profiles are provided that detail technology achievement indicators at various stages in PreK-12 education. It is recommended that the skills be integrated into a student's personal learning and social framework by being introduced in the classroom, reinforced, and finally mastered. The standards are intended to be an integral tool for technology learning within the context of academic subject areas (ISTE, 2000).
Method

In order to investigate the degree to which teachers are using computers in the classroom, a survey was designed and administered to teachers in a large urban school (N=1665). The survey targeted the areas of teacher attitudes toward computer use, integration of computers into instruction, types of software used, and teacher confidence and comfort with computer use. Demographic information, including grade level and subject areas taught was also gathered. In the context of the NETS, the sections of primary interest for this study were those focusing on the integration of computers into instruction and teacher attitudes toward computer use.

The integration section of the survey was divided into three parts consisting of both the methods used and the extent to which teachers were integrating computers and technology in the classroom. Items included instructional strategies employed by the teacher in the classroom (e.g., individual and small group instruction), software used by both teachers and students to complete school related activities (e.g., word processors, spreadsheets, graphics programs), and teachers' personal use of computers (e.g., for fun/entertainment; as a communication or research tool).

Responses to items related to the integration of technology and types of software used were provided on a 5-point frequency scale (ranging from Not at All to Every Day). In the survey section targeting general attitudes toward the use of computers in the classroom, items covered student access to computers, essential skills for students, the incorporation of computers in the classroom, and the impact of technology on teachers. This portion of the survey contained 20 items reported on a 5-point Likert scale (ranging from Strongly Disagree to Strongly Agree).

Data were analyzed for differences between school level (i.e., elementary, middle, and high school) and subject area taught (i.e., English, math, science and social studies). The Chi Square test of independence was used to compare the amount of time spent on integrating technology into the classroom by teachers across both school level and subject area. The teaching modes included in the survey were representative of standards for students in the NETS. A series of ANOVAs were conducted to examine differences in affinity and aversion to technology across school level and subject area. Affinity to technology, in this case, implies a positive attitude towards technology. Aversion, on the other hand, indicates a negative feeling towards technology. The use of software to complete school related activities was examined for both teachers and their students.

Table 1: Percent of Use by Teaching Mode and School Level

Per cents of computer integration at each school level are presented in Table 1. Statistically significant differences were evidenced among the levels for computer use for small group instruction, individual student instruction, cooperative groups, independent learning, tutoring, to promote student centered learning, problemsolving, and as a communication tool.
While statistically significant differences were found in eight of the integration items, the remaining three items (computers used as a productivity tool, as a classroom presentation tool and as research tool) evidenced no statistically significant difference across school level.

Subject Area Differences

The Chi-Square test of independence was also used to compare English, math, science, and social studies teachers' integration of computers in the classroom (Table 2). In these analyses, only middle and high school teachers were used because only these levels are subject specific.

Table 2: Percent of Use by Teaching Mode and Teacher Subject Area

Statistically significant differences were found across the subject areas when teachers used computers with students to tutor, as a research tool for students, as a problem-solving and decision-making tool, and as a classroom presentation tool. No statistically significant differences were evidenced between the groups when computers were used for small group instruction, individual instruction, in cooperative groups, independent learning, to promote student center learning, as a productivity tool, or as a communication tool.

Software Use

The means and standard deviations for teachers' software use by level are presented in Tables 3 and 4. The types of software used were divided into two groups, application software and instructional software. An examination of these means revealed that word processors and web browsers were used the most (nearly every day) in all school levels. In contrast, web publishing and programming tools were rarely used by any schools.

Table 3: Application Software Used to Complete School Related Activities by Level
In addition, the instructional software used the most was games and tutorials. It is important to note that instructional software was used significantly less than application software. Similar results were found when teacher use of application and instructional software was compared across subject area. These data are represented in Tables 5 and 6.

Table 5: Application Software Used to Complete School Related Activities by Subject

To examine students' software use to complete school related activities, a composite was created based on the classifications described above. When examined by level, teachers reported that the students in
Elementary school used instructional software more than application software. This trend was not true for middle and high school students, who had a tendency to use application software more than instructional software. In contrast, when software use was compared across English, math, science and social studies classes, application software was used more frequently than instructional software.

Teacher Attitude Toward Computers

When differences in Technological Aversion were examined, the results of an ANOVA suggested a statistically significant difference ($F(2,1694)=5.57, p=0.0039$) across school level (see Table 7). Follow-up tests revealed a statistically significant difference in Technological Aversion between the elementary and high school teachers (with means of 3.99 and 3.88, respectively). Although statistically significant because of the large sample, a difference of this magnitude (Cohen's $f=0.08$) is considered trivial. No statistically significant difference was evidenced when school level differences in Technological Affinity were investigated ($F(2,1694)=2.83, p=0.0593$). Likewise, no statistically significant differences were found in Technological Aversion ($F(3,410)=2.02, p=0.1106$) or Technological Affinity ($F(3,410)=1.75, p=0.1560$) across subject areas (see Table 8).

Table 8: Teacher Attitudes by Subject

Conclusion

When comparing elementary, middle and high school teachers, it was found that elementary school teachers were integrating computers into the classroom more frequently than middle and high school teachers, despite the fact that attitudes were comparable. Elementary school teachers reported using computers primarily for independent learning, student centered learning, individual instruction, and as a communication tool. When the integration of computers in the classroom was compared by subject area, among middle and high school English, math, science and social studies teachers, it appeared that science teachers were using technology more frequently. Most significantly, the science teachers used technology for independent learning, as a communication tool, as a research tool for students, as a productivity tool and as a classroom presentation tool more often than for other reasons. Also, English, math, science and social studies teachers used technology as a communication tool more often than for any other reason.

Application software is that which is used to complete an activity such as writing a paper or preparing a presentation. Instructional software, on the other hand, is software that is designed as a teaching tool. A game that teaches math skills and the simulation of a frog dissection are examples of instructional software. When the software listed on the survey was divided into these two categories, it was found that instructional software was used more often at the elementary level and application software slightly more often at the middle and high school levels. The specific application software used most frequently by elementary, middle and high school teachers was word processing software and web browsers. Teachers reported using these applications almost every day. On the other hand, the remainder of the application software and the instructional software were used
much less. Results were very similar when software use was compared by subject area. Web publishing and programming/authoring tools were the applications used least frequently (virtually not at all).

With regard to the NETS guidelines, it appears that the following components are being addressed in the schools that were surveyed: technology productivity tools, technology communication tools, technology research tools, and technology problem-solving and decision-making. Although not directly measured, it can be inferred from the reported use of these more complex applications that basic operations and concepts are also being covered. There is, however, still room for improvement. In the productivity area, only 40% of the schools are using computers as a productivity tool (across all levels). The largest use in this area (per subject field in middle and high schools) is found in science.

Using computers as communication tools ranks highest in the areas examined (across all grade levels), with over 50% usage at the elementary level. When examined by subject area, communication also exhibited large numbers, with over 50% in both science and social studies.

As a research tool, high schools were shown to be using computers more often than middle or elementary schools, although the difference was not statistically significant. However, even at the high school level, the total usage was less than 40%. When examined by subject area, science again ranked highest (50%), followed by social studies.

Problem-solving and decision-making scored lowest overall (with regard to the integration of computers across grade levels and subject areas). This can be a complex implementation of technology, and often requires sophisticated software or teaching strategies.

In summary, this research indicates that technology is being integrated in schools at various levels. As David Thornburg stated, "How you use technology in education is more important than if you use it at all" (1999, p. 1). With standards, such as the NETS, as guidelines, our students and our schools can gain increasing benefits from the technology investments in education.

Multimedia Tools and Case-Method Pedagogy
for Teaching and Learning

Clare Ryan Kilbane
University of Massachusetts,
Amherst, Massachusetts
The United States of America

Teacher educators face the challenge of preparing teachers to recognize and respond to educational problems as they arise in highly variable, often unpredictable contexts. Two recent innovations in teacher education offer promising possibilities for doing so: case-method pedagogy and multimedia tools for teaching and learning. The purpose of this research was to explore how these innovations interacted in CaseNET to help preservice teachers learn to address problems as they emerge in K-12 classrooms.

CaseNET is a set of Web-assisted professional development courses for educators that combines the use of case methods and Web-based technologies. CaseNET provides preservice and inservice teachers at approximately 20 universities in four countries and 15 school districts in the United States and three other countries opportunities to improve their professional problem-solving skills. Participants in CaseNET use a variety of technologies including videoconferencing, electronic journals, and online discussion groups to learn to analyze multimedia cases. Throughout a fourteen-week academic semester, participants learn to analyze cases using a specific five-step problem-solving strategy (McNergney, Herbert, & Ford, 1994; Herbert & McNergney, 1995, McNergney & Herbert, 1995) and practice this strategy when analyzing a set of multimedia teaching case studies.

Teaching case studies might be described as stories, vignettes, or “slices of real life.” These cases present predicaments from practice that demand some kind of action (Gideonse, 1999). They illustrate life in the classroom as it is, not necessarily as it should be. Learning with cases provide preservice and inservice teachers with opportunities to practice problem identification (Merseth, 1996). The skills developed through case methods are useful in a variety of settings. Experience with various types of cases also helps professionals develop a repertoire of defensible solutions for commonly occurring problems (Kleinfeld, 1992; Merseth & Lacey, 1993).

This study investigated the efficacy of a particular problem-solving method on participants' experiences with a multimedia case. The sample consisted of 33 preservice teachers participating in CaseNET at two institutions of higher education (Group One), 26 preservice teachers from these institutions of higher education not participating in CaseNET (Group Two), and 34 other students enrolled in arts and sciences from these institutions of higher education who were neither CaseNET participants nor preservice teachers (Group Three). Problem-solving proficiency, as demonstrated by participants' three-page written case analyses, was determined by a panel of professional educators, or judges, who were prepared to use an instrument measuring participants' abilities to: (1) identify educational issues, (ISSUES); (2) consider events in the case from different points of view, (PERSPECTIVES); (3) identify professional knowledge (personal, empirical, theoretical) relevant to issues in the case and raise questions about other potentially useful knowledge, (KNOWLEDGE); (4) propose actions for addressing a variety of issues, (ACTIONS); and (5) speculate about the consequences of such actions, (CONSEQUENCES).

Participants in the study assembled in groups of about 15 in computer labs where they were asked to read and analyze a case presented in hypertext and multimedia format called “Here to Serve.” The case tells the story of a middle school technology coordinator who is challenged to address the needs of mainstreamed students with special needs, attend to the professional development of teachers under her authority, and deal with the many other tasks her position demands. Information useful for analyzing the case was embedded in descriptions of the characters and events occurring in the case and in ancillary materials contained in a resource area linked to the case. After reading the case, participants submitted a three-page analysis that was then rated by a panel of judges.
In examining the generalizability of the judges’ ratings, analyses were considered the objects of measurement. Judges were considered random facets and subscale scores were considered fixed facets. The design of the study was participants’ written analyses (p) crossed with judges, (j) who were nested within subscales (i), p x (j : i). Using GENOVA, the generalizability coefficient was sufficient to propose adequate dependability (g=.77).

Scores indicating participants’ problem-solving performance were calculated and a comparison of these sub-scale scores and a total scores was performed. Participants’ subscale scores were calculated by summing the points participants received from both judges on each of the subscales on the judges’ rating instrument (issues, perspectives, knowledge, actions, and consequences). The subscales reflected each participant’s performance on the individual steps of the five-step method.

Judges’ ratings were summed to yield the total score. A direct discriminate function analysis was performed using the five variables as predictors of membership in the groups. Variables were ISSUES, PERSPECTIVES, KNOWLEDGE, ACTION, and CONSEQUENCES. One discriminant function was significant. With a combined $x^2_{(40)} = .81$, $p<.01$. After removal of the first function, there was no strong association between group and predictors. The loading matrix of correlations between predictors and discriminant functions suggests that the best predictors for distinguishing between CaseNET participants and those in the other two groups was the rating participants’ analyses received on the subscale KNOWLEDGE, ISSUES, and CONSEQUENCES. Group One had higher scores on this variable ($M=17.79$) than Group Two ($M=14.73$) and Group Three ($M=14.26$). Variables loading less than .50 were not interpreted.

The total scores reflected participants’ performance on all the subscale items combined. Group scores obtained for participants’ total scores were significantly different among groups ($F_{(2, 90)} = 57.91$, $p<.01$). A Tukey post hoc test revealed that there were differences between Group One ($M=71.06$, $s=4.37$), and Group Two ($M=63.54$, $s=3.01$) and Group Three ($M=62.24$, $s=3.07$), but not between Groups Two and Three.

Results suggest that preservice teachers in CaseNET were able to learn the problem-solving strategy and apply it when analyzing a multimedia case study. Participants in this group identified problems, applied professional knowledge, and anticipated consequences more proficiently than did the participants in the other groups.

At least since John Dewey (1910) promoted the joining of education and real life, teacher educators have tried to help preservice teachers develop reflexive teaching strategies that are adaptable to many learners. Teacher educators have provided opportunities for preservice teachers to learn from one another in college and university classrooms and from more experienced colleagues in K-12 schools. Now, multimedia technology offers teacher educators new ways to provide realistic educational experiences for teachers.

This presentation was part of a larger Institutional Session of University of Virginia, Curry School, graduate students and alumni titled: Curry School Researchers Surveying "The Field:" Snapshots of Educational Technology in Action (One of two papers included in this compilation out of six presentations within the session). November 29, 2000.
Abstract: With the onset of the twenty first century, utilizing computer technology in school curriculum has become not only a reality but a necessity in preparing students for effective transition into today's society. In addition, with the multicultural composition of today’s student population, computer technology can become a facilitative force in teaching students who originate from culturally diverse homes. The purpose of this article is to provide a brief history of how computer technology has been used in ESL classrooms. Then, a few case studies and some action research are presented as a glimpse into current ESL classroom environments where technology is being used to varying degrees.

Introduction

As predicted in John Naisbitt’s (1982) pivotal work, “Megatrends,” ‘high tech-high touch,’ (p. 35) has become a reality in today’s society. At least the increased use of technology in schools and in homes has become a reality. With the changing demographics occurring in the United States, and the consequential shift in the student populations’ needs, both have presented newfound challenges to today’s teachers.

The presence of language minority students in public schools has been significant. As stated by Diaz-Rico and Weed (1995), “minorities now constitute the majority of public school students in fifteen of the country's largest school systems” (p. 221). More specifically, Diaz-Rico and Weed stated that “California is the nation’s most racially diverse state with a greater percent of Asian and Latino residents than any other state” (p. 220). Due to this cultural diversity, the California Commission on Teacher Credentialing (1997) has tailored its standards to meet the needs of this student population by requiring teachers to be culturally sensitive, particularly in the area of language instruction.

In addition, all teachers are trained to incorporate technology in their curriculum. In states that have culturally diverse populations, teachers can meet several instructional goals simultaneously by using computer technology to facilitate English language instruction. The first goal is to individualize teaching to meet each student’s unique needs. The second goal is to incorporate computer technology into the curriculum. The third goal is to improve English language instruction through more frequent use of the reading and writing skills. All of these goals can be accomplished by using software that requires reading and writing in English. Instruction can be provided at each student’s ability level once each student’s initial instructional level is determined with a diagnostic test, which is administered by the computer. Once appropriate placement is determined, then each student may begin practicing his or her reading and writing skills, usually within the context of pictures, stories, puzzles, etc.

So, how do teachers of English as a Second Language (ESL) take advantage of technology in their classrooms? What problems have they encountered? What do they think of using computer technology in instruction?

To answer the above questions, the authors conducted case studies and action research in 2000. The paper focused on the teachers’ use of computers in the classroom. Terminology related to ESL included ELL (English Language Learners), bilingual education, and minority language education. The authors did not intend to differentiate these terms; therefore, they used the general term “ESL” for discussion throughout the paper.
The paper is comprised of three main components. It starts with a discussion of instructional methodology; then, using computers in the ESL classrooms; followed by case studies and action research. Lastly, the authors provide recommendations on employing computers in the ESL classroom, in addition to, useful Internet resources.

**Instructional Methodology**

In the last few decades, Teaching English as a Second Language (TESL) methodologies have been changing from the Grammar Translation Method, to the Direct Method, to the Audiolingual Method, and finally to the use of the Communicative Approach. Different technology has been utilized at different time periods. Lately, computers have become a common instructional as well as learning tool in schools. In this section, the authors will first introduce the development of TESL methodologies and then will present examples of computer use in ESL instruction and its advantages.

**Development of TESL Methodologies**

Prior to the mid-twentieth century, TESL methodologies, such as the Grammar Translation Method, were influenced by structuralists and characterized by the narrow linguistic view. The objectives of the Grammar Translation Method were to teach the rules of grammar and to translate sentences into a target language (Howatt, 1984). With this method, students could translate, read, and write well but had problems with oral communication.

Arising as a reaction to the Grammar Translation Method, the Direct Method viewed speech as more important than written language (Butare-Kiyovu, 1991). Learners did not have to memorize the rules but had "direct practice in speaking and reading through imitation and repetition" (Butare-Kiyovu, 1991, p. 147). However, the examples in the exercises were examples used by an "ideal speaker-listener." With this method, learners encountered problems communicating in real life situations.

In the 1940s and 1950s, the Audiolingual Method, supported by behaviorist psychologists, was commonly used (Savignon, 1983). In this method, language learning was habit formation. With audiotapes, students practiced patterns and drills repeatedly, by which they expected to master the language skills. They memorized and considered language use as automatic, not creative.

From the 1960s and 1970s, people became more concerned with communication (Hymes, 1971; Halliday, 1973; Lessard-Clouston, 1992; River, 1987; Kramsch, 1993; DeVillar & Faltis, 1994). Moskowitz (1978), Asher (1977), Curran (1976), and Gattegno (1972) stopped repetition and memorization as sole techniques of language learning and injected meaning into the classroom (Yalden, 1983). They stressed that language should be for communication. Consequently, interaction began to play an important role in second language learning (River, 1987; Kramsch, 1987).

**Classic Examples of Using Computers in ESL Classrooms**

During the 1980s, computers entered classrooms in increasing numbers, and much educational software, including software for ESL education, was developed. Computer-Assisted Language Learning (CALL) became a topic that interested many ESL educators. CALL professionals viewed computers to be a useful tool in ESL. By using computers, they argued, teachers could provide information through different venues, and through multiple exposures enhance language acquisition for ESL learners.

The English Department at the University of Texas at Austin used real-time computer conferencing in English, ESL, French, German, and Portuguese classes. Bump (1990) conducted research on English literature students and found that reticent students, i.e., women, minority students, and shy learners, tended to participate in the discussion more readily and more often than in the regular classroom. The conferencing classroom became non-threatening. In addition, the students' written messages expressing their thoughts and feelings became the focus of the learning experience. The instructor became more of a facilitator, rather than a person who offered correct answers.

Wong (1993) conducted research to explore the effectiveness of dialogue journal writing between ESL students and their instructors via E-mail at the University of Oregon. The results indicated that the students in the E-mail group wrote more per writing session than the students in the pen-and-pencil group. The instructor also wrote...
more per writing session in response to the students in the E-mail group than she did to the students in the other
group. The instructor also produced more language functions. E-mail was found to increase the amount of
interaction between the students and the instructor. In addition, the students in the E-mail group and the instructor
showed positive attitudes towards E-mail.

These studies indicated that the technology eased anxiety of minority students, encouraged students to
produce more language functions, fostered interaction between instructor and students, and lifted the social status of
minority students. In short, computers were found to be advantageous for second language instruction.

Using Computers in the ESL Classrooms

To investigate the degree in which computer technology is utilized in the ESL classroom, the authors asked
the following questions: Do ESL teachers take advantage of the technology, if so, how? What do they think of using
computers in ESL instruction?

Case Studies

The participants involved in the case studies were three ESL instructors in public schools as well as in
community colleges. One of them (teacher A) is teaching in an elementary school, one (teacher B) in a high school,
and one (teacher C) in a community college. Prior to teaching in the community college, teacher C taught ESL in a
high school for 10 years. Two of the participants have been teaching in ESL classrooms for more than 10 years, and
one of them has been teaching for less than 5 years.

Each of the participants first completed a survey and then was interviewed. They shared from their
experiences how ESL teachers used computers in classrooms and what problems they had encountered.

All of the participants mentioned that, (due to ESL students' limited language proficiency,) they had to use
a variety of teaching methods to enhance students' comprehension. For example, they spoke slowly, frequently
repeated what they said, and used objects or body language to help students understand. These additional
considerations were particularly useful when incorporating computer use into the various lessons.

In regard to computer use, the elementary teacher reported that ESL teachers conducted language arts
classes in learning centers where computers were located. They used educational software such as Reader Rabbit to
enhance students' learning. The high school teachers had students conduct research using the Internet. They
mentioned that they did not have computers in their classrooms, but instead had access to a computer lab. This
limited access discouraged ESL teachers from incorporating computer technology into their classrooms. Similar to
the high school teachers, the community college instructor interviewed stated that computers were also not
commonly used in her instruction due to limited access to a computer lab. Nevertheless, whenever her classes had
access to a computer lab, the students used the A+ Learning Skills Program and the Weaver Reading Program and
found the programs to be beneficial.

What problems have they encountered when using computers? Listed below were problems they
addressed:

(1) Lack of practice time:
(2) Unmotivated administrator and faculty:
(3) Lengthy protocol for student access to the Internet:
(4) Limited access to computers and the Internet:
(5) Lack of adult supervision:
(6) Out-of-date and/or poorly maintained computer hardware and software:
(7) Inadequate funding:

Despite the problems that the teachers addressed, all of them had positive attitudes toward using technology
in ESL instruction. They mentioned that the most significant advantage of using computer software was the self-
pacing feature. Students can work at their own speed and at their individual levels. The teachers believed that
computers could enhance learning and should be employed in ESL classrooms. In addition, teachers stated if the
various problems cited were addressed expeditiously, more technology would likely be used in ESL classrooms.
Action Research

The participants involved in the action research were students in a graduate level Computer-Assisted Language Learning (CALL) course at a university. A total of 14 students were in the class. Data of five of them was included in the research because the five participants have been teaching ESL classes in either public schools or community college in the United States (USA). Two of the participants have been teaching ESL for more than 10 years and three of them less than five years.

Data analysis was based on data collected from students' information sheets, class observations, class discussions, and students' performance in class. At the beginning of the quarter, the students filled in the information sheets, and the instructor used the information to identify students' computer knowledge prior to the course.

The data indicated that ESL teachers were not familiar with computer applications. According to the class discussions, most of ESL teachers simply used word processing in their instruction, and some of them used Internet search. The class observations and students' performance also indicated that the participants were not familiar with using computers in instruction.

The participants addressed similar problems as the ESL teachers of the case studies, for example, limited access to computers, a large number of malfunctioning computers, heavy workload, lack of practice time, and inadequate funding. Although they seldom used computers, they had strong desire for learning computer applications and using them in their classrooms. The participants revealed their positive attitudes toward using technology and willingness to implement technology in their classrooms.

Recommendations

The participants of the case studies shared various problems they encountered while using computers. Surprisingly, the researchers found that one problem was not previously mentioned by the participants in the case studies but in the action research: ESL teachers' unfamiliarity in computer use. The lack of familiarity might have caused ESL teachers not to use computers in classrooms.

To help teachers familiarize themselves with the use of computers, it is recommended that schools or school districts encourage ESL teachers to participate in technology training. As an added incentive, stipends or pay raises may be provided based on degree of teacher participation. Information about technology training can be found at California Technology Assisted Program (CTAP) website (http://rims.k12.ca.us/ctap) and university websites. The CTAP website also contains much information about technology resources and curriculum standards.

If teachers find the protocol of distributing and accounting of Internet use permission slips too time consuming, perhaps a trusted student assistant, teacher's aide, or parent volunteer would be willing to track the outgoing and incoming permission slips. Many school districts prefer to openly communicate with parents regarding various curricular issues such as the appropriate use of computer technology in the classrooms. Conversely, parents want to be assured by school districts that premium measures are being put into place to prevent student access to inappropriate websites. This understanding and agreement can be mitigated with permission slips once schools have access to the Internet. Although time consuming, the minutiae involved surrounding the distribution and collection of Internet use permission slips appears well worth the effort.

Students' access to computers seemed to be a problem for many teachers. In a classroom, teachers often only had one to four computers. It is suggested that teachers creatively utilize the limited number of computers. For example, if a teacher only has one computer in a classroom, he/she may use it to prepare teaching materials, track student academic progress and attendance, or communicate with parents. If he/she has two to four computers, she may group students and have students conduct collaborative work on a research project based on information downloaded from the Internet. If he/she has more than four computers, he/she might be able to construct class activities using computers for a spelling competition, or to create a choral reading, or to write a class newsletter.

If teachers and students do not have access to computers in their own classrooms, and instead have access to computer labs, then, computer time may need to be scheduled before school, after school, and during lunch. This could be accomplished in addition to a regularly scheduled time slot on a weekly basis. Having a computer club meet during lunch would provide additional computer time for students as well.

The elementary teacher in the case studies addressed the problem of supervision. If adult supervision is needed at computers in a classroom, it is recommended that a teacher recruit parents or college volunteers, who
would be willing to provide assistance to students. By doing this, parents and community members may be included in the children’s learning.

As to websites running slowly due to the large number of students simultaneously accessing the same website, one may use software like Web Buddy (http://www.dataviz.com/products/webbuddy/) to solve the problem. The software allows users to download websites and use them off-line. Currently, Web Buddy has been discontinued because the latest web browsers such as Internet Explorer have replicated its benefits. Whichever software a teacher uses, it may be beneficial for instructors who employ the Internet in instruction. In addition, while teachers download websites, they may select websites appropriate to students.

In regard to computer maintenance, it may be worthwhile to hire a technology specialist to remain on site. This individual would maintain and upgrade all computer equipment. In addition, he/she could provide computer training to the faculty. If the computer specialist does not have educational expertise, it is recommended that the computer specialist collaborate with the teachers who have computer knowledge and together provide training to other teachers. Of course, hiring such a specialist requires appropriate funding.

To increase the quantity of computer equipment, and, therefore, student access, the school district should allot money, specifically earmarked for computer technology, to each school on an annual basis. It is recommended that administrators, teachers, and computer specialists collaboratively construct a strategic plan. They can apply for state or federal grants that cater to culturally diverse school districts that exhibit a need for financial assistance in providing appropriate programs for their student population. They can also establish partnerships with corporate entities and institutions or conduct fundraisers with businesses like supermarket chains. The funding and strategic plan may eventually provide computers to classrooms, so ESL students can utilize technology to improve their literacy skills on a daily basis.

The case studies and the action research in this study provide an interesting look at the challenges that come with incorporating computer technology into today’s schools. It is recommended that additional research involving a larger number of ESL teachers be conducted to examine issues related to computers and ESL education. In addition, broadening the scope and investigating the use of technology, not only computers, in ESL education is recommended.

Internet Resources

The Internet contains a great deal of resources. Listed below are websites beneficial to ESL instructors and students. The website http://www.nitech.ac.jp/~ieslj/quizzes/grammar.html contains many self-study quizzes for ESL teachers and students to use. English club at http://www.englishclub.net/reading/index.html is a good website to learn English through, for example, English readings. Students may select short stories based on their reading levels—elementary, intermediate, and advanced. Teachers may find lesson plans and handouts for classes. Teacher’s Page of Lesson Plans at http://libits.library.ualberta.ca/library.html/libraries/coutts/lessons.html also provides ESL teachers with various lesson plans. One can also find many resources at the National Capital Language Resource Center http://www.cal.org/nclrc/index.htm, including articles related to performance testing and technology in language classroom.

Another worthwhile website to investigate is http://www.bedfordstmartins.com/exercisecentral/ Each student can take a diagnostic quiz, and then choose various activities for practice. Each student is required to indicate the instructor’s email address, whereby the instructor can access each student’s performance on his or her self-selected practice activities.

ESL Partyland http://www.eslpartyland.com provides a wealth of information for ESL instructors and students. Students may take interactive quizzes and participate in various discussion forums and chatrooms. Teachers may view many ESL lesson plans and conduct electronic communication with ESL professionals. The website http://esl.about.com is beneficial for ESL students because it offers interactive quizzes that link to lessons that explain language structures. ESL Café at http://www.eslcafe.com and http://www.etanewsletter.com provide teachers with ESL classroom activities and discussion forums. English Baby http://www.englishbaby.com targets teenagers and contains many English slang and idioms.

can find reviews of ESL software and books at http://www-writing.berkeley.edu/chorus/call. The site may save ESL teachers much time in search for useful software and books.

Conclusion

With the onset of the 21st century and its incorporation of computer technology, schools are required to provide relevant learning experiences for our increasing diverse student population. The case studies and action research of this paper revealed that ESL instructors, unfortunately, seldom used computers in instruction. They encountered many problems including lack of practice time, unmotivated administrators and faculty, time consuming protocol, limited access to computers and the Internet, lack of adult supervision, out-of-date or poorly maintained computer hardware and software, and inadequate funding.

Despite the problems, ESL teachers had positive attitudes toward using computers in classrooms. They believed that computers were beneficial and could enhance students' learning. To assist ESL instructors in employing computers, the authors provided recommendations and resources. It is hoped that ESL teachers may continue using technology and resources available to them to help ESL students. With technology and dedicated ESL educators, we believe that ESL students will have equal opportunities in learning that will enable them to make significant contributions to our society.

References

Butare-Kiyovu, J. (1991). Language learning for off-campus students. In T. Evans & P. Juler (Eds.), Research in Distance Education 2 (pp. 144-156). Deakin: Institute of Distance Education.
Abstract: Modern technology is changing the role of the instructor from an information-giver to a facilitator. As facilitator, the teacher guides the learners through the learning process and encourages the students to be active in their learning. The experience of independent learning may encourage the students to continue the learning process on their own in other fields and in the future. This presentation reports how the author encouraged students to be resource providers and trained them to be self-learners and self-trainers in an educational multimedia course. Class observations and students' feedback revealed that the teaching methods and new role of the instructor had a positive impact on students' learning.

Introduction

Instructors are facing tremendous challenges nowadays. They have been the main information givers and center of the classroom for the past decades. However, their role is shifting due to modern technology. Consequently, they can no longer be the information giver; their students may obtain information from a variety of resources via various channels. According to the report released by the National Council of Accreditation of Teacher Education (NCATE) in September of 1997, teachers should develop a new understanding, new attitude, new approach, and new role (NCATE, 1997). Tom Carroll, director of Preparing Tomorrow’s Teachers to Use Technology (PT3) grants of the US Department of Education, vividly described the changing role of teachers at the annual convention of Society for Information Technology and Teacher Education (SITE) 2000.

Carroll (2000) advocated that a teacher should take the role of a learner. A teacher is an expert learner while a student is a novice learner. Novice learners may become expert learners as time progresses. As an expert learner, the teacher should facilitate learning for novice learners and let them become instructional resource providers. Creating a learning community that consists of expert learners, novice learners, parents, and members who may foster the learning process is a teacher’s responsibility. He (She) should facilitate interaction and learning within the learning community and to further expand the community by involving members of other communities.

Hence learning no longer refers to learning from a teacher. A student may learn from other students or any member of the community. A student who does not know one area may be expert in another area. Thus a student may be a receiver at one time while he (she) may be a provider another time. A student may also self-learn from available resources, for example, the Internet. Learning becomes multifaceted and dynamic, and resources become essential in the learning process.

In addition to Carroll, Oliver (2000), an invited speaker at World Conference of Educational Multimedia, Hypermedia, and Telecommunications (EDMEDIA), also supported the idea of using students as instructional resource providers. In his speech, he further explained how he treated his students as resource providers and how his students contributed to the teaching materials. Similar ideas were echoed at two presentations at the convention, Leh (2000) and Santema & Genang (2000). The author of the paper was one of the presenters and was pleasantly surprised to see the idea simultaneously spring up on three different continents, North America (USA, Leh), Europe (Netherlands, Santema & Genang), and Australia (Oliver). This notion might be an indicator of a current global educational trend.

In this paper, the author will describe how she played the role of a facilitator and encouraged her students as educational resource providers in an Instructional Technology course. She will also report her students' opinions towards their learning in the course.
The Case Study

The case study was conducted in a graduate course called “Advanced Computer Applications in Education.” The goal of the course was to familiarize students with a variety of authoring multimedia software programs. Since this was the only course directly dealing with such applications in the academic program, the author structured the course as a multimedia survey course in which students studied a variety of applications rather than focused on a specific computer program.

She assessed students’ skills at the beginning of the course. On a survey, students identified their skills of using the following seven computer-based application software: Webpage development tool, HyperStudio, PowerPoint, PhotoShop, Premier, Authorware, and Director. The students circled one of the following—“don’t know”, “good”, “very good”, and “excellent”—which best described their skill levels.

The author reported the survey results in class. She intended to help the students use the information to complete their course assignments: developing a HyperStudio project, creating a webpage, integrating PowerPoint in instruction, and offering a technology training session. Course assignments emphasized integrating technology into content areas, independent learning, and learning from each other. Described below is how the students learned from each other in the “Technology Training” assignment.

For the assignment, the students selected their team members (no more than three members in a team). Each team chose and learned one of the software applications mentioned above. Overview of software and step-by-step instruction of using some of the software were illustrated in a course textbook. After selecting the software program, the students constructed a training plan for a 60 to 90 minute training session. In the training session, they were supposed to teach their classmates the use of the application software they selected. The training plan had to contain (1) assessment, (2) time length, (3) content outline, (4) evaluation, and (5) training materials like handouts or evaluation sheet if applicable. They met with the author to discuss their training. During the meeting, they had to be prepared to answer questions like what their trainees’ prerequisite skills were, what they would cover in the training, which criteria they used to decide on the content in the training, and how they would evaluate the success of their training session. The students were aware that they could ask for help from the instructor (the author) at any point of time.

Finally they delivered the training to the entire class. The author observed the class and recorded classroom interaction. She also took notes how the trainers could make the training better. After the training, the author first asked the trainers to self-evaluate their training. She then asked the trainees to critique the training session by providing good points and suggestions for improvement. She asked the trainees to provide oral input in class so that the trainers could receive instant feedback and response. She conducted the discussion and concluded with her own critiques. The trainers also received written feedback afterwards from the trainees and the instructor.

Findings

During the quarter, the author observed the class and interviewed students about their learning experiences in the course. At the end of the quarter, the author interviewed the students and also had them fill in a survey expressing their opinions about the course. The responses were analyzed and categorized. The results revealed that the teaching methods used in the course were deemed to be successful.

The teaching methods highly motivated the students. The students were enthusiastic about choosing a training topic and being actively involved in the learning process. Some of them chose software they were familiar with but more than half of them selected software that they knew little about. When asked why they selected the software foreign to them, the students answered that this would be a good opportunity for them to learn new skills. One said, “I wanted to learn this software for a while. Selecting this topic may push me to learn it.” They learned beyond the textbook. Two of them rented a videotape on Macromedia Director. Three of them bought a book and together studied Adobe PhotoShop. The students mentioned that they enjoyed learning with their partners. They also expressed their frustration when they explored software; for example, the steep learning curve of studying Director frustrated them. Despite the frustration, they cherished the learning experience and thought that they learned a lot from their peers and other resources.

The teaching methods generated students’ meaningful, active, and constructive learning. For the training plan, the students constructed their own instrument to assess the trainee’s skills, decided on training content, and determined how to evaluate their training. They mentioned that instructional design models, for example Dick and Carey’s model, made much more sense when they went through the process. They expressed that they spent much
time on the course, much more than what they spent on a regular course. However, they liked the experiences. They felt that they were the masters of their learning and were able to claim ownership of their work. They mentioned that this learning experience would influence how they learn and how they teach in the future. They would search for resources that could foster their learning and try to play the role of a facilitator rather than an information giver in their own classrooms when appropriate.

The teaching methods encouraged the students to think critically. The author required the students to critique their classmates’ training sessions. She noticed that the students could easily say, “you did a great job!” Nevertheless, they had difficulty in addressing points of improving a training session. By requiring the students to specify good points and provide recommendations for improvement, they practiced to think critically. At the end of the quarter, the author noticed the improvement that the students made on critique.

The teaching methods increased the students’ self-confidence. Before taking the course, the students often complained that they did not know how to use certain software, for example, webpage development tool, because the instructors did not teach them. The students seemed to count on the instructors and did not feel comfortable of learning by themselves. At the end of the course, the students expressed that the course increased their confidence in learning technology on their own. They mentioned that, if they could learn software with their partners and successfully provide training to their classmates in this course, they should be able to do the same elsewhere. They became comfortable of being self-learners.

Conclusion

Technology advancement is shifting our education paradigm. The role of the instructor is changing from an information-giver to a facilitator. Students no longer passively receive information but may be instructional resources in class. Given opportunities, they may be self-learners and self-trainers.

In a multimedia course, the instructor employed teaching methods allowing her to be a facilitator and her students to be self-learners. It was found that the course motivated students, fostered students’ active, meaningful, and constructive learning, encouraged students’ critical thinking skills, and increased students’ confidence. Class observations and students’ feedback revealed that the teaching methods and new role of an instructor had positive impact on students’ learning.

As a university professor in Instructional Technology, the author might have experienced the education paradigm shift and its impact on the role of an instructor earlier or faster than instructors of other subject areas might. However, the changing role is a trend. Every instructor should be open to the idea and explore the possibility and experiment with the opportunity.

As NCATE stated in 1997, teachers need to develop a new understanding, new attitude, new approach, and new role. Every instructor should be open to the changes and further create a learning community in which instructors, students, and community members may contribute, benefit, and generate meaningful learning experiences. One can only look forward to participating in the dynamic learning and expect its positive impact on our society.

Does Technology Really Make a Difference? –
Perspectives from Teacher Education Students

Edmundo F. Litton
School of Education
Loyola Marymount University
United States
elitton@lmu.edu

Abstract: This study analyzes how computers can be used more effectively in teaching in learning. The purpose of this study is to find out how the use of technology makes a difference in learning in a class designed for teacher education students. Data was gathered through a survey that asked students to reflect on their learning experiences immediately after a lesson that utilized computers. The study shows that technology makes a difference in teaching and learning. The students reported that technology made the lesson more meaningful, allowed them to be more creative, and they often learned a lot more than what was intended by the teacher. The use of computer technology in the class also gave the students an excellent way to experience true cooperative learning. The results can influence the design of future lessons that integrate technology in Teacher Education.

Introduction

Computers are increasingly being used in educational settings. Teachers are constantly striving to become more technologically literate. In my own work as a Teacher Educator, I have made a conscious effort to design lessons using technology that allow students to experience a new way of learning and teaching (see Litton, 1999a; Litton, 1999b). New teachers often use methods they have experienced. Consistent with their experiences in their own schooling, many new teachers still see their primary purpose of teaching as transmitting information. McDiarmid, Ball, and Anderson (1989) state that “students typically begin their teacher education programs with the view that teaching is telling and learning is accruing information.” (p. 223). Thus, it is important to design lessons that allow students to experience a different way of learning. Using technology in teacher education classes provides a promising way to help students see that there are other models of learning and teaching (National Council for Accreditation of Teacher Education, 1997).

This study is part of my on-going project to analyze how computers can be used more effectively in teaching and learning. The purpose of this study is to find out how the use of technology makes a difference in learning in a class designed for teacher education students. Specifically, I explored the following questions:

a. How does the use of computers help teacher education students learn?
b. Aside from content knowledge, what do teacher education students learn when they use computers in a class?
c. What are some problems that students encounter when they use computers for learning? How do the students solve these problems?

A clearer perspective of what students actually learn and how they learn can help educators develop principles for designing effective lessons using computers.

Background

Technology is used in teacher education programs in a variety of ways. The review of literature shows that the use of computers is most helpful to teacher education classes because it helps promote
interaction. Using technology in teacher education classes also allows students to use the technology in a meaningful way.

The most common use of technology in teacher education is the use of electronic mail (email). Email allows new teachers to interact with other professionals. Thomas, Clift, and Sugimoto (1996) conducted a study using email in teacher education. They wanted to find out how email functions as an environment for learning. Furthermore, the authors wanted to find out how the participants perceived the effectiveness of using email to promote learning. The authors concluded that electronic mail was an asset for meeting course requirements and for maintaining contact between students and teachers.

Although the use of email in teacher education classes is only beginning to be articulated, using email provides a promising way to increase dialogue and critical thinking among novice teachers. In order to ensure the effectiveness of email or other web-based discussions tools, Nonis, Bronack, and Heaton (2000) state that facilitators should address three key issues. First, both instructors and students should be aware of an agreed upon intended consequence for the discussion. Participants need to always be aware of what needs to get accomplished. Second, facilitators of on-line discussions must be "cognizant of the essential attributes of effective on-line discourse" (Nonis et al, 2000, p. 6). These essential attributes include convenience, familiarity, accessibility, meaningfulness and focus. Web base discussions will be effective if participants are able to access the technology without too much difficulty and are familiar with the technology and the rules for using the technology. Dialogues must also be meaningful and focused on content rather than on the technology. Thirdly, after the establishment of a discussion group, the instructor should make sure that facilitative structures exists to promote dialogue. Facilitators should create structures in the dialogue that allow students to connect the discussion to their own lives, encourage collegiality and ownership.

Another common use of technology for teacher education is the use of multimedia (Abell, Cennamo, & Campbell, 1998; Hatfield, 1996; Mazur & Bliss, 1998). Multimedia is used to create case studies that allow novice teachers and experienced teachers to talk to one another about teaching methodology. Case studies are at the heart of Mazur and Bliss’ (1998) Common Thread Case project (CTC). The project incorporates video conferencing and electronic mail in the interaction. Through the interaction, a community of learners is created and teaching practices can be transformed. Mazur and Bliss (1998) state that in order for multimedia to be a successful tool for interaction, three dimensions must be included. The first dimension is the instrumental dimension. The information contained in the cases must provide rich information that is appealing to both novice and experienced teachers. The second dimension is the relational dimension. The technology must contain tools that teachers can use to elaborate on issues that are raised. The questions, interests, or concern of the users influences the structure of the program. The last dimension is the communication dimension. The technology must allow users who are studying the same cases to interact with one another. In so doing, "teachers can revise ideas, capitalize on the experience of others and engage in the critical discourse essential to the development of professional communities." (Mazur & Bliss, 1998, p. 109).

Teacher educators have also used technology for the creation of electronic portfolios. Reed and Cafolla (1999) discuss some of the benefits and challenges of using electronic portfolios. The authors implemented the use of electronic portfolios in a preservice teacher education class. The portfolios that were created could be posted on the World Wide Web. Students attended seminars and were given a template that they could complete and modify as they created their portfolios. The researchers discovered electronic portfolios encourage students to be more reflective and responsible for their learning. The project, however, also proved to be time consuming. Furthermore, financial and technical support from the institution was needed if the project was to continue. Most importantly, however, the use of electronic portfolios allowed the preservice students to use technology in a project that was relevant for them.

K-12 schools and Teacher education programs have collaborated successfully to prepare new teachers to use technology. Hruskocy, Cennamo, Ertmer and Johnson (2000) found that such collaborative efforts increase the motivation to use technology by all stakeholders (new teachers, mentor teachers, K-12 personnel, and university personnel), change learning styles, and have interpersonal benefits. New teachers who use technology in the classrooms of mentor teachers also are able to demonstrate how technology can be used to complement existing effective teaching practices (Johnson-Gentle, Lonberger, Parana, and West, 2000).
Methodology

In my Education class (Sociocultural Analysis of Education), I use technology in various lessons. After one particular lesson towards the end of the semester, I ask the students to reflect on the class that they just experienced. The students write down their reflections in a simple questionnaire that I developed. I ask the students to reflect on what they learned, how the use of the computers helped them learn, and the problems they encountered when using computers in the class. The feedback I receive from the students helps me determine if the use of computers made a difference and I often use the reflections as a guide to design future lessons. For the present study, I analyzed 119 questionnaires that I collected over a period of seven semesters.

The technology activity in this particular class was used to learn about Sociocultural theory. Aside from learning the major components of Sociocultural Theory, a goal of the lesson is for teachers to realize that it is important to see their students' prior knowledge as a resource rather than as a liability. This is an important concept to learn especially when teaching students of culturally diverse backgrounds.

Procedure: 1) Divide the class into 6 groups. Ask the students who are experts in PowerPoint to raise their hands. These students should be in separate groups. 2) Provide a brief overview of PowerPoint. Using a pre-formatted disk, demonstrate some of the features of PowerPoint. Highlight how to create new slides, change colors, and animation. Tell the students they each group will make a presentation using PowerPoint and all groups will be required to use animation in their presentations. 3) Tell the students that they will be creating a presentation on an aspect of Sociocultural Theory. The six terms that the class will explore are Lev Vygotsky, Sociocultural Theory, Schema Theory, Cooperative Learning, Zone of Proximal Development, and Constructivism. Each of these terms will be given to a group in a disk. They will need to perform a search on the web on the term that is given to their groups. 4) Give the students ample time to complete their presentations. If one group finds information that they feel another group should be given, then they should pass on that information. 5) After the students have created their presentations, ask the groups to present their slide shows. The professor should help the students make the connections between each term in between presentations. 6. At the end of the lesson, the teacher will ask the students to talk about the practical applications of Sociocultural theory to teaching.

Results

Does the use of technology make a difference? According to the students who completed the survey, technology did make a difference in their learning. Many of the students who completed the survey stated that the use of computers helped them better understand the topic for the class because it allowed them to experience the learning theory using computers. Without the use of technology, the theory that was being taught in class would have just remained an abstract theoretical construct. Using computers made the topic more relevant for the students. One respondent echoes this thought when she states, "The use of computers was very helpful in understanding Sociocultural theory, because I just did not hear about it, I actually did it". Another student says, "[Working with computers] helped solidify the new knowledge because I had an active role in presenting it".

Technology makes a difference learning because using technology provides a meaningful way for students to work cooperatively. The cooperative atmosphere allowed all students to contribute to the learning task. A student says, "I learned that each of us has something to give to the group". Students who self-identified as having low computer skills, were not intimidated by the learning task because of the presence of other students in the group. One student said, "It [technology] was instrumental in making us work together as a group and drawing on the strengths, knowledge, and interests of all in the group to achieve our mutual goal".

The students who completed the survey stated that technology made a difference because it allowed them to be more creative. One student stated he was willing to try out more things when he created his presentation with the use of the computer. The students also found the presentations to be more entertaining and sustained their attention even more. Computers also allowed students to "experiment,
explore, and learn”. The students felt they could continue creating products until they developed one that they really liked.

The results of the survey show that when using computers, students tend to learn more than what the teacher intended. Some of the learning outcomes could not even be anticipated. I wanted my students to leave the class with a good understanding of Sociocultural Theory. Aside from learning the various components of the theory, the students stated they learned how to conduct research on the Internet, create PowerPoint presentations, and effective ways of designing and implementing a cooperative learning lesson. During the class session, it was always interesting to see students discovered various aspects of PowerPoint that were never presented to them formally. The students also reported learning how to use computers for teaching.

During the lesson, the majority of problems reported by the students were technical problems related to the software. Some of these problems include, saving work, creating animation, cutting and pasting pictures from the Internet. Some of the students also reported tension as a result of working cooperatively with others. One student says, “We sometimes differed on what we wanted to include on the slides such as the color, font, and style”. Many of the students stated they solved the problems by working within their groups and asking other groups. Others solved problems through trial and error or experimentation and exploration.

Most importantly, a majority of the students in the survey stated that they would be more willing to use computers in their teaching. The experience with technology in this lesson allowed them to see the benefits of technology. The study reinforces the concept that new teachers often teach the way they are taught. If we expect new teachers to use technology in their classrooms, they need to experience computer-based learning in their Teacher Education classes.

Conclusion

Effective technology lessons in teacher education classes create authentic learning experiences. Such lessons could encourage new teachers to use technology once they begin teaching in their own classes since they know first hand that one can learn using technology. The study shows that technology does make a difference in the learning experience of teacher education students. Teaching with technology allows students to see an alternative way of teaching and learning. In order to create more effective lessons using technology, I suggest a few guidelines:

a. When students have varied competence levels with technology, it is important for them to work in cooperative groups. Students who are more confident and experienced can assist and teach students who are less confident or less experienced.

b. Lessons must encourage active involvement by all participants. The lesson should encourage students with different computer abilities to participate.

c. Lessons must meet the needs of students with advanced and beginning computer skills. Students with beginning skills must feel that they have something to contribute and the lessons should not encourage advanced users to dominate a group.

d. Technology lessons must address issues that are meaningful to the teacher education students at the moment. Students need to see how technology is important to their own learning before they can use it to improve the learning experiences of their future students.

e. When working with technology, teacher education students need to create something that they will personally need. Students are more interested in a project when the end product is clearly defined. However, teacher educators must allow room for creativity, exploration, and experimentation.

f. Technology lessons should allow teacher education students to experience varied ways of learning and teaching.

Assessing Technology-Assisted Use of Information

Leping Liu, Ph.D., Towson University, U.S.A., Email: liu@towson.edu
Cellestine Cheeks, Ph.D., Towson University, U.S.A., Email: ccheeks@towson.edu

Abstract: This paper presented a two-year experience of assessing college students' use of information from different resources, including the methods, processes, instruments, results and some issues of the assessment. The assessment processes started from analyzing the goals of learning, defining the outcomes, then selecting or developing instruments, and the last, collecting data and analyzing results. A "qualitative-and-quantitative" (Q-Q) assessment package was developed and used, where we used portfolios to record the learning process and quantitative scores to measure the learning of specific skills. The Q-Q assessment procedures were employed into six classes during the past two years. This experience suggested that assessing the use of information and technology related outcome was a process rather than some one-time test. The Q-Q procedures also provided a structure to develop an assessment model that should apply to other fields of information technology assessment.

Background

Due to the wealth of information resources, the Web is becoming a widely used research tool. By 1996, there had been a rapid proliferation of World Wide Web pages, estimated at over 20 pages per hour (Caverly & Broderick, 1996). Since then, this rate has kept increasing; thousands of pages are available on the Web, providing information on almost every imaginable topic (Tate & Alexander, 1996; Gilbert, 1996; Caverly & Broderick, 1997; Leshin, 1998; Morgan, Batovsky, Bennett, & Schrock, 1999; & Miller, 1999). Now, “it is growing at a rate of 20 million new pages a month” (Maddux, 1999). The over-exposure of information brings out a critical issue to the college students—whether they can effectively use the information for their studies; and a critical task to the instructors—what would be the appropriate way to assess the use of information. This paper presents a two-year experience of assessing college students' use of information from different resources.

The assessment was performed in an undergraduate course titled “Using Information Effectively in Education”, which was the required course for all the undergraduate students in the College of Education, and was offered 15 to 20 sections each semester to prepare college freshmen for their studies in this information age.

Defining the Use of Information

The goal of this course was to improve students' skills and techniques of (1) searching and finding information on certain interested educational area, (2) evaluating the information, (3) managing the information, and (4) communicating the information. The use of information was defined as a combination of these four aspects. Therefore, assessing the “use of information” was undertaken in these four dimensions. In each of the four dimensions, students used certain technology tools, which makes the use of technology part of the “use of information” as well as part of the assessing content.

To ensure that we could assess the specific aspects and effectiveness of using information, we first defined the outcomes from the four dimensions. First, in searching and finding information, students learned to use a series of on-line tools, including library system, on-line databases, Web search. They were supposed to find information (articles, reports, ed/gov documentations...) from our university library system, from ERIC, EBSCO, WILLSON, and from other Web sites. Second, in evaluating information, students learned to develop a set of information evaluation criteria and use it to evaluate at least 40 pieces of information. They used spreadsheet to analyze and summarize the evaluation. Third, in managing information, students learned to develop a research portfolio and create a database to manage the information. Fourth, in communicating information, students learned the skills of telecommunication to work in team or within the class; they learned presentation tools such as PowerPoint to share the information with class; they created Web pages to post their findings; they also write a research paper, which they considered a medium to communicate information with a large audience or more readers.
Assessing the Use of Information

By analyzing the outcomes, we found that the nature of assessing technology-assisted use of information, in the current setting, was to assess a learning process as well as the learning of specific skills. This determined the "qualitative-and-quantitative" nature of the instruments—the instruments should include qualitative procedures to analyze the learning process, and quantitative measurements to analyze the learning of specific skills. Research suggested that portfolios have been widely used as the formative assessment capacity, measuring performances and learning process (Winograd & Gaskins, 1992; Camp, 1993; & Dwyer, 1993), and demonstrating what a student is capable of doing (Salvia & Ysseldyke, 1998). Therefore, in this study, the qualitative procedures were measured by four portfolios that recorded the learning process through the entire semester: (1) information search portfolio, (2) technology portfolio, (3) information evaluation portfolio, and (4) research portfolio.

Each portfolio was tailored for a specific purpose and the contents of the portfolio were consistent with the purposes for collecting work. The information search portfolio included six items/tasks/skills, providing the information of how well students used the search skills, as well as the coverage range of information in the on-line databases. The technology portfolio consisted of 12 techniques, reflecting capabilities of using technology to search, evaluate, manage, and communicate information. The information evaluation portfolio recorded the procedures that showed how students’ evaluation skills were improved, the results of the evaluation tasks provided a pattern of qualities of information from different Web resources—which had a great potential to initiate another Internet information evaluation study. Finally, the research portfolio demonstrated, via 14 tasks, the development of critical thinking skills and the process of conducting educational research.

Furthermore, quantitative scores were used to measure (1) the specific tasks/skills within portfolios, (2) team presentation, and (3) individual research paper. The results served as quantitative data.

Q-Q Assessment Structure

This measurement suggested a "qualitative-and-quantitative" (Q-Q) structure to assess technology-assisted use of information. Using this structure and the Q-Q package, the authors obtained various sets of data from six classes during a two-year period. The Q-Q assessment procedure later was adapted to other instructional technology courses, such as Computer Based Instruction, Web Based Instruction, and Technologies in Reading; and found out to be effective for both students and the instructor. It is the hope of the authors that the Q-Q assessment procedures initiated the first step toward the development of an instructional technology assessment model; further studies are to be conducted to implement and test the model.

CREATIVE USES OF DIGITAL TECHNOLOGY: DEVELOPING VISUAL LITERACY AND ICT CAPABILITY

Avril M. Loveless, School of Education, University of Brighton, UK, A.M.Loveless@brighton.ac.uk
Terry Taylor, independent artist, UK, terrytaylor100@hotmail.com
Richard Millwood, Ultralab, Anglia Polytechnic University, UK, richard@ultralab.anglia.ac.uk

Abstract: The panel addresses the progression in practice and understanding in the development of visual literacy and ICT capability using digital media in seven projects over a period of five years. These projects were conducted as collaborations between artists, teachers, pupils, undergraduate students and university researchers working in primary and secondary schools within the core and extended curriculum. The participants explored the ways in which visual literacy and ICT capability could be supported and extended in a range of relevant and meaningful contexts. The work is analysed from two perspectives - an artist focusing on children's learning and expression of visual literacy and teacher educators focusing on the development of ICT capability within meaningful learning environments.

INTRODUCTION

How do we approach research into the creative uses of digital technologies and evaluate what we have learned from the progression of practice and understanding through our experiences in recent years? The three members of the panel and authors of this paper share a commitment to the promotion of the development of visual literacy and information and communication technology (ICT) capability in children and young people. A practising artist and two teacher educators represent different practices and priorities in researching this process which provide stimulating and provoking perspectives on the growth of our understanding of issues in the area.

Over a period of five years the authors have been involved in the co-ordination, implementation, research and theorising of a range of projects in which digital technologies have played a role in creative expression, dialogue and critique in the visual arts. (References to a range of associated publications and websites are given at the end of this paper.) In reviewing these projects it has been possible to identify progression in a number of key themes relating to the nature of visual literacy, the contribution of ICT, the development of ICT capability, conceptual frameworks of subject knowledge in art and ICT, links with contemporary culture, interactions between artists, teachers, mentors and students, models of resource management and evaluation of pupils' learning in art and with ICT. The paper and panel presentation address these issues, demonstrate and contextualise key themes by reference to examples of the work made by children and young people and discuss research questions which can underpin further project developments and collaborations.

THE PROJECTS

The projects, which have been written up and presented in a number of formats and forums, are described briefly below. The asterisks indicate those projects which had a specific research focus. The research paradigm was interpretive and hermeneutical adopting ethnographic methods and a grounded approach to analysis and interpretation.

*The Glebe Project 1995
Focus: The observation and description of elements of visual literacy, the contribution of ICT to the activities and changes and challenges to pedagogy.
Context: The 24 primary pupils involved were eight and nine years old, working outside their usual classroom activities with a digital artist and a researcher, using a scanner and image manipulation software. The outcomes were presented with multi-media authoring software. The project lasted three months.

The Bristol Internet Project 1997
Focus: The collaboration between children in separate schools through the exchange and development of visual ideas
Context: Six and seven year old children in two primary schools in the city of Bristol worked with two artists who also worked in each school. Digital cameras, image manipulation software and e-mail were used to capture, develop and exchange images and text messages. The project lasted eight weeks.

Focus: The development of visual literacy as a dialogue in making meaning. Collaboration between practising teachers and an artist.
Context: Three teachers in three primary schools worked with their classes of children aged from eight to eleven years. Using the artists’ work as a starting point, ideas were explored in a variety of media. Digital cameras, image manipulation software were used to capture and develop images. The project lasted an academic year.

*Art on the Net 1999/2000
Focus: The development of the role of artists in residence collaborating with practising teachers. The contribution of digital technologies to art processes. The development of models of access to resources.
Context: Artists and Art teachers in four secondary schools worked with pupils from fourteen to eighteen years old. The artists all used a range of digital technologies within their work which encompassed sculpture, photography, video and performance art. The project lasted a year and was reviewed and exhibited a year later.

Ultralab VI Form Project 1999
Focus: The use of multimedia technologies to document and publish art work undertaken for Art Advanced Level examination. The role of ‘multimedia mentors’ working with school students.
Context: Seventeen and eighteen year old students from one school worked with undergraduates on a Multimedia Degree Course. The work was undertaken at Ultralab away from school. The project lasted eight months.

*MMM: Media and Messages Multimedia Project 1999/2000
Focus: The use of multimedia technologies to relate the art curriculum to contemporary art practice. Changes in the expectations in the teaching and learning environment.
Context: Secondary art teacher and university researcher planned and prepared. Fourteen and fifteen year old students worked within the art curriculum and examination preparation. The project lasted a year.

Genes and Makeup 1999/ 2000
Focus: An art/science collaboration to provide opportunities for young people to use multimedia technologies to explore future identities in relation to genetic engineering.
Context: Two artists and a scientist worked with a group of 8 fourteen and fifteen year old students. They worked away from the school at Lighthouse, the Brighton Media Centre. The project lasted a year.

KEY THEMES – LITERACY AND CAPABILITY

Visual literacy
The early project, The Glebe Project, recognised 9 elements of children’s experience and expression reflected in their work and evaluation. These elements – narrative, content, audience, colour, text, design, approaches to the technology, affect and ways of working – went beyond those described in the English National Curriculum for Art and encompassed wider cultural influences and affect. It also identified a range of pedagogical practices and processes in which the artist and children were engaged when supporting and facilitating the work. Subsequent projects developed this approach to visual literacy as a
cultural practice by highlighting the nature of the dialogue which developed between the work and the maker who drew upon a range of influences and techniques in order to make meanings and develop visual, expressive ideas.

The contribution of ICT

ICT can be described as embodying four characteristics which interact with each other to provide opportunities and experiences which are distinctive in the use of these technologies – interactivity, provisionality, capacity & range and speed & automatic functions. (MEE, 1998) A range of digital technologies was used for the construction, capture, manipulation, integration, projection and display of meaningful images incorporating visual art, sound and movement. The capacity for interactivity and provisionality in the use of the technologies supported the process and dialogue as the students expressed and developed their ideas, evaluated and reviewed the outcomes and displayed and discussed their work with a wider audience. Whilst the projects focused on the context of expression and learning in the art curriculum, not the technology as a medium or a tool, the characteristics of ICT played a significant role in the process and the priority of policy and funding of resources for the projects.

The development of ICT capability

ICT capability has been described as the ability to participate in a rapidly changing world of technology; use ICT tools to find, explore, analyse, exchange and present information responsibly, creatively and with discrimination; employ ICT to enable access to ideas, experiences, people, communities and cultures; and make informed judgements about the use of ICT and its implications for home and work. (DIEE, 1999) The term ‘capability’ encompasses far more than ability with particular ICT techniques and implies an active, informed and critical approach to using technology appropriately and purposefully. The development of ICT capability within formal schooling structures can range from the teaching of specific techniques to the use of ICT to support teaching within a subject area. The projects demonstrated the situated, contextualised nature of the ways in which students drew upon and developed their experience and expertise of using ICT. These embedded experiences highlighted tensions within the organisation of the students’ ICT experiences in the school, raising questions about where ICT was ‘taught’ and whether students required specific ICT techniques or support in developing approaches to working with new technologies in a range of different contexts.

‘Is this art?’ - conceptual frameworks of knowledge of art and ICT and links with contemporary culture.

Each project highlighted students’ responses to their understanding of the nature of their activity. Many did not consider the work to be ‘art’ as it related to their experiences within the more traditional art curriculum. The outcomes of the work were broadly described as ‘media studies’, ‘drama’, ‘ICT’ and ‘playing’, whilst the connections between the processes in which they were engaged and the variety of tools and techniques employed were often not considered to be ‘art’. Issues were raised about the perceptions of art within the school curriculum, its relationship to the impact of digital technologies in wider culture and teacher knowledge of and access to contemporary practice with and through ICT. Students demonstrated a range of levels of the use of ICT which related to both their confidence with the tools and their active choices about the appropriate media in which to express and develop their ideas. A strong theme in much of the work was the personal nature of the expression of meanings.

Interactions between artists, teachers, students and mentors.

A significant aspect of all the projects was the range of interactions between the participants and the ways in which they shared and developed their knowledge of visual literacy and ICT capability. One approach observed was an open shifting and sharing of roles between students, teachers, artists and mentors to provide support and challenge in techniques, process, evaluation and audience. Another type of interaction highlighted tensions between practitioners and teachers in terms of role expectations, subject knowledge and pedagogy. Such tensions provided opportunities for discussion and action in trying to resolve the issues to reflect and model different ways of working. Questions were raised about ‘what knowledge?’, ‘whose knowledge?’ and the description of a ‘community of practice’ within a curriculum which enabled students and teachers to work with practising artists and multimedia specialists in a variety of settings, spaces and times.
Models of access to resources
The projects raised important practical and political questions about the allocation, organisation and management of ICT resources in models appropriate to learning and teaching processes within different subject areas. The National Grid for Learning Initiative in the UK has provided resources for networking capability in schools. The local management of these ICT resources does not always, however, reflect the needs and working practices of subjects, particularly Art. Many of the resources have been placed in central suites shared between all curriculum areas, rather than placed in subject departments and made available with space and software appropriate to the curriculum area, thus perpetuating an approach to ICT capability which focuses on decontextualised techniques and skills. The projects demonstrated the need for flexible and appropriate models of access to both physical resources and networks of support and professional development.

Evaluation of learning and teaching
The discussion of formative and summative assessment of the process and product of art in the curriculum highlights a number of issues of exchanging ideas, supporting process, identifying criteria for assessment and engaging in evaluative judgements. These discussions arose from the nature of the work itself and the working practices developed within the collaborations, but the issue was particularly pertinent in the school phase of ‘high stakes assessment’, that is, external examinations. The assessment and examination systems within schools define boundaries and gateways to particular choices and do not always reflect the knowledge and processes of practitioners. Within the projects which involved students undertaking work for examinations there were discussions of the nature of art and the type of work expected by external assessors and the degree to which students could explore new ideas and new media without ‘penalty’. Some UK examination boards now recognise digital work with screen-based media, but the debate is ongoing as understanding develops within the profession.

The contribution of research
The overview of the work in this particular group of projects reflects a wide range of contexts, participants and areas of focus. It describes a variety of activities and interactions taking place within many different contexts. It is interesting to consider the ways in which the questions for research and enquiry which underpinned the projects have evolved and inform subsequent projects. The questions have changed in focus from enquiries into the expression of visual literacy and the development of dialogue, to the nature of the collaborations between students, teachers and practitioners and the different settings in which they can be developed. Enquiry into the particular contexts of the case studies has also identified some common themes, raising issues which reflect deeper questions and tensions in such work. These include questions about ways of knowing, expressing and analysing ideas - what knowledge?, whose knowledge?, how can it be expressed and developed? What role does ICT play in these debates? Is technology a tool, a medium, a catalyst or a new lens through which to view these questions? What is the impact of ICT in contemporary culture and how the art curriculum might play a more proactive role in the education of young people? What are the challenges to pedagogy and professional development highlighted by such collaborations? How do studies such as these provide rigour and evidence to inform decisions by practitioners and funders in future initiatives? What are the connections between being visually literate and ICT capable in the broader sense of being creative and confident learners, inspired to work with spirit and imagination; to make decisions which might be collaborative and difficult? No one case study or survey can provide easy answers to these challenging questions, but it is timely to consider the role of research in providing both a stimulus for new work and a space for reflection and critique. Patterns and processes can be observed in the ‘bird’s eye view’ which indicate promising directions for further exploration and analysis.

Classroom Community in Post-Secondary Classes: An Examination of Traditional and Distance Learning Environments

Bob Lucking, Old Dominion Univ., USA; Fred Rovai, Regent Univ., USA; Michael Ireland, US Navy, USA

Introduction

Many schools, particularly post-secondary schools, are moving toward increased use of technology to deliver courses and programs at a distance. Several models are presently in use, such as broadcast television, video and audio teleconferencing, and asynchronous learning networks (ALNs) -- people networks for anytime - anywhere learning via the Internet. An important outcome of this emphasis on delivering courses at a distance is the generation of interest among educators concerning the nature of distance learning environments and the learning possibilities achievable through technology. One aspect of this interest concerns the building and nurturing of a community of learners whose members are often physically separated from each other.

The purpose of this study was to determine how sense of classroom community develops in a higher education learning environment and to determine if there are differences based on type of learning environment (traditional or distance education). The distance education environment examined was an asynchronous Blackboard-based integrated distributed learning environment.

Method

Subjects

Students attending education, leadership, and science classes at two universities in a large urban area served as subjects for this study. The sample consisted of 452 undergraduate and graduate students, with 83 enrolled in distance education courses and 369 enrolled in traditional courses.

Instrumentation

The Sense of Classroom Community Index (SCCI) (Rovai & Lucking, 2000) was used to measure classroom community. It consists of a self-report questionnaire of forty items. Each item includes a statement followed by a Likert scale of potential responses: strongly agree, agree, neutral, disagree, and strongly disagree. The SCCI possesses a very high Cronbach alpha internal consistency (p = .93).

Design

A quasi-experimental approach was used for this research. Twenty-three groups were examined. Each group consisted of an intact class, ten distance education classes and 13 traditional classes. A state university presented 12 classes and a private university presented 11 classes. The groups were measured on sense of classroom community during the second class meeting (pretest), except for the Blackboard-based asynchronous courses, which were measured during a three day interval at the end of the first week of the course. All classes were again measured at the middle of the semester (posttest). The subjects were not presented any special treatment other than the scheduled courses in which they were enrolled.

Statistical analyses consisted of descriptive statistics, a Pearson product-moment correlation between class size and sense of classroom community, and a series of dependent t-tests to analyze the differences between pretest and posttest measurements across all classes.

Discussion and Findings
The relationship between class size and pretest was low ($r = -0.284$, $p < 0.001$) while the relationship between pretest and posttest was not significant. These results suggest that students first entering a class feel a lower sense of community in larger classes, but by the middle of the semester the size of the class is no longer related to sense of classroom community.

Pretest sense of classroom community was higher for courses taught at a distance (M = 121.98, SD = 19.76) than traditional courses (M = 113.16, SD = 15.85). However, at the posttest, courses taught at a distance (M = 120.43, SD = 22.15) reflected a lower sense of classroom community than traditional courses (M = 131.69, SD = 19.80). An analysis of individual courses revealed that classroom community increased in all traditional courses and significantly so for most cases. However, only three Blackboard courses reflected increased sense of classroom community at the posttest (two were significant), while all others showed lower levels of classroom community (five of seven were significant).

An analysis of message patterns in the Blackboard-based courses was conducted in order to obtain evidence to help explain why three Blackboard-based courses experienced increases in sense of classroom community while seven experienced decreases in classroom community. The variable that appears to explain these differences is teacher immediacy. Teacher immediacy is the verbal and nonverbal communication that takes place in the classroom, such as smiles, head nods, use of inclusive language, and eye contact. Blackboard-based courses lack the non-verbal communication. Consequently the focus of the message analysis was on an analysis of instructor messages. This analysis showed that the instructors in the three Blackboard courses that experienced increases in classroom community posted on average 36.60 messages per week to the Blackboard discussion board, while the instructors of the seven Blackboard courses that experienced drops in classroom community posted on average 3.14 messages per week. An analysis of message contents revealed that the instructor message contents of three instructor immediate courses tended to be empathetic, mentioned self, family, or spouse, or had a cooperative tone, while for the remaining Blackboard-based courses the message contents tended to be factual.

The Uses of Computers For Instruction in the Classroom: 
A Comparison of Teachers’ and Principals’ Perceptions

Abstract: This study surveyed teachers and administrators in 50 schools in a large school district in South East Texas. The purpose of this study was to compare teachers and principals in their perceived uses of technology for instructional purposes in the classroom. The teachers and principals were asked to rate the extent to which technology is used in their classrooms for the following purposes: a) drill and practice b) problem solving c) world wide web searches d) compositions e) newsletters or desktop publishing. They were also asked to indicate the frequency a typical student uses the computer in their classrooms. The computer was used significantly more often for the lower level skill of drill and practice than for worldwide web and desktop publishing. The principals perceived that students were using the computers more frequently for the higher-level skill of worldwide web use than the teachers reported.

Introduction

A survey of the literature in education points to the critical role of the principal as instructional leader in the school (LaRocque & Oberg, 1991; Henri & Hay, 1995). Pellicer, Anderson, Keefe, and McCleary, (1990) state that "...instructional leadership is likely the most important function in a school for creating a productive and satisfying environment" (p. 41). At the same time much of the current literature points to the need to reform our public schools (Sarason, 1997; Goodlad, 1997; Matthews, 1997; Wadsworth, 1997). As many States and communities across the country are learning, transforming industrial-age schools into information-age schools is easier said than done (Dyrli & Kinnaman, 1994).

The key to ensuring the success of technology in schools is the way in which technology is integrated into the school’s curriculum. As Kinnaman (1994) observes, successfully integrating technology into education requires basic changes to our current model of schooling; anything less sells short both the value of today’s technology and the future of education. School principals must understand the importance of technology for improving school management as well as its implications for improved instruction. Technology holds great promise for personalizing learning opportunities (Drake & Roe, 1999).

Technology is the means to increasing learning efficiency. Technology can be used to better display information, increase access to information, improve information sharing, and organize better class presentations. Technology is not a panacea for educational problems, but by combining technology with applicable learning models, the overall quality of education is enhanced. Students raised in an age of technology demand student-centered learning. Educators must discover and develop how to implement new technologies into the learning environments and focus efforts on facilitating learning (Adams & Jansen, 1997). Principals must accept the challenge to create supportive conditions, which would foster innovative uses of computers. Principals must respond to the public demand for increased use of technology to prepare our students to meet the expectations of the society in which they will participate.

Resistance to Technology
Schools are still limited in their ability to take full advantage of computer technology because of cost, lack of teacher preparation, and inadequacy of the school's infrastructure. Even schools that were built fairly recently do not all have an adequate power supply, and few schools have telephone lines in every classroom (Loveless, 1996). A national survey conducted by the U.S. General Accounting Office (1995) found that in 46% of schools the electrical wiring would not handle the power requirements of computers. That finding helped explain why more than half (52%) of the schools surveyed did not have access to a computer network (Seyfarth, 1999).

Principals must be prepared to deal with teacher resistance to technology being integrated into the curriculum. Many teachers perceive technology as another burden of responsibility added to the already overwhelming load of a teacher (Hartzell, 1996). Principals have to be prepared to provide extensive teacher training in the integration of technology into the curriculum (Weiss, 1994). Principals need to create an environment conducive to maximizing technology integration into the curriculum. A faculty that becomes comfortable with the ideas of technology will more easily integrate it into the curriculum.

Principals need to solve the dilemma of how to provide appropriate technology training for the entire faculty. Dyrli (1996) recommends a number of key elements for a successful staff development including: offering a variety of options, emphasizing skill development, providing hands-on experiences, tailoring programs to local realities, using genuine teaching examples and providing supporting materials. Principals need to be aware that if the teachers are not the focus of the technology training, then technology will fail (Guhlin, 1996). Teachers have to feel involved in the process of integrating technology into the curriculum. This involvement will ensure that the teachers take personal ownership for this responsibility. Once personal ownership has been established, it is easier for the teachers to work toward goals because they now have more purpose and meaning. The main thing to remember is whatever training the teachers have, it is crucial that it applies to them as professionals as well as individuals.

There are teachers and administrators who believe the lack of available money for technology is a problem when trying to integrate technology into the curriculum. It is important for principals to keep in mind that research shows that the amount of money available to a school district is not related to the innovative uses of computers. Exemplary teachers work in a representative range of communities and schools. However, they tend to be found in settings where school and district resources have been used to create supportive conditions (Becker, 1994).

Some researchers (Milone & Salpeter, 1996), have found teachers that use the computer for typical tasks, such as creating instructional materials and performing administrative tasks, perceived their computer use as having a positive impact on their work, making them more professional, more creative, better informed, and generally better educators. It is important therefore for principals to accept the challenge to create supportive conditions that would foster innovative uses of computers. After one prepares the faculty in the professional development plan for integrating technology into the curriculum, one must give the faculty the access to the computers during instruction time and planning time.

Teachers as Computer Users

The literature on teachers as computer user is complex and there are many different levels of reporting. The curriculum needs of elementary and secondary levels as well as the various preparations and backgrounds of teachers makes the understanding of computer uses more involved and difficult to study. Several authors about the use of computers in schools claim that the personal computer is the latest educational technology to fall short of its original promise (Loveless, 1996). The author goes on to claim that although United States public schools now possess 5.8 million computers, roughly one for every nine students, they are not widely used in classroom instruction. In neighboring Canada Stats Canada (1999), reports that, more than 9 out of every 10 students at the elementary, intermediate and secondary levels in Canada attended schools had access to the Internet for educational purposes. However, principals reported a number of obstacles to fuller use of computer technology in the classroom, the biggest of which were a lack of computers and lack of training opportunities for teachers. Principals of schools representing about two-thirds of students cited a need for more computers as well as more time for teachers to prepare courses that require the use of computers and to explore ways to use the Internet. In addition, these principals said teachers needed more training opportunities to upgrade their computer knowledge and skills.

Loveless (1996) argues that the most popular explanations for lack of computer use fix blame on recalcitrant bureaucracies and stubborn teachers. By enlisting technology in the cause of educational reform, computer advocates overlook some of the real obstacles to the use of computers in classrooms. These obstacles are rooted in organizational constraints of the school system and the essential nature of teachers' and students' work. We need to examine the world of teachers and students to uncover how their interactions limit the computer's impact on schooling and describes how these limitations are viewed. Computer advocates must separate their agenda from other reform agendas. Loveless (1996) states that the campaign to promote computer technology in the schools should stress three elements: (1) developing a strong technological infrastructure through investments in adequate school facilities; (2) using computers to make teachers' work easier and more efficient, not to redefine teaching; and (3) employing computers to increase student academic achievement, not for changing current ideas of valued knowledge.
Hoffman (1996) points out that of the many barriers to integrating technology into classrooms, unmotivated teachers, inadequate access, lack of training, and lack of appreciation are critical. Principals can help by providing more administrative support, staff development and technical support, equipment availability, technology-use plans, technology coordinators, appropriately maintained equipment and facilities, program assessment, and broad decision-making participation. Liu, MacMillan, & Timmons (1998) observed secondary school students’ use of computers for learning and identifies limited use of computers for learning by students, dependency of students on teachers for integration, and constraints of teachers on students in terms of teachers’ difficulties and attitudes toward computers.

Baines, Deluzain, & Hegngi, (1998) studied teacher use of computers in Georgia and report that 96% of teachers profess to use technology, but found that only 4% of teachers actually integrated technology in their instruction. The majority of schools had few computers, fewer Internet-ready computers available for student access, and teachers who had never received any training concerning how to use computers. Most teachers lacked even a rudimentary knowledge of the Internet; many could not explain how to turn on a computer. The reality of public school classrooms contrasts sharply with the rhetoric and possibilities of using technology effectively in schools as exemplified by some interesting, high-tech classrooms. The disparity between reported and actual use of computers in instruction is an issue that should have great concern for principals.

Cuban (1998) claims that public school teachers make limited, unimaginative use of new technologies, despite having equipment available. This is partially the result of teachers’ attitudes toward computers in the classroom, conflicting beliefs about the purposes of schools, and teachers’ feelings about rapidly changing technology. Cuban and Kirkpatrick (1998) in determining whether the use of computers in a classroom are effective were able to categorize activities as computer-assisted, computer-managed, and computer-enhanced instruction.

Cuban (1999) in further analysis of the situation goes on to point out that teachers vary considerably in their classroom use of information technologies. At one end of the spectrum of use there are many star performers who, in the early 1980s, learned programming and fixed personal computers when they crashed. Such teachers he categorizes as serious users. These users he describes as the teachers who bought a home computer and, in subsequent years, between home and school, prepared classroom materials, compiled grades, used email, and constructed Web sites for their classroom or school. Such serious users have their students working daily on classroom or lab computers, multimedia projects, and other uses of technology. Were computers to disappear, such teachers would be upset because they have incorporated the powerful machines into the very fabric of their lives in and out of school. He classifies the middle of the spectrum as occasional users. These teachers took a beginning computer course, even purchased one for home, and, after three or four years, have found the computer a useful addition to their classroom repertoire. They use computers to prepare grades, attendance reports, and handouts for class. For instruction, these teachers place the computer in the same category as a videocassette or overhead projector “a useful tool”. Were computers to become suddenly unavailable, such teachers would adapt without missing a beat because the technology had been marginal.

The last category Cuban (1999) is the non-users at the end of the spectrum. He describes these teachers as the ones who may have taken a course and may even have a computer at home or possibly use the computer for administrative tasks, but seldom or never boot up a computer in their classrooms. Were computers to disappear from schools, students would note little difference in how and what these teachers taught.

These categories of teacher use of computer use for instruction should be useful for principals as they prepare professional development sessions for their teachers’ growth plans. It is not unlike the concerns that business marketers have while trying to market their computer products. Moore (1999) in his best selling book on marketing and selling high tech products to mainstream customers is able to show on a bell curve that the categories are: innovators, early adopters, early majority, late majority and laggards. These categories are not unlike Cuban’s (1999) and just as marketers have to plan special strategies to sell their products, principals should plan special strategies to have teachers integrate technology into their teaching. School administrators must take seriously the need to provide a viable program in communications education to prepare students for the next century and to avoid the emergence of a deprived social class consisting of those who cannot use computers (Martinson, 1998).

Purpose

The purpose of this study was to compare teachers and principals in their perceived uses of technology for instructional purposes in the classroom.

Subjects

Surveys were administered to teachers and administrators in 50 schools in the in a South East Texas School District. Of the 500 teachers and principals surveyed, 466 returned a completed questionnaire resulting in a response rate of 90.32%. The sample was made up of 87% teachers (n=404) and 13% administrators (n=61). The major demographics of the schools and subjects are shown in Table 1 below.

Instrument

The researchers developed a 24-item survey instrument. Items 1-11 were used to gather demographic information on the schools, teachers and principals. The remaining 13 items included 8 items related to the amount of training, implementation and support of computers in the classroom; 5 items asked respondents to rate the extent to which computers were used for specific purposes. The response format was primarily closed using either a 4- or 5-point Likert-type scale. In this paper, we will compare teachers’ and administrators perceived uses of computers in classroom instruction.
Procedure

Teachers and principals in 50 schools were provided a survey and cover letter by a graduate student in one of the researcher's courses in the principal certification program. No names were used on the survey to ensure confidentiality and anonymity. The graduate student collected the surveys.

Analysis

The mean ratings by teachers and principals for each of the five uses were rank ordered. These rankings are displayed in a table. In addition, a 3(level) x 5 (use) mixed design ANOVA with repeated measures on the final factor was used to compare the mean ratings of the teachers and principals.

Results

The rankings of perceived uses of computers for instruction in the classroom by both principals and teachers are displayed in Table 1 below:

1 = Highest Rated Use

Based on a 5 point scale: 1 = Never, 2 = Once a month, 3 = Occasionally, 4 = Several times a week, 5 = Daily

The rankings are quite similar across the groups. The only differences were in the relative ranking of the use of worldwide web and desktop publishing. An inspection of the mean ratings of frequency, however, indicates some differences between the groups. This analysis was done using the ANOVA.

The results of the 2 (position) x 5 (Uses) mixed design ANOVA with repeated measures on the final factor used to compare the teachers' and principals' perceived uses of computers in the classroom indicated the following. The main effect for use was significant [F (4, 449) = 43.95, p<.001]. There was also a significant main effect for position [F (1, 449) = 27.35, p<.001]. There was also a significant interaction of effect for position X barrier was found [F (4,449) = 10.22, p<.001].

Selected post hoc comparisons indicated that the computer was used significantly more often for the lower level skill of drill and practice than for worldwide web and desktop publishing. Since the majority of the subjects were elementary-level educators, this is a predictable finding. Interestingly, the principals perceived that students were using the computers more frequently for the higher-level skill of worldwide web use than the teachers reported with means of 2.85 and 1.73, respectively. (This places the perceived use by principals somewhere between "occasionally" and "more than once a month" while teachers responded somewhere between "never" and "once a month"). Although not significant, in all other cases except drill and practice, principals assumed more frequent usage. The interaction effects of a repeated measures design are complicated and less meaningful.

Discussion

Overall, principals and teachers were fairly consistent in their rankings of the uses of technology in the classrooms. Interestingly, both ranked the lower level skill of "drill and practice" as the most used. Although "problem solving" was ranked second highest in usage, it became clear to the researchers that respondents viewed this
as either mathematics drill and practice or students using popular problem solving software games independently. These findings appear to confirm Cuban (1998) contention that teachers do not actually integrate technology into their instruction and make somewhat limited and unimaginative use of technology despite having equipment available. It was encouraging to see that computers were used in composition slightly more than once a month on average. Since many classrooms still do not have online capabilities, it is not surprising that the use of the worldwide web is limited. Lack of appropriate screens for student access no doubt enters into this limitation in many schools. Another finding from the study suggests that for all uses, principals assume a higher level of usage than teachers reported. Although these differences were not always significant, the pattern was consistent. As Adams and Jansen (1997) suggest, principals must accept the challenge to create supportive conditions, which foster innovative uses of computers. Subsequent analyses by the researchers will examine the effect of level of teacher on the uses of technology. Preliminary examination of the data suggests that high school teachers use computers less frequently for drill and practice and more frequently for composition and desktop publishing than their elementary and middle school colleagues.

Educational Foundations
University of Houston-Clear Lake
United States
Prater@cl.uh.edu

Abstract: Principals need to encourage the use of technology in learning. The barriers to the use of computers in the classroom as perceived by teachers and principals is important. This study found the rankings for teachers and principals on barriers were identical. The highest-ranking problems for both groups were lack of time and lack of computers. None of the barriers were seen as major problems. Results of a mixed design ANOVA indicated a significant main effect for barriers, no significant effects for either level of educator or interaction of level and barrier were found. Selected follow up post hoc comparisons using Tukey’s HSD were used to identify significant differences among the barriers for each of the two groups. There were significant differences in the mean ratings for the “Lack of Time” and the “Lack of Administrative Support”. Both groups rated the lack of time as significantly more of a problem than lack of administrative support.

Introduction

There is a very definite demand from the public that our schools must be more current and appropriate for students (Rose and Gallup, 1998). Educators are being told they are not keeping up with the real world. Business leaders are complaining that schools are not producing enough qualified workers. Researchers (Fullan, 1996; Goodlad, 1997; Sergiovanni, 2001) have begun to question whether we are meeting the varied educational needs of all students. There is a growing demand from the public to ensure that our schools are adequately preparing our students for the challenges that an increasingly growing technology demands.

Students raised in an age of technology demand student-centered learning. Educators must discover and develop how to implement new technologies into the learning environments and focus efforts on facilitating learning (Adams & Jansen, 1997). The key role principals’ play in schools is well documented and acknowledged (Buckner, 1997). Technology is a key tool in building a learning community within a school (Speck, 1999). The leadership responsibility of the principal is to encourage the use of technology in learning.

Principals need to be prepared to deal with teacher resistance to technology being integrated into the curriculum. They have to provide extensive teacher training in the integration of technology into the curriculum (Weiss, 1994). Many teachers perceive technology, as another burden of responsibility added to the already overwhelming load of a teacher (Hartzell, 1996) A faculty that becomes comfortable with the ideas of technology will more easily integrate it into the curriculum. As with all issues involved in collaboratively building an effective school environment, it is important that teachers and principals understand each other’s perspective. Since so many resources are currently being allocated for technology, it is critical that budgetary decisions are based on commonly agreed upon needs and that there is planning to address perceived barriers.

Purpose

The purpose of this study was to compare teachers and principals in their perceived uses of technology and barriers to their use in the classroom.
Subjects

Surveys were administered to teachers and administrators in 50 schools in a large school district in South East Texas. Of the 500 teachers and principals surveyed, 466 returned a completed questionnaire resulting in a response rate of 92.20%. The sample was made up of 87% teachers (n=404) and 13% administrators (n=61).

Instrument

The researchers developed a 24-item survey instrument. Items 1-11 were used to gather demographic information on the schools, teachers and principals. The remaining 13 items included 8 items related to the amount of training, implementation and support of computers in the classroom; 5 items asked respondents to rate the extent to which computers were used for specific purposes. The response format was primarily closed using either a 4- or 5-point Likert-type scale. In this paper, we will compare teachers' and administrators perceived uses of computers in classroom instruction.

Procedure

Teachers and principals in 50 schools were provided a survey and cover letter by a graduate student in one of the researcher's courses in the principal certification program. No names were used on the survey to ensure confidentiality and anonymity. The graduate student collected the surveys.

Analysis

The mean scores for each of the barriers for both teachers and principals were rank-ordered. In addition, a 2(position) x 5(barriers) mixed design ANOVA with repeated measures on the final factor was used to compare the teachers' and principals' perceived barriers to computer use in the classroom. Selected post hoc comparisons using Tukey's HSD were made based on significant main effect for barrier.

Results

Table 1. Rankings of Teachers and Principals of the Perceived Barriers to Use of Computers in the Classroom

<table>
<thead>
<tr>
<th>Barrier</th>
<th>Teachers</th>

<td>2.38</td>
<td>2</td>
</tr>
<tr>
<td>Lack of Software</td>
<td>2.16</td>
<td>3</td>
</tr>
<tr>
<td>Lack of Admin. Support</td>
<td>1.32</td>
<td>5</td>
</tr>
<tr>
<td>Lack of Training</td>
<td>1.75</td>
<td>4</td>
</tr>
<tr>
<td>Lack of Time</td>
<td>2.47</td>
<td>1</td>
</tr>
</tbody>
</table>

The rankings of perceived barriers to computer use in the classroom by both principals and teachers will be displayed in a Table. Interestingly, the rankings for teachers and principals were identical. The highest-ranking problems for both groups were lack of time and lack of computers. None of the barriers were seen as major problems.

The results of the 2(position) x 5(barriers) mixed design ANOVA with repeated measures on the final factor used to compare the teachers' and principals' perceived barriers to computer use in classrooms indicated the following. The main effect for barriers was significant [F (4,454) = 80.34, p<.001]. No significant main effect was found for position [F (1, 454) = 1.11, p>.05]. Likewise, no significant interaction of effect for position X barrier was found [F (4,454) = .82, p>.05].

Selected follow up post hoc comparisons using Tukey's HSD were used to identify significant differences among the barriers for each of the two groups. Among both teachers and principals, there were significant differences in the mean ratings for the "Lack of Time" barrier (means of 2.47 and 2.42, respectively) and the "Lack of Administrative Support" (means of 1.32 and 1.05, respectively). Both groups rated the lack of time as significantly
more of a problem than lack of administrative support. Again, it should be noted that neither of these barriers was regarded as a major problem.

Conclusions

Based on the results of the survey, it appears that principals and teachers in a large urban school district are in close agreement as to the magnitude and relative ranking of perceived barriers. By identifying "lack of time" and "lack of computers" as highest rated barriers, these educators can move forward to discussions of how to work together to resolve or ameliorate these barriers.

A Blended-Technology Approach to Distance Education Course Delivery

Howard T. Major Ed.D.
Eastern Michigan University

Abstract

For several years Continuing Education and the Department of Education at Eastern Michigan University have used an Interactive Television (ITV) videoconferencing system to deliver a graduate course in Education. The course is Educational Research Techniques a graduate-level course required for students in several degree programs. Students are mostly teachers in K-12 systems located in or near three Michigan cities, Flint, Ypsilanti and Jackson. Initially, the ITV system (supplemented with printed materials) was the only distance learning technology deployed. However as the limitations of using a single technology became clear, a blend of delivery technologies were used. The additional technologies include online conferencing, occasional mailed videocassettes of course lectures, a PBS-produced telecourse, and printed coursepacks.

Student satisfaction levels were measured for the blended-technology approach as a whole. Academic achievement of course goals and objectives was measured, and compared to academic achievement by former students in that same course taught by that same instructor in face-to-face and interactive television (only) delivery formats.

Results found high levels of student satisfaction with regard to use of the blend of technologies and satisfaction levels were found to be much higher when asynchronous technologies such as online conferencing were used to supplement the synchronous ITV sessions. Deployment of the online conferencing technology allowed students to timeshift and participate in the discussions in accord with their own schedules.

Academic achievement was measured by two exams, participation in online and ITV class discussions, one short paper and a submitted research proposal consisting of three components; a) a problem statement, b) a review of related literature and c) a methods/procedures section which focused on research design and measurement strategies. The instructor found overall student performance to be virtually identical with performances of students in the same course delivered either in a traditional face-to-face format or via interactive television. However the levels of discussion that were conducted via the online conferencing option were substantially higher than those conducted in the ITV environment and higher than those in past face-to-face courses taught by the instructor.

Why A Blended Technology Approach?

There is an adage that states when all you have is a hammer, everything looks like a nail. Unfortunately, this statement typifies the approach taken to distance education course development by many colleges, universities and schools. In many cases, a single distance education technology has been implemented by the institution, and faculty members are expected to make all course and program objectives and learning activities conform to the attributes and characteristics of that technology.

For example, for the past several years two-way interactive television (ITV) has been among the most frequently-implemented distance education technologies. Faculty members are scheduled to teach courses via ITV and sometimes (but not always) provided with professional development opportunities...
to allow them to learn to use the technology. Typically, the only supporting technology that is used with ITV systems is the fax. Other distance education delivery systems such as on-line/Internet computer communications, videocassettes, and telephone audioconferencing, are often ignored and not made accessible to ITV faculty members.

The results have been predictable. Students and faculty members found that the ITV system worked well for facilitating learner achievement of some course goals and objectives, but was an abysmal failure for other course goals and objectives. Overall, student and faculty satisfaction levels with ITV systems have often been lower than anticipated. This is typically very disappointing to the institution's administrators who had supported substantial expenditures on ITV infrastructure and implementation.

In some instances this result is being met with a throw the baby out with the bath-water response, with some faculty members, students and administrators concluding that distance education is flawed as a concept, and cannot lead to user satisfaction and/or high levels of academic achievement. Distance learning practitioners in other institutions have concluded that it is the ITV delivery system that is lacking, and are advocating delivery of distance education courses via on-line/Internet technologies. Unfortunately total dependence on on-line/Internet delivery has the same critical flaw as ITV course delivery, i.e., it is a single-technology approach and any single technology will be appropriate for some instructional goals and objectives and inappropriate and ineffective for others.

This pattern has led some distance education course designers to conclude that what is needed is a multiple-technology approach to distance education course and program delivery. In the multiple or blended technology approach, the organization makes a wide range of distance education technology options available to faculty members and instructional designers who plan the delivery of distance education courses. For each course, the instructional or learning objectives and the characteristics of the learners form the basis for the technology application decisions. Thus a learner-focused and outcome-driven model for instructional delivery replaces the technology-driven model that is currently typical. With this logic in mind, many distance education planners argue that replacing technology-driven models with a learner-focused, outcome-based blended-technology distance education model will result in increased learner satisfaction and increased attainment of learning objectives by students.

The Technology Toolkit

The technologies which are essential to the success of a blended-technology approach to course and program development are often described as comprising the distance education technology toolkit. They typically include interactive television/video teleconferencing equipment and facilities, on-line/Internet course delivery hardware and software, video production facilities, access to nationally-produced and typically leased video-based telecourses, audioconferencing hardware and software, audio production equipment and printed materials production equipment (Figure 1). Distribution infrastructure is also essential, e.g., a system for duplicating and mailing videocassettes to distance learners. Professional development processes to help faculty learn to optimally utilize all components of the technology toolkit must also be planned and implemented.

The Course Development Team

Traditional courses and single-technology courses are often planned and delivered by a single assigned faculty member acting in isolation. However, the blended-technology distance learning course requires integration of several technology subsystems necessitating participation by representatives from each subsystem. This requires an active involvement in the course planning and implementation process by a planning group or team acting in concert. This distance education course development team will typically be comprised of faculty members, instructional designers, technicians familiar with
all equipment, librarians and support staff members. The need for including the librarian as a member of the instructional development team results from the team’s need for knowledge of the content of specific databases and information websites and access strategies for getting the most from them (Wiltse, 1997).

The team analyzes the learners’ characteristics, including their access to and ability to use communication technologies, entry level knowledge and skills relative to course objectives, and ability to function effectively in distance education environments. With this analysis in mind, decisions are made with regard to course goals and objectives (outcomes) and the learning activities that will be used to assist learners in achieving them. Then, distance education technologies are selected to facilitate the application of the learning activities. This decision-making process considers the critical attributes of each technology (e.g., synchronous versus asynchronous, ability to display video motion and images, etc.) with regard to their ability to facilitate critical learning activities. Access to the desired communication/learning technologies for specific course times and situations is then arranged, and the course is delivered, deploying each technology at its strength in facilitating the required communication patterns.

If the blended-technology approach to distance education course planning and delivery is truly a more effective model than single-technology implementation, then educational institutions will need to become much more comprehensive in their approach to infrastructure development and professional development. They will also need to encourage and support the use of course development teams, and focus careful attention on the scheduling of their communication technology systems. In short, they must commit to a new approach to distance education system development. To be seriously regarded, such a change must be based upon empirical evidence.

Conclusions

The highest levels of satisfaction are congruent with the analysis that the distance education student is typically a mature, employed student who has family and work responsibilities that make the opportunity to timeshift instruction very attractive. Videotaped lectures can be viewed at the student’s convenience, and as often as the student would like. Similarly, e-mail correspondence can be accessed in accord with student schedules. It is interesting to note the high level of satisfaction with the students receiving course materials in a timely fashion. This is a testimonial to the importance of this logistical concern, and to the careful planning and attention to this component provided by the Director of Distance Education and the clerical staff assigned to the project.

Additional Conclusions and Recommendations

1. Distance education delivery systems will continue to grow in number and improve in quality. They are harmonious with other societal changes such as the demand for services delivered anywhere, anytime and in the format you want. They are arguably superior to traditional face-to-face instructional delivery systems in facilitating emerging employer-demanded skills such as a) self-directed learning, b) problem-solving/critical thinking, c) working in teams, and d) communication skill enhancement. They are also often aligned with constructivist pedagogical trends and learner empowerment, and support a focus on learning rather than teaching.

2. Many traditional faculty members and institutions are in the process of making the change from a focus on teaching to a focus on learning and in relinquishing control of instructional processes.

3. Single-technology distance education systems will be replaced by multiple or blended technology distance education delivery systems. While many higher education institutions are resisting this change until the single technology models demonstrate their cost-effectiveness, eventually it will be clear that investments in the entire technology toolkit are critical if an institution wants to participate in the delivery of effective high-quality distance education courses and programs. One positive by-product of
the blended-technology instructional delivery system is the recognition that several courses could share certain limited-supply technologies. For example, the blended-technology approach could function effectively while using the interactive television system only five or six times in the twelve-week to fifteen-week semester. This means that one or two other courses could, if scheduling agreements could be reached, use the same interactive television infrastructure during that same time-of-day and day-of-the-week. This has the effect of expanding the capacity of the interactive television infrastructure by a factor of three without adding any new equipment.

4. Institutions will increasingly perceive the necessity of investing in high-quality professional development for distance education faculty members. Unfortunately, many will recognize this need only after student and faculty satisfaction levels are in a crisis state. Those who wait for the satisfaction crisis to hit will face a long road in the restoration of credibility for their distance education courses and programs.

5. Learners are accepting the requirement that they be technologically literate as a prerequisite for participating in the instructional process. Just as learners have accepted that certain minimum reading levels are necessary for them to benefit from instruction, they are now recognizing that they must also have a baseline of technology utilization skills. Some student-centered institutions are assisting these learners by providing comprehensive entry assessment of students' technology skill levels and providing thorough student orientations that address technology application skill-gaps.

6. Successful application of a blended-technology approach requires collaborative efforts among representatives of several departments within an educational institution. Some members of these teams may report to different deans. It will be a challenge for many traditional educational institutions to generate sufficient collaboration to operationalize the blended-technology approach. Frankly, these units are often competitive and not used to cooperating with one another. Team-building might often be the important first-step for educational institutions attempting to implement a blended-technology approach to distance education course and program delivery.

7. There is much to learn about optimally using the communication tools that comprise the blended-technology approach. Much work needs to be done to determine which conferencing software is optimally suited for which purposes. Similarly, the question of relative advantages of synchronous vs. asynchronous communication patterns will need to be carefully studied. Finally, the question of whether any of the instruction in a program or course needs to be site-based with students fulfilling a residency requirement is a critical issue to many program and curriculum designers.

8. There is a need for more pilot-tests of distance learning delivery systems. This process will provide an opportunity for planned growth based on data and cumulative experience. The alternative is to continue to add infrastructure haphazardly with the hope that successful applications will be developed. It is a common technology-explosion error to invest resources into hardware and software without corresponding investments into developing processes for its effective utilization.

9. It is the instructor's perception that students who participated in this pilot exhibited growth in their ability to engage in self-directed learning, problem-solving, teamwork and communication skills. Employers have long argued that these skills are critical to workplace success, and are therefore important skills for all curriculum areas. This growth is characteristic of learners' experiences in distance learning programs and may be one of the more important reasons for exposing students (even on-campus students) to distance learning environments.

10. Distance learning is currently growing at a relatively slow pace. However, when a critical mass of an innovation or cultural change is reached, there is often a rapid acceleration in the rate at which the
innovation is diffused and permeates the culture. There is evidence that distance learning will fit this pattern, and that the explosive growth period is rapidly approaching. When that phenomena hits, those institutions who have established a solid delivery base and sound practices will flourish.

Scoring Activities on Integrating Technology
Into the Curriculum During Pre-Service Training
Using a Bloom/ACOT Scale

Jacqueline McFarland, Ph.D.
Niagara University

John Murphy, Ph.D.
D'Youville College

A small, private college teamed with a suburban, public elementary school to use pre-service teachers to assist in integrating technology into a fifth grade curriculum. Eight pre-service Education students were assigned to instruct fifth graders on how to use multimedia technology in an innovative fifth grade curriculum which employed field experiences, cross disciplinary skill activities, and computer multimedia writing. We sought to see how these technology activities scored on Bloom's Taxonomy (Bloom, 1956) and selected fourteen activities for scoring. The observed activities of the pre-service students were:

1. Basic hands-on learning of word processor, spreadsheet, data base, and Hyperstudio.
2. Constructed data files to understand application.
3. Constructed draft lessons to teach basic application commands to students.
4. Basic hands-on learning of pre-service students on how to adapt applications to project use.
5. Constructed draft lesson plans to guide fifth graders in using applications for notes, budgeting, analysis.
6. Planned, organized, and supervised fifth graders lab experience.
7. Taught fifth graders to use the ClarisWorks word processor to keep a journal of their activities.
8. Taught fifth graders to use spreadsheet to construct a budget and estimate savings from coupons.
9. Taught fifth graders to use data base to manage the different food product categories.
10. Taught fifth graders how to access the Internet to research food products and topics on nutrition.
11. Taught fifth graders how to use Apple QuickTake 150 digital camera to take pictures.
12. Pre-service students used video camera to make movies later incorporated as Quicktime movies.
13. Assisted fifth graders in developing ideas about shopping, organizing these ideas in a virtual reality supermarket, and expressing idea in a multimedia/hypermedia presentation.
14. Final work product presented as presentation before local District Board of Education.

Since Bloom's scale does not specifically address developmental progression in technology, we selected an ACOT (Apple Classroom of Tomorrow) scale to accompany Bloom. Just as Bloom's scale points to higher cognitive operations, the ACOT scale, developed by researchers at Apple Computer (Dwyer, Ringstaff, & Sandholtz 1991), ranks the development of increasingly sophisticated uses of technology in instruction. By combining the two scales, we constructed a scoring instrument for cognitive behavior and technology activities providing a context for examining the relationships. The corresponding relationships of Bloom and ACOT categories, as we see them, are:

<table>
<thead>
<tr>
<th>ACOT Stages</th>
<th>Behavior</th>
<th>Bloom's Taxonomy</th>
<th>Behavior</th>
</tr>
</thead>
<tbody>
<tr>
<td>Entry</td>
<td>Little inclination to change mode of instruction.</td>
<td>Knowledge</td>
<td>Basic recall or recognition of facts.</td>
</tr>
<tr>
<td>Adaptation</td>
<td>Adopt technology to support traditional approaches.</td>
<td>Comprehension</td>
<td>Ability to receive and use information.</td>
</tr>
<tr>
<td>Adaptation</td>
<td>Venture beyond traditional approaches.</td>
<td>Application</td>
<td>Using information in concrete situations.</td>
</tr>
<tr>
<td>Appropriation</td>

</tr>
</tbody>
</table>

The chart below shows Table 1 and 2.

Our Bloom/ACOT scale showed that many of the activities reflected our students gaining a conception of computer use in new instructional patterns. We see the value of classifications on the scale, while not empirical data, as guides to planning pre-service activities in technology integration (Apple Computer, 1995). Future studies are needed to develop and strengthen the model. The authors recommend that pre-service students be given pre and post program surveys for correlation to and support of the classification of activities on the Bloom/ACOT scale.

Abstract: This paper is a report of a study conducted of a federally funded technology innovation grant, C*R*E*A*T*E for Mississippi. Qualitative techniques were used to examine the benefits of school based Educational Technologist in increasing teacher knowledge and integration of technology. Preliminary results indicate that teachers do benefit from the Educational Technologist. Teachers feel more confident in their use of technology, use more technological resources in planning and implementing their lessons, and are integrating technology into their lessons.

Introduction

Schools are gaining more and more access to technology. However, research indicates that teacher knowledge and integrated use of technology is not increasing proportionate to the technology available in the schools (U.S. Department of Education, 2000). A possible cause for this discrepancy may be the lack of training, support, and time that teachers have to learn how to effectively integrate technology into day-to-day classroom learning (U.S. Department of Education, 2000). A consortium of schools and other partners was funded through a Technology Innovation Challenge Grant by the U S Department of Education to support technology integration. Four diverse middle schools were chosen from one congressional district to participate in the first year of the C*R*E*A*T*E for Mississippi project. The schools were chosen for their
innovative insight and potential to infuse technology into learning. The administration at each chosen school named four core teachers to directly participate in the C*R*E*A*T*E for Mississippi project. The core teachers at each school were expected to interact with members of the C*R*E*A*T*E for Mississippi project and to help disseminate technology innovations to other teachers in their school and district. To address the lack of technology training, support, and time that middle school teachers have to integrate technology, core teachers participating in C*R*E*A*T*E for Mississippi were provided one hour per day of release time to use for planning and professional development. The position of educational technologist (ET) was created to assist the core teachers, other teachers, administrators, and students in the school in educational technology.

The educational technologist (ET) is responsible for providing support to core teachers, other teachers, administrators and students in the use of technology in all phases of learning. The ET is also expected to orchestrate the improvement of student learning and academic achievement through the effective use and integration of technology. This research was conducted to investigate the benefits of the educational technologist in increasing teacher knowledge and integration of technology.

The Study

Researchers in the four different schools conducted this qualitative study. The research data was collected through interviews, observations, and created documents, such as lesson plans and presentations.

Release time was studied at each school. Formal documentation of release time as well as observations during release time and interviews with teachers regarding release time was used to verify and study the use and benefits of release time at each school.

Researchers working both individually and in teams observed interactions between the core teachers and the educational technologist. Observations were also made to document the interaction of the ET with other teachers within the school and interactions between the core teachers and other teachers within the school.

Interviews were held with the educational technologist, core teachers, and other teachers. These interviews were informal and conducted with individual researchers as well as with teams of researchers. Interviews helped document the infusion of technology into the school culture. The attained information documented the relationship development between the educational technologist and members of the school community (i.e. teachers, administrators, and students).

The researchers also collected documents. Lesson plans developed by the teachers that integrate technology were evaluated for meaningful technology infusion and for evidence of the educational technologists’ support and assistance in the development. The schools’ curriculum plan and technology standards were examined for changes and improvements following the influence of the educational technologist.

The observations, interviews and permanent products were used to form a cohesive description and explanation of the work performed by the educational technologist in each school.

Findings

Magnolia Middle School

The core teachers at Magnolia Middle School (pseudonyms will be used for all schools and teachers in this research) decided to take their release time one hour after school each day. Records indicate that core teachers work a minimum of five hours a week after school developing lesson plans which integrate technology, planning for technology integration, and learning new software to integrate into lessons. However, observations and interviews revealed that core teachers were not consistently working for one hour after school each day. Rather, the core teachers were managing their release time to accommodate day-to-day needs. For instance, if a core teacher was working on locating Internet sites to use with an upcoming lesson, that teacher did not necessarily log off and leave one hour after school was dismissed. Instead, the core teacher may search for sites, follow links, and investigate sites for periods of time up to three hours after school. Additionally, if a parent needed to visit with a core teacher after school
or if a staff meeting was called for after-school hours, the core teacher may not stay the additional hour after the delay to complete his one-hour of release time. In each instance though, the core teacher kept up with time and spent a minimum of five hours per week on technology related activities. Observations of classroom activities, critiques of lesson plans, and interviews with core teachers and administrators indicate that the core teachers at Magnolia Middle School made very productive use of their release time.

Magnolia Middle School made unique arrangements for the position of their ET. Magnolia Middle School administrators did not feel they had any appropriate candidates to fulfill the duties of the ET. Hence, the role of ET was split between two individuals already on staff at the Magnolia Middle School. A journalism/technology teacher assumed the role of half-time ET, taking on the responsibilities of teacher technology support and technology integration. An administrative intern also assumed the role of half-time ET, taking on the responsibilities of technology curriculum development and in-house technology training for the staff.

The half-time teacher, half-time ET has been observed to have a very good relationship with the core teachers. Her interactions with the core teachers, though limited, have been positive. The teacher ET teaches five classes per day and seems to have very little time to interact one-on-one with the core teachers. The core teachers do, however, seem to be independent, highly motivated individuals who do not require a lot of support from the teacher ET. The teacher ET has been noted to provide technical assistance to at least one core teacher.

The administrative ET has not been observed to have a strong relationship with the core teachers. The administrative ET has been observed to be pulled away from many of her ET duties by her administrative duties. Her administrative duties do not seem to permit much time to interact with the core teachers or with other teachers in the school. The administrative ET has attempted to maintain interaction with all the teachers by publishing technology tips via email to all the teachers every week. She also regularly invites all the teachers to request any assistance she can provide to them.

The teacher ET has been observed to have a very good relationship with other teachers in the school. The teacher ET has been noted to interact more frequently with other teachers in the school than with the core teachers. The teacher ET has provided technical support to other teachers, as well as as-needed assistance and training in such areas as sending attachments with email and finding feared lost. The teacher ET has also provided other teachers with researched Power Point presentations to use with lessons they teach. The time the teacher ET saves other teachers within the school (i.e. finding web sites for them and making Power Point presentations for them) has enabled other teachers within the school to integrate more technology into their lessons.

Interactions between the core teachers and other teachers within the school have been noted to be very positive. The core teachers have willingly shared lessons that they have developed during their release time. The core teachers have been noted to provide software training and technology support to colleagues who wish to implement their lessons, but who do not have the technological savvy. These other teachers have voluntarily stayed after school to get training and support from the core teachers without receiving any monetary compensation.

The researchers have noted positive changes in the use and infusion of technology in both the planning and teaching process at Magnolia Middle School. The core teachers, confident in their technology use and self-motivated, have recently added more technology use in their lesson planning process and have infused more technology into their lessons without the direct aid of either ET. However, each ET has been observed to have an impact on the technology use and infusion of other teachers in the school who may not be as confident or self-motivated as the core teachers.

Hilltop Middle School

The core teachers at Hilltop Middle School decided to take their release time during the school day. The administration at Hilltop Middle School hired a first year teacher as a half-time teacher, half-time coach to fulfill the teaching responsibilities of the core teachers during their release time. Therefore, the core teachers at Hilltop Middle School have their regular planning period each day in addition to an extra planning period of release time made available through the grant. The core teachers at Hilltop Middle School use their period of release time for planning technology infused lessons, researching internet sites for resources to use in lessons, and setting up technology for student use (i.e. setting up probes, bookmarking internet sites, preparing documents with linked sites for students to explore, etc.). The core
teachers at Hilltop Middle School have faced some obstacles with their release time during the school day (i.e. the loss of their classroom during their release time, inflexible time frame to complete release time work within).

The ET for Hilltop Middle School was hired from a Technology and Education position at a high school in another district. Early in the academic year, interactions of the ET with the core teachers seemed to vary from good to a bit strained. The core teachers were noted to be somewhat dependent on the ET for guidance, support, and training. As the academic year has progressed, the interactions of the ET with the core teachers have been observed to be reserved with some and even strained with others. The ET responds to the core teachers' request for help in finding resources to integrate and infuse technology into their lessons, however, it has been observed that the core teachers do not use the ET as efficiently as the role was intended. For example, the core teachers do not call on the ET to assist with classroom exercises involving technology or to help train students in the use of technology used in the classroom.

Other teachers at Hilltop Middle School have been observed to have a good relationship with the ET. The ET readily makes herself available to the teachers for assistance, support, and training in educational technology. She also assists the technology coordinator in technical problems with computers within the school. Other teachers within the school seem to be comfortable calling on the ET for assistance and they appear to be confident in her ability to guide them.

Interactions between the core teachers and other teachers within the school have been observed to be limited. The sharing of information noted at Magnolia Middle School has not been evident at Hilltop Middle School. Likewise, the core teachers seem to somewhat resentful of the assistance of the ET to other teachers within the school. Additionally, some resentment has been noted from other teachers within the school toward the core teachers due to the extra planning period they get through release time each day.

Researchers have noted some positive changes in the use and infusion of technology into the lessons planned and taught at Hilltop Middle School. The teachers at Hilltop Middle School have had more access to technology than any of the teachers at the other schools. In the past, much of the technology available to the teachers at Hilltop Middle School sat dormant in the classrooms. The ET has provided training, support, and encouragement to the teachers to empower them to make better use of their resources. The researchers have observed increasing use of technology by the teachers, but for planning and for teaching.

Valley Middle School

Release time at Valley Middle School, like release time at Hilltop Middle School, is during the school day. During each core teacher's release time, the ET works one-on-one with the core teacher providing her with training in computer skills, help in locating websites for lessons, and assisting with lesson plan development. The core teachers decided on this release time format.

The ET at Valley Middle School was a teacher in the school system before accepting the position of full-time ET for the school. Researchers have observed a strong relationship between the core teachers and the ET at Valley Middle School. Interactions between the core teachers and the ET are very positive with the ET spending time in the classrooms assisting the teachers with lessons that integrate technology by working with groups of students in the classroom.

Other teachers at Valley Middle School have also been observed to have positive interactions with the ET. The ET has conducted professional development workshops for all of the teachers in the school. Researchers have noted that other teachers recognize the ET as an important resource person for troubleshooting and addressing their technology concerns.

Valley Middle School is a small, rural school with one teacher responsible for a content area for all the Middle School grades. Given the small size of the school, the core teachers are the only content area teachers for the Middle School grades. That is, all the middle grades teachers are core teachers. Interactions between the core teachers and other teachers at the school have not been observed or noted.

Researchers have observed that the ET at this school has proven herself and the position as vital to the growth in technology use by the teachers and students. This is a very small school with veteran teachers; change is slow to come. The change of teachers' practices has been evident in very small ways. The ET at this school has encouraged teachers to learn basic computer skills and shown them how to use technology in their lessons. Researchers have observed the teachers' excitement about their newly acquired
skills. Yet, the researchers have noted a reluctance of the teachers to use their new knowledge with their students.

**Leesburg Junior High**

The school administrator decided the release time for teachers at Leesburg Junior High. Release time for the teachers is scheduled for one hour after school. After school hours were decided for Core teachers because teachers were already scheduled for two planning periods during the day. The planning periods were built into the school schedule before the release time for C*R*E*A*T*E for Mississippi was considered. Because the teachers work separately after school, there is no collaboration with the ET during release time. Release time documentation kept by the ET indicate that teachers use their release time to find technology resources to integrate into their classrooms, planning technology infused lessons, and searching for sites that will be useful for lesson enrichment. The researchers have noted that the teachers approve of the after school arrangement because of the flexibility that the hours offer.

The ET at Leesburg Junior High was hired from a technology coordinator position in a nearby school district. Previously, the ET had extensive professional experience in the community college and business sectors. The ET and the core teachers at Leesburg have not been able to establish a working relationship. The teachers are located in the main school building and the ET is located in a building separate from the teachers. The teachers do not readily seek assistance from the ET and have worked independent of the ET throughout the entire project.

The ET has yet to establish a relationship with the other teachers in the school. This may be attributed to the fact that the ET is located in a separate building. The ET does not make an effort to establish relationships outside of the building in which she is housed. The teachers do not go to the technology building unless they have a class scheduled for the computer lab located there. However, the ET does have a good relationship with the technology coordinator. The ET shares office space with the technology coordinator and this arrangement further fosters the relationship between them.

The core teachers interact positively with the other teachers within the school. There has been evidence of the core teachers sharing information with the other teachers about technology integration and lesson plan ideas. There have been cases where the core teachers have taken extra time to train other teachers on software in an effort to help the other teachers in their quest to integrate technology into their classrooms.

There has been evidence of changes in teacher use of technology from the beginning of the project to the present. During the previous school year, none of the four core teachers used the computer lab for their class sessions. This year, three core teachers have utilized the computer lab. One teacher who had previously been very uncomfortable using technology has used the computer lab this semester and has also trained another teacher on the technology skills that she has acquired. Researchers note that these changes occurred because the teachers are self-motivated. The ET had very little impact on the changes that occurred with these teachers.

**Conclusions**

The researchers have noted greater levels of positive interactions between the ET, the core teachers, and other teachers when the ET has a background similar to the teachers in the school. When the ET has teaching experience at the grade level of the teachers, there may be a greater level of understanding of the needs of the teachers and the students that the ET is attempting to assist.

The ET was noted to be more successful at interacting with both the core teachers and other teachers in the school when the ET was housed in the building with the teachers. This may be because the ET was more assessable to the teachers. The close proximity of the ET to the teachers may lead to the building of relationships in which the ET can better understand the needs of the teacher and the teacher will better trust the ET to provide appropriate assistance.

All of the core teachers have expressed positive reactions to the release time made available to them through the grant. The more independent, self-motivated core teachers were noted to be successful with after school release time for planning and infusing technology into their lessons. This may be due to the flexibility afforded to them for planning around interruptions and the ability to accommodate the
varying times required exploring and navigating various software and Internet sites. Less confident teachers were noted to benefit from one-on-one daily assistance from the ET. This may be due to the support and encouragement that the ET is able to provide.

The researchers have noted varying degrees of success in technology learning and technology infusion into learning environments in this study. The schools in this study have experienced various benefits from the ET. It is noted that some schools benefited more than others, however, all schools in this study have experienced an increase in the technology used by teachers in the planning process and in the technology teachers have infused into learning experiences in the classroom.

Abstract: Middle school girls, selected from several rural and urban school districts in northeast Louisiana, participated in a three-week program at The University of Louisiana at Monroe (ULM). Pre and post-attitude surveys as measured by the Computer Attitude Questionnaire were compared to assess the effectiveness of the program. The analysis measured the effects of attitude changes in the following categories: interacting with the WWW, a word processor, a database application, and e-mail. Significant changes in attitudes in three of the four categories were observed. Positive attitudinal changes were observed in the areas of the WWW, word processing, and e-mail.

Introduction

Living in the information age has increased the complexity of our forms of communication, especially in education (Casey, 1997). The forms of communication and access afforded by the Internet have helped to define cultural assumptions and realities in relationship to technology. Studies focusing on gender in conjunction with practices relating to technology offer an important insight for studying the impact of the union of technology and culture. From these abundant studies many researchers have focused on the imbalance in education particularly at the upper elementary and middle school levels. Whitley (1997) states that computer use, in our society, has been portrayed as more appropriate for boys than girls. The design and delivery of technological knowledge through educational software, web designed sites, and computer games appeal more to boys than girls (Kiesler, Sproull, & Eccles, 1985; & Swanson, 1997). Computer use in schools has traditionally been linked to 'masculine' subjects such as science and mathematics rather than traditionally 'female' subjects such as liberal art and literature (Hawkins, 1985). After conducting various studies on gender equity the American Association of University Women (AAUW) Executive Director Janice Weinman (1998) refers to the technology plight as “the new boys’ club in our nation’s public schools”, while Janese Swanson, senior vice president of the Girl Tech Web site, states, “Shying away from technology not only restricts girls from certain life choices and successes, but also limits the potential for their future products, inventions, and discoveries—a disservice to the entire society” (Swanson, 1997).

Research has reported various explanations for the disinterest of girls with certain subject matters such as computer science, mathematics and science. Researchers have included factors such as, the societal views of an appropriate female career, the lack of female role models in these areas, gender bias in the classroom setting at this critical time in the female life, and gender stereotyping in computer software. The NSF/ Girls Research Opportunities in Computing (Girls R.O.C) project was designed to address these issues by conducting an intense three-week summer program that would encourage enthusiasm by providing female role models such as ULM computer science faculty and majors, a non-competitive environment and group research. The program provided both formal and informal activities for the girls in areas of computer science, computer application, Internet research, listserv activities, data mining, along with a variety of classroom and hands-on activities that exposed them to ways that computers are used in research, business, and the home.

The Study and Conclusions

The selection of the 24 participants for the program was from incoming eighth and ninth grade girls from predominantly rural school districts in northeast Louisiana. The girls were selected using several criteria that
included a written essay, transcript of grades and a recommendation from a counselor or teacher. Special consideration was given to minorities and students with disabilities. This study consists of the pre and post survey results for 19 of the initial participants that finished the three-week program. The five participants that left the program and their five replacements were omitted from this study due to lack of either the pre or post testing survey results.

The research instrument used to assess the attitudes of the participants was the Computer Attitude Questionnaire (CAQ) (Knezek & Christensen, 1998). Emphasis was placed on the questions from the CAQ that addressed the issues relating to the WWW, word processing, database application, and e-mail. The pre-survey was conducted online with the girls on their arrival at the university, and a post- survey was conducted on the last day of the program. A paired t-test was used to perform the comparison of the before and after attitudinal responses relative to these areas for the group of participants. Table 1 lists the results of the paired t-test that evaluated the research hypothesis of what changes in attitudes did participants exhibit as a result of their participation in the three-week program.

</tr>
</tbody>
</table>

Table 1. Results of paired t-test

The participants' attitudes toward the WWW, word processing, and e-mail were significantly improved after the three-week program. The 19 participants collectively had an average of 3.95796, 3.4421, and 4.1842, respectively for these areas prior to the workshop. After the three week intensive study the average attitude improved significantly to 4.5868 (p=0.0010), 4.2000 (p=0.0015) and 4.6140 (p=0.0105), respectively. Even though the participants' attitudes toward database application did not reveal a significant change at the 0.05 significance level, it could be declared significant at the 0.0650 level. The average attitudinal responses for database application were 3.2982 and 3.6667, respectively for the pre and post survey.

From this study, it can be seen that the Girls R.O.C. Program did have a positive impact upon its participants. Whether this impact will sustain over time is another question. The girls will return to ULM three times throughout the 2000 fall term to work on science fair projects with the project directors. The CAQ will be given each time to monitor any changes in attitudes toward technology along with the participants' attitudes toward school.

Session 419

The Effect of Multimedia Training on Teacher-Centered Vs. Student Centered Classroom Behaviors

As we enter the 21st century, the questions remain: Are teachers creating active learning environments that enable student to become independent learners and creative problem solvers?

One tool that helps teachers shift the control of learning from teacher to students is the use of multimedia in the classroom. Multimedia can motivate students to explore new learning environments through research, collaboration, and problem solving. Students can gather information from online resources and create interactive presentations that combine text, graphics, sound, and digital video.

In order to integrate multimedia into classrooms, students and teachers must learn both the technical and application nature of multimedia programs. One of the problems with PowerPoint and other multimedia programs is that teachers have the tendency to use these programs to reinforce their presentations. The result is the reinforcement of teacher-centered behaviors.

In this study, 15 teachers from one school district representing various levels from K to 12, enrolled in a one-credit graduate course titled "Instructional Applications of Multimedia Using PowerPoint." The question asked in this study was "Does the introduction of multimedia training to teachers and students help shift classroom learning from teacher-centered behaviors to student-centered behaviors?"

The purpose of the graduate course was to teach the use and classroom application of Microsoft PowerPoint to practicing teachers. The course was offered at the beginning of the school year and none of the teachers had prior experience using PowerPoint. The school district installed PowerPoint software for all teachers who enrolled in the course. In
addition, PowerPoint was installed in all computer labs throughout the school district.

The graduate course required teachers to create PowerPoint presentations; however, the course also required teachers to have students integrate PowerPoint in student-centered projects. Thus, the teachers had to teach PowerPoint to their students and require students to create classroom projects utilizing PowerPoint software.

At the end of the course teachers were required to report and demonstrate the results of their projects. A survey was also conducted to determine (1) the teachers’ attitude toward multimedia as a learning tool and (2) teacher plans to use multimedia in a teacher-centered vs. student-centered activities.

Some of the other questions this study addressed were (1) What is the teacher perception of the application of multimedia to student-centered activities? (2) What are the difficulties associated with incorporating multimedia into the classroom? (3) What learning difficulties are encountered with special-needs learners and younger learners in creating and using multimedia in the classroom?

Preliminary results indicate that the teachers enrolled in the course had a positive attitude towards multimedia. Most teachers planned to use PowerPoint for both teacher-centered and student-centered activities. Most teachers agreed that they would have the students use PowerPoint for both individual and group projects. Teachers reported problems with lab access, storage on floppy disks. Very few teachers reported technical problems. Teachers reported that the younger learners (K-2) had more problems working with PowerPoint than older learners.

Teachers will be surveyed throughout the school year to determine the frequency and type of PowerPoint use in the classroom.

Final results and recommendations will be reported at the conference.

Abstract: Young scholars introduce a diverse selection of current trends, practices, and research findings. A discussion of constructivist-oriented practices that support K-12 technology use is followed by discussions of the implications of technology integration and the cost-effectiveness of technology use in elementary and secondary settings. Technology application issues are addressed next, including the effectiveness of virtual field trips, instructional courseware, online discussion tools, and computerized tests. These areas represent just some of the research on educational technology that effective teachers must remain aware of.

Educators at all levels from PreK-16 now have a vital need to be aware of current instructional technology trends, practices, and research findings in order to provide effective learning environments for their students. Findings of research in this area are often mixed, and best practices are frequently not shared among educators. This collaborative paper written by young scholars conducting research in the field will introduce a diverse selection of current trends, practices, and research findings in a sequence that will give the reader a unique overview of the educational technology field.

Constructivism Overview

Constructivism is the new educational buzzword in education. Dewey, Vygotsky, Bruner, and Johnassen have all developed principles that can be called 'constructivist natured', but what is constructivism? What does a constructivist classroom look like? What role does constructivism play in education? How do we apply constructivism to technology? This session will explain the key components of constructivism as well as the assumptions and myths.
Implications of Technology Integration

Technology plays a key role in how the world functions. Schools are now being faced with how to effectively and efficiently integrate technology into their classrooms and curriculums. Technology integration involves challenges—including access inequities among schools, courseware material purchasing decisions, and computer (il)literacy levels--of students and teachers. Schools need to meet these challenges one at a time.

Cost-Effectiveness of Educational Technology

Most schools are funding education technology but is the money being spent simply for the sake of technology or are these investments proving to be beneficial to students? Several large-scale studies, which give some insight on how computers can best be used to raise student achievement, will be discussed.

Virtual Field Trips

How effective is an educational museum web site as an alternative to a museum field trip? The data regarding the educational outcomes of a virtual field trip will be presented to provide a better understanding of the educational opportunities afforded when using the Internet in the classroom.

Courseware

Educators find it difficult to locate effective educational courseware that will work reliably, hold student interest, and meet the requirements of the curriculum. Factors that must be considered include appropriate teaching style to scheduling student computer time with limited computers availability. Findings on the impact of educational software on technological confidence, competence, and teaching effectiveness of high school teachers will lead to a better understanding of these issues to enhance the effectiveness of its use in a teaching and learning environment.

Online Discussion

Do social factors such as intimacy and immediacy, derived from the concept of social presence, affect student learning and satisfaction in computer conferencing? With the introduction of the Internet to education, computer-mediated group interaction has been facilitated for both online courses and face-to-face courses as an instructional supplement. This presentation will present factors that achieve effective student learning in computer conferencing from the sociological perspective.

Assessment

Recent technological advancements in the development of testing software allow teachers more flexibility in assessing student learning. Research and experiences in writing and developing computerized mathematics tests will be discussed. In addition, the advantages and disadvantages of generating computerized alternative forms of tests and of administering the tests via a computer will be presented.

Conclusion

The ongoing research introduced in this collaborative paper is one small portion of the research on the use of technology for teaching and learning that teachers must be aware of to remain effective. The sheer diversity among these few topics emphasizes the types of current trends, practices, and research that will impact teachers and students in the near future.
A Comparison of Preservice, Inservice, and Non Teacher Education Majors on Technology Confidence, Ability, and Use

Abstract

This paper describes the findings from a study based on a newly enacted state technology standard for new and experienced teachers. Teacher education students rated their confidence level, ability, and usage on technology areas. A control group of non-education majors was used to determine whether the technology competencies were acquired within the teacher education program or general university requirements. The results of the study were also examined to determine whether there is a progression from juniors to seniors to graduate students, and whether there are specific criteria of the new standard that students have not met.

Introduction

The state of Kentucky has enacted a new standard for technology knowledge and use for new and experienced teachers (Kentucky Department of Education, 1999). Nationally, all teachers are expected to meet a new technology standard designed by the International Society for Technology in Education (ISTE, 1997). As a result of these new requirements, teacher preparation programs and graduate programs for experienced teachers must assure the opportunity for students to become competent in technology skills and usage.

At Eastern Kentucky University, faculty members in the College of Education have been busy infusing elements of the new technology standard into required courses at pre-service and in-service levels. In an attempt to assess needs and how well current courses were addressing those needs, an earlier study was conducted which surveyed skills in sample groups of students (Long & Reehm, In Press). However, the survey form used to collect data was not specifically related to the performance criteria outlined in the Kentucky Department of Education's (KDE) new technology standard. The current study addresses this limitation. The authors designed a new survey instrument, administered it to a larger group of students, included a control group, and used the data collected to answer questions raised by the earlier study. Results were examined to answer the following questions: (1) Is there a correlation between the three aspects of student usage of technology which were identified as confidence, ability, and frequency of use?, (2) Is there a progression of technological competence from juniors to seniors to graduate students?, (3) Were the specific criteria of the new standard met by senior preservice teacher education students? (4) Was there a significant difference between the mean scores of the control group of non-teacher education students and the preservice senior teacher education students?, And (5) When comparing the mean scores of the senior groups of elementary, middle, and secondary preservice teacher
education students, is there a difference in the number and types of standard criteria met?

Study Design

The study was conducted at Eastern Kentucky University, a regional comprehensive university of approximately 15,000 students that serves primarily south eastern and south central Kentucky. The college of education offers a variety of undergraduate, graduate, and certification programs to approximately 1,300 students.

A computer survey was designed based upon the 16 performance criteria listed in KDE’s new technology standard for teachers. Several of these performance criteria incorporated more than one technology area, which could lead to confusion in determining strengths and needs of students. Therefore the final survey form was delineated into 27 specific technology areas. Each subject who completed the survey was asked to respond to each of the 27 technology areas in relation to his/her level of confidence, ability, and frequency of use. The subjects were asked to indicate on a likert scale of 1 to 5 the following: their feeling of confidence for operating or applying the particular technology area; their current level of ability to use the technology area; and their current frequency of use of that technology area. A score of 1 would indicate a low level of confidence, ability, or frequency of use. A score of 5 would indicate a high level of confidence, ability, or frequency of use. (See Table 1 for a list of the 27 specific technology areas)

The population surveyed included 180 undergraduate preservice teacher education students, 70 graduate inservice teacher education students, and 81 undergraduate non-teacher education students. Specifically, 59 elementary, 33 middle, and 37 secondary senior level methods course preservice teacher education students were surveyed. At the junior level, 51 elementary and middle grade preservice teacher education students enrolled in a course that was pre-requisite to the senior level methods block were surveyed. The graduate inservice teacher education students surveyed were enrolled in various elementary, middle grade, and secondary level education courses. The non-teacher education students surveyed were students enrolled in 200 and 300 level economics courses. The survey was given within the first half of the fall 2000 semester.

Analysis and Results

The SPSS program was used to analyze the data gathered from the survey instrument to answer the above written questions. In order to answer the first question (Is there a correlation between the three aspects of student usage of technology which were identified as confidence, ability, and frequency of use?) correlations were computed using the mean scores of the answers given by all the study participants in the areas of confidence, ability, and frequency of use as follows: (1) between confidence and ability means scores the correlation equals 0.99; (2) between the frequency of use and the ability mean scores the correlation equals 0.80; and (3) between the confidence and the frequency of use means scores the correlation equals 0.83. It was concluded that the means scores between all three participant response areas were highly correlated. Based on this conclusion, the rest of the analyses computed in this study were targeted at the ability response area.

A t-test was computed to analyze statistically significant differences of student group mean scores to answer question # 2, is there progression of technological competence from juniors to seniors to graduate students? Mean scores for senior level teacher education students were consistently higher than those for junior level students, but none of these differences were statistically significant. No significant differences were computed or observed between the means scores of the senior preservice students and the graduate inservice teacher education students. These findings indicate there is some progression from junior level to senior level, but not from senior to graduate levels.

In order to answer the third question, whether the specific criteria of the new technology standard were met by senior preservice students, an analysis of the ability means scores was conducted in all 27 technology criteria. The criteria was considered met if the mean score was greater then or equal to 3.00 on a scale of 1-5. Five criteria were not met by the elementary preservice teacher education group of students as follows: #6, #10, #11, #18, and #19. Three criteria were not met by the middle preservice teacher education group of students as follows: #11, #18, and #19. And, seven criteria were not met by the secondary preservice teacher education group of students as follows: #5, #6, #8, #10, #11, #18, and
#19. Only three criteria (#11, #18, and #19) were not met by all three groups of students.

Use of the control group was designed to determine the answer to question #4, whether skills are gained during the teacher preparation program or as a part of general university requirements. Therefore, a t-test was computed to compare the ability area means scores between the non-teacher education undergraduate students and the senior teacher education preservice students. Eight statistically significant differences between the mean scores of these two groups were found. The non-teacher education student means scores were higher in the 6 criteria of #5, #6, #8, #4, #14, #17. The senior, teacher education student mean scores were higher in the criteria of #19 and #20.

A series of t-tests were computed to determine the answer to question #5, whether there were statistically significant differences between the mean scores of the three different groups of senior teacher education preservice students (the elementary, the middle, and the secondary groups). Results of these analyses are as follows: (1) the elementary group's mean score for the criteria of #6 was statistically significantly higher than the middle group's means score, (2) the elementary group's mean score for the criteria of #25 and #26 were statistically significantly higher than the secondary group's means score, (3) the middle group's mean score for the criteria of #3, #4, #7, and #10 were statistically significantly higher than the elementary group's means score, and (4) the middle group's mean score for the criteria of #5, #7, #8, #10, #11, #18, #23, and #25 were statistically significantly higher than the secondary group's means scores (p < .05).

Discussion

High correlations between the mean scores of confidence, ability, and frequency of use computed from all survey participants indicate that students' self-reported perceptions did not vary significantly between all three areas. Therefore, the ability scores were used to pursue the answers to this study's questions. The focus on these scores was made to align language used by national, state, and teacher education program technology standards.

Although there was a slight progression detected between the junior and senior preservice teacher education ability mean scores, this progression was not statistically significant. Finding no positive increase between the senior preservice teacher education and the graduate inservice teacher education student ability means scores indicates a need to continue to implement the use of information technology into graduate level course work or other professional development efforts.

All three senior preservice teacher education groups of students met a majority of the 27 specific criteria in the new technology standard but there were some criteria that were not met. The elementary preservice teacher education seniors should specifically pursue study in the areas of: (1) demonstrating knowledge of the use of technology in industry, and (2) creating multimedia presentations using scanners. The secondary preservice teacher education seniors should specifically pursue study in areas of: (1) demonstrating knowledge in the use of technology in business, (2) demonstrating knowledge of the use of technology in industry, (3) demonstrating knowledge of computer/peripheral parts, and (4) creating multimedia presentations using scanners. All three groups of senior preservice teacher education students (elementary, middle, and secondary) should pursue the development of skills in the areas of: (1) creating multimedia presentations using digital cameras, (2) using computers and other technologies such as interactive instruction, audio/video conferencing, and other distance learning application to enhance professional productivity and/or support instruction, and (3) requesting and using appropriate assistive and adaptive devices for students/clients with special needs.

An unexpected finding was the significantly higher mean scores on 6 criteria for the control group as opposed to the preservice teacher education students. An examination of the demographic data collected in the survey provides insight into this finding. The control group reported a much higher number of technology courses taken (mean = 3.30) than the number reported by teacher education students (mean = 1.50). The teacher education programs are demanding and include few or no elective courses in their general education programs. This may explain the significant difference in the number of technology courses taken. In order to address the problem of limited exposure to technology courses, it is imperative that the teacher education faculty focus more on infusing technology into existing courses.

The differences found among the mean scores of the three different groups of senior teacher education students were a validation and an extension of the findings of the earlier study conducted by two of the authors (Long & Reehm, in press). Means for the middle grades teacher education students
were generally higher than those for either the elementary or the secondary group. This is similar to the finding of the previous study, and suggests the infusion of technology into existing courses is currently more successful in the middle grade education courses than in either the elementary or secondary teacher education courses.

Means for the secondary group were generally lower than those for both of the other groups. The previous study did not include secondary teacher education students, so this was a new finding. It can be explained in part by the fact that secondary teacher education students take more content area courses and fewer education courses in which technology skills can be developed. It also indicates a need for incorporating techniques used in the middle grade education courses into the required secondary education courses.

The successful middle grade model involved having four middle school faculty members working as a team to decide on technology skills that they felt were important for the middle grades education students to use in their education methods classes. These instructors conducted technology seminars for students at the beginning of the semester and then required students to use skills taught as part of course assignments. The College of Education technology coordinator assisted in developing the seminars, and trained the faculty members to deliver the seminars to students. Through this process, faculty members became proficient in teaching one area of computer skills to five different groups of students. Faculty members also developed an online component for all courses in the middle grades education methods block. Resources such as course syllabi, schedule of class times, electronic addresses, forms needed for the course, assignment guidelines, and other materials were available to students only through this online mode. Students therefore found it necessary to use this web enhanced component of the course, and as a result became familiar with a distance learning application which used online materials for learning.

Recommendations

As indicated in the discussion section, one recommendation is that each of the three undergraduate teacher education programs (elementary, middle grades, and secondary) examine the list of criteria not met by students in the specific program. Faculty members in each program could use this list to design and infuse new strategies into required courses that would promote skill development for the specific criteria identified as a need area.

A second recommendation is that the teaming and training techniques used in the middle grades methods classes be adopted by both the elementary and the secondary programs, with the goal of increasing the overall technology skill level for students in each program. A key element seems to be finding ways to make the use of technological skills necessary for successful completion of course requirements.

A third recommendation is that future studies should continue to examine aspects of the new standard and the degree to which students are able to meet specific criteria of the standard. As changes are made in the education programs, data should be collected to determine the effectiveness of the changes. One way to do this is to develop a longitudinal data set. Another way is to collect data from graduates of the specific programs as they begin working in public school classrooms.

This paper presents the findings of a three-year research project that explored the integration of technology in graduate teacher education classes and the impact of that on the K-12 classrooms in which these graduate students teach. Specifically, it addresses integration of technology in graduate teacher education classes, effective integration of technology in teacher education university classes, and how and in what ways is technology being integrated in the K-12 classroom?

In the 21st century, students will have access to more information than any other students before them. Students can use technology to gather information, produce and disseminate their work. Students are going to have to learn to use and access this information wisely and judiciously. Teacher educators have a responsibility to assist their students in becoming comfortable and facile in the integration of technology in their own and their future students' educational lives. This is particularly true in the area of literacy education. Surely, we know how vital it is for youngsters to become fully literate, but, especially in the information age in which we reside, reading and writing have become even more significant. Before teachers can effectively help their students read, write and utilize technology effectively, they must themselves be comfortable with technology and be cognizant of the additional rewards and demands the technological revolution has placed on education.

Teachers must use effective strategies to help their students read independently, additionally, they need to help them read independently with wisdom. Teachers too, must help their student’s access information judiciously and critically. While there has been some concern among educators and other interested parties that technology will take the place of reading and writing, the reality is that reading and writing have taken on an even more significant role in our students' lives due to the internet. In order to access information and telecommunicate using email, our students must know how to read and write effectively. Teachers must also become knowledgeable and at ease with technology and its impact on literacy.

Teaching today's students involves an awareness of the strong forces that are impacting on their lives. Students today are in the throws of the information revolution where they are inundated with reading material. Clearly this is advantageous in terms of motivation for learning to read. But, reading in and of itself is not an end product. The end product is what do readers do with the information that they gather. As Bruning, Schraw and Ronning note, “The aim of teaching . . . is not so much to transmit information, but rather to encourage knowledge formation and development of metacognitive processes for judging, organizing and acquiring new information. (1995 p.216)” Our ultimate goal as educators was, and still is, to help our students become independent and thoughtful readers and learners who use a wide variety of reading materials. Technology is changing teaching and learning.

Any change or paradigm shift comes with attendant concerns and frustrations thus it is necessary for educators to look closely at the process as we engage in varying our classroom practice. The use of technological advances has been an easy accommodation for some educators. For others, this is not the case. Richardson (1990) notes the importance of reflection on the teaching/learning process and on affecting change. Educators must continually make decisions as to the role of technology in their classrooms and the form, function and feasibility of using specific computer programs. To make informed decisions we must clarify our view of the role of technology in our literacy programs and define their relationship to existing curricula. The primary consideration should be the purpose of using technology (Jordan and Follman, 1993). Programs should support interactions between teachers and students and not be used as “teaching machines” to supplant teachers.

While numerous questions arise as to the efficacy of technology integration in K-12 educative environments, we must also look to teacher education programs and why, how and in what ways they are preparing
the teachers who will teach these students of the new millennium. How do we realize the true potential of technology in our university classrooms? Similarly, how can K-12 teachers integrate and utilize technology effectively? This study was initially designed to look at technology integration in graduate literacy education classes. As questions from the students emerged, the study was then expanded to include an examination of the real world practice of those students who were teaching in K-12 classes.

Many of us embrace the integration of technology in our classes but that doesn't mean that it is the right way to teach everything nor does it mean it is right for every teacher. Teachers, by the very nature of the profession, are continual decision makers. We (hopefully) decide how best to teach a particular subject to a particular group of students in a particular context. We decide on the pacing, and we decide what resources would be helpful to our students. These are informed decisions, based on years of study and experience. Decisions about the integration of technology must follow a similar thoughtful pattern. This paper explores what aspects of technology are helpful in given contexts and in what ways are they effective. This paper explores such issues as:

Does the integration of technology in graduate teacher education classes impact on students practice in K-12 classrooms?

How is technology most effectively integrated in teacher education university classes? How is technology being integrated in the K-12 classroom?

In what ways can teacher education programs facilitate the integration of technology in K-12 classrooms?

During the first phase of this project the process of engaging both preservice and in-service students in the use of technology in university classes was examined (Rhodes and Flank, 2000; Rhodes, 1998). The findings from these studies led to the current investigation.

Initial analysis of the findings from this current three-year study reveals several key issues and themes related to both teacher education students and those with whom they work. Themes specific to the graduate students include the level of knowledge and expertise they bring to the class; the impact of the use of technology in graduate teacher education classes; and graduate students' perceptions of their ability to incorporate technology into their teaching. The most recent and ongoing aspect of this study involves looking at the classes of those graduate students who were engaged in a technologically rich graduate literacy education class.

This study involved more than 140 students who were enrolled in five different graduate literacy education classes at two metropolitan universities within very close proximity to New York City. Although all of the classes were taught by the same professor the courses and their content was different in four of the courses. None of the courses were advertised or described as involving technology. Three of the classes were "theory to practice" literacy education courses, two were courses on research. With the exception of five students, all were teaching either in New York City Public Schools or schools in the neighboring suburbs.

In all cases, the prime focus of the courses was the content as described above. The manner in which the students were engaged however, often involved technology. Programs were demonstrated, students had the opportunity to work with software, but much of the technology infusion involved engaging students in distance learning environments as described in the previous cited studies.

Baseline data gathered at the beginning of each semester revealed that sixty percent of the students owned or had easy access to a computer but only five percent of the students were comfortable with their ability to use technology. Ninety percent of the students reported using computers only for typing term papers or doing assignments. Ten students indicated that they hated computers; three said they had no interest in learning about or with computers. The three self reported "technophobes" were in different classes but, upon learning that there would be a technology component to the class all indicated that they wanted to drop the class or transfer to another section—only one did. The other two were reassured by their professor and their classmates that they would help them through the process and if at any time they still felt uncomfortable with the technology, accommodations would be made. Almost all of the other students reported varying degrees enthusiasm or excitement at the prospect of using technology in our classes. The following case study of Jennie, typifies the experiences of those students who reported negative feelings about technology.

At the beginning of one semester, for example, Jennie, a self-described technophobe wanted to drop the course because "I have no interest in computers, I think they are a colossal waste of time. To do something with a computer takes too much time and energy." Jennie, like others was given assurances by her professor and classmates that they would help, but she reported having grave doubts and little interest. The semester progressed with the inclusion of an online component to our course. Although the class met face to face each week, there was additional work that had to be done online.

I met individually with Jennie and others each week to guide them through this process. Jennie described her feelings as "a little bit like I would imagine a child learning to read... it's clearly something I have to learn and..."
perhaps something I need to learn, but I just don't want to do it. I don't want to go through the angst and pain especially, if I end up being unsuccessful.” At another point Jennie wrote in her journal, “Sure Carole is there for me, and she’s really trying, but I’m not sure she fully understands how difficult and frustrating this is for me. I’m trying to do something that I don’t see the need for, something that makes me feel like a failure. I don’t like confronting difficult tasks.” The fifteen-week semester progressed with Jennie getting a bit less frustrated each week. Through her meetings with me, she began to voice her feelings and concerns. As she did so, her progress and interest began to emerge. Within two months, she was working on line by herself and her comments reflected her new, minimal level of confidence. She indicated, “This is not as bad as I thought. I don’t fear it as much... I’m not so bad at it.” By the end of the semester, Jennie delighted in sharing her technological expertise with other members of the class. At the last class meeting, she proudly announced that she told her husband that she wanted a computer for her birthday.

Jennie identified her biases early on in the semester and clearly struggled with them and worked through them as the semester progressed. She drew parallels to others aspects of her life in which she felt successful and those in which she felt unsuccessful. She related it to the plight of some of her students as they struggled with learning to read. She looked at the process of acquiring technological literacy and then thought about her students. She teaches in an urban school district where many of the students are from homes where the parents cannot afford computers. Though the school has some computers, they were not be used very often. At her request, this year, I began working with Jennie in her school since she wanted to incorporate the use of technology in her daily class activities. Jennie, like others has requested such assistance. Of the 140 students involved in this study, more than eighty percent (n=120) reported having computers in their classrooms, but approximately twenty percent (n=25) indicated that the computers were used for more than a half hour a week. Through extensive site visits and interviews, it was clear that the level of incorporation of technology in these teachers’ classes was very minimal and usually engaged the students’ in simple word processing tasks or basic internet searches. Technology, thus far, has not become an integral part of the teaching learning lives within theses classes. The current phase of this study is a response to the “cry of help” from many of the teachers who have experienced technology integration in their graduate classes but report needing assistance in doing so in their own K-12 classrooms.

These in-service teachers reported many drawbacks in this process. Among these are that there are not enough multimedia computers available to children-- especially those from impoverished homes; there is not enough time for teachers to scrutinize materials or learn to use programs; too little thought is given by teachers as to whether programs are developmentally appropriate; there is not enough time devoted to teacher staff development and there is clearly a failure on the part of too many administrators and school boards to understand the importance of technology in the future.

The future of education will involve more, better, real, international and current materials; more sharing and collaboration; more threats of censorship; more need to emphasize the human side of teaching and learning; more use of critical thinking skills, more of a need to evaluate and use good judgment and above all more good teachers

Technology will not “fix” poor teaching. It will not take the place of the human side of teaching. It will not solve all of the problems related to teaching and learning. The most important thing we must remember is that the students we teach are going to live in the future and teacher education programs have a responsibility for preparing the teachers and supporting them in their classrooms.

Abstract: An inductive analysis of the adaptation of graduate education students to an interactive televised (ITV) classroom generated four primary domains within which much of their adaptation occurred. These emically-derived categories – student relations, technological aspects, instructor’s role, and content/class participation – provided a framework within which to assess the complex social and cultural aspects that influence student adaptation and consequent learning in ITV classes. The paper draws on analysis of hundreds of hours of observations, interviews and informal conversations with students, teachers and staff.

Introduction

Gibson (1998a), in her discussion of the success of distance learners reported that “by fall 1998, 90% of all institutions with 10,000 students or more and 85% of institutions with enrollments of 3,000 to 10,000 expect to be offering at least some distance education courses” (p. vii). Technologically mediated distance education has been around since the 1930’s (Johnstone, 1991) and clearly will continue to be an increasing part of the University environment (Chute, Thompson, & Hancock, 1999). Therefore, the more we understand about teaching and learning in distance education the more capable we will be of improving it (Mitchell, 1997).

There is a significant amount of general literature on distance learning in higher education that is produced regularly (Chute et al., 1999; Ludlow & Duff, 1998; Moore & Thompson, 1997; Willis, 1993). It includes fairly standard suggestions for managing, implementing, and succeeding in interactive televised classrooms (Herrington, 1993; Moore & Kearsley, 1996; Ostendorf, 1989). Nevertheless, the call has gone out to researchers to move toward a thorough understanding of the complexities that affect teaching and learning and determine success in the distance classroom (Gentry & Csete, 1991; Gibson, 1998b; Thach & Murphy, 1995; Wagner, 1995).

In Gibson’s (1998c) exploration of these complexities, she considered Bronfenbrenner’s ecological theory and its relation to distance education. She concluded that the learner exists in a social context that can “profoundly affect success of the distant teaching and learning transaction.” (p. 113). She challenges researchers to consider “the existence and impact of multiple forces” (p. 124) that are at work on the distant learner. In this paper we respond to that challenge by sharing some of the results of a yearlong ethnography of graduate students in an interactive televised classroom.
The Study

Cultural anthropology (Geertz, 1973) and symbolic interactionism (Prus, 1996) provided the theoretical framework for this study in which traditional ethnographic and qualitative research methods were used to gather and analyze data (Agar 1996; Maxwell 1996). Data was gathered during a one-year ethnography of graduate education classes in the inaugural year of an interactive televised distance learning classroom called the Interactive Distance Learning Studio (IDLS) (Clevenger-Schmertzing, 2000). There were two sites involved in the study, a host site which was the instructor's classroom and a remote site which had a facilitator and interacted with the instructor via technological media. Sites were located approximately 70 miles apart – one at the main university campus and the other at a branch campus. Of the 13 graduate classes included in the study the branch campus served as host for 2 courses. There were 278 students involved in classes that varied significantly in course content, course objectives, teaching style, and student responses. A database was constructed to house open-ended survey information that was completed by 140 students. The Ethnograph v.5.3 was used to analyze data that was gathered in more than 400 hours of participant observations in classrooms, formal interviews and informal conversations with students and faculty, weekly e-mail correspondence, focus group interviews, and transcripts of videotapes. Thematic coding, frequency counts, and frequent debriefings between ethnographers L. and R. Schmertzing contributed to interpretation and ongoing analysis of the data (Spradley & Mann 1975).

The quotes that have been incorporated into this paper are direct quotes from student participants that are thematically representative of statements that were made by significant numbers of students and are provided to substantiate the complex effects of elements across all four domains on students, their learning, and their attitude toward class. This data set was selected to enhance teacher educators understanding of students' dilemmas and adaptations in order to inform teacher educators on student needs and enhance their instructional design processes.

Domains: Frameworks for Data Analysis

Our approach in this study was to let students map out their significant cognitive territory around distance education and to see what categories emerged. From our analysis of student interview transcripts we defined four emic domains in which students worked to adapt. Although the domains are not unique to distance education the adaptation process through which students developed their own way to succeed within each domain was unique to the unfamiliar, complex environment of the interactive televised classroom. Consequently, establishing the domains as a way to process the complexity associated with the new technologically mediated learning environment offers insight into the multiple forces Gibson (1998c) recognized as at work in the teaching and learning processes. The domains localized issues of technological aspects of the environment, student relations within and across locations, the interrelated roles of student and instructor, and communication of content related information. In this paper we introduce three of the domains and provide examples of issues raised by students. For the domain related to instructor roles we provide only a brief overview. For a more complete discussion of Instructor Roles see Schmertzing and Schmertzing (2001).

Technological Aspects

Technological aspects of the environment surfaced as a domain in response to students who repeatedly voiced concerns about the complicated nature of the technology, the problem of associating the monitors with their traditional television viewing behavior, and their dislike of being on camera (Clevenger-Schmertzing, 2000).

In an e-mail received towards the end of the second semester of research, Milly, who had had two classes in the distance room shared her thoughts about the environment. Her primary issues during the first semester were related to technology. "I wonder what those black things are on top of the TV box things?"
They really should tell us what all of this stuff does, some of us really do not know what all the 'bigger/better' stuff are supposed to do much less how it operates, its not like we have it at our school" (HP F E 150.6.26) !!!

During her second semester she modified her position somewhat. "I am still learning by doing, but perhaps because it was not my first time, I felt less threatened by the equipment. I still feel an explanation of what it does, what it is, is in order at the opening session if we are to be put upon to work them" (HP F E 150.6.26).

Milly raised four significant issues in her comments. First, she had a curiosity about the technology but at the same time she felt somewhat threatened by it. Second, she did not think that she had enough training and information to get confident in her use of the equipment so she continued to "learn by doing." Third, she believed an explanation about the technology is "in order" and last, her perception was that she was being "put upon" to have to learn the equipment. These four technologically related issues were typical of the complex dilemmas that Milly and others struggled to resolve in their efforts to adapt to the distance classroom.

Mariah, a student who watched the instructor on television, realized that she was distracted because she had trouble accepting the TV as a two-way medium. "You forget that you are in a classroom. You are so used to watching TV this one way. You can do whatever you want in your living room in front of the TV and no one can see you but in this instance, it is two-way and you forget that. [...] I find myself doing things that I wouldn't do if an instructor was sitting right in front of me" (RFt F I v17). Mariah was aware that her behavior in class was different because she connected the television to her home atmosphere and had to force herself to work toward proper classroom behavior, something that came naturally to her in the traditional classroom. Other students identified feelings of "awkwardness" and "separatedness" and complained of "struggling" and "daydreaming" as consequences of having to "watch the TV screen."

In the IDLS, students were required to push a button to activate their microphone if they were to participate properly. When the button was pushed the camera focused on the student who could then be seen and heard at both sites. Essentially this technology required students to shift their cognitive processes away from the central issues of the course to the use of the technology in order to actively participate in the class. For some the shift was only a momentary distraction while for others it was monumental. Monique was asked about memorable experiences she had in her distance learning classes. She replied, "Not knowing which camera to look at. Oh dear, so that you're not facing the wrong way. The first few times that camera panned in on me, that was frightening and you pushed that button and you froze" (RFt F I v8.880). Monique initially admitted her own lack of understanding when she said she didn't know "which camera to look at," but then she shifted to talking about her response to what she saw as the action of the camera. The "camera panned in on me," she said. Then, as she described her reaction to being on camera, she used words like "frightening" and "froze." She was not alone in her perception that the technology acted on her. Molly e-mailed me to say, "I didn't speak for a couple of weeks in class because I didn't want my face to pop-up on the screen" (HP F E 10.5.17). In her mind the technology made her face "pop-up on the screen."

The active role students assigned to the technology and the complexity associated with understanding how it worked are two of the elements that defined the technological aspects domain and were of fundamental importance to students and teachers in the IDLS. When technological aspects of the room were attended to in intentional ways that allowed students to openly express their concerns or anxiety about the technology, students adapted more quickly to the environment and were more capable of maintaining a focus on learning.

Student Relations/Location

One of the elements that allows classrooms to function effectively is the symbiotic relationship between the social structure of the classroom and interaction that occurs there (Metz, 1978). In the IDLS when the physical structure of the classroom was changed such that the four walls of the room no longer defined membership in its social structure, students had to re-formulate their understanding of membership in their classes. Though membership in the academic structure of the classroom was defined by the schedule and the instructor that was not the case for membership in the social structure. The academic structure required all the students in a given class to meet at the same time with the same instructor to study the same subject even if they were in different locations. The academic structure did not, however, translate into a social structure that accepted all students as equal or like participants in the class. Moreover, the structure often spawned two separate and competitive groups with distinct ideas about membership in their own group, as well as
membership in the other group (Clevenger-Schmertzing, 2000). The student relations/location domain accounts for this reformulation of class membership and the complications that accompanied it.

Mary judged her fellow classmates differently based upon whether they were members of her own site or the other site.

I judge the people in my classroom [her sitemates] and I know they judge me. But maybe we get to know each other a little bit, maybe not on a personal level but you can listen to their conversations when they are talking with somebody that sits across from them, you pick up a little bit on that or you say, "Hi," to them. You chat for a minute, [...] So they become more a part of what your environment is when you're in there. Where the people in [the other site], I don't think are part of my environment. They're not people that I know and see their personalities, but they're like people on the screen. I don't know, it is weird. [...] It is different because they are not in your classroom. You don't walk in and see that they are sitting over there with their coke and talking to somebody about something. (HFt F I v14.1336)

Mary was struggling to make sense of classmates who were an extension of her class but not directly part of her environment.

Stan, one of the remote students also noticed that relations were different when all the classmates were not in the same room. "It's easier not to listen when they [other students] are not really in the room with you. [...] It's disrespectful when someone's talking to you and you are not listening. It's easier to be disrespectful when they are in another city. It's easier not to listen (RFt M I s11.8)." For Stan, the natural division created by the televised classroom changed the make-up of the class and introduced complications in the way he defined himself in the class in relation to his fellow classmates. Now, if he chose to accept the students at the other site as his classmates, he had to work harder to maintain the image of being a respectful classmate than if he chose not to accept "their" presence as part of his class.

Stephanie's comments provided further insight.

Some people really get off to being on camera. [...] And, because I don't know her and she is in [the other site], not here, it is not fair for me to assess somebody that I can't be in the classroom with [...]. But my opinion, being over here and not knowing her is something else. And, it doesn't bother me but I just think, well, I guess it does bother me or I wouldn't be speaking about it but I think, is this just who she is or is it the fact that, "I can be on camera" and I just don't know. (RFt F I v14)

Stephanie was struggling with how to think of her separated classmates, but she did not quite know what to think or how to act.

As students made sense of the situation and developed their own way of adapting to the new physically divided, yet socially connected classroom, they constructed meanings about what it was to be a member of “their” site and what it was to be a member of the “other” site. These meanings affected the way students then related to one another, which in turn, had the potential to, and did, affect the class as a whole, most often in negative ways.

Understanding who constitutes a class is important because classes are shared experiences where interaction between students contributes to successful learning, (Burnett, 1973; Maher & Tetreault, 1994; Wilcox, 1982). On the simplest level such interaction may involve being courteous to others and on the more complex level it may involve the exchange of significant ideas (Musgrove, 1973). The level at which student to student interaction occurs in a class is effected by issues in the student relations/location domain. Those issues include how students feel about each other, how trusting they consider other students to be, and how they construct the list of who they think of as “their class” (Jackson, 1968).

Instructor Role

As students adjusted their thoughts on what the instructor’s role in the new classroom was to be, they simultaneously adjusted their thoughts on what their own role was in creating successful classroom experiences. The patterns of adaptation that students worked through as they experienced classes in the IDLS seemed to take one of two directions. They either moved toward a team approach of sharing responsibilities with the instructor, or they moved toward maintaining expectations that the instructor was more completely responsible for activities and learning in the classroom. Student statements within this domain often
expressed the expectation that the instructor needs to offer new rules for classroom behavior, bridge the distance gap between the sites, maintain a focus on content, and help students adapt to the new learning environment (Schmertzing & Schmertzing, 2001).

Content/Class Participation

“Competent participation in classroom contexts requires knowing what context one is in" (Mehan, 1980, p. 137). Context here refers to the complex interactions that occur as participants in the classroom build the floor of conversation by simultaneously listening and speaking to each other (McDermott & Roth, 1978; Shultz, Florio, & Erickson, 1982). In order for these interactions to occur in a way that communicates the intended course related content, participants in the traditional classroom learn to read the cues used by other participants to find the appropriate time and place to take the floor (Doyle, 1977; McDermott, 1977; Snow, 1968).

Students pre-IDLS understanding of how these cues worked was not sufficient to guide them in developing cues for efficient communication of content-related material in the distance classroom. The technological filter changed the procedures associated with speaking in class, the consequent pacing of the class, and the ways students viewed themselves and their involvement in class activities.

Mannie, a student from Pensacola, spoke of the way the technology changed communication patterns and disrupted the traditional ways that students were accustomed to participating in class.

"Usually [in a traditional classroom] their hand goes up, they are called on, usually start talking, and another thing, we're so used to interrupting each other. Even if we're quiet we wait until someone has finished and then just speak out before raising our hand. Now [in the IDLS] I think some people aren't, might not be, quite as willing to do that, because they have to, there's the button war over the microphones. If they were all open mics, that would be more fun I think, but we, being so spread out the camera needs to go to each of us. (HP M I p220)"

In Mannie's words, the technology changed the procedure from "speaking out as someone finishes" to a hesitation to get involved in a "button war." Maggie, another host student, was concerned about the loss of freedom that accompanied the procedures that Mannie termed "button wars."

"There's not this sense of, if we're in a classroom, you and I and many others in the class, we can just talk freely. And move in and out of conversations without being invited to do that. [...] I think in distance learning you cannot do that. I've seen a couple of times where people have pushed buttons at the same time, from [both sites], and they say, "Oh no, you go," and "Oh no, you go." And it tends to be like, "Well, maybe I didn't have anything to say," when it comes back to me, because it's no longer spontaneous. I think that discussions have really lacked, because of the environment of the system forming at this point in time. (HP F I p4.13)"

What started out as a well-intended contribution to class got side tracked because of the awkwardness associated with trying to navigate the discussion through a technological medium.

Claire: Often times, especially at the graduate level, jumping in [to a class discussion], in a smaller setting is acceptable. The rules are not quite as stringent as they are in an undergraduate setting with a large class. [...] I think it is a little more difficult to just jump into a conversation [in the DL classroom] because you have to actually, physically make an effort to hit a button and wait a second before you're recognized. You can't just say, "Oh yea, that reminds me blah, blah." I think a bit of the spontaneous comments are curtailed. [...] I know that I don't jump in unless I know that I know the answer, whereas, in another classroom, I might just throw something out. [...] Whereas, in a distance setting, I tend to not do that, but respond only when I'm pretty sure I have a good idea of what I'm saying.

Interviewer: Why do you think that is?

Claire: I don't know. I think there is something about everyone being in one room that feels more intimate, that feels more private and, I think that when you add the cameras, you feel like you're going public. I feel more like I'm speaking publicly, like I do when I'm standing in front of a class. [...] If I'm teaching a class and I stand up in front, I get this little nervousness, even if you do it every day, and you feel, okay, I'm on display, I'm on show, here we go. I get a little bit of the same feeling
when I jump into a conversation in [this environment] because everyone, all of a sudden, looks at you. Whereas, if you are sitting at a desk in a room and you just throw something out for comment, I don't feel in charge or on display or like I'm the presenter. Instead, I feel just like one of the group. (RF F I v17.196)

Claire identified three things that inhibited the spontaneity that she expected in her graduate classes; the “physical effort” that was required, that there was a need to “get [formal] recognition,” and the “intentional pause” that slowed things down. She also identified an awkward new awareness of herself in the class. Claire felt more like she was “speaking publicly,” “standing in front of the class,” “on display,” and being looked at by everyone. Participation in class discussion in the IDLS did not “feel” the same to her as “being one of the group” in the traditional classroom where she would be “sitting in a desk and jump into the conversation.” Thus we can see that the effort to adapt to the process of communicating course-related material through a screen of unfamiliar technology hindered students’ class participation in the two-way interactive televised classroom. Furthermore, it is clear that teachers and instructional designers, who make an effort to understand the complexities associated with content related interaction in the distance classroom, will be able to make adjustments that will significantly improve the teaching and learning dynamic in such contexts.

Conclusions

This brief introduction to the four domains of an interactive televised classroom in which students attempt to adapt, suggest the complex and varied nature of that process. By identifying these domains we are locating the complexity of distance education in a research-based context that also allows us to begin to understand that complexity. We believe that this research has implications for the way instructional designers think about learner needs, provides important informational context for teacher educators who are concerned with facilitating student adaptation, minimizing their frustration, and freeing them to focus on content rather than process. Further, the concepts referred to in the domains not only provide a basis for a discussion of new strategies for instructors, but also incorporate the ideas of graduate students into the equation of what it takes to more effectively move both learner and instructor toward accomplishing their goals.

The impact of instructional technology on student achievement

Lorraine Sherry, Shelley H. Billig
RMC Research Corporation, Denver

Abstract

For the evaluation of The WEB Project, a Technology Innovation Challenge Grant (TICG), RMC Research Corporation developed a conceptual framework to measure the impact of instructional technology on student achievement, based on an extension of Sternberg's (1998) Developing Expertise Model. Structural equation modeling, using student surveys, teacher observations of student learning processes, and teacher-scored student products, revealed paths that correlated motivation -> metacognition -> learning processes -> student achievement. This model may be replicable for evaluators who must report impact on student achievement for TICG or PT3 grants using assessments other than standardized test scores.

The WEB Project is a five-year Technology Innovation Challenge Grant that was completed in September 2000. The purpose of this project was to infuse standards-based instruction in multimedia, digital art, music composition, and online discourse into the general arts and humanities curricula of Vermont K-12 schools. Multimedia technology was incorporated within six academic content areas: art, music, technology, history/social studies, English/language arts, and interdisciplinary studies.

Students shared their works-in-progress with a virtual community consisting of teachers; other students; and digital artists, traditional artists, musicians, composers, Web page designers, and other experts via a virtual learning environment called The WEB Exchange, which resided on The WEB Project's server. Through threaded design conversations, students requested feedback on their works of art, music, and multimedia, filtered the feedback they received, and used it to improve their final artistic products, which many of the participating students then posted on The WEB Exchange. Concurrently, language arts students, facilitated by language arts teachers and mentors from the Vermont Center for the Book, discussed curriculum-related texts. Moderating their own discussions, students engaged in deep, rich dialogue that focused on standards-based activities such as responding to text, substantiating arguments with evidence found in the text, informed decision making, and the like. These interventions were stable over the last 2-3 years of the 5-year grant.

One of the research questions posed by the RMC Research Corporation evaluation team in evaluating this project was, "What is the impact of The WEB Project on student achievement?" Our intent was to generalize our methodology to other instructional technology grants in which student achievement must be reported. Findings from an online survey of The WEB Project teachers and administrators, repeated in spring 1998, 1999, and
2000, indicated that a connection between student motivation, metacognition, and learning processes, as outlined in a conceptual model developed by Sternberg (1998), might be applicable.

According to Sternberg, motivation drives metacognition, which, in turn, stimulates the development of thinking and learning skills. Thinking and learning skill development further stimulates metacognition, resulting in the development of expertise. The evaluation team extended the Sternberg Developing Expertise model to define "expertise" as student achievement, as measured by teacher-created rubrics. Participating teachers developed, refined, and benchmarked rubrics for student-created products over the past three years. Teachers also selected a rubric for measuring student learning processes from Marzano et al.'s (1993) Dimensions of Learning model. The rubric addressed depth and richness of revisions of student-created products and performances.

Using mixed methods that consisted of the online survey, student pretest and posttest surveys, and scores on teacher-created/selected rubrics that assessed students' learning processes and final products, the evaluation team used structural equation modeling to correlate the various elements of the extended Sternberg model. The hypothesis was that motivation would drive metacognition; metacognition would drive thinking and learning processes (specifically, inquiry learning and application of skills – two scales derived from WEB Project-based activities identified by participating teachers); and increases in thinking and learning processes would result in increases in teacher-scored measures of student achievement. The student survey was pilot-tested in spring 1999, and three derived scales (metacognition, inquiry learning, and application of skills) had high internal consistency (alpha = .72 to .84). Two ten-item sets of questions for "in this class" and "in school in general" motivation were added to the survey in spring 2000.

In January 2000, the survey was administered to 165 students in nine cooperating schools. 137 responses were from students who had not yet been exposed to the intervention, and could therefore be used as pretests. Internal consistency reliability for all scales (class motivation, school motivation, metacognition, inquiry learning, and application of skills) ranged from alpha=.70 to alpha=.87. In May 2000, at the end of the spring term, the survey was re-administered as a posttest to the same group of students. 131 completed surveys were returned by all nine schools as of August 2000. About 75% of the students who responded were from high schools, 25% from middle schools. Gender was about equally distributed.

Seventy-six valid data sets were matched in order to conduct a true repeated measures methodology (pretest vs. posttest). Only the "application of skills" scale increased during the spring term (2-tailed significance = .0165).
For the path analysis, the posttest survey results were correlated with teacher assessments. Participating teachers assigned a "product" score of "0" (no evidence), "1" (approaches standards), "2" (meets standards), and "3" (exceeds standards) to their students' final products. Products were re-scored by a jury of experts to increase reliability, resulting in 91 reported "product" scores. 107 teachers assigned a "process" score of "1" (low) to "4" (high) to each of their participating students for the quality and depth of revisions of their final products, which they construed as a measure of student learning processes. These data constituted two independent measures of student achievement, which served to complete the model.

Four separate simplified path analysis models were tested. The first pair addressed process and product outcomes for class motivation, and the second pair addressed school motivation. The statistically significant (p<.05) results were as follows:

Motivation was related to metacognition. The relationship between class motivation and metacognition was slightly stronger (R=.307, p<.0001) than the relationship between school motivation and metacognition (R=.282, p<.0001).

The relationship between metacognition and inquiry learning (Beta = .546, p<.0001) was stronger than the relationship between metacognition and application of skills (Beta=.282, p<.0001).

The relationship between inquiry learning and the student learning process outcome (Beta=.384, p=.001) was stronger than the relationship between application of skills and the student learning process outcome (Beta=-.055, not significant).

The relationship between application of skills and the student product outcome (Beta=.371, p=.004) was stronger than the relationship between inquiry learning and the student product outcome (Beta=.063, not significant).

Clearly, correlation does not imply causality. However, when each of these elements was considered as an independent variable, there was a corresponding change in associated dependent variables. For example, there was a significant correlation between motivation and metacognition,
indicating that students' enthusiasm for learning with technology may stimulate students' metacognitive (strategic) thinking processes. The significant correlations between motivation, metacognition, inquiry learning, and the student learning process score indicate that motivation may drive increases in the four elements connected by the first path. Similarly, the significant correlations between motivation, metacognition, application of skills, and the student product score indicate that motivation may drive increases in the four elements connected by the second path.

Based on the significant correlations of the two teacher measurements of student achievement with the student survey data, these data validated the evaluation team's extension of the Developing Expertise model to explain increases in student performance as a result of engaging in technology-supported learning activities. Moreover, nearly all students across the project met the standards for both the teacher-created student product assessment and the learning process assessment. This indicates that, in general, the project had a positive impact on student achievement.

These preliminary findings suggest that teachers should emphasize the use of metacognitive skills, application of skills, and inquiry learning as they infuse technology into their respective academic content areas. Moreover, these activities are directly in line with the Vermont Reasoning and Problem Solving Standards, and with similar standards in other states. The ISTE/NETS standards for assessment and evaluation also suggest that teachers apply technology in assessing student learning of subject matter using a variety of assessment techniques; use technology resources to collect and analyze data, interpret results, and communicate findings to improve instructional practice and maximize student learning; and apply multiple evaluation methods to determine students' appropriate use of technology resources for learning, communication, and productivity.

Rockman (1998:3) suggests that "A clear assessment strategy that goes beyond standardized tests enables school leaders, policy makers, and the community to understand the impact of technology on teaching and learning". RMC Research Corporation's extension of the Sternberg model can be used to organize and interpret a variety of student self-perceptions, teacher observations of student learning processes, and teacher-scored student products. It captures the overlapping kinds of expertise that students developed throughout their technology-related activities.

One of the greatest challenges facing the Technology Innovation Challenge Grants and the Preparing Tomorrow's Teachers To Use Technology (PT3) grants is to make a link between educational technology innovations, promising practices for teaching and learning with technology, and increases in student achievement. We believe that this model may be replicable in other educational institutions, including schools, districts, institutions of higher learning, and grant-funded initiatives. However, to use this model, participating teachers must be able to clearly identify the
standards they are addressing in their instruction; articulate the specific knowledge and skills that are to be fostered by using technology; carefully observe student behavior in creating and refining their work; and create and benchmark rubrics that they intend to use to evaluate student work.

Use of Nvivo for Classifying Synchronous Dialogue Resulting from Web-based Professional Development

Paul G. Shotsberger
Department of Mathematics and Statistics, University of North Carolina at Wilmington, Wilmington, NC USA, e-mail: shotsbergerp@uncwil.edu

Abstract: A SITE 99 paper by the author (Shotsberger 1999) extended the work of (Blanton, Moorman & Trathen 1998) to generate a framework for analyzing synchronous dialogue generated from a Web-based professional development program. The current study attempts to further refine the framework through the use of qualitative analysis software called Nvivo (Scolari Software 1999). The Nvivo program was used to analyze chat transcripts from two different years of a Web-based inservice program for mathematics teachers. The 1997 transcripts from the previous study were re-analyzed using the Nvivo program. Then transcripts from 1998 were analyzed using Nvivo to attempt to validate the new classifications suggested by the re-analysis.

Background

(Blanton, Moorman, & Trathen 1998) classified forms of dialogue that take place in a telecommunications environment, focusing exclusively on asynchronous dialogue. The authors defined Convergent situations as those in which participants assume one correct answer, as opposed to the Divergent condition in which multiple interpretations are possible. Critical situations are defined as those involving some kind of analysis, questioning or perhaps skepticism, and this is contrasted with an Inclusive environment in which each participant’s contribution is valued and accepted. The classifications therefore represent intersections of pairs of these situations: Instruction (convergent-critical), Debate (divergent-critical), Inquiry (convergent-inclusive), and Conversation (divergent-inclusive).

A SITE 99 paper extended this framework to encompass synchronous dialogue generated from a Web-based inservice program for mathematics teachers (Shotsberger 1999). Chat transcripts were analyzed from online meetings held during Fall semester 1997 among 13 participants and three facilitators. Participants were primarily high school and middle school mathematics teachers. Analysis focused on the portions of the chat transcripts that dealt specifically with some aspect of the training materials. The following categories of synchronous dialogue emerged from the analyses (an example of each is provided in parentheses):

Affirmation of another participant’s efforts (“I like that ….”)

Belief about teaching/learning (“I think that a group needs half and half strong [students].”)

Concern about implementation (“The really smart kid may talk too much like a teacher…and turn the weaker kid off.”)

Current practice (“I use groups on the average of once a week…it is not my main thing.”)

Desire to implement (“I also want to do some on line researching for some things that I don’t have time to search for now.”)
Intent to implement ("I had planned to use the scoring sheet and their scores as part of the analysis.")

Question about implementation ("Does everyone else sit [students] in rows and then move to groups or are your desks in groups?")

Result of implementation ("My other 2 groups with the exception of a very few that are full of raging hormones really work well in groups.")

The categories of dialogic behaviors identified from the chat transcripts seemed to fall under the classification proposed by (Blanton, Moorman, & Trathen 1998) in the following way:

Instruction: Current practice; Question; Result

Debate: Belief; Concern; Current practice; Result

Inquiry: Affirmation; Desire; Intent; Question

Conversation: Affirmation; Current practice; Belief; Concern

The 1999 study was presented as a work in progress. The current study attempts to further refine the framework through the use of qualitative analysis software called Nvivo (Scolari Software 1999). As an organizational tool, Nvivo is superlative. It allows for annotations of transcripts using any desired classification scheme, and thus affords the user the ability to generate reports that can isolate one category of dialogue as well as compare instances of a given category across transcripts. (Fig. 1) shows one page of search results for instances of participant Beliefs about teaching and learning. Nvivo also provides the capability to graphically organize categories into an integrated whole, building up nodes and connections layer by layer in order to derive a sound theoretical framework from the analysis. (Fig. 2) displays the theoretical framework resulting from the (Shotsberger 1999) analysis.

The Nvivo program was used to analyze chat transcripts from two different years of the Web-based professional development program. The 1997 transcripts from the previous study were re-analyzed using the Nvivo program. Then transcripts from 1998, which represent dialogue generated by a different group of eight middle and high school teachers and one facilitator, were analyzed using Nvivo to attempt to validate the new classifications suggested by the re-analysis.

As a result of using Nvivo, the following additional categories and sub-categories of dialogic behavior were identified:

The category of Current practice needs to be differentiated into sub-categories that include separate considerations of Students, Curriculum, and Methods.

The category of Results of implementation needs to explicitly address whether outcomes were Positive or Negative.

The category of Affirmation needs to add sub-categories that differentiate between affirmation for Actual Implementation or Proposed Implementation.

A new category of Realization needs to be added to the framework, which will take into account new participant understandings resulting from dialogue with other participants. This new category of Realization might be classified under either Inquiry or Instruction in the framework.

Presentation of project results at SITE 2001 will include a demonstration of the Nvivo program, samples of annotated transcripts, reports and graphics generated using Nvivo, as well as the latest version of the framework.
the questioning part is the key to most of my teaching

basic classes have to be "led" a bit differently...but once you get them to listen to each other...it can be quite productive

I think that good questioning is one of the most valuable teaching skills we have

It is still hard for them to think of anyone but themselves at the 8th grade level

I think it's important to let students think alone for a few minutes before putting them into groups. Let the slower ones participate

think-pair-share is also good for groups

i believe the eoc will be "covered" if the kids really understand...that's why they need to talk

Support for the purchase of Nvivo software was funded through a Charles L. Cahill Award for Faculty Research and Development from the University of North Carolina at Wilmington. The information presented, the statements made, and the views expressed are solely the responsibility of the author.

Figure 2: Sample of Nvivo graphical organization
Abstract: This paper describes the first phase of a research study to examine the role played by Internet-based teacher professional development in the implementation of an innovation. The innovation in this study is the software application (StageStruck) for the performing arts. The professional development web site has been developed to support inservice teachers in best practice use of the software. The cases investigate the effect of this on-line professional development strategy and teacher implementation of the software with elementary and secondary inservice teachers.

In this first phase the web site portal (http://www.stagestruck.uow.edu.au) has been established to build and support a community of practice in the performing arts areas of learning. The web site development has been an iterative process based on an understanding of best practice in professional development, a review of the literature and exploration of cases available in and about on-line communities, and the contributions and ongoing evaluation of our community members (teachers and students). The current phase of the research begins the data collection of data on the efficacy of the on-line professional development strategy employed.

Professional Development

There is an imperative for new professional development strategies and for teachers themselves to take more control and have ownership of their personal professional development (Fullan 1993). Principles of effective professional development emphasise ongoing activities that build on current practices, in a climate where teachers can take risks as part of a "learning community" (Bull et al. 1994, ACOT 1995, US Dept Education 1996, Grant 1996, Loucks-Horsely & Hewson 1998, Stager 1998). This learning community can be a space where teachers support and learn from each other and take the time to reflect on the effectiveness of change. Novices in the community may collaborate with peers, work alongside experts, share, explore and learn as part of a network. Members can embrace more than a change in skill-set, they can test out new pedagogical frameworks and environments. Technology allows such a community to break out of its geographic confines by linking the members on-line. It is recognised that the best work with on-line communities of practice is still to come. It is suggested that this will happen as the technology becomes more accessible and projects develop that embody the research findings (Ravitz 1997).

The on-line technology has become quite readily accessible. In 2001 nearly all Australian schools will access the Internet through ISDN (64K) connections and figures from a 1999 census show 22% of Australian homes had Internet access with projections showing this figure steadily increasing (ABS 1999). There is much the same picture of technology uptake across many other nations.

The research findings alluded to by Ravitz (1997) relate to new paradigms for professional development and web site design. Designs of on-line communities that are needed to support teachers as professionals in both technical skill development and the broader issues of implementation of constructivist learning theories in their classrooms. Much of the on-line professional development available for specific information technologies or programs will deliver activity directed toward skill development and mastery of the application. Many web sites deliver step by step tutorials to develop competence in the mechanics and productivity of the software. However there is good evidence that teachers, like many other professionals, will not take the time to learn a new piece of software unless they perceive sound practical classroom use which is in keeping with the needs of the curriculum.
This study employs an on-line approach to facilitate not only teacher development of skills but, most importantly for them to explore, model, lead, design and evaluate constructivist learning activities and environments in their classrooms. The site offers teachers many opportunities to make explicit for themselves the connections between activity, pedagogy and curriculum.

The Innovation

StageStruck, the University of Wollongong's award winning interactive CD-ROM product, introduces the learner to the world of performing arts by exploring a performing arts venue (the Sydney Opera House) which showcases contemporary companies, performances, processes and people, and provides theatres and 'tools' with which a learner can create and direct scenes. The StageStruck project sought to focus on the construction of multiple meanings in a field that many would argue is highly subjective and open to numerous interpretations.

Many students have a narrow perception of how a theatrical performance is devised due to the lack of exposure or opportunity to view or take part in the performing arts. By extending the boundaries of interactivity in the context of a virtual setting, learners are provided with opportunities to express their own cultural interpretations and understandings. In this theatrical journey there is the advantage of working with many visual metaphors. The world of theatre, opera, music theatre, dance and contemporary performance styles can be explored through devices such as 'The Green Room' where the user can interrogate a database of the contemporary world of performing arts. The ‘Stage’ space provides the opportunity to view sample scenes from productions which have been created by professional directors, and more importantly to individually direct and design their own scenes with access to the same theatrical elements. In this process individual users explore processes of visual design, sound development, and the concept of direction and motivation. In this project the construction tools have also been extended to enable the user not only to collect from a defined set of resources, but also to construct their own resources based upon combinations of sets, costumes and performers. This supports the theatrical outcomes of many interpretations of each scene.

Key to the communication of the experience within this application is the facility to save and share files between learners or to re-present a constructed performance and interpretation to others located within the same classroom or across the Internet. This last act offers the potential to create a range of resources that are not bounded by the storage capacity of a prepackaged CD-ROM but are collected and shared from an ever growing unbounded Internet learning environment.

Emerging software programs like StageStruck offer teachers a pedagogical sophistication unavailable until now. This software itself is an innovation. The program's learner centred approach gives students the opportunity to write, build and direct performance pieces, theatrical sets and costumes. It allows them to design, experiment and problem solve in a visually rich and stimulating environment. Use of StageStruck therefore, like many other technological innovations, will go through a process to reach implementation. Diffusion is defined by Rogers (1983) as the process by which an innovation is communicated through certain channels over time among the members of a social system. The four main elements are the innovation (StageStruck), the communication channels (the on-line technology), time and the social system (performing arts teacher K-12). The on-line community has been chosen because it has the potential to be an efficient and cost effective way to promote all these elements and to realise professional development goals.

Professional Development and Information Technology for Pedagogy

Current literature and best practice for professional development and on-line learning converges on the concept of on-line communities of practice. What is a community of practice and how might it serve to offer pedagogical support to practicing classroom teachers? Community is a much-argued concept. Long before the “community” went on-line social scientists had disagreed about what a community was. Thousands of print and web pages are devoted to trying to adequately define, refine and finesse what an on-line community is. Rather than define the term 'community' this study examined the available on-line activities that were promoted as communities, their goals, attributes and activities. We did this in order to develop a set of hallmarks for community.

We found community in Tenenbaum’s (1998) Media Center Project and Cannings & Stager’s (1999), NetAdventure, EdNet@UMass (Reilly, 1999) and the Indiana University (1999), Internet Learning Forum to mention a few. These projects have all explored the development of communities of practice with a particular
focus on support for pedagogical change, a focus that is critical to the StageStruck Professional Development Community. The hallmarks of these projects are:
- A clear focus driven by the members
- Employment of appropriate technologies and styles of communication
- Membership of a social network where their expertise, leadership, content, and contributions are valued.
- Providing ongoing discussion, sharing of, and collaboration on, commonly valued things.

The StageStruck Professional Development Community web site strives to be recognised by its community members for the same hallmarks. Preliminary research has provided insights into member's needs and laid the foundation for the community's goals. The web professional development approach incorporates varied opportunities for teachers to be leaders and mentors, learners, and to share their teaching programs and products to support the main goal of creating a community of best practice.

The Research Program

The professional development program has been designed for cognitive flexibility to allow teachers (and students) to visit and revisit aspects of the site and enter from many different perspectives. Whether through animated tutorial sequences or a series of events, units of work, student work samples, mentor and project activities or discussions, teachers have the opportunity to share, reflect on and lead the practice of their peers.

Table 1 Community Hallmarks Mapped Against Planned Internet Activities and Features
A central tenet of professional development and school reform is the creation of an enabling participant-driven environment for students and teachers alike. Web technology shares and promotes this same imperative. The key dynamics of the World Wide Web and school reform are exactly the same. (Tenenbaum 1997 p485)

The StageStruck Professional Development Community aims to test this tenet over a two year period. The research seeks to explore how and to what extent an Internet-based professional development network can support the implementation of innovation. The research seeks to answer the following questions.
- What affordances of Internet technologies (WWW, e-mail, listserv, chat, Java, and CGI) can be harnessed to create effective professional development experiences?
- Through which professional development experiences can teachers express and work to address their needs and concerns about the innovation?
- How can Internet activities be designed and developed over time to attract and maintain a community of users?
- What Internet activities best build and sustain a community of practice?

The central research methodology uses instruments adapted from the Concerns Based Adoption Model (Hall et al 1973, Hall & Hord 1987). These instruments are used to assess teachers' entry level of adoption of StageStruck and the level after 6 months, 12 months and 2 years of involvement as a community member. The innovation configuration (best practice components of use) will be surveyed to describe the pedagogical environment that teachers have developed in their adoption of StageStruck. Structured interviews, focus groups, and system logs will also used to build a thick set of quantitative and qualitative data about the efficacy and life of the community.

Diagram 3 Mixed Mode Research Design
The research and consultation into community building and design was carried out over 2000. The web site was designed and refined with consultation and feedback from in-service and pre-service teachers during latter half of that year. The site was promoted widely to schools in NSW and internationally during November and December through faxes, conferences and presentations. During this time content was sought from teacher to initiate the resource database and to prepare the site for its first case study selection in early 2001. The StageStruck Professional Development Community web site was launched on 29th November at the Apple Innovative Technology Schools Conference 2001 and first member registrations and activities began on the same day. The main project activity and teacher support will begin with the start of the Australian school year in February 2001. The research will follow the community and its members into 2002. The preliminary phase presented in this paper and conference presentation describes the challenges for, and successes of, the community design, content development, recruitment of teachers and initial implementation. Data collection is in a very early stage but we are able to report on the willingness of teachers to join the community and their motivation for involvement. Teachers have responded very positively to the site design and activity ideas, most particularly to the opportunities to share and publish.

Abstract: The current research involved an undergraduate electromagnetism course at a reputable engineering university with traditionally high levels of attrition. A team of physicists, psychologists, and computer scientists engaged in a five year project in an effort to improve student performance in the course. Based on an extensive task analysis of both expert and novice performers, poor performance was determined to result from a lack of fluency on lower-level skills involved in solving problems. Subsequently, an extensive series of web-based materials were developed based on the principles of precision teaching (Lindsley, 1972). The current research reviews the precision teaching approach in general. Then, in turn, the paper discusses the process of the development of the materials, the computer-based presentation of the materials, and the successful application of the materials at Georgia Tech. Finally, the advantages of using the web-based materials are discussed.
Introduction

Over 80,000 students enter engineering programs as freshman each year (Lashley, 1997). Unfortunately, research shows that less than half will graduate with an engineering degree (Astin, 1993; Hayden & Halloway, 1985). Further, most of this attrition has been found to occur within the student's first two years on campus. For example, Budny, Bjedov, and LeBold (1997) found that over one third of engineering majors left Purdue by the end of their second year. More generally, McCaulley, MacDaid and Walsh (1987) found 40% attrition prior to the third year for a heterogeneous eight-school engineering consortium in the United States. Indeed, our own research at Georgia Tech (Marr, Thomas, Benne, Thomas & Hume, 1999) indicates that the majority of academic-related attrition results from poor performance in basic core courses such as calculus, chemistry and physics. Interestingly, this attrition often occurs prior to students taking classes in their chosen engineering major. Given the social and economic costs associated with such high attrition rates, interventions that improve performance in these courses are clearly warranted.

A common complaint voiced by educational psychologists is that they develop effective teaching techniques only to see them fail to be implemented in mainstream education. Viable solutions to America's so-called "educational crisis" are developed by researchers but are not applied by teachers in the classroom (Goodlad, 1983). Alternatively, they are applied and proven to be effective in the classroom only to simply fade away over the course of time. The current paper will first reintroduce the basic tenets of precision teaching (PT) as a potentially viable instructional technique. Then, a brief discussion of a five year project designed to improve student performance in an introductory physics course will be discussed. The resulting set of web-based materials, the procedures for their use, and the success of the intervention will then be described. Finally, the benefits of using the web-based approach instead of traditional paper-and-pencil implementation will be evaluated.

Precision Teaching

The basic tenets of PT are fairly straightforward. According to Lindsley (1972), in order to develop fluency on higher-order skills, fluency must first exist on lower-level skills. A task must be broken down into the basic skills necessary to complete it. Then, fluency must be established on each of these so-called "tool skills." These "tool skills" must then be recombined into bigger pieces, and fluency subsequently obtained on these larger chunks. Daily measurements are necessary to determine the learning rate and to serve as a vital source of reinforcement for the learner (Pennypacker, Koenig, & Lindsey, 1972). Stringent but realistic fluency goals are established and the learner is not allowed to progress to the next level until fluency has been attained on the preceding level.

The most important point that differentiates PT from traditional methods of instruction is its emphasis on fluency. For precision teachers, fluency consists of much more than simple accuracy. If an individual could only speak 10 words a minute in a foreign language we would not describe that individual as being fluent. This would be true even if the individual enunciated and utilized all 10 words perfectly. Generally speaking, most people would consider a person fluent in the foreign language only if they speak correctly at a "normal" speaking rate. That is, true fluency is a function of both accuracy and speed. PT is quite novel in its emphasis on speed, not accuracy, as the true measure of learning. Traditionally, of course, our educational system has emphasized percent correct and other measures of accuracy as the bottom-line criterion of student performance.

The most often cited example validating the effectiveness of PT is The Great Falls Project (Beck & Clement, 1991). This project started as remedial instruction aimed solely at mildly handicapped students. The investigators found that 79% of precision taught groups performed better than control groups receiving traditional instruction. When PT was implemented in the regular curriculum, PT students out-performed control groups on the Iowa Basic Skills Test by 40 percentile points in math and 20 percentile points in reading. In a separate study Johnson & Layng (1991) found that PT instruction resulted in learning disabled (LD) children improving their reading level by two years per year of study. This is quite impressive in that LD children traditionally show only about a half-year gain in reading level per year of study. Finally, William Beneke (1991) introduced PT principles in an introductory psychology course at Lincoln
University. With an intervention that lasted less than five minutes a day, Beneke increased college students' reading rate by 49%. This increase in reading rate was also accomplished with a 75% increase in the recall of the material. Thus, the intervention resulted in the students reading both faster and having greater retention of what they had read.

The Problem

Despite the above examples, numerous other success stories, and a journal dedicated solely to PT research (Journal of Precision Teaching), PT has failed to catch the eye of mainstream educators. Four primary reasons may be given in explaining this lack of mainstream support. First, there is a perception that PT can only be applied to very low-level skills. Most examples discussed in the literature have indeed involved remedial-level skills. Second, PT is also assumed to be very expensive by most people. As traditionally implemented, PT requires a very low student to teacher ratio due to the need of constant monitoring and continual feedback/reinforcement for the learner. Third, PT requires a large investment of preparation time by the teacher. A large data-bank of "tool skill" items is required for daily practice by the student. Moreover, this large investment of time must be undertaken before the student ever enters the classroom. Combined with the short term focus of many educators this large investment of preparation time is seen as a major shortcoming of PT. Finally, PT has been termed a bureaucratic nightmare due to the extensive paper-work involved. PT emphasizes the need to graph and plot student performance and provide the student with the continuous feedback. This process results in much more data tracking and performance monitoring than traditional instructional techniques.

One Potential Solution: Computer-based Presentation

The advent of computer technology and the world wide web provide some answers to these commonly voiced complaints, however. First and foremost, web-based PT would reduce the man-hours involved. The computer could handle the presentation, measurement, feedback, data tracking, and record-keeping. Not only would this reduce the bureaucratic nature of PT, but the time saved here could be used for the identification of tool skills and problem generation required up front. In fact, researchers have shown that when implemented correctly PT actually saves total teacher time (Haring, Liberty, and White, 1970-1980). Second, the amount of paperwork would no longer be a concern since all of the data could be easily tracked and stored by computer. Similarly, student feedback can be directly presented to the student via the computer. Third, the teacher-student ratio would no longer be a concern since immediate reinforcement is accomplished by the computer, not by the teacher. The only remaining concern would then be to see if such a proven instructional approach can be implemented on a non-remedial high level skill. The problem course investigated in the current study was a sophomore level introductory electromagnetism course at Georgia Tech where traditionally 40% of students fail to make C or above in the course.

Task Analysis

The development of the current web-based materials involved a five-year collaboration of physicists, psychologists, and computer scientists. The first step was to determine the cause of poor performance in the electromagnetism course in question. An extensive task analysis was undertaken. First, several focus groups were conducted with both good and poor performers. Second, skills analysis of both expert and novice performance was conducted in the actual testing situation. Students completed the tests long hand and several subject matter experts analyzed both performance and procedural consistency for all students. Finally, to validate the conclusions reached by the subject matter experts, several laboratory studies with verbal protocol of problem-solving behaviors by both expert and novice performers were also conducted. All in all, the three approaches found clear differences between expert and novice performance. For a full discussion of the methodology used to determine these differences please see Cabrera, Marr, Thomas, Walker, Thomas, Wood, Hodges, and Thompson (1994).

In short, the conclusions reached in Cabrera et al. (1994) were that expert performers had automated the lower-level skills involved in solving the more complicated physics problems. This manifested itself on several lower-level skills such as calculator skills, basic math skills, basic physics
skills, etc. Novice performers seemed to engage in much more controlled processing of information at all levels of problem solving. These results are quite similar to the well-published differences often found between expert and novice performance on various different skills and abilities (Koedinger & Anderson, 1990; Simon & Simon, 1978).

Material Development

Based on the overwhelming evidence that poor performance in electromagnetism resulted from a lack of fluency on lower-level skills, we felt precision teaching might be an effective instructional technique. Further analysis found that physics novices suffered from a lack of fluency in, at least, four main areas. The first problem area was a lack of fluency in basic math skills. Many students could solve basic quadratic equations and vector sums, for example, but were far from being fluent in those tasks. Thus, come test time, valuable time was lost recalling and solving the quadratic equation during the testing period. Given the speeded nature of the test this deleteriously effected their grade. A second troublesome area involved what might be termed intuitive skills. These skills included such concepts as knowing the direction of an E field without actually working the math of the problem or knowing what $1/X^2$ looks like without explicitly having to take the time to plot it. Again, time spent on such issues during the testing period negatively affected student performance on the test. A third lower-level skill deficiency demonstrated by novices as compared to experts concerned units of measurement. Experts just “knew” that a joule was a newton-meter or even a kg-m per s². Novices had to “think” about the appropriate units and often gave numerical answers that could have been eliminated as incorrect based solely on the presence of inappropriate units. Finally, novices lacked fluency on simple one and two-step physics problems. For example, novices took extensive time and expended valuable cognitive resources solving basic Coulomb’s law problems or Gauss’ law problems that experts could solve automatically. When combining several of these simple problems into an entire problem on the test, these skill insufficiencies were only magnified.

The Materials

Based on these four areas of deficiency in fluency, a team of physics professors and teaching assistants developed thousands of problems for each of the four areas. Additionally, the content of each domain was carefully tied to the traditional flow of an electromagnetism class. That is, math skills early in the quarter were concerned with fractions and vector addition since traditionally Coulomb’s Law and Gauss’ law are covered early in the quarter. Later in the quarter, math skills were more likely to be concerned with skills traditionally needed later in the quarter. For example, given the Biot-Savart Law is usually covered quite late in such a course, the math skill materials for that week might heavily stress integration and differentiation. Eventually, ten sets (weeks) of materials were developed. For each week or set, there were five days worth of materials. Each day contained four modules: math, intuitive, units, and basic physics.

Implementation of the Materials

While the material development was a long and tedious process, the implementation of these materials may be more important in determining the success of any precision teaching program. Students were instructed to go onto the web page daily during the week. Once on the web page, the students were prompted by the computer to complete each of the four modules for that day. The sessions were timed with math, units, and intuitive sections limited to around five minutes each and the physics modules averaging about 25 minutes (specific times varied due to the number of skills necessary during various parts of the quarter). It is important to note that this meant that the student was on the computer for only around 40 minutes per day.

Students were carefully instructed about the nature of fluency. Again, the students were instructed that the program emphasized fluency instead of accuracy. Each day, the student completed the math section, then the units section, then the intuitive section, and finally the physics section. The student received instantaneous feedback on each item; however, the program immediately went to the next item in an effort to promote the development of fluency. At the end of that section (i.e. math, units, intuitive, or
physics), feedback was given for performance on the entire section. At that point, the student could assess their performance for that section. Then, the student went to the next section until all four sections were completed. This process was repeated for five consecutive days. It is also possible to display day-by-day performance on each section across the five days. The materials and the procedures utilized can be found at www.blackbox.psych.gatech.edu.

Program Evaluation

Over the course of several years this procedure was evaluated against various other educational techniques. In particular, in successive quarters interventions were conducted where the web-based precision teaching approach's effectiveness was compared directly to several carefully designed control groups. These included: groups doing extra homework problems equated for time on task, groups doing paper and pencil precision teaching, groups receiving traditional recitation instruction equated for time on task, and control groups receiving no extra intervention. Generally speaking, students receiving precision teaching instruction outperformed those that did not receive PT by an average of one full letter grade. The intervention was especially successful for students predicted to be at risk in the course. Combining the various control groups, fully 54.6% of students that did not receive the PT materials made a C or below. In comparison, only 22.7% of the precision taught students made a C or below. This is a truly amazing result if one realizes that traditionally at Georgia Tech around 40% of all students take this course more than once due to poor performance. Precision teaching resulted in not only these students completing the course at a much higher rate, but also in 77.3% of PT students making either an A or a B. The overwhelming success of these materials have been presented elsewhere (Marr et al. 1999) and due to space constraints will not be repeated here. Suffice it to say, the intervention has been extremely successful to date.

Conclusions

The current effort demonstrated that PT can be efficiently implemented at the collegiate level. First, the instructional approach was highly successful despite the high-level skill involved in the training. Further, the web-based approach was able to track the performance of several hundred students at a given time. Likewise, the program provided instant feedback for the students without requiring any additional expenditure of teacher or teacher-assistant time. In fact, when compared to both traditional recitation instruction and additional homework assignment, the PT intervention actually required less total teacher time. Finally, the availability of the materials on the web, complete with timed modules and programs for data management allowed students the flexibility to complete the materials at their own pace and according to their own schedules. Similarly, the availability of these materials via the web should allow other educators easy access to both view and implement the materials (in whole or in part) in their own programs.

The main goal of this project was to resurrect a proven approach to teaching. Precision teaching is a very effective means of instruction. In fact, Binder and Watkins (1989) called it the most powerful instructional tool ever developed. PT failed to be adopted in the 1970s simply due to the fact that there was no way to efficiently implement it at that time. The cost of implementation far outweighed the benefits of PT. Today's technology provides us with a new way to implement this proven approach. This project has proven that the proliferation of personal computers and the world wide web make it possible to implement PT efficiently and very effectively via the internet.

Abstract: This study investigated preservice teachers' perceptions of the teachers' role in classrooms with computers versus in classrooms without computers. Based on the literature review, three research questions were formulated. (1) What are the preservice teachers' perceptions of the teachers' role in the classroom with computers? (2) What are the preservice teachers' perceptions of the teachers' role in the classroom without computers? (3) Do the preservice teachers' perceptions of the teachers' role in the classroom with computers differ from their perceptions of the teachers' role in the classroom without computers? The teachers' role is to be measured as teacher-centeredness versus student-centeredness.

INTRODUCTION

The information age presents teacher education with a new challenge - preparing future teachers to teach with computers. "Learning environments based on new technology impose new challenges on the teachers and on the teacher training system" (Haugen et al., 2000; p. 205). Not only should teacher education train future teachers on how to operate computers, efforts should be taken to ensure that future teachers develop appropriate teaching styles and a clear vision of the teachers' role when they teach with computers.

LITERATURE REVIEW

Microcomputers were made available in school settings since the 1970s. Although technology opens possibilities for innovative and creative learning environments, its potential to impact student learning has been thwarted by ineffectual teaching practices. "Teachers' use of technology often forces it into traditional teaching paradigms that have existed for decades" (Sprague, 1995; p. 52). Technology was primarily used to support the traditional instruction mode (Becker, 1991; Dwyer, Ringstaff & Sandholtz, 1991). Computers were routinely used to reinforce memorization of facts rather than promote higher-order thinking and problem-solving skills. "In spite of this increased variety of available software, though, the pattern of software use in typical subject-matter classes remains fairly traditional" (Becker, 1991; p. 7).

Teaching with computers requires a shift from the traditional teaching practice. In order for technology to transform teaching and learning, there is a need to redefine the teachers' role and to change existing teaching practice. "To make real changes in classrooms, so that technology is truly used each day as a thinking, creative, and research tool, requires significant work in changing instructional approaches, assessments, and management strategies" (Wiburg, 1997; p. 181).

Teachers' teaching behaviors were rooted in their perceptions of the teachers' role in teaching and learning. Teachers teaching with traditional approaches in the classroom with computers had to confront their deeply-held beliefs and perceptions of their roles as teachers in order to alter their teaching practices (Dwyer, Ringstaff & Sandholtz, 1991). "Technology forced a re-evaluation of the authoritative teacher role" (Chin & Hortin, 1993-94; p. 83). Technology-rich classrooms tend to be more student-centered rather than teacher-centered (Collins, 1991; Grabinger & Duffield, 1996; Kolderir, 1990; Sheingold, 1990). "Roles and teaching
and learning strategies are changing because technology fosters the use of more student-centered learning strategies" (Norum, Grabinger & Duffield, 1999).

The discussion of the teachers' role shift has significant implications for teacher education. "The way that teachers teach is a product of their own schooling, training, and experiences as teachers" (Becker, 1991; p.8). Earlier studies found that preservice teachers' computer use during the practicum fell into the similar traditional pattern. Preservice teachers generally used computers in a limited way. Computers were used as a supplement to their teaching. Drill-and-practice was their first choice for classroom use (Byrum and Cashman, 1993; Downes, 1993; Wang & Holthaus, 1998-99; Wang, 2000). Preservice teachers did not seem to consider the computer's role as one of helping to develop students' higher order thinking skills as much as their students' computer skills (Dunn & Ridgway, 1991). These studies were not designed to explore preservice teachers' perceptions of their roles as teachers when teaching with computers. Possibly, preservice teachers' perceptions were influencing their computer use.

Up to now, little research has investigated preservice teachers' perceptions of the teachers' role when teaching with computers. Research on preservice teachers' perceptions in the field of educational computing primarily focused on their computer attitudes and computer competence (Beaver, 1990; Boone & Gabel, 1994; Reed, Ervin, & Oughton, 1995; Savenye, 1993).

Preservice teachers' beliefs and perceptions about teaching plays a central role in shaping their professional development and subsequent teaching behaviors. Understanding preservice teachers' beliefs will help to improve their professional preparation. Unexplored beliefs and perceptions of preservice teachers might result in the perpetuation of inefficient teaching practices (Pajares, 1992). With computers becoming an essential part of the learning process in classroom settings, it is imperative to investigate preservice teachers' perceptions of their roles as teachers in this new digital learning environment.

The STUDY

This study was designed to explore the preservice teachers' perception of the teachers' role in teaching and learning. The preservice teachers' perception of the teachers' role is measured as teacher-centeredness and student-centeredness. Three research questions were formulated based on the review of literature.

(1) What are the preservice teachers' perceptions of the teachers' role when they teach in the classroom with computers?

The review of literature established the importance of investigating preservice teachers' perceptions of the teachers' role teaching in the classroom with computers. The research hypothesis for this question is that preservice teachers would perceive their roles to be more teacher-centered rather than student-centered when they teach in the classroom with computers. The null hypothesis is that preservice teachers would not perceive their roles differently in terms of the teacher-centeredness and the student-centeredness when they teach in the classroom with computers.

(2) What are the preservice teachers' perceptions of the teachers' role when they teach in the classroom without computers?

The review of literature points to the fact that teacher-centered teaching behaviors in the classroom with computers are guided by teachers' beliefs and perceptions about teaching and learning in traditional classrooms. If preservice teachers would more likely take the teacher-centered role while teaching with computers, it indicates that preservice teachers' perceptions about teaching remain within the paradigm of traditional teaching and delivery. Therefore, the research hypothesis for this question is that the preservice teachers would perceive their roles to be more teacher-centered rather than student-centered teaching in the classroom without computers. The null hypothesis is that preservice teachers would perceive no difference in the teacher-centered role versus the student-centered role teaching in the classroom without computers.

(3) Do the preservice teachers' perceptions of the teachers' role in classrooms with computers differ from their perceptions of the teachers' role in the classroom without computers?
Based on the first two hypotheses, it is hypothesized that preservice teachers' perceptions of the teachers' role in classrooms with computers would not differ significantly from their perceptions of the teachers' role in classrooms without computers. There would be no significant difference between the preservice teachers' perception of the teacher-centered role in classrooms with computers and their perceptions of the teacher-centered role in classrooms without computers. There would be no significant difference between the preservice teachers' perceptions of the student-centered role in classrooms with computers and their perceptions of the student-centered role in classrooms without computers.

SAMPLE

The setting for the study was at a public university in an unincorporated territory of the United States in the Pacific Rim. The sample for this study was all the preservice teachers (N=78) who had completed all their course work and were ready for student teaching. All the 78 students participated in the survey. Out of 78 questionnaires, four were deemed not usable because of missing items.

INSTRUMENT

The data collection instrument for this study was a survey questionnaire adapted slightly from one originally developed by Bichelmeyer, Reinhart and Monson (1997) at Indiana University to measure teachers' beliefs about the teachers' role when teaching with technology. Two constructs were tested in the survey; teacher-centeredness and student-centeredness. Two scenarios were presented, teaching in the classroom without computers and teaching in the classroom with computers. The participants were asked to answer the questions on their perceptions of the teacher's role teaching in the two different scenarios - in the classroom without computers (e.g. When I teach in the classroom without computers, I believe my role is to keep quiet and order in the classroom.) and with computers (e.g. When I teach in the classroom with computers, I believe my role is to provide individualized learning objectives).

DATA ANALYSIS

Data was analyzed by using SPSS (Statistical Package for Social Sciences).

(1) What are the preservice teachers' perceptions of the teachers' role in the classroom with computers? The result showed that there was no significant difference (t=.48 p=.630) between the preservice teachers' perceptions of the teacher-centered role (M=4.1227, SD=.598) and their perceptions of the student-centered role (M=4.0926, SD=.672). The null hypothesis is not rejected.

(1) What are the preservice teachers' perceptions of the teachers' role in the classroom without computers? The test showed that there was significant difference (t=2.85 p=.006) between preservice teachers' perceptions of the teacher-centered role (M=4.1366 S.D.=.598) and their perceptions of the student-centered role (M=3.9861 S.D.=.647). The null hypothesis is rejected.

(3) Do the preservice teachers' perceptions of the teachers' role in classrooms with computers differ from their perceptions of the teachers' role in the classroom without computers? The comparison showed that there was no significant difference between the preservice teachers' perceptions of the teacher-centered role in the classroom with computers and their perceptions of the teacher-centered role in the classroom without computers (t=.21 p=.837). The preservice teachers' perceptions of the student-centered role in classrooms with computers did not differ significantly from their perceptions of the student-centered role in classrooms without computers (t=1.49 p=.141). The null hypothesis is not rejected.

DISCUSSION
When placed in a classroom with computers, the preservice teachers would likely take balanced teacher-centered roles and student-centered roles when the computers are available in the classroom. To put it in another way, the preservice teachers were neither more teacher-centered, nor were they more student-centered when teaching with computers. It appears that due to the presence or mediation of computers in classroom settings, the preservice teachers considered they would become less teacher-centered, if not more student-centered, than they were in the classroom without computers.

There is no doubt that the computer is a tool that can be used to transform teaching and learning. The review of literature points out that technology can serve as a catalyst to change teachers' teaching pedagogy. Nevertheless, unless preservice teachers confront and restructure their deeply-held teacher-centered beliefs and perceptions, they would not be able to take the full advantage of the technology to impact student learning.

Worth mentioning here is a study conducted by the same researcher focusing on the same group of preservice teachers (Wang, in press). This group of preservice teachers were tested on specific computer use by means of a survey. Six items in this survey were teacher-centered computer uses and six items were student-centered computer uses. Preservice teachers overwhelming pursued teacher-centered computer uses. There was a significant difference between the preservice teachers' choice of teacher-centered computer uses and the student-centered computer uses. The preservice teachers would more likely use the computer as a teacher-centered tool than as a student-centered tool. This study, as well as the other studies investigating preservice teachers' computer use, demonstrates clearly that preservice teachers need to restructure their perceptions about teaching in order to transform their teaching practices in classrooms with computers.

The result of the second research question lends support to the claim that there was a need for the preservice teachers to reconstruct their beliefs and perceptions about teaching. The preservice teachers were more teacher-centered when teaching in the classroom without computers, which obviously is the result of their own educational experiences in the traditional classroom. This result supports findings of the previous studies on preservice teachers' perception of teaching. Despite the current trend in teacher education of the paradigm shift from the traditional didactic delivery of instruction to the constructivist learner-centered approach, preservice teachers' perceptions of teaching gives cause for concern. Most preservice teachers entered teacher education with perceptions that teaching is telling, lecturing and dispensing information. Teachers are information givers. The preservice teachers often underestimate children's capability of understanding and learning (Kagan, 1992). Most studies found that preservice teachers' perceptions about teaching are resistant to change. Faculty were more likely to reinforce preservice teachers' beliefs and perceptions rather than confront and restructure them (Brookhart & Freeman, 1992).

This study found that there was no significant difference between the preservice teachers' perception of the teacher-centered role in classrooms with computers and their perception of the teacher-centered role in classrooms without computers (t=.21 p=.837). The preservice teachers' perception of the student-centered role in classrooms with computers did not differ significantly from their perceptions of the student-centered role in classrooms without computers (t=1.49 p=.141). This result could well be interpreted that preservice teachers would conduct teaching business in the classroom with computers as they do in regular classroom, guided by their beliefs and perceptions of the traditional way of teaching.

CONCLUSION

This research investigated preservice teachers' perceptions of the teachers' role in the classroom with computers and without computers. Few would argue that computers will be more pervasive in our schools in the future. Preservice teachers are potential change agents. It is imperative that preservice teachers develop appropriate teaching styles and perceptions about teaching, especially about teaching with computers. More research needs to be conducted in this area. Such investigations would provide useful information to teacher education training programs. Although preservice teachers' perceptions of teaching is often resistant to change, research has shown that preservice teachers were capable of going through a transformation of their beliefs and perceptions. It is up to teacher educators to guide and direct preservice teachers to challenge, confront, and reconstruct their beliefs and perceptions about teaching and learning.

Internet Based Learning Environments in Higher Education: Experiences from the HALÜBO-Project

Sabine Hornberg, International Comparative and Intercultural Education, Ruhr-University of Bochum, Germany. sabine.hornberg@ruhr-uni-bochum.de

Peter J. Weber, Institute for International Comparative and Intercultural Education, University of Hamburg, Germany. weber@erzwiss.uni-hamburg.de

Abstract:
In our paper we present experiences from a joint Project, which was started in 1998 and since then has been realised every summer term by the Universities of Hamburg, Lüneburg and Bochum (HALÜBO,GER), involving at times up to 80 students. In the respective seminars selected European policies and practices in general and higher Education were studied and discussed by means of traditional seminar working techniques as well as new working tools, e.g., the internet, chat rooms, etc. In our paper we reflect on the advantages and restrictions related to such a mixture of working techniques in view of developing social competence within the Internet.

The European process of integration is steadily moving forward, since 1993 and the coming into force of the Maastricht contract also with a greater effect on European general education systems. Even though this development is by no means yet a central topic for future teachers and others in higher education, it clearly affects their professional and personal future. Another world-wide rapidly developing movement takes place in the field of the new media, especially in the area of internet based teaching and learning: Virtual contact situations, claiming for intercultural as well as media competencies. Why are these important competencies? Intercultural competence in virtual contact situations can contribute to a globalized and regionalized society, permitting peaceful co-existence and leading to the dismantling of prejudices and stereotypes. Up to now the interaction between intercultural and media key competencies has been rarely considered; the subject of social competence, which can be regarded as decisive in global as well as regional contact situations in the Internet, is by no means a central topic of academic research and practice. In our presentation of the HALÜBO-project we will deal with the relationship between intercultural competence and the Internet, in order to enrich the very technically oriented discussion by an often neglected aspect: Based on the presumption of a mutual influence between the Internet and intercultural competencies, the influence of a social competence through the Internet will be discussed on the basis of three case studies, which, due to their paradigmatic character, are of definite importance for the development of a 'global social competence' in the Internet.

Just how far the Internet poses a chance for intercultural learning depends very much on how far the Net lends itself to learning processes. So the important question is, which new opportunities the Internet-based learning environments offer for the development of intercultural competence for learners of different cultural backgrounds. One possible target size lies in the connection of the effects of the new media with a differentiated understanding of society. At the same time, the technical development allows for the integration and creation of an interactive design of the various media. It is at this point where the process of community building becomes increasingly important, since social actors can join forces with one another or with many others because of a common interest. This process will be encouraged in the international context and by the Internet, creating trans-national societies, consisting of many sub-societies. The new media therefore has the potential of being identity-founding, because trans-national societies unite people of different cultures; for example, through trade, immigration and emigration or shared activities in the Internet. This doesn't mean though that the state or the related concept of the international community becomes obsolete nor that the artificial parcellization of the society must increase (Kleger 1997). But because trans-national spaces are at the same time trans-cultural, they require a corresponding competence from the social actors going beyond the traditional intercultural understanding. It must concern itself with a trans-cultural competence which allows the social actors to deal with many cultures of the trans-national society, since with the multitude of contact possibilities, not all specific cultural competencies can be conveyed. Objectives for a global
social competence can therefore be culture-overlapping fundamental competencies, of which a trans-cultural social competence is one, consisting of sociability, communicative flexibility and sensitivity.

The three case studies of the HALÜBO-project represent typical characteristics of international learning environments within the Internet; and although the range of possibilities for their technical design will continuously change, they are of a paradigmatic character because they are based on the following three basic sensitization possibilities: The project is concerned with learning environments working by sensitization through explanation and training (Type 1), through consensus creation (Type 2) and through knowledge construction (Type 3). For Type 1, case study CCED (Cross-Cultural Explorations and Dialogue) was chosen, which online-communication training which since winter 1998 has been expanded by accompanying video conferencing. DEMETER (Distance Education Methods in Teacher Education and Research) was chosen for Type 2 and HALÜBO (Hamburg-Lüneburg-Bochum) for Type 3. On the whole, all three learning environments proved capable of initiating a learning process centered around the creation of a social competence going beyond one culture toward a sociable, open and considerate learner. Within the framework of the exploratory character of the study, it can be suggested that the Internet is well suited to the construction of trans-national societies since, through the development of social competence, the process of community building is supported, whereby people of different nations and cultures band together out of common interest. This bond can also be understood in terms of the perceptions of one's own subjectivity which is part of identity and culture developmental processes.

The best learning effect though, we are convinced, would be the result of a combination of the three types of seminars, since a comprehensive trans-cultural competence cannot be provided by just one type of Internet learning environment. This would be conceivable in serial modularity, a type of seminar not easy to realise in the European university system because of its organisational constraints. The teletutoring structure should therefore have a more pronounced influence on the virtual and partially virtual universities of the future (Geyken et al. 1998). At the same time, only a few universities are likely to prevail as truly virtual institutions (single model). Instead, they are more likely to become Add-on or More-Quality models (dual mode), which perform parts of their services virtually.

Abstract: The significance of technology in today’s society is self-evident. What is less clear is how to ensure that today’s children, the workforce of the future, will have the technological literacy and skills to successfully function and support our highly technological society. Public education is charged with the mission of providing the foundation in not only the basic workplace and personal skills of reading, writing, numeracy, language, and communication, but also, “a high level of competence with computers, telecommunications...and the ability to quickly adapt to new technologies and new ways of working” (National Governor’s Association, 1999). In considering the charge to prepare a future technological workforce the school’s role is to demonstrate technology as an object that is to be used and manipulated. On the other hand, the school’s role as society’s institution of cultural perpetuation emphasizes the use of technology as a tool for learning. These two roles are not necessarily mutually exclusive but they are distinct and schools must have an idea of which role they play—where, when, and how. It is this situation which shaped the Technology in Arizona study—an overview of the state of technology in Arizona’s schools at all levels.

Introduction
To succeed in the nation's economy, workers must be well versed in computers and other high-technology systems. In addition, workers must be able to adapt to changing work structures and be willing to perform a wide range of tasks. Workers today and tomorrow can expect to change jobs several times during their careers. As a result, workers will have to constantly upgrade their skills and expand their knowledge base. They will be lifelong learners. (National Governor's Association, 1999)

The significance of technology in today's society is self-evident. What is less clear is how to ensure that today's children, the workforce of the future, will have the technological literacy and skills to successfully function and support our highly technological society. Public education is charged with the mission of providing the foundation in not only the basic workplace and personal skills of reading, writing, numeracy, language, and communication, but also, in today's world "a high level of competence with computers, telecommunications...and the ability to quickly adapt to new technologies and new ways of working" (National Governor's Association, 1999). Schools across the nation are struggling to educate children about a technological revolution using the technology itself.

In considering the charge to prepare a future technological workforce the school's role is to demonstrate technology as an object that is to be used and manipulated. On the other hand, the school's role as society's institution of cultural perpetuation emphasizes the use of technology as a tool for learning. These two roles are necessarily mutually exclusive but they are distinct and schools must have an idea of which role they play—where, when, and how. It is this situation which shaped the Technology in Arizona study—an overview of the state of technology in Arizona's schools at all levels.

The report is divided into three parts. Part one focuses on Arizona's universities and how they prepare pre-service education students with respect to technology. Part two focuses on the results of two roundtables, one involving business and technology industry leaders and one involving educational leaders, examining the role of technology in education. Part three focuses on five case studies of K-12 schools/districts around the state whose technology programs, and in particular professional development programs, were considered exemplary by K-12 educators, technology coordinators, and education professors.

The Project

The project began when the Senior Project Coordinator of the Arizona Board of Regents (ABOR) asked the Arizona K-12 Center to assist in assessing and evaluating how K-12 schools and universities in Arizona were preparing a technologically literate workforce. A five-part project was initiated to look at various components of Arizona's education system to try to get the "big picture" of exactly how Arizona's schools are preparing students to take their places in an increasingly technological society.

The project team faced its first challenge in finding a frame of reference to shape the project: the standards of business and technology industries or the standards of education could be used. Because the study was sponsored by the ABOR, being carried out by the Arizona K-12 Center, and the team was made up of educational and educational technology participants it seemed appropriate to use educational standards from the International Society for Technology in Education (ISTE) to frame it. Consequently, though the study benefits from the input of the business and industrial sector, it emphasizes how teachers and professors at the K-16 levels can improve the delivery of educational technology education to ensure that students are well-prepared to be successful as a computer/technology workforce and for successfully utilizing computers and technology in their personal and professional lives.

The report begins with the chapter examining the syllabi of educational technology syllabi courses at the three state universities with respect to the International Society for Technology Education (ISTE) standards.

Syllabi of Educational Technology Courses
Using the ISTE Recommended Foundations in Technology for all Teachers as a guide, the project team found that Arizona's universities prepare pre-service teachers in educational technology very differently.

Syllabi of required undergraduate teacher preparation courses in technology from three of the Regent's universities were reviewed for a match with the ISTE Recommended Foundations in Technology for all Teachers in three categories: (1.) Basic Computer/Technology Operations and Concepts; (2.) Personal and Professional use of Technology; (3.) Application of Technology in Instruction. Results of the review indicate that two of the universities mention the ISTE Standards in their syllabi and, in some way, address each of the three general foundational categories. One university does not note the ISTE Standards in their syllabi, but offers activities in courses supporting one category, Basic Operation and Use of Applications. It would seem that there would be less variation about what educational content is taught in required courses. However, it should be noted that the findings of the evaluation were based solely on the syllabi and do not reflect what may have actually been taught, nor does it take into consideration the variability of instructors.

Clearly, universities differ among their conception of educational technology courses and which ISTE standards should receive highest priority if included at all. Whether this is problematic is another issue. If the three Arizona Regent's universities are preparing at least fifty percent of the Arizona teacher workforce, there should be some articulation within and among them as to what content is being covered in educational technology courses. This articulation might help ensure that at least a basic and uniform level of competency and expertise in integration and application of technology in classroom instruction occurs.

In addition to the analysis of the syllabi to determine educational technology course content, it is equally important to know the students' perceptions of their own technology skills. A survey based on the ISTE standards was designed for student teacher participation. A discussion of the survey and its results follow.

Survey of Student Teachers Using ISTE Standards

Again using the ISTE Recommended Foundations in Technology for all Teachers as a guide, the team designed and created a web-based survey to determine how the 243 student teachers at the three Regent's universities perceived their own levels of computer technology competence. Researchers designed and created a twenty-five item Likert-type survey questionnaire based on the ISTE Foundations for All Teachers that included items about Basic Operations and Concepts, Personal and Professional Use of Technology, and the Application of Technology in Instruction. The survey response choices were on a five-point scale ranging from (1) Strongly Agree, to (5) Strongly Disagree, with (3) as Not Sure.

The survey site on the World Wide Web (WWW) allowed students to complete the questionnaire online. Email listservs (distribution lists that allow for one message to be sent simultaneously to many people) provided communication access to student teachers at U1 and U3 to inform them of the survey web site and provide information about the study. Student teachers at these two universities received an emailed invitation to participate through the listserv set up at each school. Students at one university were given the invitation and survey to complete with paper and pencil when they met for a general student teacher orientation. Included in both on-line and hard copy invitations was the added incentive for participation of being entered in a drawing for a gift certificate. With data collected from the student teachers on the questionnaire, researchers sought to determine the perceptions of competence of student teachers graduating from Arizona institutions with respect to meeting the ISTE standards.

The results of this survey have significant implications. First, they provide an indication of which areas of technology in which newly graduated teachers feel they are most and least competent. Second, such results might provide insight into how universities should and/or can better prepare teachers in educational technology.

Results of the survey suggest that the students feel very competent about their basic computer skills and knowledge, but less confident about their competence in more advanced uses of educational technology, such as integrating technology in diverse classroom settings. As this is the area which has the greatest potential direct impact on K-12 students, specifically high school graduates about to enter the workforce, there is a concern about the current preparation of pre-service teachers.

The first finding from the survey questionnaire was the lack of participation from the student teachers who were contacted through email and directed to the survey web site: a total of forty three respondents from
two universities, out of five hundred sixty contacted. There are several possible explanations for this low level of on-line participation: (1) student teachers were very busy and felt that they could not take the time; (2) student teachers did not use their university email addresses and so did not get the invitation; (3) student teachers were uncomfortable taking surveys on line; (4) student teachers were not interested in supporting the study, even with the incentive of a gift certificate drawing.

In general, the student teachers reported competence with, Basic Operations and Concepts, Personal and Professional Use of Technology, and the Application of Technology in Instruction. Although there is little difference among the means, the lowest reported competence is the Application of Technology in Instruction or Integration, and the highest competence level reported is for the Basic Operations. This finding seems reasonable and indicates that teacher education technology courses should perhaps emphasize curriculum integration concepts rather than the basic concepts of using hardware.

Although one might be tempted to claim that student teachers believe they are well prepared to meet the ISTE Foundational Standards, a few important exceptions should be noted. Students appear to have become competent with respect to simple standards that affect their personal use of computers, however significant numbers of students teachers do not feel competent in the more complex uses of computers, especially more complex instructional uses. As this is the area which has the greatest potential direct impact on K-12 students, specifically high school graduates about to enter the workforce, there is a concern about the preparation of teachers.

The ISTE Foundational Standards for Teachers guided the syllabi review and student teacher survey. To explore how Arizonans viewed the use of technology in education two roundtable discussions were held. First, in order to determine what technological skills high school graduates need to enter the workforce, a business roundtable was held. There, recommendations were collected from professionals in business and labor about what high school students should be learning in school in order to improve their chances for employment.

Following the business roundtable, an education roundtable was held, with educators from different schools in Arizona, to share the list of recommendations from the business roundtable. The educators came up with their own recommendations concerning pre-service and in-service teacher education. The ultimate goal for both roundtables was to determine what should be done so that teachers can prepare graduating high school students for the workforce.

Roundtable Discussions

Two roundtable discussion sessions were held to solicit input from various stakeholders in the educational technology in Arizona issue. One roundtable consisted of business and technology industry leaders from companies such as Hewlett Packard, General Motors and US West (Q-west). The main goal was to collect a set of recommendations from three tables of participants about how to better prepare students for the future workforce.

The second roundtable included educators from K-12 schools, universities, and community colleges. The main goal of this roundtable was to collect a set of recommendations regarding both pre-service teacher preparation in using technology as part of instructional delivery and in-service teacher professional development.

At both roundtables participants discussed, from their unique perspectives, their perceptions of how the educational system in Arizona is preparing students to be technologically literate citizens. Business leaders and educators agreed that teachers and their preparation are critical in meeting the workforce needs of the new economy. To provide students with the experiences they need to enter the workforce, teachers need better preparation and professional development that provides them with rich and sustained opportunities to observe, develop, practice, reflect upon, and evaluate technology lessons that meet important content objectives. Roundtable discussion participants recommended that school-university and school-business partnerships could play an important role in improving technology education.

The next section discusses six districts/schools whose technology programs were considered exemplary. Through interviews and on-site visits, six case studies were developed that focused on each school’s
technology programs and more specifically professional development in this area. Professional development of teachers is a crucial factor because it ultimately impacts how technologically adept students will be.

**K-12 Case Studies**

Six case studies examined the technology programs of a variety of Arizona K-12 districts and schools that were deemed "exemplary" by professors, K-12 educators, and technology directors around the state. The case studies focused on the professional development programs and activities in educational technology to determine how in-service teachers are being educated in technology skills and literacy. Six case studies were conducted. Forty-seven individuals were interviewed in thirty-three sessions. This information summarizes findings across all the cases, which varied along many socio-economic and geographic dimensions. Schools and districts in the northern, central and southern part of the state were represented. Large urban districts and small rural districts were represented. Districts with 100%, 50%, and 0% free and reduced lunch were represented. Finally, districts with high and low minority populations were also represented. Thus, the schools and districts making up this part of the project are a diverse set.

These descriptive studies revealed that a complex set of variables impact professional development and the implementation of technology programs for in-service teachers. Professional development programs that promote the effective use of educational technology are based on:

- Ongoing substantial support by the school district
- Commitment of resources
- Leadership with a clear vision
- Clear communication
- Meeting the real needs of the participants
- Partnerships

Teachers interviewed in the case studies appear to believe strongly that the above components lead to the improvement of teaching and learning.

**Conclusions and Recommendations**

The Technology in Arizona project highlights a number of areas in Arizona's K-16 educational system in which the teaching of educational technology might be enhanced. The following recommendations stem from the four parts of the study: review of university syllabi, survey of student teachers, business and education roundtables, and the case studies.

**Arizona's Regent's Universities**

- University educational technology courses should further focus on and emphasize the ISTE Foundation Standard category Application of Technology in Instruction
- All the university teacher education programs should ensure that all the ISTE standards are addressed through any combination of courses offered
- All course content offered in the Regent's universities’ educational technology courses should be assessed using performance-based measures rather than just content knowledge assessment
- University faculty working with pre-service teachers should have the necessary skills to teach and model the integration of technology in diverse K-12 classroom settings and do so in their own instruction
- University faculty teaching educational technology courses should be provided opportunities for ongoing professional development
- Exemplary teachers who integrate technology should serve as mentors to pre-service teachers
• All graduating pre-service teachers should be held accountable by demonstrating a minimum level of proficiency with respect to a set of educational technology standards, i.e., the ISTE Recommended Foundations in Technology for all Teachers.

K-12 Instruction

• Encourage teachers to be “coaches” of learning in order to facilitate their students’ learning of technology
• Promote team teaching partnerships between teachers and mentors from business and the technology industry
• Provide options of different tracks in schools for student who want to enter the workforce immediately following high school rather than attend college, but ensure that students of either track have basic literacy, numeracy, and technology skills
• Integrate technology into the school curriculum with a focus on providing a “wholistic,” integrated educational model for the student of reading, writing, numeracy, problem-solving, and technology skills
• Provide opportunities for authentic applications of technology both inside and outside the classroom
• Hold practicing teachers accountable to a minimum level of educational technology proficiency, i.e., ISTE Recommended Foundations in Technology for all Teachers, through their district evaluation process
• Develop district technology plans to guide the implementation of the classroom and computer lab use of technology
• Ensure equitable access to computers and technology for both students and teachers

Professional Development for Educators

• Use a peer mentor “teacher-coach” model for staff development in educational technology
• Ensure that professional development in educational technology is relevant to teachers’ needs and the school curriculum
• Provide time during the school day and school year for ongoing professional development
• Develop professional development activities in educational technology which are continuous and sustained
• Obtain the support and endorsement of school and district administrators for professional development and evaluation in educational technology
• Base professional development in educational technology on research in best practices in learning and teaching
• Evaluate and reward teacher proficiency in computer/technology use in the classroom
The 2001 SITE Annual Meeting Science section offers 21 presentations that encompass a wide range of topics related to use of instructional technology in a variety of classroom settings, from the elementary school classroom through the university setting. Authors provide information about both preservice and professional development projects, specific project and program reviews, and research about how students and teachers learn. Inquiry in teaching, integrating the science disciplines, is a common theme across the articles. Roach has a Ph.D. in science education. She teaches science methods courses and curriculum courses at Northwestern State University of Louisiana. Her e-mail address is roachl@alpha.nsula.edu.

Project and Program Reviews

Assumpcao, Passow, Corder, Baggio, and Ortiz describe a unique, on-line, distance learning teacher training project called Earth2Class. This series of workshops focuses on integrating technology into an Earth Science curriculum. Presented by scientists, teacher-participants gain content background about earth science concepts through videoconferences and work through classroom-ready instructional materials at a supporting website. Other resources on the Earth2Class web pages provide links to scientific, education, and government sites.

Beal explains an innovative project in which preservice teachers work with middle school students to preserve a North Carolina inner city wetlands area. After completing real-world, action research the participants compiled data and presented their research to the North Carolina State University Spell of the Land Symposium. Beal describes the process of building a meaningful service learning program.

Coverdale presents results of research on the value of a technology-rich interdisciplinary curriculum, Quests (i.e. AfricaQuest, AsiaQuest, AmericaQuest). It analyzes the projects with respect to students’ abilities to conduct investigations, and understand both science concepts and the nature of science, after completing the curricular units. Preservice teachers’ reflections on their own participation in Quests are also reported.

Dove and Zitkovich report on a collaborative project, Boardman Local Schools Our Lake Online, in which elementary students take a digital expedition to the Lake Erie shoreline. Results of one set of 33 students’ onsite observations and experiments were digitally transmitted to over 450 students who participated remotely through asynchronous inquiry-based science. High school students provided technology training and assistance for the elementary teachers and students. Information about student learning about science and technology are presented as well as “lessons learned” by the researchers in undertaking this innovative learning experience.

Gao reviews a technique for embedding problem-based-models into a class web site as a supplement to traditional instruction. The model includes problems to be solved, review, tutoring, hints, self-tests, and solutions.

Hochman, Marshall, and Oyenarte demonstrate how technology can make outdoor education more authentic. At Camp Crystal Lake, 2nd grade and 5th grade students collect data in each of three ecosystem environments. Prior to their field experiences, students participate in online activities which coincide with the types of activities they will be doing in the field. This presentation provides an overview of the camp experiences, including data collection techniques and the connectedness of the on-line and field experiences.

Lustigova and Zdena review an Internet-based package called Remote and Open Laboratory based at Charles University in Prague, Czech Republic. Geared toward both initial teacher training and in-service professional development, participants use modern tools and techniques for data acquisition and processing. Large databases of experiments and computer models provide teachers with a wealth of information and allow them to compare the results of their own experiments to those of others. Users can download experiments and models and adapt them to their own classroom conditions and needs.
Technological Field Trips

Clark, Hosticka, Scharlier, and Bedell report on use of technology to create virtual field trips. They provide advantages and limitations of such an undertaking and review types of technology commonly found in public schools which can be utilized in such efforts.

Slator, Saini-Eidukat, and Schwert take us into a virtual world where learners become geologists, planning an expedition, and dealing with the virtual environment to report their findings. As goals are satisfied, learners move to progressively higher levels of expertise as they learn to think and act like real geologists. In addition to a description of the field trips, a report of research into student learning and accomplishments is presented.

Technology in the Classroom

Akpan outlines the use of computer simulations to prepare students for dissection activities.

Jones, Superfine, Taylor, and Andre use advanced technology in high school classrooms. They provide detailed information about the use of the Atomic Force Microscope, controlled by scientists, via the World Wide Web, in biology classrooms. Research conducted by this team with regard to gender differences, students' understandings of the nature of science, scientists, and scientific careers is also reported.

Mochon offers a description of a program in New Mexico that utilizes mathematical based explanations to support science teaching at the high school level. Students use spreadsheet technology to enhance science learning.

Molenaar presents multimedia techniques used in a high school physics classroom and preliminary research results.

O'Toole and Doe provide strategies for integrating diversity issues into the science classroom through the use of the Internet. A review of the web-site is presented as well as suggestions for use at all grade levels.

Ray, Patterson, Jenks, and Hocutt show how to use Palm Pilots, hand held computers to grade student laboratory activities in real time.

Slough, Chamblee, and Auli describe an integrated middle school weather unit. Local weather measurements, taken by students, are supplemented with TV weather reports. With Internet enhancement, climatological data, not previously available can be included in classroom experiences. A fully developed unit will be shared.

Suits shares results of three types of instructional technology are used to help students make meaningful connections between phenomena and scientific principles. Microcomputer-based laboratory experiences, computer-simulated experiments, and multimedia learning modules are discussed.

At The University

Garcia and Faria present an integrated, Environmental Science based inservice studies via an online course. Teachers develop integrated learning activities for use in their own classrooms.

Kiser, Bell, Flory, Miller, and Pushnik work to enhance the basic core university science curriculum with an integrated course based on the topic of Global Warming. Using computer modeling, traditional laboratory experimentation, web-based research, and problem-based learning in an integrated format, the emphasis is on the processes of doing science.

Marshall, Pringle, Dawson, and Hochman, at the University of Florida offer an integrated math, science, and technology block to undergraduate education majors. They offer information about the course, program planning, and preliminary research results.

Teixeira describes a game developed to teach students the intricacies of lymphocytic immunogenetics. It consists of steps which simulate the developmental stages of lymphocytes.
Using a Computer Simulation Before Dissection to Help Students' Learn Anatomy

Abstract: The scientific community and the nation's schools have been experiencing a self-proclaimed ethical crisis over animal dissection in classrooms. While this issue involves intractable ethical and philosophical positions, one ethical implication of the debate is that if dissection is used in schools, it should be used for maximum educational benefit. One intriguing previous finding was that use of an interactive videodisc dissection learning from subsequent actual dissection. This study examined the prior use of simulation of frog dissection in improving students' learning of frog anatomy and morphology. There were four experimental conditions: simulation before dissection (SBD), dissection before simulation (DBS), simulation-only (SO), or dissection-only (DO). Results of the study indicated that students receiving SBD and SO learned significantly more anatomy than students receiving DBS, DO. The genders did not differ in achievement.

Introduction

Use of computer simulations for dissection in the classroom has gained popularity. The idea that experiences are most essential to conceptual development is central to several theoretical perspectives. Piaget's (1954) theory argues that knowledge is constructed through action. Bruner (1966) adapted Piagetian theory into the idea that learning requires experiences at an enactive level before iconic and symbol experiences can become meaningful. Andre (1986) argued that developing effective problem-solving schemata required appropriate experiences to promote the development of the pattern recognition component of a schemata. Simulations provide a potential means of providing learners with experiences that facilitate conceptual development. As Thomas and Hooper (1991) put it, when a simulation precedes didactic instruction, the simulation experience may provide motivation, improve performance, provide an organizing structure and may reveal misconceptions. Thus, a simulation of frog dissection provided before actual dissection may function as a conceptual model that allows students to better understand and encode the dissection presented information. Students who experience simulation after dissection may not have a meaningful model with which to assimilate the dissection information. The effects of engaging students in simulation tasks either before or after completion of actual dissection have been the focus of a number of research studies for example Kinzie, Strauss, & Foss (1993) compared the achievement and attitudes of students who conducted a frog dissection either with or without the use of interactive video (IVD) simulation as a preparatory tool before actual dissection. In these studies, students who received simulation as preparatory tool before actual dissection learned more effectively than those students who received
no preparation and more effectively than students whose preparation consisted of viewing the linear videotape. We further explore the use of simulation before or after dissection in the present study.

The Study

The participants were approximately 127 students (59 males, 68 females) ranging in age from 13-15, enrolled in a seventh grade life science course in a mid-size mid-western middle school of 800 students. These students had some experience in animal dissection, but had no experience in the use of a simulated dissection. These students participated in the study as part of a normally scheduled laboratory involving frog dissection. Because it was a regularly scheduled class activity, all students in the classes participated in the activity. Data, however, were used only for those students for whom signed permission was obtained from both the student and a parent. Of the 127 eligible students in the participating teacher's sections, 44 were absent during at least one of the experimental sessions due to illness or inclement weather. Two students whose identifiers could not be matched with their ITBS scores were also excluded from the study. These factors reduced the total number from 127 participants to 81 (34 males, 47 females). To maintain student confidentiality, all data were coded with assigned identification numbers rather than names.

Design

Participants were unsystematically assigned to the periods at the beginning of an academic school year based on teacher recommendation and final grade in sixth grade science in a manner so as to roughly equalize ability across sections. In this study, class periods were randomly assigned to four experimental conditions: In the simulation before dissection (SBD) condition, students completed a simulated dissection before completing an actual frog dissection. In the dissection before simulation (DBS) condition, students performed an actual frog dissection before the simulated dissection model. In the dissection only (DO) condition, students completed an actual frog dissection only. In the simulation only (SO) condition, students completed only the simulated dissection.

Simulation sessions

The simulation sessions for the SO, SBD and DBS conditions were conducted as follows. Students met during class times in the regular computer lab. The participants were seated individually at computer stations. The participants were introduced to the computer simulation and given an instructional guide, which included pictures of dissected frog parts and a description of their functions. The students were shown six systems of the frog dissection that they could navigate on their own in any sequence they chose. They were also shown four interactive minilabs, in which they could investigate the frog's respiration, digestion, circulation and muscular capacity.

Dissection sessions

In the dissection laboratory, student worked at one lab table side by side in the room. Two researchers were present during dissection sessions. When a student was not able to perform an assigned step or could not remove an organ, the researcher assisted the student after the finished dissection products had been evaluated. The achievement posttest was administered three days after the dissection was completed.

Findings

The anatomy and morphology achievement test. Preliminary internal consistency analysis using Cronbach's alpha indicated that five items had negative or zero item total correlations. These items were eliminated from the achievement pretest for that reason. The internal consistency estimate (using Cronbach's alpha) of the remaining 20-item scale was 0.55. The alpha for the posttest was 0.60. While low, these reliabilities were judged acceptable for this research. Lower internal consistency should increase error variance and reduce the likelihood of finding a significant effect. Thus relatively low internal consistency should increase confidence in any significant effects found.
Pretest Data

In the analyses of differences between conditions, an alpha level of .05 was assumed unless otherwise specified. F-values are reported for significant effects only.

Achievement pretest. Differences between the four conditions on the pretest were assessed by Gender (male versus female) X Treatment (SBD, DBS, SO, DO) ANCOVA with ITBS Science score as the covariate. There were no significant main effects or interactions found indicating pre-experimental equivalence of the four conditions and the two genders. The treatment means are reported in Table 1.

Posttest Data

The anatomy and morphology achievement posttest. The posttest achievement data were analyzed using a 2 (Gender) X 4 (Condition) X Test Time (Pretest vs. Posttest) between/within ANCOVA with ITBS science score used as a covariate. Test time was the within subject variable. The ANCOVA revealed a significant main
The results of this study supported the theory that prior use of a simulation before dissection can improve learning. The treatment group that completed the simulation activities before the actual hands-on dissection performed significantly better on the achievement posttest and dissection performance test than the other three groups. These results are consistent with those of Kinzie, Strauss, and Foss (1993) who compared the achievement and attitudes of students who conducted a frog dissection with and without the use of an interactive video-based simulation used as a preparatory experience for the actual frog dissection. As in the present study, their results indicated that students in the interactive video simulation preparation group scored significantly higher on the posttest achievement measures than did other three conditions.

The results obtained in the current study offered little support for the hypothesis that there would be a significant difference in the learning patterns of male and female on the posttest achievement means and the dissection performance test. No differences in posttest achievement or dissection performance were found between male and female participants in any condition. This failure to find a gender difference in the present study run counter to the results of Andre and Haselhuhn (1995). Andre and Haselhuhn found that males who completed a simulation activity before reading a text on principles of motion learned more from the text than males who did not use the simulation before reading. For females, no significant differences were found. In a followup study, Andre et al. (in preparation) found positive effects of a prior simulation on learning the principles of motion for both males and females, but overall males did better than females. The differences between the Andre and Haselhuhn and the present study may be due to gender differences in interest and experience with the content. The present study focused on biological content whereas the Andre and Haselhuhn study focused on physics. Differences between females and males in interest in the biological sciences are substantially smaller than differences in interest in physical science and in physical science course taking (Kahle & Meece, 1994; Andre, Whigham, Hendrikson & Chambers 1997).

A second possibility is that the nature of the simulations used related to the gender differences. The simulation used in the Andre and Haselhuhn (1995) study was more exploratory and less directive than the simulation used in the present study. In the present study, the simulation directed students to remove particular organs.

It may be that directiveness and prior knowledge, experience, or interest interact. When interest, experience or knowledge are low, as is typically the case with women and physical science, students may have difficulty connecting experience in an open-ended exploratory simulation to later didactic instruction. With higher knowledge levels, or greater directiveness in the simulation activity, connections between a simulation experience and a later experience may be easier for students to perceive. However, these interpretations are speculative; the large number of differences between Andre and Haselhuhn (1995) and the present study preclude firm conclusions. But the differences in the studies raise fruitful lines of inquiry for subsequent research.

In the current study, the lack of gender differences support the results of Tylinski (1994) who found no significant difference in the learning patterns by gender when using either a computer simulation or traditional hands-on method of dissection. The present results also are consistent with Choi and Gennaro (1987) who found no gender differences in their study of the use of simulations to teach volume displacement to eighth grade students.

The most intriguing result of the present study was that a simulation used before dissection led to better achievement performance than a simulation used after dissection. This difference cannot be attributed to a difference in the amount of instruction received as the students in the simulation before dissection and dissection before simulation conditions had equivalent amounts of instruction. Nor can the difference be attributed to a Hawthorn effect of using a new instructional tool or to a motivational effect of the computer based simulation. Both the simulation before dissection and dissection before simulation conditions received the same computer experience. The difference has to be due to the sequence of presenting the simulation before the dissection.
The study also looked at the students' attitudes toward dissection. The dissection-only condition was more accepting of dissection than the other two conditions; dissection before simulation and simulation before dissection. However, attitude toward dissection did not change differentially as a function of experimental condition over the study. Similarly, the students' attitude toward computers and attitude toward school and science scale remained consistent from the pretest to posttest. These results supported Kinzie, et al. (1993) who found that the attitudes toward dissection remained relatively stable from pretest to posttest. McCollum (1988) also compared lecture versus dissection in a high school biology and found no significant differences in group attitudes toward frog dissection before and after the end of the experiment. One reason why the student attitudes did not change may be that their opinions were formed across experiences in six school grades. A single experience is unlikely to change such long-term attitudes.

The results obtained in the current study offered little support for the hypothesis that there would be a significant difference in the learning patterns of male and female on the posttest achievement means and the dissection performance test. No differences in posttest achievement or dissection performance were found between male and female participants in any condition.

There are a number of limitations in the present study. The participants were mostly white, middle class, seventh grade middle school students in a single, midwestern, homogeneous school district. The limited diversity in students obviously limits generalization to students in other environments and grades or from different cultural and socioeconomic backgrounds. Nevertheless, it is assumed that students in the present study were reasonably typical of the population of white, middle-class, midwestern middle school students. In addition, we excluded data from all identified special education students from the study; generalizations to special needs students should not be made. It is possible that taking the pretest influenced posttest scores. This potential influence may mean that data obtained from the study could not be generalized to situations in which pretests are not used. Because the pretest was administered three weeks prior to the time of the actual dissection, it is possible that learning occurred between the pretest and the beginning of the study. However, as this difference occurred for each of the groups, it is unlikely that it influenced the different results found between the conditions. Finally, because the standard error of the statistic is decreased with an increased in sample size, the smaller sample size of this study may limit its generalizability.

Conclusion.

The results of the present study suggest that presentation of a computer simulation before the actual dissection may provide an experiential base that enhances learning. This finding suggests that computer-based simulations can offer a suitable cognitive environment in which students search for meaning, appreciate uncertainty, and acquire responsibility for their own learning. These results are in agreement with previous results that the use of computer simulation before actual dissection or alone can provide a better experiential base for students to master the anatomy and morphology of frogs than can the use of simulation after dissection or dissection-only.

Although the use of simulation before actual dissection may provide an experiential base that enhances learning of new information, simulation may not be equally effective for all students. The degree to which students benefit from simulation before actual dissection may depend on the prior interest, knowledge, and experience that the student brings to the instructional situation.

Abstract: “Earth2Class” (E2C) is a unique science, math, and technology learning resource for K-12 students, teachers, and administrators created through the collaboration of researchers at the Lamont-Doherty Earth Observatory, curriculum and technology integration specialists at the Institute for Learning Technologies, a Maury Project Peer Trainer, and teachers from the New York City metropolitan area and rural upstate New York. During the winter and spring of 2000, E2C presented workshops for teachers at the Lamont-Doherty campus in Palisades NY that were transmitted live to others in Glens Falls. Before, during, and after each workshop, participants and others were able to utilize the resources available on the E2C Internet site, www.earth2class.org. E2C relies on a unique synergy of specialists in curriculum, educational technology, and scientific research, but the key feature is involvement of the Lamont scientists. Their availability through workshops, web site postings, and e-mail expose teachers to stimulating cutting-edge research that help the teachers develop K-12 curriculum activities linked directly to “real world questions.” Drawing on the scientists' expertise, teachers can show students how the science they are learning applies outside the classroom, as well as to other aspects of their studies.

Introduction

While expectations for student achievement are increasing, many teachers do not have adequate content knowledge to effectively teach science or math; nor do most undergraduate-level science and math courses model the pedagogical approaches prospective teachers will need in the K-12 classroom. Once in the classroom, beginning teachers are usually expected to be fully qualified, and often do not receive the support needed to improve and refine their content knowledge or pedagogical skills (CEO Forum on Education and Technology, 1999). Teacher education should be viewed as a career-long process that allows teachers of science, mathematics and technology to acquire and regularly update the content knowledge and pedagogical tools needed to teach in ways that enhance student learning and achievement in these subjects (CEO Forum on Education and Technology, 1999; Getting America's Students ready for the 21st Century: Meeting the Technology Literacy Challenge, 1996).
“Earth2Class” (E2C) is a unique science/math/technology learning project that combines workshops by research scientists with on-line resources available at www.earth2class.org and distance-learning staff development programs. E2C has the potential to become a major resource for educators in the atmospheric and related sciences. This paper provides a general description of the “Earth2Class” project.

Project Background

“Earth2Class” developed out of a series of workshops organized by AMS Maury Project Peer Trainer Michael J. Passow and held at Columbia University’s Lamont-Doherty Earth Observatory in Palisades NY. In each session, participants gained background information concerning atmospheric, oceanographic, climatic, and other concepts related to the theme, then interacted with the featured scientist describing his/her cutting-edge research. In addition, teachers worked through teacher-training and classroom-ready instructional materials developed by the Maury Project, Project Atmosphere, and other AMS Education Program efforts, among others. Kelly Corder proposed a collaboration that could make the benefits of the scientists’ presentations available to more teachers, using as a pilot program those associated with the North Hudson Electronic Education Empowerment Project. Cristiana M. Assumpcao and Frederico Dalmas Baggio from the Institute for Learning Technologies, Teachers College, Columbia University, provided the hardware and expertise to develop the supporting web site (www.earth2class.org) and handle the videoconferences, as well as bring in the technology integration components to the curriculum. Through teleconferencing links with the North Hudson Electronic Educational Empowerment Project (NHEEEP), based at Adirondack Community College, Glens Falls NY, they were able to present the “live” presentations at LDEO to teachers more than 320 km away. Using a supporting web site, www.earth2class.org, participants were able to access and work through some of the workshop activities as they were being presented. These were later edited and made available to anyone interested in the PowerPoint, activities, and other components of the workshop. In addition, other resources on the www.earth2class.org web pages provide educators and their students with links to many useful government, science and science education, and other Internet sites; web-based classroom activities; and examples of appropriate curriculum and assessments.

Workshop Themes

Briefly, the themes for this year’s Spring series and guest scientists included:

“Predicting Natural Disasters” with Arthur Lerner-Lam

“Nothing can beat the excitement of collecting a singular piece of data, of measuring it delicately, of pronouncing it fit, and extracting its story. One thing an academic program in science must do is communicate science by current example and past history. Columbia’s Department of Earth and Environmental Sciences and Lamont-Doherty Earth Observatory combine to do this very well. Whether we’re in the field, at the bench, or in front of a computer, we all seem to feel and draw on the institutional memory here. You have to keep poking at the earth to learn its secrets. As a seismologist, I do a lot of field work collecting data from earthquakes and explosions. I use these data to model the structure of the upper mantle and crust.”

But just how predictable are natural disasters? How can appropriate information and warning reach the general public? What about other kinds of natural hazards—hurricanes, tornadoes, winter storms, heat waves, etc? This workshop will provide the chance to find out more about such problems, and develop some ideas about how to present these topics to your students.

“El Nino, La Nina, and the North Atlantic Oscillation” with Martin Visbeck

My main research interest is to understand the ocean’s role in the climate system and its consequences for society. How is decadal climate variability orchestrated? Does the ocean influence atmospheric variability in mid-latitudes? What is the North Atlantic Oscillation? Does primary productivity depend on decadal variability? Can we forecast deep convection in the Labrador Sea? And what role do the polar oceans have
in the climate system? I have worked on a number of problems using ocean models and data from sea-going expeditions and enjoy thinking about the nuts and bolts of the daily science as much as developing new multidisciplinary research programs for the years to come.

"Winds, Currents, and Cores" with Donna Witter and Rusty Lotti Bond

The recently launched QuikSCAT satellite scatterometer (NASA) is returning high-quality data that will be used by oceanographers and atmospheric scientists to study winds over the ocean on a wide variety of time scales. From a climate perspective, one of the most exciting applications of this technology is that statistical analysis of short records of satellite data can be used to improve estimates of wind variability on long time scales (e.g., decades to a century). On these longer time scales, the wind record from ships at sea is spatially and temporally filled with gaps and subject to larger errors. Several of us at LDEO are using satellite wind observations to better understand deficiencies in the historical data sets and to develop new wind climatologies for the historical period. My presentation will describe this work, and discuss its use for assessing climate change during the past century. The specific topics which will be covered in the presentation include: 1) the technological aspects of measuring winds from space; 2) using these measurements to understand recent wind variations, and 3) using these measurements to understand wind variations on climatologically significant time scales and for times prior to the launch of wind-observing satellites.

Rusty Lotti Bond, Curator of the Lamont-Doherty Deep-Sea Sample Repository, oversees the collection, processing, archiving and physical properties analyses of the largest collection of material from the below the ocean floor. The Lamont-Doherty Deep-Sea Sample Repository collection of sediment samples provides material for scientists worldwide to research many facets of our earth's systems. Deep-sea cores contain microfossils and minerals that can be used as environmental indicators, or reveal climate change. The cores hold a permanent record of geological events such as earthquakes, changing sea levels and shorelines, and the earth's magnetic history. Variations of color and texture resulting from changes over time in the sediment are clearly visible in the cores. Samples from the different intervals can be easily processed for observation of the variations in number or kinds of microfossils or minerals. The dynamics and significance of these changes will be explored in the workshop.

"Climate Changes over Various Time Scales" with Joseph D. Ortiz

The objective of this workshop was to provide teachers with an introduction to the factors that drive climate change on a variety of time scales. Dr. Ortiz will discuss processes that drive climate on a variety of timescales from the seasonal to 10's of thousands of years. Study of the Monsoon system serves as an example of how some of these climatic forcing functions interact. On seasonal timescales, Monsoon circulation systems in African, India and Asia are driven by the thermal contrast between land and sea. Likewise, during times in the geologic past when orbital parameters maximized seasonal contrast, enhanced Monsoon systems existed. This effect has been successfully simulated with global climate models (GCMs) and observed using geologic data such as lake level records. Material presented in the workshop, including a presentation of educational software on the Monsoon, and lists of internet-based educational material provides a rich context for teacher to explore the natural phenomenon of climate with their students on a variety of levels.

"Studying the Sea Floors and Sea Surface from Space" with Christopher Small

Studying the sea surface and deep ocean floors has come a long way from the lead weights on piano wire lowered over the side of the "HMS Challenger," and even from sonar so widely used since the 1940s. Today, satellites flying high above the surface can send radar and other beams that reflect off the sea surface and bottom, and can be translated into detail images. Such satellite data has made possible new understanding of how changes in sea surface temperatures can affect global climates. They can measure variations in sea surface heights, revealing that the "sea level" is actually far from "level." They can discover previously-unknown volcanoes and other features lying in the ocean depths.
Dr. Christopher Small shared his expertise in Geophysics and Remote Sensing. His current research involves analyzing seamount volcanism in the southern Indian Ocean using multibeam sonar data and image processing software.

"EarthView Explorer (part 1 and 2)" with O. Roger Anderson, Raymond Sambrotto, John Armbruster and Kevin Griffin.

Earth View Explorer (EV) is a novel, computer-based learning application based on constructivist principles that encourages students to explore data, invent hypotheses and test them, and in many respects inquire about their environments as do scientists. The EV application contains four units: 1. Geosphere, 2. Hydrosphere, 3. Atmosphere and 4. Biosphere. In the first session, we will introduce the basic rationale for this curriculum innovation and its use, and through group, hands-on, experience develop with the workshop participants how to use the first two modules in teaching. All participants received a free copy of the CD-ROM disk.

In the second session, we explored the use of the modules on Atmosphere and Biosphere though presentations by Columbia University scientists and science educators and explore, through hands-on use of the modules, how these can be applied to teaching earth and environmental sciences in pre college education.

**General Workshop Setup**

Briefly, for each session, video cameras and two-way audio connections enabled participants at each location to view what was happening on large-screen projections, so interactions were easily made. Computer connections allowed participants to work through activities as the presentations were in progress. By using Netmeeting, one computer was connected just to share the desktop of the scientist's computer in order for the distance teachers to be able to follow more easily what was being demonstrated, while a second computer was connected with video and audio, so that the distance teachers could see the presentation and ask questions. Teachers could also explore other aspects of the CDs and web-based activities during the sessions. In this way, the workshops moved far beyond the "talking heads" often involved in distance-learning formats.

**Teacher Enhancement**

Announcements about these workshops were distributed through List-Servers, regional teacher centers, conference fliers, and other formats. Teachers involved in the workshops at the LDEO campus came from a variety of public and parochial schools in the New York/New Jersey area. They paid a nominal fee of $10 per session toward costs. Credit for attendance was possible, but no graduate course credit arrangements were available. Teachers at Adirondack Community College were participants in the North Hudson Electronic Educational Empowerment Project, a three-county consortium serving many districts in the region. Assessment of E2C workshops was obtained from the teachers through an on-line section of the web site. Information from the responses is being used to shape future offerings to enhance technological skills and subject area knowledge of participants.

**Future Plans for Earth2Class**

Based on the experiences obtained in this series, the "Earth2Class" team is engaged in efforts to expand the scope of the program considerably in the 2000 – 2001 academic year. Nine workshops are planned for the current year. These include updated presentations by most of the past presenters, stand-alone online asynchronous modules using the scientists as instructors in association with Earthscape, Columbia University Press, as well as new themes dealing with applications of educational technology, rocks and minerals, core/mantle studies, and hydrology. Partnerships with established Columbia University electronic education programs are underway that will significantly improve the technological basis of E2C offerings, as well as expand the potential participatory base.

**Conclusions**
“Earth2Class” provides an excellent example of how research institutions schools of education can work with classroom educators to enhance science achievement. Despite occasional glitches from pushing the limits of bandwidth and other aspects of currently available technology, this approach received excellent responses from participants. E2C will expand to include additional scientific areas, for-credit training in both science content and educational technology, and more effective use of Internet-based resources.

Using Technology to Help Strike a Blow for Education and the Environment – A Case Study in Real World Preservice Teacher Education

Dr. Candy Beal, Department of Curriculum and Instruction, North Carolina State University, USA
candy_beal@ncsu.edu

Abstract: This research paper follows a process used to build a meaningful service learning project that integrated all core subjects and the arts and enabled preservice teachers to aid classroom teachers in teaching and learning about issue driven curricula whose study is enhanced by technology. The project was built around an effort to study and save an inner city wetland. The team of teachers, preservice teachers and students used computer technology to research the issue and build a case for preservation which they presented at a university-wide symposium. This project clearly demonstrates that technology integration is most powerful when used as a tool for real learning, especially about real world issues.

WANTED: Early adolescents and their teachers in need of a reality based/service learning project to serve as a capstone for their eighth grade year, preservice teachers eager to put middle school teaching and learning theory into practice and university professors seeking meaningful ways to teach the importance of sense of place, interdisciplinary curriculum development and technology integration. JOB DESCRIPTION: Work with a coalition of church groups, Partners for Environmental Justice, to learn about and champion a woefully neglected wetland area in the capital city that is home to plants, animals and educationally and economically deprived minority citizens who have been under served by their city government representatives.

One hundred eighth graders and their four teachers teamed up with North Carolina State University professors and their students and representatives from the State Department of Public Instruction to become part of a reality based integrative service learning project. It was a match that enabled the middle school students to see that what they learned in school could be applied to solve real world problems. College students found the same. Theories of adolescent development and approaches to teaching and learning using technology could be observed and practiced in a middle school setting rather than just read about in college textbooks. University teacher educators were able to demonstrate theory to practice by developing a service learning project that partnered schools and community in an issue driven curriculum (Beane, 97).

Schools are struggling today to balance the teaching of discrete facts and skills demanded by the testing craze with the importance of students understanding how to apply what they have learned in a thoughtful and reflective manner. Increasingly, it has also become more difficult for teachers to compete with the high tech toys that promise flash and dash and give immediate feedback and gratification. Helping students focus on their studies, set goals for their own achievement and see themselves as successful learners demands meaningful, worthwhile lessons. The added pressure of having all students ready for tests and jobs that require technology competence leaves teachers wondering how to get it all done.

Selecting a high interest service learning project is the answer to many of the challenges that face teachers today (Arnold & Beal). Students achieve focus in their study of a meaningful project and see the application of what they have learned in school to a real world situation. They are able to apply technology skills to the study of that problem and understand the importance of developing and using technology to get facts and information that was previously unavailable through conventional means. They are empowered and feel valued by the contributions they make to their community.

Teachers at the Centennial Campus Middle School and at North Carolina State University in Raleigh, North Carolina, joined forces to engage the middle school students in an environmental service project of a neglected capital city wetland that bordered an impoverished housing area. The middle school teachers taught a theme based, multidisciplinary, integrative unit that addressed all facets of wetlands research from the study of science -- living systems and habitats, flowcharts of problem cycles, topography mapping, social studies -- GIS mapping of demographics, disenfranchised groups and social change throughout history, community activism, city government and history (Beal, 92), environmental justice, laws and the
decision making process, understanding diversity and respect for differences, math -- study of proportions/ratio, cost calculation, preparation of a spreadsheet to show the types and amount of garbage found at the site, language arts -- reflective and creative writing, preparing effective letters to city officials. Case studies of the Centennial Campus development and Neuse River water quality, as well as labs that dealt with erosion, river systems, and area profiling were augmented by exploratory classes in the use of Excel to graph data findings, word processing and PowerPoint to prepare presentations, use of the arts to express appreciation or concern through photojournalism, song writing and sketching.

Preservice teachers were part of the process from the beginning. One student teacher with expertise in environmental education planned and presented a workshop about the plants and animals that students would see in wetland areas. She and a botanist brought in tubs of wetland plants for the students to touch and feel. They discussed environmentally sensitive ways to conduct a field trip to a wetlands. Students brainstormed what was needed to live, how much of our own bodies were water and the importance of water to everyday life. They discussed the purpose of the wetlands and shared the information that they had gleaned from their weeks of research on the web. College students from a middle school foundations class attended the workshop and had the opportunity to interact with the students. Following the hands-on workshop at the school, 100 students did field research in the wetland area.

The field trip involved an entire day. Fifty students conducted action research in the morning and fifty did the same in the afternoon. Each time the fifty were divided into three groups. One group sketched and observed the area, another heard from community leaders about the history, scope and timeline of the project and a third walked the area and took digital pictures of interesting flora and fauna, planted trees and shrubs and kept a tally of the trash as well as identified types and sizes of trees. Middle school teachers, parents, university faculty and student teachers were involved in the planning and execution of the trip.

Teams of preservice teachers spent several days with the students at the end of the unit to help them prepare for a university-wide presentation of their findings. The middle school students and their research project were featured at the Tenth Annual Spell of the Land Symposium. The title of the symposium was Sense of Place, Use of Space. The students reflected on how their own sense of place changed as they became proactive for a better use of space for the wetlands area and the neighborhood. They developed their own 30 minute program to share their research findings and help the audience understand the importance of stewardship of the land. They determined that the questions they had investigated would guide their presentation. Questions: 1. Where does your water come from and is it safe? 2. How does a massive, new interstate highway built next to the wetland area impact the nearby creeks and the neighborhoods? 3. Why should we save a wetland? 4. Does development always equal progress? 5. How do you break a cycle of environmental injustice?

Preservice teachers helped the groups prepare a mock newscast that described this wetland, discussed its purpose and importance, issues and conditions that influenced how this particular wetlands was being addressed by city government, the importance of an open space bond issue that the voters would vote on and what would happen if the wetland was so destroyed that it would not be able to serve its purpose. Students also prepared dances and poems to be recited. The presentation culminated with a digital picture stream that showcased their field research. Many students took part in the digital presentation as they rose and spoke from the audience about their feeling and hopes and dreams for the wetland area.

This technology enhanced community service learning project was a success for all of its participants. Teachers successfully taught an integrated unit that captured the interest of their students, students developed a strong sense of place for their community and felt empowered through the recognition of their accomplishments to involve themselves in more community projects, university faculty were able to demonstrate to preservice teachers how theory informs practice and visa versa and preservice teachers got valuable observation and practice with early adolescents. Finally, everyone saw that technology is most powerful when used in the context of a real world problem. It captures the interest of the students, enables timely action research and is seen as a tool to help everyone achieve success.

Abstract: Scientific visualization tools have shown tremendous promise in drawing today's increasingly visual learners into in-depth inquiries in mathematics and science. One of the critical questions surrounding the use of these relatively advanced tools is the stages which teachers go through in moving these tools into their own practice. In this paper we examine existing schemas for these stages of development. Then we relate one of those schemas to Project VISM, an ongoing NSF-funded project intended to help middle school and high school math and science teachers learn the techniques and application of data visualization for their own classroom. We describe these stages of development for each of four different scientific visualization tools. Then we conclude the paper by proposing some further development of the models based on our experience followed by a brief discussion of related issues.

Scientific visualization tools offer a rich use of the more powerful computers that are becoming more and more plentiful in school districts today. These are a set of inquiry-based tools, many of which were originally designed to help scientists understand and explore different datasets or physical phenomenon. Visualization tools have shown great promise in drawing today's increasingly visual learners into in-depth study of scientific and mathematical topics (Baker and Case, 2000; Greenberg et al, 1993; Gordin and Pea, 1995; Jonassen, 2000; Thomas, 1996).

Both the promise and the relatively advanced nature of this software leads to the question of how to get more teachers involved in using visualization tools in their classrooms. Many projects offer extended training for teachers in one tool, but extended training is often too much, too soon. Project VISM is an NSF-funded project intended to focus more broadly on the techniques of visualization and not so much on particular tools. In addition, the project intends to build a cadre of trainers able to introduce teachers to techniques in short, focused sessions and then enable them to go back to their classroom and try an initial lesson or two.

One of the critical questions surrounding the work of this project is the stages which teachers go through in adopting these new and relatively advanced technological tools (such as scientific visualization) into their own practice. In this paper we first examine two existing descriptions of these stages of development: The CERA conceptual framework and the ACOT model. Then we describe Project VISM in greater detail, relating the ongoing work of the participating teachers in the project to the ACOT model. We propose some refinements to the ACOT model in conjunction with our work in Project VISM and conclude with a brief discussion of some of the larger questions related to how teachers bring these tools into their teaching practice.

Stages of development in using technological tools

Discussions of using inquiry-based technological tools to promote better learning in science and mathematics often begin with concerns about the preparedness of teachers to use these tools in the chronically undersupported technological infrastructures of K-12 education. In the midst of these concerns, it is often
recognized that teachers progress through identifiable stages of development in using these tools in their classroom. There are two outlines of these stages of development that are particularly noteworthy for consideration: the CERA framework and the ACOT model. Both of these have been articulated in the context of long-term professional development efforts carried out in the field with practicing educators.

Researchers at the Center for Highly Interactive Computing in Education (hi-ce) proposed a conceptual framework called CERA. CERA stands for Collaborative construction of understanding; Enactment of new practices in classrooms; Reflection on practice, and Adaptation of materials and practices (Krajcik et. al, 2000). This framework provides the background for a number of collaborative professional development efforts carried out with a particular urban school district. Thus far their work suggests that it takes teachers about three years to become proficient in doing inquiry-based science supported by technological tools (Blumenfeld et. al, 1994). These researchers have used this framework to enact five middle school curriculum projects that address particular topics using an inquiry-based science approach that utilizes scientific visualization tools.

A second and more general model of the stages of development teachers progress through in adopting technological tools into their teaching practice was first articulated as part of the Apple Classroom of Tomorrow (ACOT) project. The ACOT model suggests that teachers may progress through as many as four stages of development in using technological tools in their teaching practice (Sandholtz, et. al, 1997). Those stages are:

- **Entry** level-competent using the tool
- **Adopt** the tool into their teaching practice
- **Adapt** the tool into their teaching practice
- **Innovate** with the tool in their teaching practice

The ACOT model suggests that it often takes about three years to progress through these various stages, and in fact adopting the tool often corresponds to the first year's use, adapting the tool corresponds to the second year's use, and innovating with the tool corresponds to the third year's use. It is important to note that this is not a causal model. It is not suggested that all teachers inexorably progress through these stages. Many remain at one or another stage of development. In fact, with the proliferation of different software tools of increasing sophistication, it may not be possible (or even desirable) for many teachers to reach the innovation level with all the tools they use in their teaching practice.

**Project VISM**

The Integrated Science and Technology program at James Madison University (with the sponsorship of the National Science Foundation) is holding summer workshops in the techniques and application of data visualization for math and science teachers. These three-week long workshops are intended to help teachers see the forest (data visualization possibilities in the classroom) as well as the trees (software and curricula). Teachers will learn four specific data visualization tools:

- **Image processing with NIH Image or Scion Image software**
- **Geographic Information Systems (GIS) with ArcView GIS software**
- **Molecular visualization with RASMOL and Chemscape Chime software**
- **Systems modeling simulations with STELLA software**

The overall intent of the project is to help more teachers and students involved in using data visualization to learn more about science and mathematics. Below is a brief description of each of these four tools.

Image processing involves the manipulation and analysis of digital images. It has a significant heritage in biomedicine and planetary science research, and images can come from spacecraft in the far reaches of the solar system or from a digital camera in a student's hand. Geographic Information Systems (GIS) have been described in a recent popular journal as "mapping applications that take spatial data for a variety of topics and layer them on top of the other in order to see a correlation that is otherwise difficult to notice" (Geographic Informations Systems in the Classroom, 2000). GIS systems are currently being used in everything from environmental research to urban planning to marketing and law enforcement. Molecular visualization is a technique that has long been in use by research scientists on high performance computers. But recently the tools have become available for students and teacher to be able to create sophisticated molecular models that play in readily available web browsers with the use of a simple plug-in. Systems modeling tools such as STELLA allow
students to create a linked set of processes in a given situation without first getting bogged down in the mathematics. Teachers and students can create models of the spread of infectious diseases, or the trajectory of a water balloon, or the stresses in the life of a high school senior.

Instructors who have used these tools in their own classrooms, both high school and university faculty teach these sessions. This ongoing project has already worked with its first cadre of teachers in the summer of 2000. Online and limited in-person follow-up in the classrooms of these teachers will permit us to follow the stages of development that they follow in moving these tools into their own teaching practice. In addition, the project is recruiting participants for the next two summers. Middle school and high school teachers who have experience in using technology and want to learn to use these new visualization tools in their classes and share their skills with other teachers are encouraged to apply at the Project VISM (2000) webpage listed in the references section: http://www.isat.jmu.edu/common/projects/vism/summer.htm

Deliberate discussions of the ACOT model were held with the instructors during this past summer's workshop. Initially they were presented with a summary of the model and then asked to specify what the use of each of their respective tools would look like at the entry, adopt, adapt, and innovate level in the classrooms of the teachers in the project. In this way they were asked to make explicit their expectations for the participant's use of each tool.

Table 1 lists the a summary of those conversations. This matrix was initially developed to assist in identifying each participant's stage of development for each tool at the end of the first year of the project. Thus some of the descriptors may be a bit cryptic for readers not involved in the project, and further explanation is in order. The first column of the figure lists the four different tools. Then the at the top of the next four columns there is a list of the four stages of tool development: entry, adopt, adapt, and innovate.

For this project we defined the entry category as being competent to use the listed tool after the workshop was completed (see Table 1). Under each tool we listed what the instructors described as the competencies that each participant accomplished through the course of the workshop. For example, the instructor for the image processing portion of the project listed the specific image processing skills that were taught. The instructor for the molecular visualization tool listed the particular software-related skills, and then described the tutorial that each participant created that applied those skills to telling a molecular story. The instructor for the geospatial analysis tool listed the three main activities that all participants completed in the course of the workshop. The instructors for the systems modeling software took a somewhat different approach. They listed in order of increasing difficulty the things they hoped the participants would be able to accomplish using STELLA software. Thus at the entry level they state that the participants will be able to add an interactive "shell" or front end to an existing simulation and use it with their students. That is precisely what the participants did during the workshop with the instructors, but the next step for the participants to take is to create such a front end for a model that relates to their own curriculum.

The adopt category in Table 1 is defined as having the participants use the tool with their students in the context of their own teaching. Typically it is associated with the first year of use of a new tool. For the image processing and geospatial analysis tool, this stage is characterized by the participants taking one of the activities from the workshop and trying them out with their students. This process of adoption was facilitated by the instructor of the molecular visualization tool by an activity she had the participants carry out at the end of the workshop. The participants compiled a list of RasMol files of other molecules to use with their own students. These files, also called .pdb or Protein Data Bank files, are 3-D macromolecular structure data files. One of the ways in which the participants might adopt this tool into their teaching practice is to use this list to build molecules related to topics that they are studying in the classroom. Two other ways in which participants might use RasMol are listed in the adopt category: 1) participants might use RasMol files to create molecules for presentations to their students and 2) participants might use the interactive webpage they created in the workshop with their students. The instructors of the systems modeling portion of the workshop described the adoption phase in two different ways as well. First, participants in this stage will operate a STELLA simulation with their students, perhaps in a teacher-directed activity to simulate something related to a topic in their curriculum. This might be a part of a lecture or demonstration in the class. Second, participants in this stage will

</tbody>
</table>

Table 1. A matrix of the stages of tool use by the participants in the VISM project
read and interpret STELLA system diagrams with their students as part of efforts to better understand a particular topic that is being studied.

The **adapt** stage in this model is the step when the participants begin significantly changing the activities that they have already adopted into their teaching practice. Judi Harris describes this process in another context as "tweaking" an activity (Harris, 1998), pointing out that good teachers modify activities to make them their own. In fact she points out that this reinvention process is a critical part of effectively using any new learning. This stage is generally not reached until the second year of use of a new tool, though it is not expected that all participants would necessarily reach this stage. For both the image processing and geospatial tools in this workshop, the adapt stage is described in Table 1 as modifying one of the activities that was completed in the workshop in such a way that it better fits the curriculum of the participant’s classroom. For the molecular visualization tool, the adapt stage was described in two possible ways. First, that participants would locate new.pdb files from the Internet and use them to write new scripts in RasMol. A second possibility is that participants would write animated scripts in RasMol that tell a molecular story related to a topic in their curriculum. Note that both of the activities could be part of enhancing teacher presentations of material to their students, versus being tools that the students themselves would use for their own projects. For the systems modeling tool, the adapt stage is described as when the participant’s students can name and document an existing STELLA model. For example, if the students are given a generic system diagram and a physical description of a system, the students can name and document the various features of the STELLA model and input any necessary equations. Note this is not the same as “authoring” a STELLA model. In a sense it is the ability to “rough out” such a model on paper before working to write such a simulation with STELLA.

The **innovate** stage is the one that almost any workshop leader hopes their participants reach for any given tool. But as was pointed out earlier, it was not an expectation of the leaders of Project VISM (nor is it a realistic expectation for any suite of software tools) that all participants would reach this stage. In the ACOT project it was generally found that it took at least 3 years to get to this level. For all the tools in Projects VISM, the innovate stage can be summed up in one word: authoring. With the image processing tool, the innovation stage means that participants help their students bring in their own images and use their image processing skills to help students carry out (or author) their own scientific inquiries using this tool. In the case of the geospatial analysis tool, the innovate stage means that the participants create (or author) their own GIS activity using original (and, in many cases, local) data. For the molecular visualization tool, the innovation stage means that the participants create (or author) their own webpage that uses Chemscape Chime structures to create a tutorial for their students. For the systems modeling tool, it means that the students can build or author their own STELLA model from a written description of the system with coaching from their teacher.

**Refinement of the ACOT model for scientific visualization tools**

As part of our work with the instructors and participants Project VISM, we have developed some refinements to the ACOT model that we think are pertinent to the kinds of more advanced tools we are asking teachers to use with their students. The current ACOT model bases each of the stages on a given level of competency with the technological tool, and describes their development in using that tool with their students. But in working with scientific visualization tools with teachers we have noticed that this competency really has three component parts. Those three parts are:

- Competency with the software tool
- Competency with the scientific data that the tool uses
- Competency with the **pedagogical content knowledge** needed to teach curricular content using the tool

We believe that these three components help determine a teacher's ability to move forward into the next stage of development in using a given tool. For example, imagine a teacher has just attended a workshop and learned how to use NIH Image, an image processing tool, and also has some images and classroom-ready activities prepared for their first efforts at using this tool with their students. What I've just described there is a teacher ready to **adopt** image processing into her classroom because she has the capabilities to use the tool (NIH Image), has the necessary data (the images) and has a first "cut" at knowing how to "chunk" this activity to achieve particular educational objectives that are in her curriculum (classroom-ready activity she received or created at the workshop). These same three components come into play as that teacher moves to the **adapt** level.
of development. For example, in the second year that same teacher uses the activity, she might significantly "tweak" the materials and/or the approach she uses to teach the same activity. One might argue that this "tweaking" is a prerequisite for even first time use of the activity, but the kind of changes we are suggesting here are more substantive and often require teaching the material once to "kick the bugs out" of a given lesson or project. In addition, tweaking the activity might also involve learning some new aspect of the software tool, or refining one's approach to teaching the tool to students. Then in the innovate stage many teachers begin to bring in their own (and often locally more meaningful) data with their students. In NIH Image that might mean learning how to bring in a JPEG file from a digital camera at the best level of resolution, or how to find uncompressed TIFF files at a NASA website and download them onto their local computer from the World Wide Web. Moving to the innovate stage is often dependent on learning how to bring in new data sources. Or it might be dependent on certain kinds of new pedagogical content knowledge, such as how to better enable student-initiated projects in the context of increasingly high stakes testing and standards-driven curriculum. Our idea is that significant development in one of these three components is consistently linked with moving forward to the next stage of development for many teachers.

Discussion

At this writing we are still completing our discussions with the first year participants in Project VISM. We have not yet determined what stage they have reached with each of the different tools nor whether our notion of the importance of these other three components will be confirmed in our experience. We do expect that there will be some of the tools that they will have adopted into their practice and some that have not yet been used.

But we do note that in many of our conversations with colleagues about the journey that teachers go through in using new technological tools to enable better learning situations in their classrooms, there is a good deal of discussion of "building capacity" in the system and "ramping up technological change." To our ears these sound like production metaphors. And while they may be helpful in reminding us to strive to create "sustainable" professional development efforts, they may also miss the fundamentally constructivist nature of teacher learning. In following up with our participants in the coming years we look forward as much to the parts of their professional development that do not find a place on matrices such as we have included in Figure 1, but nevertheless have terrific personal significance to the teachers in their day to day work in the classroom.

Abstract: This paper will discuss the use of technologies, commonly found in schools, to develop and create virtual field trips. The discussion will focus on the advantages of both using and creating these field trips for an instructional situation. A virtual field trip to Cumberland Island National Seashore, St. Marys, GA will be used to discuss the technologies involved and the value of their use for instruction in a science classroom. While this field trip is being used as a discussion point, the techniques and advantages identified can be applied over a P-16 grade range in all subject areas. Thus creating a virtual field trip can be as simple as using digital pictures and text in Microsoft Power Point or Hyper Studio or as complex as using digital video and panoramas in Macro Media Director. The level of complexity will depend on the technology available and skills of the developers.

Virtual field trips are a hot buzz word for integrating the Web into the curriculum. If one does a web search using "Virtual Field Trip" as a key phase, hundreds of sites will be identified. These sites overwhelmingly provide an abundance of pictures with limited information about locations that are deemed to have educational value. Krupnick states that, "The Web is now crowded with sites that are considered "Virtual Field Trips" and they vary a great deal in content and usefulness." She further states that, "For teachers who already have a curricular unit assembled and are looking for online enhancements, these are adequate. But for teachers who are looking for a source of new and exiting curriculum such sites are only a starting point. In order to make them useful, an instructor would need to develop curriculum." (1998, p. 43) A virtual field trip should be much more than a web-based presentation of a location. The focus should be to design a field trip, not confined to the WWW, that allows the student to "learn" from the field trip in a way that is similar to actually taking the field trip. Coulter states, "The key is for (instruction) to drive the technology implementation and not vice versa, despite pressures to integrate technology into the classroom....Virtual field trips in the form of Web sites...enable students to refine and extend their growing understanding as they explore other parts of the world." (2000, p. 49). In addition, a virtual field trip coupled with an actual field trip to the site will vastly increase the educational value of the experience. However, this requires teachers to control creation of the trip to meet their curricular needs.

A major concern of using field trips in educational situations is that they are 'just a day away from school', with limited tangential educational purpose. Many teachers state that there is not time to take full advantage of
what the site has to offer, so by definition the experience becomes superficial. Bellan and Scheurman (1998) discuss ideas about actual and virtual field trips and list the pitfalls of both. In their article, they outline the teacher involvement necessary to alleviate some of the pitfalls. Among these are; the teacher visiting both the actual and virtual site, the teacher's plan for student use of a virtual site, student use of the virtual site before visiting the actual site, and follow up instruction using both the virtual and actual trip experiences. All the concerns about how field trips are used are not eliminated by taking the field trip on the computer. Two important points are made, first that the virtual field trip is usually not sufficient by itself and second that pre-planning the trip and the follow-up experiences should all be an integral part of the teacher's curriculum.

Definition of a Virtual Field Trip

Stainfield, Fisher, Ford, & Solem (2000) feel that virtual refers to 'digital alternative representations of reality' and that a virtual field trip is not an attempt to create a virtual reality. Virtual field trips are computer based simulations of an actual field trip which allow the user to experience the environment of the intended location. They provide the teacher and learner the opportunity to experience aspects of an actual trip without leaving the classroom. They should include all elements of a well designed field trip and provide the student with experiences that are beyond those that could be obtained from a pamphlet or a photo display of the location.

Advantages of Creating a Virtual Field Trip

The main advantage of a teacher created virtual field trip is that it can be specifically designed to meet the objectives of the curriculum and the needs and ability levels of the students. Other advantages of virtual field trips are that they:

- can be used either as a replacement for or in conjunction with an actual trip to the same location.
- provide opportunities for repeated visitations to the site for further study.
- encourage learners to plan and prepare for activities to be carried out on the trip.
- allow the teacher to focus on one specific aspect of the trip at a time.
- provide for the presentation of a wider variety of experiences than may be possible on one trip.
- can be designed to illustrate time sensitive issues, i.e. seasonal changes, etc. that could not be viewed on a single actual trip.
- provide integration of multiple aspects of the field trip into a number of different curriculum areas.
- allow for commonality of experiences.
- allow students to take a closer look at areas that they could not fully explore during an actual field trip.
- provide a simulation for students who may not have been able to attend an actual field trip.
- can be used for assessment purposes.
- can be shared with colleagues and parents.
- can be used repeatedly by the teacher year after year.

Limitations of Creating a Virtual Field Trip

The main limitation is the time needed to create the experience. However, if the teacher views the design of the field trip as dynamic, construction of both the actual and virtual field trips will grow over time. Also, involving others; colleagues, community members, students and parents can help to reduce the extended amount of time that the teacher spends in creating a virtual field trip.

Because curriculum design requires content expertise, another limitation is the teacher's knowledge of the content area of the field trip and the curricular objectives. As teacher's get involved with the design they often need to extend their knowledge of the content of the field trip thus increasing the time necessary to design the experience.

A third limitation is the availability of the technology. However with the increasing availability of technology in the schools, homes and work places this is becoming less of a barrier. Coupled with the availability of the technology is the teacher's ability to use the technology effectively. Again this can become a
learning situation and thus increases the time to create the product. This limitation can also be minimized by the involvement of colleagues, community members, students and parents.

**Student Involvement in Creating a Virtual Field Trip**

Student involvement in the creation of the virtual field trip can take the form of; collecting information at school, using aspects of the technology in the construction of the product, taking the actual field trip and gathering the images and information to present in the virtual field trip. This involvement focuses student attention and learning on the intricate aspects of the content presented. In addition, it provides ownership by the student of the project. Last, but not least, it provides opportunities for students to use the technology in a real world situation, which addresses the NETS standards by preparing them to function in a technology rich information society.

**Creating a Virtual Field Trip**

The field trip we chose to illustrate the process of creating a virtual field trip is used within a course for Middle Grades pre-service teachers. This trip is a visit to Cumberland Island National Seashore. The objective is to prepare pre-service teachers to design and use field trips effectively in their classrooms.

The steps for creating a virtual field trip are:

1. Examine the objectives of the course and choose a field trip that includes experiences that fit within the realm of the objectives while enhancing learning.

   The purpose of this virtual field trip is two fold, it provides information that will be used on an actual field trip and it provides information about parts of the island that are inaccessible to the students. The objectives of the field trip are: to learn about the ecosystems of a barrier island located off the southeastern coast of the United States; to understand the history of man’s inhabitation of the island and his impact on its ecosystem; and to design and carry out experiments that survey the island and its inhabitants.

2. Create a concept map of the experiences to be included in the field trip.

   A concept map provides an overview of all the elements to be included in the virtual field trip and acts as an organizing framework to build upon in construction of the final product. The concept map should not be considered the final blueprint for the field trip, rather it should be seen as a dynamic overview and a starting point from which the product evolves. The concept map for the virtual field trip to Cumberland Island can be seen in Figure 1.
3. Select the appropriate technology to be used based on the content and the curricular objectives of the field trip. The technology includes the organizing program and tools for collecting and presenting data. The equipment and software used will depend on the complexity of the trip and the grade level of the students. Virtual field trips can vary in their complexity based upon the experience of the creator with the technology available.

Based on the concept map, the technology used for the Cumberland Island trip included; digital cameras, computers, scanners, CDR's. In addition, a variety of software was utilized including: word processing, database management, electronic spreadsheet, graphics program, Quicktime VR, and an authoring program.

4. Collect and organize materials to be included based on the curriculum objectives to be accomplished and the concept map. Examples of desired materials might be:

- still pictures, both digital and photographs,
- videos,
- text,
- databases and graphs,
- sound clips.

As materials are collected and organized decisions must be made. For example, panoramic videos can be used to give an overview of the location. If panoramas are to be used, decisions will have to be made before hand as to the location and the concept to be illustrated.

The decisions made for the Cumberland trip were centered around the curricular objectives. Decisions were made concerning:

- whether flora and fauna should be presented as single pictures organized as a field guide or presented in a database which could be continually updated.
- presentation of the history of man's inhabitation of the island.
- presentation of time sensitive aspects of the ecosystems (high/low tides, seasons, effects of long term drought, etc).
- the use of panoramas to give the learner a holistic feel for the elements of each ecosystem and location.

Both panoramas and time-lapse videos were used to show the ebb and flow of tides in the marsh areas.

5. Convert all materials to digital format.
When converting materials to digital format the question of designing for dual platforms (Windows and Mac OS) must be considered. While designing for dual platforms is not more difficult or time consuming, the decisions made about the format of the individual parts (pictures and text) must be considered to insure that they are appropriate for the platform(s) chosen.

When converting the materials for the Cumberland Project we converted all images to JPEG format. Both the Windows and Mac platforms have the ability to use the JPEG format and if at some future date the decision is made to make the materials web based this format is standard to the web. Apple Quick Time was chosen for all video production for the same reason and at this time is the only program that allows one to view 360-degree panoramic movies. Since some text came from National Park Service brochures or previously written documents they were converted to digital format with the use of a scanner. The scanner also was used to convert photographs taken with non-digital cameras, such as the historic pictures.

6. Assemble all elements in the organizing program based on the concept map.

Here decisions on the presentation format of the field trip must be made. Will it be one stand-alone program presentation or a series of parts that can be accessed separately? Also, before assembling the materials one must consider the platforms that can present the materials. Will the field trip best meet the needs of the teacher if it is dual platform or is one platform sufficient? These decisions along with the assemblers knowledge of presentation programs will determine if Macro Media Director, Hyper Studio, Power Point or any of the other available authoring program meet the needs of the designed field trip. The choice of the authoring program used is often the assemblers personal choice based on familiarity and skill with the program.

For the field trip to Cumberland Island the authoring program Macro Media Director was used to provide access to all the different parts of the field trip. For development of the field guides and databases File Maker Pro was chosen. The main reasons for choosing these two programs were; their power, their dual platform capabilities, and copyright issues. These programs provide run-time viewing programs that can be provided to the user royalty free. (Hyper Studio and Power Point also provide the dual platform and royalty free advantages.)

7. Evaluate the finished product to be sure it meets the objectives.

In a teacher created product, evaluation will be formative in nature, providing a continuously changing and evolving product. There will always be questions of: how could the product be improved, what additions should be made; have the needs of the learners using it changed; and how can new learner groups add to the information presented?

The Cumberland Island field trip has evolved over several years. At first, it was designed as an actual one day field trip. Then the question of how technology could be used on the field trip arose. Teacher use of digital cameras to record student participation in information collection was added. Next, students were provided with digital cameras and recorded information on the ecosystems and other related data. The use of technology to present pre and post field trip information and the teacher's organization of student input was the next challenge. The most recent effort is the result of trying to solve the question of how to present material that was not available to the student on a single trip and how to organize all elements into a product that will be available to the students in an easily accessible manner.

This paper uses the terms teacher created, creator, and assembler in an interchangeable manner. This is due to the principle that while the teacher is the driving force in the design and creation of the virtual field trip, the tasks can be done in conjunction with students, parents, interested community members and colleagues. The technologies used to develop and create Virtual Field Trips are commonly found in public schools today. The Cumberland Island Project used Macro Media Director whose cost at this time may prohibit public school usage, but the project was not dependent on this choice. The process of creating virtual field trips can be as simple as using digital pictures and text in Microsoft Power Point or Hyper Studio or as complex as using digital video and panoramas in Macro Media Director. The technology skills necessary in the creation of the field trip all are within the scope of the National Educational Technology Standards (NETS) for Teachers, and many are within the scope of the NETS for students.

The Quest for scientific inquiry: A document analysis of Quest projects

Gregory A. Coverdale, Ph.D.
College of Education
St. Cloud State University
United States
gcoverdale@stcloudstate.edu

Abstract: The 1996 release of the National Science Education Standards (NRC, 1996) energized the national focus on improving U.S. science education in K-12 schools. The standards provide a strong emphasis on inquiry as the primary pedagogical framework in promoting science literacy. Similarly, the recent release of the National Educational Technology Standards (ISTE, 2000) has catalyzed the process of integrating information technology across the curriculum. The ISTE standards provide a curricular framework for technology integration and correlate technology-rich learning activities to standards in several content areas. Thus, these two policy documents provide teachers and students a detailed roadmap for pursuing science and technology literacy; the cornerstone of both literacies being the inquiry process. This paper is a qualitative document analysis of one commercially produced Quest project: AsiaQuest. The paper also examines preservice teachers' reflections on their participation in Quests as part of their professional preparation.

Introduction

In reflecting about the history and philosophy of the natural sciences, Edward O. Wilson (1998) states:

Today the greatest divide within humanity is not between races or religions, or even as widely believed, between the literate and illiterate. It is the chasm that separates scientific from prescientific cultures. Without the instruments and accumulated knowledge of the natural sciences—physics, chemistry, and biology—humans are trapped in a cognitive prison. They are like intelligent fish born in a deep shadowed pool. Wondering and restless, longing to reach out, they think about the world outside. They invent ingenious speculations and myths about the origin of the confining waters, of the sun and the sky and the stars above, and the meaning of their own existence. But they are wrong, always wrong, because the world is too remote from orderly experience to be merely imagined (p. 45).

While Wilson’s view of the natural world seems to ignore the world view of indigenous peoples and non-Western cultures, it does delineate the two periods of human existence: the scientific and the nonscientific. A similar chasm exists in K-12 schools today vis-à-vis the use of information technology as a learning tool. A so-called digital divide (Tapscott 1998) exists in society, in individual school districts, and within individual schools. Even though current technology standards require teachers to be technologically literate, there remains a long continuum from the technophobe to the technophile. Most K-12 teachers whom I have observed or worked with are somewhere in the middle of the continuum.

The purpose of this paper is twofold. First, the paper provides a qualitative document analysis of Classroom Connect’s AsiaQuest curriculum guide. Next, the paper examines preservice teachers' reflections on their participation in Quest projects as part of their professional coursework requirements.
Rationale

The National Science Education Standards (NRC 1996) established the direction of science education for the 21st century in K-12 schools. In contrast to traditional science instruction, the standards promote inquiry-based learning situated in constructivist classrooms (NRC 2000). The inquiry standards (NRC 2000) describe the following essential features of classroom inquiry:

- learners are engaged by scientifically oriented questions;
- learners give priority to evidence, which allows them to develop and evaluate explanations that address scientifically oriented questions;
- learners formulate explanations from evidence to address scientifically oriented questions;
- learners evaluate their explanations in light of alternative explorations, particularly those reflecting scientific understanding;
- learners communicate and justify their proposed explanations (p. 25).

The National Educational Technology Standards (ISTE 2000) boldly pronounce “our education system must produce technology-capable kids” (p. 2). The reasons are utilitarian and pragmatic: "Parents want it! Employers want it! Communities want it! The nation wants it!" (ISTE 2000, p. 3). This mandate sets the table for establishing classrooms and learning environments that are technology-rich and produce a technologically literate populace.

The NETS standards are congruent with most content area standards in that they promote inquiry as the key vehicle to teaching and learning. The standards also promote a new paradigm of educational practice that highlights increased emphasis on collaborative work, information exchange, inquiry-based learning and informed decision-making, all situated in a real-world context (ISTE 2000).

Over the past decade, network science projects have extended the curriculum to include the integration of emerging technologies into the extant curriculum. These technologies allow students and teachers to create electronic communities of learners who are focused on common, "real science" problems (Feldman et al. 2000). These projects have evolved from simplistic email exchanges in the late 1980's to sophisticated web-based projects today. How effective is network science as an instructional strategy? What do these projects look like? How much real science is involved? These are all questions posed by classroom teachers and curriculum developers interested in taking the plunge into network science projects.

Study Participants

In teaching elementary science and social studies methods courses, I have integrated several Quest projects into my syllabi as a method of introducing preservice teachers to thematic, interdisciplinary, technology-based projects. While the number of students in these classes is relatively small (n = 150) they encompass a sample from two different universities: a small liberal arts college in the Midwest and a large, research institution in the northeast. My rationale for introducing Quest projects in preservice education classes focuses on two salient points: 1) the need for novice teachers to develop technological literacy and 2) to expose students to a sample of Quest and other network science projects.

AsiaQuest Project Overview

Classroom Connect Quest projects are Internet-based, interdisciplinary, and focus student inquiries on a common issue or question. For example, the inquiry question in the AsiaQuest project is "Did Marco Polo actually go to China?" Anyone can participate in the month-long Quests on the Internet but a subscription is necessary in order to utilize all the Quest features. Subscribers are provided user ids, passwords, and the
curriculum guide to help teachers implement the Quest in their classrooms. Below is a description of the AsiaQuest project:

AsiaQuest is an adventure into a fascinating and complex world. For five weeks, you and your students will travel with our team of explorers on an exciting expedition to China. Together, we'll search for clues regarding the history of Marco Polo's expeditions and we'll investigate the contemporary culture and environment of the areas we visit, attempting to determine the effects of one upon the other. Along the way, we'll mount camels, cross deserts, visit temples, and explore cities of the past and present. AsiaQuest's interactivity makes it possible for students to have an effect on the expedition logistics, latest scientific developments, and ethical debates (Classroom Connect 1999, p. 3).

Thus, unlike many Internet-based activities, teachers and students are active participants in the Quest. This interactivity is further described in the analysis section below.

AsiaQuest Curriculum Guide

The curriculum guide is 142 pages in length and provides a step-by-step set of instructions for K-12 teachers to follow. The guide begins with a 10-page overview that introduces teachers to the project, provides a detailed map of China, and provides a weekly and monthly schedule called the Trek Calendar. The features of the web site are explained and the navigation bar includes areas for research, communication, and accessing online resources (Classroom Connect 1999).

Teaching tips are delineated into different grade levels: K-2, 3-5, 6-8, and 9-12. Thus teachers at any grade level can utilize a specific section of the guide without feeling the need to browse the whole guide. Teaching tips also include a useful section on assessment, a piece that is often missing from network science projects (Feldman et al. 2000). Descriptions of assessment methods include sections on ongoing embedded assessment, self-evaluation, portfolio use, and culminating activities. Sample evaluation rubrics cover the following: cooperative learning project, portfolio, and oral presentations.

The technical tips section provides a step-by-step procedure for setting up the computer, downloading plug-ins, setting the preferred browser, setting preferences, registering and using passwords, and navigating the site. Instructions are also given for the interaction component of AsiaQuest. Students are encouraged to email the AsiaQuest travel team in China to help set travel schedules and explorations strategies. Students can also email content experts, subscribe to the listserv, participate in online discussions, and access an extensive Quest library. Thus, one of the hallmarks of the Classroom Connect approach to designing network science projects is the high degree of embedded interactivity.

The rest of the curriculum guide is devoted to a large Background section for teachers, and specific descriptions of the Quest activities. Each week, activities are focused on specific themes. The tables below illustrate the daily activities and the thematic sequence of the project.

Table 2 – Curricular Themes

The activities listed above are designed to allow students to probe the topic from a variety of perspectives. The scope of this paper does not allow detailed descriptions of the activities, but every activity allows students to engage with the inquiry questions embedded in the project and in students’ own research.

Preservice Teacher Reflections

Preservice teachers in this sample were asked to reflect on their own participation in the Quest projects. Specifically, they were asked to describe how the Quest promoted scientific literacy and inquiry, and how they might implement a Quest project in their own classroom. Responses include reflections from the AfricaQuest and AsiaQuest projects.

How did the Quest promote inquiry?

Teacher 1: I found that all of the different sections promoted inquiry. This was done through the way the information was presented. For instance, in Dan’s Dilemmas, Dan asked questions as if he were having a conversation with a person about the dilemma. The dilemmas make you stop and think. The next thing you know, you’re trying to figure out a solution. In all the different sections the material was presented with questions that left you wondering. If I were working with students and AfricaQuest I would encourage the students to act on the questions that the team posed. Although the sections make students wonder, it takes a teacher to move them beyond wondering and toward inquiry.

Teacher 2: This AfricaQuest team offers numerous opportunities for students to go beyond the traditional classroom walls and interact with experts, team members and other students. The interactive features on the Web site pose challenging questions and compelling mysteries for students to solve. Voting and posting in these areas enable students to take an active role as they direct the expedition and help solve the mystery. As the students take part in this interactive adventure, they broaden their research skills, their communication skills, and their skills in accessing online resources.

How did the Quest promote scientific literacy?

Teacher 1: AfricaQuest promotes scientific literacy and technological literacy. This occurs by allowing students to interact with the scientists, asking them questions and helping them find a solution to problems that scientists are investigating. The adventure team poses problems every week to the students and makes them a part of the research. It promotes inquiry with the students as they work to find answers to the problems. It also allows the students to respond, and express their ideas with real scientists.

Teacher 2: While using AfricaQuest, students are also exposed to scientific and technological literacy by following individual interests and sharing their findings with the rest of the class and with people from around the world. In order to get students to explore science in more detail and become scientifically literate, teachers need to allow their students to build on their own ideas. Whether stumbling onto their theories by accident or by intentions, students love the challenge of discovering new ideas or inventions, especially if it comes from them. Thus, by including the Internet in the classroom, teachers can provide the students with an opportunity to navigate, investigate, experiment, and extend
their scientific inquiry through active scientific investigations rather than through passive lectures about science facts.

How might you implement a Quest project in your own classroom?

Teacher 1: To incorporate a project like AsiaQuest in the classroom, the teacher needs to be familiar with the background of the program and how to use it. For instance, one evening when I accessed AsiaQuest, I read a comment from a student and wanted to respond. However, I could not figure out how. I then discovered there are directions on how to use their web site. To use AsiaQuest in my classroom, it would be necessary to first understand how to navigate the site. I would also have to be able to connect with other teachers so I could share and get ideas of how others are using the project.

Teacher 2: Since not every person has the same interest I think it is important for each child to find a topic in AsiaQuest that interests them. I have a strong interest in literature and would like to integrate trade books into the AsiaQuest project. For example, I would read a trade book relating to an Asia elephant. The children could then find information about Asian elephants in Christine’s Critters. The children could then create a collage based on Asian elephants.

Findings

The activities included in AsiaQuest provide ample opportunity for students to pursue inquiry-based science. The activities and related projects described in the curriculum guide are closely aligned to national standards in several content areas, including science. Information technology is central to the project’s design and thus many of the national technology standards are met.

Most participants found Quest projects to be exciting new technology tools although data indicate many students also found some aspects of Quests to be problematic. The table below summarizes some of the implementation issues raised by participants.

<table>
<thead>
<tr>
<th>Issue</th>
<th>Participant Comment</th>

</tbody>
</table>

Table 3 – Problematic Issues of AsiaQuest

Conclusion

Network science projects such as Quests present teachers with a bold vision of learning and technology integration. In their recent findings, Feldman et al. (2000) have found that in many cases, network science projects fail to live up to their stated vision. Areas for further research might include a closer analysis of the vision of Quest projects and how teachers and preservice teachers implement this vision.

Abstract: The evolution of Internet-based communications and capabilities of mobile digital technologies have empowered teachers and students to move beyond “click and learn” science classroom environments to one whereby learners can conduct onsite science expeditions and showcase their investigations online. This paper documents the collaborative efforts of a public school system, a county joint vocational school, a non-profit outdoor learning organization, telecom corporations, a state park system, a state division of wildlife, and universities to launch a digital expedition to study environmental conditions. The paper examines the opportunities related to these emergent technologies and elementary students’ abilities to engage in onsite group investigations at the Lake Erie shoreline. The Our Lake Online project involved more than a year of collaborative planning and was funded by a foundation grant, telecom corporate financial support, and non-profit organizational sponsorship. The expedition can be viewed at [http://www.digitalexplorers.tzo.com/erie/default.htm].

Introduction

The use of the Internet as a tool to facilitate collaborative projects for science data-sharing investigations is a fairly recent phenomenon (Berg & Jefson, 1999). However, the evolution of Internet-based communications and capabilities of mobile digital technologies have empowered teachers and students to move beyond “click and learn” science lessons posted on URL sites. Now learners can use mobile digital technologies, laptops, the Web, and environmental analysis tools to launch expeditions at onsite/outdoor locations and conduct their own science investigations. Students that are driven by their own curiosity and natural exploratory instincts can gather scientific data and conduct independent analyses that they can post and share with fellow students and the WWW community.

This paper describes the Boardman Local Schools Our Lake Online project, a first-of-its kind “digital expedition,” to the Lake Erie shoreline. The Our Lake Online expedition was conducted by thirty-three elementary students (identified as gifted and talented) from Boardman Local Schools located in Northeastern Ohio. The fourth, fifth, and sixth grade elementary students’ Internet-enabled outdoor learning adventure can be viewed at the website [http://www.digitalexplorers.tzo.com/erie/default.htm]. The students’ digital pictures capture the day they spent collecting baseline data for an environmental study of the Lake Erie shoreline contiguous to Geneva State Park, Geneva, Ohio. The results of the students’ onsite work and experiments were transmitted via digital connections back to students at their respective six home schools, thus also enabling approximately four hundred and fifty students to participate remotely in the online adventure.
Descriptive Narration About the Our Lake Online Website

Digital photographs posted on the website show students, teachers, parents, administrators, and resource experts engaged in collaborative learning as well as individual inquiry-based science investigations. Rotating through five workstations, this community of learners used digital cameras to photograph erosion control practices and wetland plants and creatures, including plankton samples. From a microscope lab housed in a tent near the shore, students magnified images of the microscopic samples and digitized these images for transmission. Sensor-based lab kits by Imageworks and PASCO Scientific Corporation were used by students to gather data about the water quality of Lake Erie. The students graphed water temperature readings, analyzed oxygen levels, conducted salinity readings, and determined pH levels. The graphs were then downloaded to four of eight laptop computers set up at base stations (two tents and a recreational vehicle). From the four laptops housed in the RV, information was sent via four temporary telephone lines provided by ALLTEL Corporation to students at the six home schools to enable remote participation.

Background Pertinent for the Design and Implementation of the Our Lake Online Project

The expedition, which involved more than a year of planning, was the first-of-its kind to be conducted in Ohio or on one of the Great Lakes. It was primarily organized and headed by expedition leader Joyce Zitkovich, teacher for Boardman’s Gifted Services program, Boardman, Ohio. The model for the digital expedition was drawn from the goals and methodologies of the Digital Exploration Society (DEX) [www.digiteexplorers.com]. DEX refers to its excursions as “digital expeditions” or DEXpeditions. Joyce Zitkovich first worked with DEX in 1999 when the non-profit group launched a DEXpedition to Carlsbad Caverns in New Mexico. Based in Los Angeles, California, DEX was founded in 1998 to foster a better in understanding of the interdependence between people, our planet and the technologies we create. The all-volunteer organization supports and launches Internet-enabled learning adventures for students and educators, and was instrumental in providing the guidance and technical support to ensure the success of Our Lake Online Erie project. DEX also hosts the Our Lake Online website. Robert Lindstrom, executive director for The Digital Exploration Society traveled to Ohio to participate in the expedition.

Implementation of the Our Lake Online digital expedition was also made possible by grant monies ($3,984) awarded by the Martha Holden Jennings Foundation, Cleveland, Ohio. ALLTEL Corporation provided telecom services free of charge. PASCO Scientific provided the Science/Workshop Interface 500 Starter Bundle for students to use free of charge, as well. This kit included the Science Workshop and DataStudio Software on CD, an experiment library, teacher's guide, student workbooks, and a set of Starter Sensors that were used to conduct shoreline and water experiments.

Technology assistance and training sessions for Boardman students and teachers were provided by the Mahoning County Joint Vocational School under the direction of Steve Bennett, Susan Dunn and Melissa Thomas- Hackett, vocational education instructors. Eleven MCJVS high school students served as technology assistants and provided the help necessary to support elementary students’ technological endeavors at Lake Erie. Four Bloomington, Indiana high school students and two Indiana University college students also provided onsite technical assistance. These students had prior experience with an ongoing environmental study program known as the Wetlands in the Wild Project. Under the guidance of project director, Jo Gilbertson, the Indiana students guided the elementary students in the use of the water quality sensors and palm-held computers.

Few technology projects are successful unless a lot of other people want them to be and are willing to share their expertise. Additional members of the digital expedition included: Carl Myer, ALLTEL Corporation; Neil Cramer, PASCO Scientific; Kevin Kayle, aquatic biology supervisor at the Fairport Fish Station, ODNR Division of Wildlife; and, Jonathan Fuller, Lake Erie Geology Group, ODNR, Division of Geological Survey. Geneva State Park personnel included: Doug Burgett, Park Director; Rick Alderman, Park Ranger; and Dean Heisey, Marina Manager. Support and consultation regarding gifted education teaching models (group investigation and problem based learning), evaluation procedures, and construction of evaluation survey instruments was provided by Marianne Dove, Department of Teacher Education, Youngstown State University.
Boardman Local School District personnel that participated remotely from the six home school sites (Boardman Center Middle School, Glenwood Middle School, Market Street Elementary School, Robinwood Lane Elementary School, Stadium Drive Elementary School, West Boulevard Elementary School) included: Claar Barbour, David Brenner, Eva Convery, Jan Harvey, Mark Haverstock, Debbie Hinkle, Judy Lipkovich, Lee Messerini, Terry O’Halloran, Paula Ritter, Janet Sandy, Marilyn Scheetz, and Pam Tabak. Educators who served as onsite teachers were Bob Campbell, Pam Murray, and Michele Nespeca. Bob Wright, District Technology Coordinator, coordinated technical services at the six home schools and also provided technical assistance at the Lake Erie site. Librarians Cathy Santangelo and Judy Carson catalogued and housed reading materials and resources at the school system’s libraries. Elaine Raffety, retired mathematics teacher, graciously permitted the expedition team to use her recreational vehicle as a home base for the expedition. In addition, thirteen Boardman parents served as chaperones for the expedition.

**Purpose and Goals for the Our Lake Online Project**

The purpose for designing the Lake Erie expedition centered on investigating the ecological vulnerability and sustainability of Lake Erie, the eleventh largest lake in the world. Although Lake Erie is the most biologically productive of the Great Lakes in the United States (e.g., the walleye fishery is considered the best in the world), discharge of municipal and industrial wastes by the early 1970’s had severely polluted the water and threatened the ecosystem. Thus, an onsite/outdoor experiential learning opportunity such as Our Lake Online held promise to spark students awareness about their connection to this important natural resource and their understanding about environmental interdependence. The digital adventure to the lakeshore also held promise as the means to enable students to understand the power technology holds to study, analyze, and investigate present day ecological conditions of this vitally important natural resource.

Goals for our Lake Erie digital expedition included the following: (a) to develop learning activities that integrate best practices in gifted education and reflect science learning goals stated in the National Science Education Standards; (b) to integrate emerging technologies in the elementary curriculum to personalize learning; (c) to extend the public school's classroom walls electronically; (d) to design onsite/outdoor learning activities that spark children's intrinsic joy to learn; (e) to work collaboratively to facilitate children's learning opportunities; (f) to understand the power technology holds to study and communicate ecological concerns; (g) to learn and experiment together as a local and co-local community of learners.

**Our Lake Online Project Learning Activities**

In the initial planning stage, (September 1999), Joyce Zitkovich, expedition leader, contacted several agencies, and requested curricula and resource materials specific to the environmental study about Lake Erie. These materials were used for in-service sessions with teachers and were also used as research resources by the elementary students. Some of these materials were the Great Lakes Atlas from the United States Environmental Protection Agency and the Government of Canada, numerous materials compiled by the Ohio Sea Grant Program/Ohio State University, and The State of Ohio - 1998 State of the Lake Report: Lake Erie Quality Index prepared by the Ohio Lake Erie Commission. Librarians catalogued and housed these materials in the schools' libraries to ensure easy access for teachers and students.

In January 2000, all fourth, fifth, and sixth grade gifted learners began to read, study, and discuss the ecological state of the Great Lakes and specifically, Lake Erie. Students became aware of the major issues regarding the vulnerability of Lake Erie. Since Lake Erie is the warmest and shallowest of the Great Lakes, it is the most easily affected Great Lake in regards to pollution, endangered aquatic plant and animal life, and invader species. Viewing the film “Great Lakes Ecology: Unwelcome Visitors in America’s Great Lakes” produced by Jim Danielson for Ohio Educational Telecommunications also served to establish a motive learning state with the children.

Based on these initial studies, the fifth and sixth grade academically gifted children selected independent study topics to research and develop reports and presentations. The children were given
guidelines for these individual research projects that included student reading logs and completing all necessary steps of the research process (e.g., library research, Internet searches, note card compilation, research paper writing according to Modern Language Association [MLA] style, and bibliographic documentation). Regarding class presentations, students were required to deliver oral reports, and develop a visual aid related to their topic. The students were afforded the opportunity to select a visual medium of their choice. Student choices for visual aids included: PowerPoint presentations, art work, puppets, models, mobiles, photographic displays, posters, story boards, flip charts, and brochures.

Boardman Local Schools employs the strategy of curriculum compacting for academically gifted learners, therefore some of the children's instructional time was freed so that they could use the school library and computer labs for their individual investigations. Students also used the public libraries to obtain resources, and conducted Internet searches and visited established science URL sites from both school and home computers. Notably, six students engaged in telementoring experiences with science experts throughout Ohio. Email exchanges between the students and telementors were made on a weekly basis for approximately two months. Professionals who served as telementors were Jonathan Fuller, Lake Erie Geology Group, ODNR, Division of Geological Survey; Nancy Leonard and Geoffrey Steinhart, Aquatic Ecology Laboratory, The Ohio State University, Columbus, Ohio; and, Joseph Koonce, Department of Biology, Case Western Reserve University, Cleveland, Ohio.

Some student research projects were entitled: “Round Gobies Invading Lake Erie,” “Zebra Mussels,” “The Spiny Water Flea,” “Erosion Control Practices at Lake Erie,” “The Effects of the Eurasian Watermilfoil and Purple Loosestrife Plants on Lake Erie,” “Yellow Perch,” “Identifying Rocks on the Shore of Lake Erie,” “Sea Lamprey: An Invader Species,” “Plankton,” “Wetland Aquatic Creatures,” and “Shoreline Pollution on Lake Erie.” The academically gifted students made research presentations to classmates in the regular class rooms two weeks prior (early May 2000) to disembarking on the expedition to Lake Erie. The students also made formal presentations about their Lake Erie adventure to graduate students at Youngstown State University, Youngstown, Ohio in July 2000.

Fourth grade academically gifted students’ learning tasks did not involve independent research projects. After assessing learner readiness, educators believed that directed study was most appropriate to engage fourth graders in mini lessons regarding topics such as microorganisms, aquatic life, water quality, shoreline erosion, and wetland plants and creatures. These mini lessons were taught by teachers of gifted educational services, and provided the necessary foundational learning these young children would need to successfully accomplish onsite tasks at Lake Erie. These fourth grade students, however, were required to make oral presentations about these mini lesson topics to classmates in the regular fourth grade classrooms two weeks prior (early May 2000) to the expedition to Lake Erie.

All fourth, fifth, and sixth grade gifted students completed two days of training (March 30th and April 7th, 2000) at the Mahoning County Joint Vocational School (MCJVS) to learn how to use several forms of technology prior to their Our Lake Online expedition (May 18, 2000). On the first workshop day, students learned several basic technology skills in the Visual Arts & Design Lab and Tech-Prep Computer Lab. For example, the elementary students learned about the operation and features of the digital camera and the use of photo editing computer software. To determine if students could apply these newly learned skills, they were asked to venture outdoors and take digital photographs of the natural setting, download these images to laptops, and send them as email attachments to their home schools. Thus, students practiced the procedures they would use the day of the onsite expedition. Vocational education teachers also shared design possibilities for students to use to compose web pages, storyboards and PowerPoint presentations to create dynamic records about their Lake Erie experience. The second workshop afforded students the opportunity to use microscopes, micro projectors, and Elmo visual presenters to magnify and project samples from pond water found at the MCJVS site. Once again, students were directed to apply these skills with the help and guidance of the vocational education teachers and twenty-nine MCJVS student assistants.

The Our Lake Online expedition was conducted on May 18, 2000. Students embarked for the expedition at 6:30 a.m. (1.5-hour bus ride, one way, to lake) and returned to Boardman schools by 5:30 p.m. Five workstations were set up on the Lake Erie shoreline so students could conduct group investigations about the natural environment. These work stations dealt with pollution, geology, wetland plants, microorganisms, and water quality. The educational technologies used to complete assignments were IBM and Mac laptop computers, palm-held computers, water quality sensors, digital cameras, microscopes, and a micro projector. Results of the students’ onsite work and experiments were transmitted
via digital connections back to classmates at their respective six home schools, thus enabling approximately four hundred and fifty students to participate remotely in the online adventure.

Evaluation

The recent literature on evaluation regarding technology implementation indicates that “effectiveness is not a function of the technology but rather of the learning environment and the capability to do things one could not do otherwise” (Jones, Valdez, Nowakowski, & Rasmussen, 1999). Certainly this onsite digital adventure provided learning opportunities that had previously not been possible for Boardman school children. The Our Lake Online expedition was the first-of-its kind in many respects. It was the first DEXpedition to be conducted on Lake Erie or any one of the Great Lakes in the United States. It was Boardman Local School District’s first pioneering effort to discover and understand the potential of digital technology and Internet-based communications for expanding learning beyond the boundaries of the classroom. In addition, it was the first time students had used environmental analysis tools such as water quality sensors and palm-held computers; it was the first time students had used mobile digital technologies; and, it was the first time a collaborative effort of this magnitude had been implemented. According to these “firsts,” the Our Lake Online expedition has been considered a highly successful undertaking.

Evidence of effective teaching and learning that occurred during the Our Lake Online project was also compared to criteria specified by Barbara Means of SRI International. This researcher identified variables that, when present, indicate engaged and effective learning. These variables include: (a) children are engaged in authentic and multidisciplinary tasks, (b) assessments are based on student performance of real tasks, (c) students participate in interactive modes of instruction, (d) students work collaboratively, (e) the teacher is a facilitator in learning, and (f) students learn through exploration (Jones, Valdez, Nowakowski, & Rasmussen, 1999). The Our Lake Online project participants were involved with collaborative online learning opportunities that concerned real-life tasks that valued learners’ personal interests, and supported multidisciplinary learning. The data students collected serves as an ongoing baseline for study of the lake region by Boardman students as well as the WWW community. The Our Lake Online project is a prototype for other teachers of gifted services to use for onsite/online learning opportunities.

Evaluation data that involved triangulating students, parents, and educators’ responses to survey instruments about the expedition also revealed a resounding endorsement for the digital learning adventure. Parent chaperones were delighted to watch the children “actually do science” and see “state-of-the-art technology” in use. Parents also indicated they enjoyed being part of a “leading edge experience” and acknowledged the “tremendous effort” undertaken by the expedition organizers and teachers. Educators were very pleased with the development of students abilities to use advanced technologies; engage in research projects; collaborate with fellow students; and, demonstrate problem solving, communication, and presentation skills. Perhaps most important were the responses from the student surveys that indicated overwhelmingly that they would like to participate on another expedition and that they greatly valued the opportunity to study and learn in an environmental setting.

Conclusions

Designing an Internet-enabled outdoor learning expedition that integrates mobile digital technologies and environmental analysis tools is a multifaceted task. The Our Lake Online project required months of planning and collaboration with countless individuals, corporations, organizations, universities, and state agencies. Our experience with the project has revealed that educators should embark on such a venture with the understanding that this is an emerging process. Therefore, it is realistic to expect that technology glitches and disruptions will occur. Although the Web environment is rapidly moving toward complete interconnectivity, we experienced a number of connectivity challenges. At times, it was impossible for the students to quickly and efficiently log on to the network. We also experienced difficulties due to hardware and software incompatibilities given our attempts to use both Macintosh and IBM platforms with young children. Also, given the budgetary constraints of public school systems,
educators often do not own the hardware and software necessary to embark on mobile digital adventures. Simply stated, the Our Lake Online project would have been impossible without the digital equipment, environmental analysis tools, and technical assistance provided by ALLTEL, Pasco Scientific, and the Digital Exploration Society as well as grant monies awarded by the Martha Holden Jennings Foundation.

Indeed, the use of new technologies translates into trouble shooting at a moment's notice, being able to accept product failure, and coping with systems' incompatibility. Traditional teaching practices are also inadequate for such learning expeditions and onsite student learning requires a radical departure from students seated at classroom desks. Onsite learning requires student mobility and invites learners to be actively engaged and independent to investigate their interests at multiple workstations. The Our Lake Online project represents a significant pedagogical shift as compared with traditional science instruction, and definitely a step beyond using the Internet as a static tool. In the traditional classroom, the role of the teacher is one of transmitter of knowledge. The role of the teacher on a science digital expedition is one whereby the teacher is a guide and facilitates the students' ability to use technologies to learn and create their own dynamic learning records. It enables teachers to teach to the moment quite unlike teaching to a specified, sequential lesson plan. Although a digital learning expedition requires formulating a well thought out plan, there simply is no teacher's guide appropriate for such an adventure. In fact, the highly experimental and exploratory nature of the project embodies the learning philosophy on which it is based. Namely, a digital expedition is an attempt to encourage and enhance the natural tendencies in young children to explore, discover and share.

Today, the true power of digital exploration is connectivity. One day, it will be routine for students to explore, discover and share with others all over the planet in real time from anywhere. Although the Our Lake Online project is an account of just a single digital expedition, we hope that this description will encourage others to embark and experience the power and promise of using mobile digital communications for Internet-enabled outdoor learning adventures.

Problem-solving-based Model of WBI

Tianguang Gao
Department of Curriculum and Instruction
Purdue University
United States
tgao@purdue.edu

Abstract: This paper describes a problem-solving-based model of web-based instruction. The model is based on the idea that the teacher can model a problem-solving process to help students to solve problems as an expert does. It was designed and embedded in a class web site that was designed for Heat and Mass Transfer, an engineering class. There are five parts in this model: answer(s) and relevant reading, your own tutor, hints and solutions, self-test your understanding, and report generation. Informal feedback from students showed positive results from using this model.

There are two broad categories of Web-based instruction. One is using the Web as a supplement to a normal class, while the other is using the Web as the sole instructional resource for the teaching. In the first category, a class web site is created to provide valuable information such as course, syllabus, assignments, grades, projects, and useful links (Rank, 2000). This kind of class web site provides students convenience in getting class information, checking their grades, interacting with the instructor and other students, and finding other information online. However, this approach may not help improve students' problem-solving skills very much. Another format of Web-based instruction focuses on improving students' problem-solving skills by integrating cooperative learning strategies with asynchronous communication technologies like listserv, newsgroup, bulletin board, and discussion groups. Currently, the first category of using the Web as a supplement is the most popular format. We explored how to make use of this supportive format to improve students' problem-solving skills when we implemented a class web site. In addition to maintaining the basic format of a class web site, we explored embedding a problem-based-model into the class web site to foster students' capability to build models and solve problems.

It is believed that modeling plays a very important role in the problem-solving process and is actually an essential part of the problem-solving process not only in science and math education but also in other disciplines (Starfield, Smith, & Bleloch, 1990). One way to solve a problem is to build a model and then refine it. To help students learn skills to build models and solve problems with a class web site, the problem-solving-based model was developed and embedded in the ME315 class web site. The idea is that the site acts as an expert tutor to guide students to build a model based on a specific problem, to get the answer(s), to use existing knowledge, to refine the model and explore further, and to reflect on the problem-solving process.

The model is composed of five components: answer(s) and relevant reading, your own tutor, hints and solutions, self-test your understanding, and report generation.

Figure 1. Diagram of problem-solving-based model

Answer(s) and Relevant Reading gives students the answer(s) and the information needed to solve the problem either from the textbook or and other resources with the intention of helping the students locate and review the needed materials related to the problem. The purpose of providing relevant reading is to lay the
foundation for the students to get the needed prior knowledge to solve the problem.

*Your Own Tutor* asks students questions to help them really understand the problem and acquire the needed information to solve the problem. In this part, very specific questions about equation(s) and variables, and how to interpret the relationship among variables in students' own words, were asked to ensure that students really understand them.

*Hints and Solutions* provides some clues to students for solving the problem and one or more ways of solving the problem. The first part provides some clues that could lead to a solution by the students themselves. If students still have problem(s), the second part provides a diagram model of the problem and one or two ways to solve the problem.

*Self-test Your Understanding* asks students about the solution(s), how to interpret the solution(s), what if the conditions change, if the solution is efficient or not, and finding the cause(s) if an error occurs.

*Report Generation* asks students to write a report for the whole process. This process lets students reflect on what they have learned from their problem-solving process.

This model is a variation of the ideal process of how to teach a novice to solve a problem as an expert does. Research shows that novices have a different problem-solving process from experts due to their different knowledge structure and ways of seeking additional information and better definition of the problem (McCown, Driscoll, & Roop 1996). However, the teacher can model a general approach with the students, which includes identifying, defining, representing the problem, making assumptions, predicting solution(s), evaluating solutions, and reflecting on the problem-solving process to train them to solve problems as an expert does. That is the theoretical base for using this model.

The model was implemented and embedded in the HEAT AND MASS TRANSFER class web site, which is a class for mechanical engineering students, for a one-semester trial. During the trial, students tried one specially selected representative problem each week and twelve problems for the semester by using the class web site. Due to time limits, no formal evaluation was done to evaluate the impact of this model on students' learning. However, feedback from some of the students showed that this model has positive results. A student was even inspired to go to graduate school because one semester's learning made him feel that doing research was very interesting. More trials and formal evaluations need be conducted in the future.

Although this model was implemented with an engineering class, the author believes that it has very positive implication to Science and Math Education in K-12 and can provide a way to use regular web sites for improving students' problem-solving skills.

Sustainable Environmental Education for Brasilian Teachers

Lenise Aparecida Martins Garcia
Departamento de Biologia Celular

Universidade de Brasilia, Brasil
dfaria@unb.br

Abstract: Environmental Education (EE) is considered, in international declarations and in brasilian laws, as a dimension of the Education itself. One implication of this is that all teachers are involved in it. In Brazil the 9795 law, April 27 1999, determines that all teachers have to study EE, when they are in graduation or by inservice studies. In order to facilitate these studies for teachers from all the country, we began at Brasilia University an online course in EE. The methodology they learn at the course helps them to insert EE in their own school discipline, considering their own surrounding reality. The focus includes sustainability, and we call the methodology “Sustainable Environmental Education”.

Introduction

The need for an increasing awareness on environmental problems is being emphasized in several forums and congresses especially since the early seventies. Indeed the decrease of human impacts upon the environment and the sustainability perspective depend, to a large extent, on the education of new generations that will take care of the local and global problems in the future.

At the First World Conference on Environmental Education (Tbilisi, 1977), Environmental Education (EE) was identified as a dimension given to Education contents and practices. This aspect of dimension was a new way to see the question. It was not a matter of introducing new isolated contents, such as pollution, contamination, water quality, solid waste disposal, bio-diversity, deforestation and reforestation, nature conservation and management of natural resources. In order to live in harmony with the environment, and to promote sustainable development, it is essential to create methods, techniques and new approaches to EE, as an important part of Education in general.

The solution of environmental problems also needs an interdisciplinar approach. So, EE needs to be inserted at all disciplines and to promote the active and responsible participation of the society. In this perspective, EE represents a way to see things, a new focus on reality.

Environmental Education in Brazil

One implication of this way of thinking EE is that all teachers must be involved in it. But in Brazil, only recently EE is reaching the schools. It is more given as isolated initiatives, by associations for nature protection or even public initiatives, in extra-curricular activities.

Statistics of 1999 (MEC/INEP/SEEC, 1999) show that Brazil has 36 million students at the first 8 years of school and 7 million from the 9th to the 11th series. It’s a large population to receive EE.

Recently, Environmental Education National Policy was regulated by 9795 Brazilian law, April 27 1999. This law determines that:

- EE is an essential and permanent component of national education, and needs to be present, in articulated manner, in all levels and modalities of the educative process, in formal and informal types.
- The environmental dimension must be present in the curricula of teachers' formation, in all
levels and in all disciplines.

- Teachers in activity must receive complementary studies in their actuation areas, in order to adequately approach the principles and goals of the Environmental Education National Policy.

We have, in order to reach these goals, to offer inservice studies to a great deal of schoolteachers. Statistics from 1999 (MEC/INEP/SEEC, 1999) show that Brazil has over 2 million teachers in activity at Basic Education.

Inservice studies for teachers

How can teachers from all the country, however, take inservice studies? Thinking about that, we began at Brasilia University an online course in EE for teachers. The objective of this course is to enable teachers at any place in Brazil for the insertion of EE in his own school discipline (Faria 1997). Along the course teachers learn fundamentals in EE and in pedagogic methodology, doing also practical exercises (Faria & Garcia 1997). At the end of the course, they have a study program (made by themselves) to apply with their students (Garcia 1997).

The focus of the EE given by us includes sustainability and sustainable development. The methodology is itself sustainable, because it is adaptable to all circumstances of the students and teachers. So, we call it "Sustainable Environmental Education (SustEE)."

SustEE is a methodology, a way to give EE at school Education. It goes through the curriculum and does not suppose the study of any specific environmental question. On the other hand, it allows the treatment of any environmental problem or goal that is important to that community at that moment.

All teachers do their work in the course considering their own reality. So, they work with their students in context situations.

The online course involves a group of tutors, so every teacher that is our student can have a personal guide. He can make questions by e-mail and he sends, also by e-mail, all the personalized activities he has to do for his personal learning and evaluation. We have also a discussion list and some chats.

Our students can be from any part of the country. We have the opportunity, so, to change ideas with fellows that live in very different circumstances, and have to cope with many different environmental problems: from those characteristic to big cities as São Paulo to those existing in areas of recent (or maybe present) deforestation. In a new course version, we are introducing mechanisms of cooperative learning, with activities in which the students work together on a teaching program proposal. Afterwards, each of them works on his own proposal, considering his own circumstances.

SustEE methodology

An important aspect of SustEE methodology is the link that is made between EE and all contents of the official curricula. We will describe here the basic steps teachers do to apply it in school, after learning the SustEE in the course. Really, most of them do both things together and bring to discussion the results and the problems they have.

Step 1: Survey of the necessities, interests and problems (NIPs) of the community, particularly the students. This is done by the application of questionnaires to the students and their parents, interviews with school and/or local authorities, observation of the surrounding environment. At this moment we are interested in all NIPs they have, independently of an involvement of environmental questions.

Step 2: Determination of the region and the community profiles. To do that they consult region statistics and other data, verify local documents and so on. Here we are interested in social, economical, technological educational profiles. They see also the environmental policies for the region and the community initiatives and habits referring to the environment.

Step 3: Analysis of the official or school curriculum. At this point they study some principles of pedagogical sciences and apply them on the analysis of the school programs and of their own practices.

Step 4: General elaboration of Integrated Learning Unities (ILUs). To do that, they consider together what they have after the first 3 steps. ILUs congregate some of the disciplines – or preferably all them – over a same goal, which is related with a NIP, frequently a local environmental question. At this point we try to encourage the teacher to be creative, looking for themes that could be attractive for the students.

Step 5: Proposition of some interdisciplinar activities, to be made by the students, that could
"nucleate" the ILUs. Those activities could be: a visit to some place, a search in Internet (if they have access to it), a laboratory experiment, a bibliographic investigation, prepare a theater presentation and so on. They can think about some independent activities or also plan a school project.

Step 6: Determination of specific links that can be made between the contents of the curriculum and the ILUs, on each one of the activities; selection of disciplinary contents, ethical and behavioral aspects that will be developed on each activity.

Step 7: Elaboration of a teaching program, in the discipline of the teacher that is having the course, covering all the contents he selected to that ILU. It is the moment to specify Learning Generating Nucleus (LGNs). A LGN is a nucleus that congregates contents of his own discipline and the collective goals of the interdisciplinar activities. Each LGN is expressed in a creative manner, trying to attract student's attention and interests.

**EE at hotspots and other significant regions**

Although everybody needs EE, some need it urgently. Brazil is a country of continental dimensions, and is widely recognized as the world’s leader in terrestrial biological diversity, a significant portion of which is threatened today. (Mittermeier et al. 1999). We can focus on 5 very different biomas that deserves a citation here:

**Atlantic forest** is considered one of the most threatened ecosystems on World. It has been reduced to less than 8% of its original area. Even the name of the country, Brazil, is derived from “pau-brasil”, a tree from this forest that began to be devastated in the early 1500, by the first portugueses that arrived at the country. 70% of Brazil’s population resides in this region. In spite of it, this bioma still contains an extraordinary amount of biological diversity and levels of endemism. For example, it is estimated that 54% of the region’s trees and 80% of its primates are not present at any other place on Earth.

**Amazon** is the largest remaining tropical rain forest, with 4,2 million square kilometer. It expands into 9 South American countries, but 62% of it are in Brazil. It has from 5 to 30 million living wild species, only 1,4 million already identified. Today it is the target of rapid economic development, with 16 million habitants already living in the region. Projects to improve conservation and sustainable development are very important to Amazon.

**Caatinga** is the prevalent ecosystem on the least populated and poorest region of the country. The long cycles of severe droughts periodically force local populations to either migrate to urban zones or temporarily exhaust the region natural resources. Understand their ecosystem characteristics and identify possible alternatives of economic development is very important for the communities there and EE has a central role on it.

**Pantanal** covers 140,000 square kilometers and are home to the largest concentration of wildlife in South America. Its wetlands are vital to the survival of countless migratory birds. There are very beautiful places there and tourism is increasing rapidly. It could be an excellent alternative for improving sustainable development of the region, if adequately accomplished. Otherwise, it can be very dangerous to the ecosystem if not controlled.

**Cerrado** is the ecosystem at the central region of the country. Agriculture, cutting for crops and cattle has destroyed much of the forest. Heavy pollution from nearby cities and from pesticides used in agriculture contributes to the degradation of forest ecosystems. It was recently included among the hotspots. One reason for that is its diversity of plants. Of the 10,000 species of plants, 44% are endemic, being not found anywhere else on Earth.

Except the Atlantic forest, most of these regions are distant to big cities and the more developed centers. In many cases the teachers working there haven’t even the necessary formation in the discipline they inservice studies. Communication technologies, however, are reaching rapidly these places, by government and private initiatives.

So, online studies appear as an excellent alternative to these teachers. In fact, we have already in our course students that live in all of the mentioned ecosystems. Some of them acquired a computer and a phone line in order to do the course. They bring very interesting experiences to change with their colleagues and are already applying SustEE at the schools they work.

We know that capacitating teachers, we can multiply our effort to preserve our environment and to have a real sustainable development.

Abstract: This exploratory study investigated the use of an Internet controlled nanoManipulator and atomic force microscope to allow students to explore properties of viruses. The activity was embedded in a week long learning experience in which students interacted with scientists. The study demonstrated the technical feasibility of using such advanced equipment in classrooms. It also demonstrated that students gained in the understanding of the structure and functioning of viruses and changed their conception of scientists as people and science as an activity. A majority of the students were excited about the activity.

Science classes around the world have become involved in Internet-based investigations such as the JASON Project and Journey North (e.g. see http://njnie.dl.stevens-tech.edu/cyberteacher/realtimeprojects.html). These internet-based science programs engage students in using the technology for conducting and sharing science. The American Institute of Physics (1997), and Linn, Shear, Bell, and Slotta (1999) argue educational technology should: a.) focus on learning with technology; not about technology, b.) emphasize content and pedagogy, not just hardware, c.) provide accessible goals so students can connect new ideas with those they already have, d.) ensure the social context of learning supports the process of building on ideas of others, and e.) promote autonomy by creating learners who can move on into life with new skills and knowledge. In the present study, we investigated a new technological innovation called the nanoManipulator (nM) connected to an Atomic Force Microscope (AFM). The nM allows students to investigate nanometer-sized materials through an Internet connection to an AFM located at a university. An unusual aspect of this technological tool is that students get tactile feedback about the nanometer-sized object they are studying.

When using the nM, students move a pen-like joystick that sends signals to the AFM. The AFM probe moves across a sample (such as a virus) and the deflection of the probe is used to provide tactile feedback through the nM. The feedback includes sensations of hardness, elasticity, friction, shape, and stickiness. The combination of physical manipulations and tactile feedback is known as haptic perception.
(involving kinesthetics and touch). The nM also uses 3D graphic technology to provide a visual 3D image of the sample. Haptic perception potentially provides the learner with information about viscosity, softness, texture, elasticity, graininess, pressure, temperature, and involves kinesthetics (muscle, tendon, joint). Klatzky, Lederman, and Reed (1987) noted that haptics is oriented towards the encoding of substance (microstructure). By providing haptic as well as visual feedback, the nM technology provides students with the opportunity to combine visual and verbal representations with haptic. In this exploratory study we sought to understand how students' use of the nM and AFM in collaboration with scientists influenced their knowledge of viruses, microscopy, nanometer scale, the processes and nature of science, science as a career, and perceptions of scientists.

Method

Participants

24 male and 26 female students in two introductory biology classes (n=22, n=28) in a rural-suburban high school in North Carolina participated. The school included 72% Euro-American, 24% African-American, 3% Hispanic students, and 1% other. In each class 6 males and 6 females were followed for qualitative research.

Instruments

Pre-Knowledge Test (PKT). The researcher developed PKT had four constructed response items to assess students' knowledge of viruses. Students were asked what viruses looked like, how viruses function, how viruses cause disease, to draw a virus, and to describe nanometer and name things measured in nanometers.

Beliefs Questionnaire (BELQ). The BELQ assessed students' ideas about scientists and their reactions to science. It asked: What do scientists do when they are doing science, describe scientists as people, and have you ever had a scientist come to your class.

Pre Opinion Questionnaire (PROQ). Students rated, on a six point Likert scale, their reactions to working with a microscope and indicated their degree of belief about how scientists work and what they do.

Post-Knowledge Test (POKT). The 6-item POKT asked 6 students were asked to describe the nM and AFM, different types of microscopes, adenoviruses, to list things measured in nanometers, and to draw a virus.

Post Experience Questionnaire (EQ). The 5-item EQ asked students to describe how the instructional experiences influenced their feelings about science, additional experiments they would have performed with the AFM, what scientist do when they are doing scientific research, and any new impressions they had of scientists.

Post Opinion Questionnaire (POOQ). The POOQ contained the eight reaction items from the PROQ and two additional rating items. They asked students to rate how much they had learned and how much the instructional experience had changed their views.

Pre- and Post Interview Questionnaire. The pre and post interview questionnaire contained questions that guided intensive interviews with the subsample. The items asked about the AFM and nM, adenoviruses, how big viruses were, and their perceptions of the learning experiences. Items were used to initiate interactions with the students; interviewers probed their understandings more deeply than with written response assessments. Also, students were asked to construct and explain a clay model of a virus.

Equipment

The students used a Phantom nM device connected to a desktop computer to access, over the Internet, an AFM. A second computer connected to the internet provided two-way video-audio access to the scientist running the AFM.
Procedure

Pretesting. 1.5 months before the instructional activity, participants received an explanatory letter and permission forms. Two weeks later, participants completed the Pkt, BELQ, and PROQ. Instructional Activity. The instructional activities occupied 5 science class periods. At the beginning, students were told that they would write a newspaper article that would be published in a Web newspaper. An activity packet was provided which gave directions for each activities described below and suggestions their newspaper article. On the first day, a participating scientist lectured on metric scale, the AF microscopes and how the nM/AFM provided magnified images and tactile feedback. For the next three days, students (divided into teams of four or five) completed two activities per period with each activity lasting for 20-25 minutes. The activities were: use of nM/AFM, use of a simulation of the AFM, interview a scientist, and writing, (described below). Nanomanipulator/atomic force microscope. In this activity, each student used the nM/AFM guided by a physicist. Each student controlled the nM to touch a virus and use the nM to make individual investigations such as moving viruses or trying to break the protein coat of the virus. The students were encouraged to talk to scientist running the AFM while one of their team members was using the AFM. Simulator Activity. The Simulator activities consisted of a mechanical model of the AFM. The model could allow a tip to travel across a stage and over a sample. A tracing was produced on a sheet of paper. Students made a model of an icosahedral adenovirus from a cut out cardboard sample and used the Simulator to trace it. This activity helps students the scale of cells and viruses. The students were told that if a human cell were magnified 300,000 times it would be about the size of their classroom and an adenovirus magnified 300,000 times would be about the size of their softball-sized model. The students completed tracings of their model adenovirus. The tracing activity demonstrates how the AFM images only the top of objects. The scientist in charge asked probing questions to help students understand the AFM. Interview a scientist. Students had 2 opportunities to interview scientists including physicists, information scientists, and computer scientists. The instructional packet had suggested questions, but encouraged the students to be creative and to their interest. This activity gave students an opportunity to learn about scientists in different contexts and to provide a image of scientists that contradicted popular stereotypes. Writing Activity. In the writing activity, students planned and began writing their newspaper story. Students were provided with a possible outline, but were encouraged to be creative in their story. Students were asked to give readers a description of what they personally found worth noting about the experiences. Post-Test Activities. On the fifth day, students completed the post-assessment instruments (POKT, EQ, and POQO) and their newspaper stories. Individual Interviews. The first two authors interviewed students in the subsample individually two weeks before the instructional week. Each interview took about 15 minutes. Interviewers audiotaped and took field notes. Post interviews were conducted similarly to the pre-interviews in the week after instruction. Analysis. The knowledge test, opinion questionnaire, and interview questions were analyzed by item for pre- and post-assessments. Interview tapes were transcribed and pre- and post-instruction item responses were placed in a matrix for comparison. Frequencies of responses for each item on the knowledge tests, opinion questionnaires, and interviews were determined and for open-ended items student responses were grouped into categories (described below). Videotapes of the clay models were categorized. These categories included: presence of: angles, 2-dimensions (2D), 3-dimensions (3D), irregular edges, bumps, appendages, 20-sided, spherical and angled, cell-like, phage-like, rounded icosahedral, ball-shaped, and amoeba-like. Students’ responses to the beliefs questionnaire about science and scientists were compared to students’ responses related to the learning experiences on the experience questionnaire and the post-interview transcripts to examine how the investigations influenced their perceptions of scientists and science. The newspaper stories were read and reread across individuals and categories of analysis were identified by the major areas addressed in the stories. The categories that emerged and were subsequently coded included references to or descriptions of: the research team, feeling or manipulating the virus, the shape or texture of the virus affective reactions to the experience and changes in students’ ideas or opinions.

Results
The knowledge tests, opinion questionnaires, and interview questions revealed changes in students' knowledge of viruses, microscopy, nanometer scale, understandings of the nature of science, knowledge of science as a career, and understandings of scientists. The qualitative analyses of students’ drawings, responses, and clay models also found important pre- and post-differences.

Knowledge of viruses

On each of the knowledge test questions that were parallel from pretest to posttest, students improved significantly and substantially on the: structure of viruses question -- 0% correct to 60% correct; how viruses cause disease question -- 0% correct to 32% correct. Prior to instruction most of the students typically represented viruses as similar to cells, amoebas, or paramecia. The results of the clay model virus task showed that students’ concepts of viruses moved from conceptions of bumpy, round, 2D images, to conceptions that were more typically 3D, angular, 20-sided, and spherical with angles (like the isocahedral paper models made during instruction. The clay models and the drawings showed an increase in the number of dimensions represented. After instruction, 35% of the students' drawings were 3D, no pre-instruction drawing was. After instruction, about 16% of the drawings included the bumpy surface features of the adenovirus. The changes form 2D to 3D conceptions of viruses were noted also on the written pre- and post-knowledge tests. We coded description as 2D or 3D (88% interrater reliability). A chi-square indicated a significant change from 2D to 3D language from pre-test to posttest \( \chi^2(1)=18.5, p<.01, N=41 \). On the pretest, students described viruses as "circles" or "curvy lines;" on the posttest references such as "dice," "spaceship," or "robot."

Knowledge of Scale

Responses were scored as correct, partially correct, or incorrect. Chi\(^2\) indicated a significant increase from incorrect to partially correct or correct descriptions from pretest to posttest. \( \chi^2(1) = 29.4, p<.01, N=43 \).

Knowledge of Microscopy

Prior to instruction students typically named only the light microscope (70%); a few named the electron microscope (20%). After instruction 50% also named the AFM. Students' post descriptions went beyond the naming to include how the nM and AFM operate and the impact of tip size on images produced. Tammy, one of the students explained the use of the nM and the AFM in her story: "(T)he nM... is a little box with a pen attached to it. The box is attached to a computer. When we walked in, we saw a purple bumpy surface on the computer screen. You then touched the pen to the surface by looking at the computer. Rapidly you start to feel the pen jump and vibrate as it makes you feel as if you are touching the virus." Darren wrote: "The nM is pretty complicated to explain. There was a colorful image on a computer screen. The image looked like a globe with the actual elevations on it. It was a flat surface with different lumps. We used a hand-held pen to move a point on the screen around. When you moved the point over the lump, which is an actual virus, you could feel the surface of the virus..."

Knowledge of Scientists and Science Careers

Students were asked during the pre-interview if they had met a scientist. 82% said no. Students also were asked to describe a scientist. Their pre-responses reflected the typical stereotypes scientists, boring old white men. On the posttest, students were asked if the activities had given them new impressions of scientists. 63% said “yes.” Many students who said no also noted that they already had high opinions of scientists and the activities reinforced their positive impressions. Students who indicated a change in perceptions described changes in their feelings about science, science careers, and characteristics of scientists. For example, Fred wrote “Yes, they aren’t just old men that sit in a lab all day.”
erspectives of their work as well as the scientists' lives outside their research. Nearly all the students commented on scientists' lives outside of work.

Students' Affect For Science

Eight students noted that they had more positive feelings about science as a result of the experiences. Responses included: "It showed me that there was more to these jobs than old men in white lab coats doing boring experiments; they showed it can be fun." Sixteen students commented that after the instructional experiences their understandings of the nature of science careers had changed. For example: "They have a fun, hard job to do. They are not all that boring after all." "I never knew that science can vary in meanings. Like people consider computers to be science when it doesn't deal with science at all." "I enjoyed my experience learning about viruses. It opened my mind to a possible new career path as a scientist and gave me a new outlook on viruses."

Students were asked on the pre- and post-questionnaires to describe what they thought scientists do when they are doing scientific research. Twelve of the students' responses showed a change from a pre-conception of scientists as searching for answers to a post-conception of scientific research as a more dynamic and flexible process of inquiry. A recurring theme that emerged from the interviews and written reports was new understanding of the collaborative nature of modern science research. The stereotype of the isolated scientist working alone shifted to a concept of teams of scientists working together as noted by these students.

In summary, the investigations with the nM and the AFM influenced students' conceptual understandings of the morphology and 3-dimensionality of viruses, microscale, microscopy. Students' beliefs about science, science careers, and scientists were also altered as a result of the experience.

This study was exploratory in nature and the results should be viewed in light of the limitations of the study. It isn’t possible to separate the impact of the technology from the influence of working alongside the university scientists. It is also highly likely that the mere novelty of participating in this type of unusual instructional experience would alter students' motivation and interests. The writing task was a rich source of information for the research but was generally disliked by the students. As a result, some of the students’ wrote little and did not elaborate on their ideas.

Discussion

Students' understandings of virus morphology and dimensionality changed as a result of learning experience. Students' mostly depicted viruses as having 2D before using instruction and as 3D after instruction. These results suggest that the use of haptics as a tool for learning about morphology of invisible materials may be of benefit. The nM technology adds physical manipulation and an element of "hands-on" exploration to the study of nanoscopic objects. This study showed that use of an Internet-based nM/AFM technology in classroom was technically feasible. Further research is needed to examine how manipulation of nanometer sized materials contributes to conceptual understandings and how to scale up this technology to make it more widely available. The rapid development of Internet-based high quality 3D graphics and virtual reality software opens up new worlds to science teachers. The potential for students to visually and physically explore microworlds is within our grasp. The challenge for researchers is to develop new ways to measure how
these technological innovations influence students’ learning. Students also made gains in their understanding of microscale as a result of participating in these investigations. Scale is a difficult topic for students to understand and yet is a major theme that cuts across science disciplines (AAAS 1993). As a result of using the simulator and the nM/AFM, students began to develop understandings of the limitations of trying to visualize in 3D an object that is laying flat on a surface. The use of the nM to move, roll, and probe the viruses appears to have made a difference in the dimensional concepts students held of viruses.

Interviewing and working with scientists on the nM/AFM appears to have changed students’ understandings of scientists and their work. Students were particularly interested in the normal lives that the scientists held outside of their work. They were surprised that the scientists actually had families, pets, and did normal things like go dancing and play in sports. These interactions with the scientists made science as a career seem plausible.

The Internet science education environment 
(ROL)

Zdena Lustigova, Stanislav Zelenda
Department of Physics Education, Faculty of Mathematics and Physics
Charles University Prague, Ke Karlovu 3, Praha Czech Republic
Lustigo@plk.mff.cuni.cz, Zelenda@plk.mff.cuni.cz

Paper deals with the ROL (Remote and Open Laboratory) - a component of the open educational and informational electronic supportive environment for science education of a broad scale of target groups (from pupils and teachers to technicians). The ROL on the Internet contains different kinds of materials (experiments, models etc.) and tools for teaching and learning science via network. A brief description of the content and ways users can work with the ROL is given. Some examples starting from "sharing ROL environment via the Internet" to the Web delivery of online courses and learning environment are presented.

ROL – history and brief description

The Internet based "Remote and Open Laboratory" (ROL) - is a part of the Laboratory for Computer Aided Physics Instruction at the Department of Physics Education, Faculty of Mathematics and Physics, Charles University in Prague. At the beginning (1996) the ROL was mostly oriented to initial teacher training. Now, thanks to increasing number of schools connected to the Internet the laboratory serves more and more in-service teacher training and classroom applications.

The ROL is focused mainly on support of experimental activities in physics, biology and chemistry, gives teachers and students possibilities to get familiar with methods of data acquisition and data processing, offers large number of experiments and models for studying and better understanding of different phenomena and systems behaviour.

The aim and idea of the ROL

The Remote and Open Laboratory's main aim is to give:
• supportive environment for teaching and learning experimental and modelling skills and for getting familiar with useful modern tools and techniques for experimenting and modelling
• learning environment with a set of well structured online courses with tutoring and with large amount of slightly structured learning materials in open learning area, both mostly oriented to initial teacher training (laboratory works), but also relevant to in-service teacher training
• flexible, easy and powerful tools for communication and desirable co-operation among students, users, teachers, experts and developers (using the Internet to share laboratory working desk)
Content of ROL

1/ Information sources and databases

The Remote and Open Laboratory contains large databases of physics, chemistry and biology experiments (including downloadable data), computer models, descriptions and explanations of many phenomena.

Experiments with computer measuring systems

This largest part of the Remote and Open Laboratory consists of more than two hundred experiments for computer measuring systems complemented with downloadable data and multimedia descriptions of experiment set-up. This database can be viewed by keywords, titles and areas, enriched with fulltext searching.

Most of the experiments was developed originally for the measuring system ISES [1] and cover the following areas: acoustics - musical instruments sounds and their frequency analysis, mechanics, optics, electricity and magnetism, electronics - semiconductors, and so called "mismatch" - e.g. a human heart and blood-vessel system measurements, etc.

The user can use the database in following two ways: If his laboratory is equipped with the software and hardware supported by Remote and Open Laboratory, he can launch an application, carry out the experiment described and, for example, immediately compare the results of their experiment with the downloaded data.

If the user’s laboratory is not equipped with the measuring hardware, he can download data prepared for different kinds of application (e.g. ISES demo, spreadsheets like MS Excel, QuatroPro, etc) and work with the data in this environment.
Computer models

In the Remote and Open Laboratory a user can find sets of computer models and simulations, from the simplest to highly developed ones. These models are created in different modelling environments which allow users to choose and to reflect their modelling preferences, competence, skills or the tools they know.

The models and simulations were developed in different modelling systems - e.g. Interactive Physics [3], Famulus, IP Coach [4] and spreadsheets. Models are mostly ready to be used in schools by students or by teachers. Some of them are completed with commentaries, others are intended to be refined by teachers or students. Models are presented in many different ways and they are usually combined with questions to be answered. If users do not have the modelling system in which the model has been developed, they can use a spreadsheet or have a look at the model as a movie and continue studying the problem in a slightly different way.

![Figure 2: Living "3-D Lissajoux patterns" pop up as a running model from the WWW page specifically structured learning materials.](image)

Experiments without computers

There a certain number of experiments in Remote and Open Laboratory which do not need any computer measuring system. These experiments are presented in form of hypermedia guides including video records, animations or series of pictures and schemes. Usually they are extended by questions and suggestions for further experimenting and complemented with brief remarks about how to perform and explain the experiment. This explanation is usually supplemented with useful data, additional knowledge and references.
Technical and general information

The indispensable part of the ROL contains important information on computer measuring systems: technical details of hardware and software, recommendations, manuals, and guides.

2/ On line courses

The ROL offers different kinds of on-line courses mostly oriented to future teacher training and in service teacher training. These courses are offered as a part of combined courses [5] (together with face to face training) or delivered independently for different purposes (e.g. for "home preparation" of university students).

![Figure 3: Web page with movie - recorded experiment on "Surprising magnetic behaviour of distilled water"](image)

![Figure 4: Part of course CAL (Computer aided laboratory) media room.](image)
3/ Communication tools of the ROL

The ROL uses standard Internet communication tools for “off-line problem-sharing”: FTP, e-mail, Web forums, last both with attachments. We use the capabilities of videoconferencing tools, the Internet telephone, and chats for “on-line” consultations.

![Image of a user working with downloaded models]

Figure 5: The user working with downloaded models “Charging and discharging capacitor - comparison of experimental data with models” and performing the recommended experiment (using downloaded set-up of the experiment and different modelling environments Famulus, QuatroPro) found and emailed a severe problem.

The ROL addressee can immediately rerun the whole problem situation -“shares the problem situation with the user:”

The Remote and Open Laboratory in action

The Remote and Open Laboratory is able to become an open environment for learning, teaching and co-operation among users (students, teachers) and developers, providers (experts, students, teachers etc.). Simple examples of work in ROL learning environment follow.
Figure 6: Example of the learning environment in the ROL (right frame – configuration and setup of the experiment, upper frame – experimental data obtained by system ISES, left lower frame – description and theoretical explanation, including simulations).

Figure 7: Example of learning environment in ROL (background window – content items and problems, lower right window – "a hint on the problem situation", upper right window – a simulation of the studied phenomena.

Users can change downloaded models and experiments, adapt them to different conditions or needs. They can also develop, verify and describe their own experiments or models and present them to other users in the Remote and Open Laboratory.

Users can simply ask authors and contributors the Remote and Open Laboratory for more information, send their comments or ideas via e-mail or other ROL communication channels.

Teachers can use their own modification of the ROL in the school LAN to distribute data or tasks to students via ROL environment. In the same way they can “open” school science labs to students, allowing them to learn science by exploring data, modelling, verifying hypotheses and looking for interpretations, whether the school labs are occupied or not.

Meeting the Need for Technology Integration: Math, Science and Technology Integration for Pre-service Teachers

Skip Marshall, University of Florida
Rose Pringle, University of Florida
Kara Dawson, University of Florida
Alan Hochman, University of Florida

Abstract
Historically, teacher education programs offered methods courses offered in isolation, neglecting the integrated manner in which many elementary classes are taught. This presentation focuses on the importance of curriculum integration in pre-service teacher education programs. The presenters explore the Math, Science and Technology (MST) integration block developed by the School of Teaching and Learning at the University of Florida for its Proteach II teacher education program with a focus on the technology integration course. The MST program goal is to develop the skills required by teachers to effectively create and implement an integrated curriculum.

Introduction
Historically, teacher education programs offered methods courses, such as science, math, reading, language arts, and social studies, taught in isolation. Although elementary educators often integrate subject matter, teacher-education programs have limited the inclusion of this skill in the coursework. Implemented in the fall of 2000, the School of Teaching and Learning at the University of Florida began the Math, Science and Technology (MST) Integration Block, providing pre-service teachers with opportunities to learn curriculum integration in a technologically connected environment.

Unable to conceptualize what curricular integration requires of teacher and student, pre-service teachers find it difficult to effectively integrate technology with multiple content areas. Carlson and Gooden (1999) state that “in order to become fully comfortable with use of educational technology, pre-service teachers need to actually see technology use modeled by their professors and their supervising teachers.” This applies to all content areas. The MST block implements curriculum integration in a manner that allows pre-service teachers to benefit through both university learning and classroom activities. Specifically, the pre-service teachers are taught in the manner in which they are told to teach.

According to Carlson and Gooden (1999), technology mentoring is an essential component of pre-service development. Pre-service teachers also need better preparation in the use of technology (Carlson and Gooden, 1999), making them ready for what they will face in the 21st century classroom. By modeling effective and appropriate technology implementation, MST instructors offer students a vital component to the teacher education program.

The MST Block
Creating an integrated teacher education program offers many learning experiences for instructors and students. Bringing together departments that have taught independently elicits many challenges. How do instructors bring three separate courses together? How do you create a curriculum that focuses on the integration of the material yet accounts for the individual needs and requirements of the subjects? How do you maintain an integrated environment and still prepare your students to enter a classroom guided by standardized tests and isolated content? Answering these three questions is essential in creating a program
capable of providing pre-service teachers with the skills necessary to integrate content areas and technology.

Although the three courses are taught separately, content integration serves as the focal point for each class. In the integrated environment, students are provided with first-hand experience of how subjects can be integrated with technology serving as a tool to enhance the learning. Instructors teach about content and technology integration through unified lessons while maintaining the importance of the respective subject area material. Examples of lessons and experiences include trips to Camp Crystal Lake, an outdoor science education environment operated by the School Board of Alachua County. While visiting the camp, university students work with elementary school children as they complete water quality surveys, ecosystem investigations, and other camp activities. Math and technology are integrated throughout the traditional science curriculum. Activities include estimation, measurement, and calculation, followed up by entering the collected data into web-enabled database from wireless computers. Students and pre-service teachers take digital pictures as well as video tape of students participating in the lessons. The images and video are later combined into presentations.

The MST block provides an additional opportunity for student-teachers to experience curriculum integration in the elementary classroom setting. During the course of the semester, student-teachers are placed in elementary classrooms with the intention of observing integrated lessons involving math, science and technology. While in their field placements, the pre-service teachers observe how integration works (or in some cases does not work) and apply that to what they learn in the university classroom. These experiences are intended to extend the student-teachers’ knowledge beyond the theoretical framework of the university setting.

During the course of the semester, the professors and graduate assistants met to evaluate and adjust the course material. In addition to these meetings, instructors (from math, science and technology) met to evaluate student projects. Although this proved time-consuming and difficult to schedule, the thorough feedback the instructors provided offered the students an opportunity for tremendous growth. While the feedback focused on the integration aspect of the assignments, comments specific to subject content reinforced the importance of maintaining the specific content of each subject. Although the student-teachers initially missed the value of the collaborative assessment, they understood its importance by the end to the semester.

Conclusion

Three times during the semester, students in the MST block had the opportunity to write reflective journals about their experiences. The first journals written by the students could best be characterized as tentative and uncertain about how they would benefit from the technology portion of the MST block. Students expressed concerns ranging from being unsure about their technical skills to being incapable of learning the technical skills necessary to integrate technology and teach students whose technical skills may likely exceed that of the teacher. By the end of the semester, students’ attitudes changed dramatically. In their final journal entry, most students expressed surprise and satisfaction with how far they had come. Many students stated that they were looking forward to entering the classroom and providing meaningful learning for their students.

As today’s pre-service teachers are prepared to teach in 21st century schools, education programs must ensure that pre-service teachers are able to meet the educational objectives while avoiding the lack of technological expertise that is the "norm" in today’s teacher (Carlson & Gooden, 1999). If future teachers are to be qualified to present a technologically integrated curriculum that meets the ever changing demands of a standardized world, they must be trained through modeling and experience. The Math, Science and Technology block is determined to provide those necessary skills modeled in manner that allows the pre-service teacher to see its effectiveness. In its first semester, the MST block has taken huge strides in improving the way in which methods courses are taught. Although only time will tell how effective it will be, the MST block is on track to impact many pre-service teachers, making them ready for the 21st century classroom.

Aiming a Better Understanding in Science Courses through Mathematical Reasoning

Simon Mochon
Department of Mathematical Education
Center for Research and Advanced Studies, Mexico
smochona@mail.urmex.mx

Abstract: In this article we present a project which has the purpose of using mathematical based explanations to support the teaching of the sciences (chemistry, biology and physics) at the secondary level in Mexico. The article describes the structure of the worksheets developed and the pedagogical model followed within the classroom to ensure an efficient use of the activities. Spreadsheet models to be explored by the students accompany many of the worksheets. We will also show some of these spreadsheet models designed for this educational project.

Introduction

We can predict natural phenomena because it follows some ordered behavior. Behind this order, we find a few principles that can be formulated mathematically. A deeper understanding of science requires the use of these principles as mental tools. For example, diffusion can be better explained and understood using Fick's law about the net flux of particles being proportional to concentration gradient.

Thus, this project is based on the idea that the students can achieve a better understanding of some scientific phenomena if they are imbedded in proper mathematical formulations that will give them a more precise structure and the possibility of quantification.

In some countries like in UK, mathematical modeling is used as a strategy to teach math and science. In this didactical approach, we are interested in the construction of the math model as a tool to learn the surrounding mathematical and scientific topics.

The Ministry of Education of Mexico has being sponsoring, since 1997, a national program to teach mathematics and physics with technologies at the secondary level. Parallel to this educational project, there is an ongoing research project that has as its main purpose to investigate the impact of this technological implementation in students' learning, teaching practices and curricular transformation.

The project presented here was born as an extension to the previous project to cover the subjects of chemistry, biology and physics, but with the difference of stressing the math modeling approach and de-emphasizing the technological aspect. In this paper we will describe the materials that were designed for this educational project. In each of the science courses, chemistry, biology and physics, we developed around 60 worksheets on different topics. About half of them can be used in the science classroom directly since they do not require any computational tool. The other half, guide the students to explore mathematical models constructed on spreadsheets. We will talk about both of these types in the following sections.

The activities developed for this project have the aim of complementing the normal presentation of subjects done by the science teachers in their classrooms. Although they have a mathematical content, the purpose of these activities is to learn scientific concepts and ideas and not math (although the students also learn math as an extra benefit).

In addition to the activities proposed to the science teachers, there are also computational tools to support them in expanding these mathematically oriented activities. For example, Figure 1 shows a prepared spreadsheet where the students can introduce any data very readily to obtain the corresponding graphs. There are more graphing tools, like a pie chart graphing spreadsheet or a spreadsheet drawing automatically the least square approximation line to some given data.

Worksheets Requiring only Paper and Pencil

Within the classroom, we have used very effectively a teaching strategy that in part consists of coupling a math modeling approach with worksheet guidance.
An antecedent of this method is a collaborative Mexico/UK research project (Sutherland et al. 1996) aimed at investigating the role of modeling with spreadsheets across a range of subject areas (physics, chemistry, and biology). In this early research, the spreadsheet was introduced into the students’ science classrooms to construct models, called by Mellar (et al. 1994) "artificial worlds". This activity helped the students to understand the scientific concepts behind the model.

In this new project presented here, we were not interested in the students constructing models but on the advantages of exploring and analyzing some aspects of a mathematical model to enhanced students’ understanding of the scientific ideas related to the model.

For the design of the worksheets, we defined a structure that turns out to be very useful. In the next lines we give the sequence followed:

i. Posing a real situation as background.
ii. Asking some intuitive questions for the student to reflect on the problem.
iii. Analyzing the situation through questions and feedback.
iv. Expand on the analysis, giving questions about results, challenges and open questions.
v. Discussion and conclusions (it is important for the students to summarize their conclusions).
vi. Extra work (for fast thinking students).

The worksheets start with very directed tasks and progressively leaves the student with more freedom to try his own ideas.

The worksheets designed fall into two different categories. About half of them described a scientific situation using mathematical ideas but no computational tools were needed. The other half were based on mathematical models constructed on spreadsheets. In the first type then some aspect of a mathematical model was analyzed through the use of graphs or tables. In the second type, the students explore the spreadsheet model.

To illustrate the previous points, the following is a worksheet of the biology series of the first type:

**The breathing cycle.**

*Observe the graph of the variation with time of the lungs’ volume of a person (in liters) during rest. Note how the graph repetitively goes up and down. Explain why: Show in the graph the intervals where the person is breathing in and breathing out. Which is the maximum volume reached by the lungs? Which is the minimum volume reached? Do they empty...*

*The actual lines in the worksheets are bigger so the students have enough space to answer. Here we reduce them for lack of space.*
out completely? How much air comes in and out during each breath? Now observe the time axis to answer: How many seconds lasts each breath? Note in the graph that there are 5 complete breaths in 15 seconds. According to this, how much time does a single breath last? (Compare this answer with your previous one). How many breaths will this person take in a minute? We obtained above that this person inhales 0.6 liters of air in each respiration and that he takes 20 breaths per minute. How many liters of air does the person inhale per minute? The air contains 20% oxygen. How many liters of oxygen does the person introduce to his body per minute? The air coming out of the lungs contains only 15% oxygen. How many liters of oxygen does the person take out of his body per minute? How much oxygen does his body use per minute? (this is 36 liters per hour). Observe now the graph of the variation with time of the lungs' volume (in liters) of a person right after exercise. Show on the graph the intervals where the person is breathing in and breathing out. What is the maximum volume reached by the lungs? What is the minimum volume reached? Do they empty out completely? How much air comes in and out during each breath? How many seconds does each breath last? Note on the graph that there are 5 complete breaths in 10 seconds. According to this, how much time does a single breath last? (Compare this answer with your previous one). How many breaths does this person take in a minute? In this more intense respiration, the person inhales 3 liters of air in each breath and he takes 30 breaths per minute. How many liters of air does the person inhale per minute? The air contains 20% oxygen. How many liters of oxygen does the person introduce to his body per minute? The air coming out of the lungs contains only 15% oxygen. How many liters of oxygen does the person take out of his body per minute? How much oxygen does his body use per minute? (this is 90 liters per hour). Compare the values obtained for the person at rest with the ones after exercise. Write down and explain the differences and draw some conclusions from these findings.

Worksheets to Guide Exploring Math Models in Spreadsheets

As we mentioned before, about half of the worksheets were designed to guide the students to work with prepared spreadsheets. Some of them have data about a specific topic or facilitated calculations. Others contained mathematical models for the students to explore. In this section we will show some of the spreadsheet models with controls that were designed to support this project (we can only show here a static version of the screens. The dynamic power of these spreadsheets will be shown during the conference). Some of the spreadsheets have the purpose of facilitating calculations, making it easier for the student to concentrate on the scientific content. For example, in the first two columns of a spreadsheet (not shown here), the student introduces the symbols and the number of atoms of the elements in a given formula. The program returns the molecular weight of the compound and the percentage participation of each element. Also using this spreadsheet, the students discover formulas if the percentages of the elements are given. Figure 2 shows a simulation of the process of electrolysis (for the chemistry course). As the level of water is reduced, the amounts of hydrogen and oxygen increase accordingly. The students can take data and learn the relationships of mass and volume of these three substances (the control makes the effect of a dynamic process). Other spreadsheets for chemistry have reaction models, distribution of electrons in orbits for each element, etcetera.
Figure 2: Spreadsheet modeling the process of electrolysis

Figure 3 shows a spreadsheet containing a simulation of diffusion in two dimensions (for the biology course). In it, we can start with any quantity of particles in each of the 100 cells and by pressing the F9 key repeatedly, we can observe the particles diffusing through the cells. On the left side of the screen, the diffusive constants in each of the four directions can be changed.

Figure 3: Spreadsheet modeling two-dimensional diffusion

Figure 4 shows a spreadsheet containing a mathematical model of two competing species (for the biology course). Each specie has a number of parameters that can be change through controls. The dynamic movement of the graphs allows the students to visualize the effect produced.
Other spreadsheets for biology model populations in different ways, genetics, epidemics, nutritional data, etcetera.

Figure 7 shows a spreadsheet containing a simulation of radioactivity (for the physics course). Pressing the F9 key repeatedly, we can observe the atoms being disintegrated. The half-life of the material can be chosen and data can be obtained as a function of time.

Other spreadsheets for physics model heat conduction, free fall or with air resistance, circuits, etcetera.
Pedagogical Model

The pedagogical model for this project was described in a previous article (Mochon 2000). Here we will mention only its main components:

✓ The work of the students is directed through worksheets to “discover” important ideas in the sciences.
✓ The students become the most important elements in the classroom, through active participation and reflection.
✓ Communication is crucial in the learning process of the student. Thus, the work is done in groups.
✓ The teacher in the classroom has the role of guiding the students to discovery and orchestrating the discussions.

As can be seen, the design of the worksheets is as important as how they are used. Our previous experience shows that the teacher is a very important component in this model. He should encourage the discussion between the students during and after the activity is done.

Conclusions

We have seen once again that the use of controls in spreadsheets has great potential to support the teaching in science, where mathematical models with dynamic graphs can give a visual image of the situation involved. Although this has to be confirmed further by the classroom results, there is already data supporting the idea that an approach of quantifying the sciences through models, tables and graphs can be useful to improve the understanding of the concepts and ideas.

Finally we should stress that computational tools where the students act independently have a lower chance of success than those supported by worksheets that guide the students through the “right path” to discover relevant ideas. Also, an appropriate pedagogical model is needed.

Abstract: Hand held devices, such as Palm Pilots, have the potential to revolutionize the science classroom. These small, inexpensive devices make it possible for science teachers to grade students' laboratory and group projects in real time. A team of science teachers and university educators will discuss what they have learned about these devices and their effectiveness as tool for learning and instruction.

Introduction

A Personal Digital Assistant (PDA) or handheld computer is a small hand held computer with built in applications such as word processing, spreadsheet, personal organizers, and calculators. Grade book and disciplinary programs expand the usefulness of the devices for busy educators. With a shift from teacher-centered to student-centered classroom environments, PDAs may play an important role in enhancing teaching and learning experiences.

Literature Review

While research on PDAs is in its infancy, it is useful to examine the literature relating to the use of laptops and PDAs in schools, as they relate to portability and ease of use. Of particular interest is the documented shift from teacher-centered to student-centered classroom environments in laptop schools (Stevenson, 1998; Rockman, 1998). Increases in both cooperative learning and project-based instruction were documented by Rockman (1998).
Pownell and Butler (2000) identified ways that PDAs can benefit educators. Pownell and Butler argued that PDAs are only effective when they support how teachers work and use information in their classrooms. Their website, The Online Educator's Palm Web Site, identifies four differences between PDA/handheld computers and desktop computers. One difference relates to portability and size. While laptops are smaller and more portable than stationary computers, PDAs are small enough to be carried in a pocket or a student's backpack. Like laptops, PDAs offer teachers and students portability (Bell, et al, no date; Byers, 1991; Concord Consortium, 2000) and on-the-fly note taking. They are also useful as field journals or in traditional lab settings (Berlanger, May 2000; Cooke, no date; Trotter, October 27, 1999). Accessibility is another area of comparison between laptops and PDAs. Handheld devices are considerably cheaper to purchase and to operate than laptops (Belanger, May 2000). Trotter (October 27, 1999) calls them "equity computers" because of their low cost and ease of use. A third category of comparison is mobility. Teachers are not restricted to a stationary computer and can access and retrieve information anywhere, anytime, including in the field or on fieldtrips to museums or historic places (His & Manus, no date). The fourth area of comparison relates to the adaptability of PDAs. PDAs can change the way educators use technology and the way they access information, particularly information on the Internet. (Pownell & Butler, 2000).

While research on the effectiveness of PDAs in educational settings is sparse, relatively few K-12 schools have had PDAs in place long enough to generate longitudinal studies of their instructional impact. Several groups are actively researching PDAs' classroom effectiveness. Among these groups is the Multimedia Portables for Teacher's Pilot in the United Kingdom. This project put 1,138 high-specification portable computers in the hands of practicing teachers in a range of schools. The program reported high levels of motivation and self-reliance (Fisher, 1999). The program concluded that the PDAs were flexible and adaptable and successful in providing a context for teacher professionalism to flourish (Fisher, 1999).

The Kentucky Migrant Technology Project, a division of the Ohio Valley Educational Cooperative, piloted a PDA program at Eminence Independent Schools in Eminence, Kentucky in 1999. One teacher and a group of eighth graders participated in the program. Preliminary findings included less teacher time spent photocopying tests and other papers and more efficient instructional time. Not only did the teacher use the PDA to beam tests and electronic texts to students' PDAs, but also the students used the devices as journals and as personal organizers. The PDAs' spreadsheet programs and the device calculators were used as well. Conclusions from the first year suggest PDAs are effective tools in the hands of teachers (Lifestyle Passport, 2000). The project is also piloting an online course using the devices, with course materials available for online download. Once downloaded to the desktop computer, the course can be beamed to an instructor's and the students' PDAs.

Other research efforts using PDAs are underway. The National Classroom Project (NCP) at the University of Mississippi (Cooke, no date) supports the use of PDAs as portable labs. One objective of the project is to test whether classroom sets of PDAs can be effective when wheeled from classroom to classroom. NCP literature suggests that PDAs will assist teachers in measuring student progress even as it allows them to conduct individualized re-mediation. Another group examining the effectiveness of the PDA in an educational setting is the Concord Consortium. Research conducted with second and fifth grades found that while both groups were
comfortable with the technology, older students used the devices more effectively (Staudt, October 1999). Both groups "easily moved between note taking and data collection" (p. 1). The devices gave students "opportunities to connect questions and investigations to the data a real time setting that enhances "systematic investigations, critical thinking and cooperation" (Staudt, October 1999, p. 1). Additional research suggests that PDAs facilitate group work, the immediate analysis of data particularly during laboratory exercises or when conducting scientific investigations in the field rather than in the classroom (Belanger, May 2000).

**Overview of the Study**

The main objective of this study was to determine the feasibility of implementing the personal handheld devices for instructional use in the middle school science classroom. Three science teachers in a local middle school participated in the pilot program. They were selected for participation based on how they envisioned using the devices in their classrooms. The researcher used an interest inventory that allowed teachers to explain their vision of how the PDAs would assist their instructional purposes. Teaching experience varied from less than one year to 19 years. Technological comfort levels, as self-report on the pre-survey, ranged from a lack of comfort to very comfortable.

**Discussion**

Like laptops, PDAs may not be for every teacher. The ability to write lesson plans to incorporate the PDA may be beyond those teachers who continue to struggle with the integration of desktops and laptops into their classrooms. Yet without this integration, PDAs continue to function effectively as personal organizers. Indeed, it was popular with teachers who did not like using other forms of technology in their classrooms. Even with the reduced costs of PDAs, costs for many school districts will remain an issue. The cost of purchasing the devices, software, and providing adequate training may deter districts from these devices. However, what is certain is that these devices have a lower start up and maintenance costs when compared to laptops and desktop computers. It remains to be seen what additional research will reveal about the long-term impact of PDAs on effective teaching.

Abstract: The Geology Explorer provides a multi-modal virtual environment that implements an educational game for teaching principles of geology. The game is a networked, multi-player, simulation-based, educational environment that illustrates our role-based pedagogical approach. This takes the form of a synthetic, virtual world (Planet Oit) where students are given an authentic experience and the means and equipment to explore a planet as a geologist would. Each student's experience includes elements of exploration of a spatially-oriented, virtual, world; practical, field oriented, expedition planning and decision making; and scientific problem solving (i.e. a "hands on" approach to the scientific method). Students assume a role and learn about real science by exploring in a goal-directed way and by competing with themselves and with other players.

In this paper, data are reported from a 1999 study, in which students enrolled in a freshman-level Physical Geology course explored the planet for credit. These data were collected in two forms: 1) a survey of student perceptions, positive and negative; and 2) a data mining analysis of student histories which reveals apparent categories of student problem-solving style. Planet Oit can be visited at http://oit.cs.ndsu.nodak.edu/

Introduction

The Geology Explorer (Saini-Eidukat, Schwert & Slator 1999; Schwert, Slator & Saini-Eidukat 1999) is a virtual world where learners assume the role of geologists on an expedition to explore a mythical planet: Planet Oit, which is designed to replicate the physical environments of Earth (and in the same orbit, but directly opposite the Sun). Learners participate in field-oriented expedition planning, sample collection, and "hands on" scientific problem solving.

To play the game, students are transported to the planet's surface and acquire a standard set of field instruments. They are issued an electronic logbook to record their findings and, most importantly, are assigned a sequence of exploratory goals. The students make their field observations, conduct small experiments, take note of the environment, and generally act like geologists as they work towards their goal. A scoring system has been developed, so that students can compete with each other and with themselves.

The Geology Explorer is being developed as a synthetic environment using the freely available Xerox PARC LambdaMOO (Curtis 1997; Bruckman, 1997), which is an environment for creating text-based virtual worlds, to simulate a portion of Planet Oit. Students armed with tools and instruments created as LambdaMOO objects land on the planet to undertake an exploration exercise. They are given an authentic geologic goal, e.g., to locate and report the position of potentially valuable mineral deposits. Accomplishing each of these goals entails mastering several geologic concepts and procedures, and demonstrates student mastery of the material. The first module involves mineral exploration, where students are expected to plan an expedition, locate
mineral deposits, and survive the somewhat hostile virtual environment in order to report on it (future modules on hydrology, metamorphic facies, etc. are underway). The first version of the Geology Explorer is text-based; (Slator, Schwert, & Saini-Eidukat 1999); a graphical interface was launched in Fall, 2000.

Planet Oit is designed to emulate the geologic features and processes of Earth. The first version is based on a realistic planetary design, consisting of a single, super-continent composed of roughly 50 locations (Figure 1), arranged so as to be both diverse and coherent. A variety of Earth-like environments, ranging from tropical coastlines to volcanic calderas to glaciated peaks, allows for multiple geologic terrains to be explored. A museum of rocks and minerals is available at the landing site for use as a standard reference collection. Coordination of navigation on the planet is made possible by using directions relative to Earth-like geographic poles (North, South, etc.).

Implemented, as well, are almost 40 scientific instruments and geologic tools (streak plate, acid bottle, magnet, etc.), nearly 100 different rocks and minerals, and over 200 boulders, veins, and outcrops. In the text-based version, students use a command language, which allows for navigation, communication, and scientific investigation while on the planet. Command verbs dictate the student’s application of instruments (“streak,” “scratch,” “hit,” etc.) and senses (“view,” “taste,” “touch,” etc.). Students can communicate, and therefore work, with one another through verbal commands. An on-line "user card" listing all these commands and functions is available at: http://oit.cs.ndsu.nodak.edu/oit/usercard.html.

Once the layout and artifacts of Planet Oit were implemented, the rules of the game were imposed over top. After being transported to the planet's surface, students are automatically assigned an initial exploratory goal and can acquire whatever equipment they wish. The goals are intended to motivate the students into viewing their surroundings with a critical eye, as a geologist would. Goals are assigned from a principled set, so as to leverage the role-based elements of the game by gradually leading students to more difficult and interesting goals.

In order for a student to achieve a goal (and therefore earn points), they must address a multitude of tasks identical to those faced daily by field geologists. These include the selection and use of proper field tools, navigation across the planet to the correct region, and interpretation of the tests applied to the problem. As each goal is satisfactorily completed, the student is automatically assigned new goals requiring progressively higher levels of expertise and decision-making. Through this practical application of the scientific method, students learn how to think, act, and react as geologists (see Duffy & Jonassen 1992). This is a particular strength. Student progress is tracked in terms of goals achieved -- and students have a self-paced, anytime/anywhere learning experience.

Classroom Context

Physical Geology at North Dakota State University is a large-enrollment (400+ students in one large lecture section), 3 semester hour course. Aside from lecture, the course content is augmented by slides, a set of course lecture templates, a textbook, and a web resource site that includes self-quizzes, photographs, course news, and links to related resources. Testing is by multiple-choice exams, with students submitting their results on optical scan sheets. Nearly 100% of the students enroll in the course to complete either general education science requirements or specific course requirements within their majors.

Because the class is so large in enrollment, it demonstrates the obvious impracticality of field-training each student to think and behave as a scientist, and as a geologist.

In the Fall semester of both 1998 and 1999, the Geology Explorer was incorporated into the Physical Geology curriculum. Data were gathered with a view toward 1) answering several questions about student use of technology and 2) student perceptions of, and satisfaction with, the Planet Oit simulation using an on-line evaluation questionnaire.

The primary goal was to investigate the effect on the student experience with Physical Geology as consequence of introducing the Geology Explorer prototype as a supplementary resource to classroom instruction for a non-major introductory course. To do this, we implemented tracking routines on Planet Oit in order to get statistics for time-on-task, correlations for computer literacy and attitudes towards technology, effect on final grade. We anticipated that these data would lead to a classification by learning style.

The Student Experience

In the Fall, 1999, 81 students completed a Geology Explorer assignment, scoring the required 500 points, and then completed an on-line follow-up evaluation form. This form is web-based and requires
identification information (e.g., name, student ID number, and e-mail address), and is composed of 35 questions about the Planet Oit experience (the full form is on-line at http://oit.cs.ndsu.nodak.edu/~mooadmin/cgi-bin/oitform.html).

In the post-test evaluation, 82.8% of the students said they somewhat agreed or strongly agreed they had learned something from the game, and only five students (5.4%) disagreed or strongly disagreed that they had learned something. At the same time, only 9.7% somewhat or strongly disliked the concept of game, and 62.4% thought they might like to play the game again. Meanwhile, the students perceived the game to be at an appropriate level of difficulty, with only 8.6% describing the game as much too complex, and 0 students believing it was much too simple.

For the 81 students who completed the assignment and the post-test evaluation, the average actual time on task was 3.47 hours with a range from 0.83 hours to 8.04 hours (while the average estimated time on task was 5.2 hours with a range from 1 to 12.5 hours). Of this group, 11 (13.6%), underestimated time spent on the planet, 12 (14.8%), overestimated their time on task by 25% or more, and 58 (71.6%), accurately estimated the time they spent on the planet.

Learning Style

Through the course of the experiment, and by interacting with students both off- and on-line, we came to believe that identifiable learning and problem-solving styles were being employed by the students. Some students appeared to take an analytical approach: frequently referencing the on-line help, conducting sequences of experiments, and making diagnoses leading to their scoring points in a deliberate fashion. Other students seemed to take a pattern-matching approach: exploring far and wide in search of outcrops that seemed to match the description of what they were looking for, and then scoring points with relatively few experiments. There was also a small but noticeable group taking a straight "brute force" approach, simply visiting location after location and identifying everything there, one after another, as their goal, eventually succeeding after many tries. One monument to this approach was a student in 1998 who made 1,244 guesses on the way toward obtaining just five correct answers.

To investigate the nature of the apparent trends, an analysis was conducted using logging data to count the number of "reports" (i.e., guesses), the number of locations visited, and the number of experiments conducted (e.g., hit, scratch, streak, etc.), for the same 81 students who had completed the game and the evaluation survey in 1999. These data are summarized in Table 1.

Table 1: Student Reports, Moves, and Experiments in 1999

Using these values for average and standard deviation, we developed a classification of behaviors by looking for combinations of either much higher or much lower than average activities in terms of reports, moves, or experiments, or combinations of these. These data are summarized in Table 2. There are a total of 24 clusters, each marked with a code, which represent the three significant categories.

The values in Table 2 indicate that a wide range of approaches are supported by the Geology Explorer, a testament to the user-centered and user-controlled nature of the simulation. Further, almost half of the students can be classified as consistently efficient, not only economizing on their problem-solving effort, but doing so across all three dimensions.

Meanwhile, over half were above normal in one or more dimension, with 17 making excessive reports (code "R," the "brute force" approach); 19 making excessive movements around the planet (code "M," the pattern matching approach), and 22 making more than the normal number of experiments (code "E"). Note that three students were excessive on all three dimensions, and only two students were within 1/2 standard deviation on all three.
Discussion

We can only speculate, at this point, what these data mean. We would seem to be seeing a great deal of apparent variability in student style which could point to basic differences, or which might simply be a function of pre-conceived notions on the part of the students as to how interactive software games usually work. That is, a certain number of students might be tempted to “game” the system -- i.e. devote their energies toward learning to “beat the game” rather than learning the geological content the game is meant to convey.

Gaming the system in more-or-less constant concern in efforts of this type and a problem that we, as designers, must be constantly vigilant against. However, it must be recognized these issues are not strictly confined to computing media. Students are resourceful, and there is a long history of anecdotal accounts of students, for example, “cracking the code” of lab samples in order to pass a test. Anyone who has taught laboratory sections for any length of time has similar stories on this theme.

We can make only preliminary claims, at this stage, to a definitive classification of student problem-solving categories. For example, above normal “M” in Table 2, indicating movement and exploration more than 1/2 standard deviation above the mean, might not directly indicate the “pattern matching” strategy mentioned above, but it could simply indicate a high degree of curiosity in some students. Alternatively, it could mean (modesty forbids our promoting this alternative), that our virtual environment is so exciting and filled with wonders that students are exceedingly engaged and feel compelled to see everything they can (19 students were coded “M,” we note, over 23% of the total).

By the same token, 22 students were “excessive,” if that’s the right word, in terms of code “E,” for experimentation in Table 2. This is hard to criticize on any level, as experimentation is, in one sense, what we hope to teach. Perhaps these students were repeating experiments because our logging procedures were too inaccessible and they re-did experiments rather than refer to their logbooks. If so, this is a failing of the software that we must try to address.

Lastly, we find that 17 students made excessive reports. This was the indicator that led us to this data-mining investigation in the first place: the intuition that some students (in these data, 21%) were taking a “brute force” approach to their assigned goals. Is this supported? We suspect so. But there are many open questions, the primary of which is how to encourage these students (if we’re right in this supposition), to be more analytical in their approach. One aspect we would like to track in the future is the effect of our software tutors in terms of steering the gamers, and the truly overwhelmed, towards more deliberative strategies.

Abstract: Reform documents in mathematics, science, and technology increasingly call for meaningful integration of technology in K-12 classrooms. Simultaneously, schools are being held more and more accountable for increased content at lower grades by both the reform documents and the popular press. Middle school models call for more focus on the student as independent learners and less focus on specific "school-based disciplines" or classes. One approach to addressing these concerns is through interdisciplinary units. In this paper, an interdisciplinary middle school unit on weather is briefly described as a model that addresses the multiple concerns related to (1) meaningful integration of technology, (2) increased accountability, and (3) less focus on historically independent mathematics, science, and technology classes.

Mathematics, science, and technology educators include the use of technology as a common goal in their most recently developed standards. The National Council of Teachers of Mathematics Principles and Standards for School Mathematics (NCTM, 2000) suggests a framework for the types of technology-based activities and content that should be taught. Similarly, the National Research Council's National Science Education Standards include suggestions for science education reform in technology-based content and professional development. Finally, the Standards for Technological Literacy: Content for the Study of Technology (ITEA, 2000), administered through the International Technology Education Association and funded by the National Science Foundation and the National Aeronautics and Space Administration, identifies the development of technological literacy as the major goal for technology education. A technologically literate citizenry has the ability to "use, manage, assess, and understand technology" (p.7). It is only by inspecting and integrating technology-based activities that include mathematics, science, and technology education goals will a technological literate society be possible.

In addition to this change, these same organizations assert that a more in-depth study of each discipline's content at earlier and earlier grades. This is especially true in the middle grades. To address these issues, the National Middle School Association calls for more focus on the student as an independent learner, developmentally appropriate teaching, and a more integrated approach to teaching and learning in general. One approach to addressing these concerns is through interdisciplinary units. This paper will discuss (1) the need for interdisciplinary teaching, (2) how interdisciplinary planning, teaching, and learning can occur between the mathematics, science, and technology disciplines via technology-based interdisciplinary unit, and (3) other content themes for interdisciplinary development.
The Need for Common Goals and Integrated Assessments

Mathematics

The National Council of Teachers of Mathematics Principles and Standards for School Mathematics (NCTM, 2000) Technology Principle states "technology is essential in teaching and learning mathematics; it influences the mathematics that is taught and enhances students' learning" (p. 24). In particular, "when technological tools are available, students can focus on decision making, reflections, reasoning and problem solving." (p. 24) While "technology is not a panacea for teaching computational strategies, teachers should use technology to enhance their students' learning opportunities by selecting or creating mathematical tasks that take advantage of what technology can do efficiently and well – graphing, visualizing and computing." (pp. 25 – 26) Calculators, databases and spreadsheets provide opportunities for these types of experiences to occur.

The Principles and Standards for School Mathematics additionally suggest in each of its process standards (Problem Solving, Reasoning and Proof, Communication, Connections and Representation) that "solving problems that arise in mathematics and in other contexts" (p. 52) are crucial to students better understanding their world. More specifically, "school mathematics experiences at all levels should include opportunities to learn about mathematics by working on problems arising in contexts outside of mathematics." (pp. 65–66) Thus, creating a method of demonstrating that "the link between mathematics and science is not only through content but also through process." (p. 66)

Science

According to the American Association for the Advancement of Science (AAAS, 1993) scientifically literate people should understand the interdependence of science, mathematics, and technology. Science instruction should include mathematics and technology as tools for observing, thinking, experimenting, and validating. This merger of mathematics and technology into scientific inquiry holds promise for a scientifically literate society. Technology is one way of defining the human experience. Paleontologists use the technology of tool making as one of the chief indicators of emerging human culture. Technology allows us to interact, shape, or more fully understand our environment. The distinction between technology and science blurs as technology becomes more sophisticated. Modern scientific research requires computers for data collection, analysis (statistics), and display. Technologies shape science as they develop, providing motivation and direction for theory building. For example, knowledge of subatomic particles increases with the expanding technology to control collisions between smaller, faster particles and to detect smaller particles as a result of these controlled collisions.

The National Science Education Standards grew from the work of the AAAS and several other groups dedicated to the improvement of science instruction. As with mathematics, it is our belief that rich technology-based instruction is integral in nurturing the development of students as active science inquirers. The science and technology standards "establish connections between the natural and designed worlds and provide students with opportunities to develop decision making abilities (NRC, 1996, p. 106)." Using databases, spreadsheets and calculators will assist students with their developing scientific inquiry skills.

Technology Education

The International Technology Education Association Standards for Technological Literacy: Content for the Study of Technology (ITEA, 2000), states "technology is created, managed, and used by societies and individuals, according to their goals and values" (ITEA, 2000, p. 7). It has the potential to improve the human situation or damage it. Technology has the potential to save or destroy lives. "The promise of the future lies not in technology alone, but in people's ability to use, manage, assess and understand it" (ITEA, 2000, p. 7). The major goal of Technology Education is to develop a "technologically literate" citizenry. A technologically literate citizenry has the ability to "use, manage, assess, and understand technology" (ITEA, 2000, p. 7). In order to be technologically literate one must understand that technology has consequences. These consequences or "impacts" affect individuals, society, and the environment (ITEA, 2000).
In order to gain technological literacy and minimize the negative impacts of technology students must gain an understanding of "the universals of technology." (ITEA, 2000, p. 10) These include the knowledge, processes and contexts of technology (ITEA, 2000). The development of technological literacy goes hand in hand with the development of both scientific and mathematical literacy. Technologists use math and science, scientists use math and technology, and mathematicians use science and technology. Together these three disciplines have moved society toward new horizons. A technologically literate society will help the scientists and technologists of the future make wise decisions for the benefit of all.

Planning an Interdisciplinary Mathematics, Science and Technology Unit

Individually and in common, these mathematics, science and technology reform documents describe a classroom environment where students are involved in hands-on manipulations that subsequently lead to minds-on engagement. Technology is used because it increases learner's ability to interact with and learn from their environment. Interdisciplinary units are a mechanism for integrating hands-on, multi-discipline, technology-based activities. Mauer (1994) describes four methods of developing interdisciplinary units: correlated, multidisciplinary, interdisciplinary, and integrated day. In a correlated unit, teachers apply the same scope and sequence to their respective courses but make minor adjustments in the time the different elements are taught (p. 3). A multidisciplinary approach consists of designing a course whose purpose is to integrate the content area of different disciplines into a single course of study based on the study of specific themes (p. 4). An interdisciplinary approach centers on organizing curriculum around broad themes which by their design must contain most subject areas (p. 4). An integrated day approach uses the entire school day as an integrated learning experience (not subject based) (p. 4). Regardless of the approach implemented, all true interdisciplinary units have a "curriculum organized around broad themes which by their design must contain most subject areas" (p. 4).

Effective interdisciplinary units incorporate eight characteristics (Erb & Doda, 1989; Mauer, 1994). While each of these characteristics (Figure 1) is expected in all classrooms, when taken as a whole, these characteristics describe and multi-layered approach to teaching and learning, where diversity in the daily routine is valued.

| 1. | A wide variety of instructional objectives (Bloom) |
| 2. | Important Theme |
| 3. | Balanced Activities (teacher-centered and student-centered) |
| 4. | A Wide Variety of Student Learning Activities (hands-on, lecture, technology, etc.) |
| 5. | An exciting culminating activity |
| 6. | Develops new skills |
| 7. | Applies/develops same skills across disciplines |
| 8. | Motivating |

Figure 1 Characteristics of Effective Interdisciplinary Units

The development of an interdisciplinary unit is a five-step process (Figure 2) (Erb & Doda, 1989). The net result of this process is a unit that begins with a central theme and is refined through more and more specific goals and objectives so that ultimately a variety of subject-specific activities reinforce all objectives and the common theme.

| 1. | Central Theme |
| 2. | Instructional Goals (Broad) |
| 3. | Content Objectives (Math, Science, etc.) |
| 4. | Student learning activities |
| 5. | Implementation Plan |

Figure 2 Era & Doda's Five Step Planning Model
An Interdisciplinary, Internet-Based, Middle School Unit

The authors have selected the central theme of weather to demonstrate how an interdisciplinary, Internet-based, middle school unit addresses the variety of concerns previously described. A typical unit on weather includes the broad science topics of hydrology (the water cycle) and meteorology (the atmosphere, weather phenomena and their effect, and factors that cause weather). The science processes of describing, recognizing, investigating, interpreting, and forecasting are explicitly stated. Further, the concepts of relationship, composition, structure, effect, and interaction are foci as well. Implicitly, students are to measure weather phenomena; analyze, interpret, and display the data; and diagram the relationships inherent in the study of weather. Mathematics processes that support the learning of weather include, collecting and organizing data along with reading, interpreting, comparing, and analyzing data. Specific technology-based problem-solving skills include the use of scientific calculators and computer skills to solve problems, to discover patterns and sequences, to investigate situations and draw conclusions along with the use of computer software and applications to research, investigate, and analyze data using charts, tables, graphs, or other presentation forms.

Several years ago a unit of this sort would have been restricted to local measurements with locally purchased—or even locally constructed—instrumentation with TV weather reports used to supplement student data gathering. The World Wide Web (WWW) has dramatically changed the potential of this learning experience. Today, a well-constructed unit would be expected to include additional data not previously accessible. Two broad instructional goals that would encompass these additional features would be: (1) collect and use weather data to visualize weather phenomena, including local and Internet sources; and (2) collect and use weather data to make weather-related decisions, including local and Internet sources.

The Georgia Quality Core Curriculum (Georgia QCC found on-line at http://www.glc.k12.ga.us/qstd-int/homepg.htm) was developed to specify the broad competencies for all students in Georgia public schools from kindergarten through high school. Competencies are organized by subject matter and grade. The national standards in mathematics, science, and technology education—along with other resources—were used to frame the development of the Georgia QCCs. The following eighth-grade Georgia QCCs were utilized to develop the interdisciplinary mathematics, science and technology education weather unit.

Science

16. Describes the water cycle and its relationship to the movement of surface and subsurface water.
18. Describes the composition and structure of Earth's atmosphere.
20. Describes atmospheric factors which interact to cause weather: heat energy, air pressure, winds, and moisture.

Math

3. Uses scientific calculator and computer skills to solve problems, to discover patterns and sequences, to investigate situations and draw conclusions.
4. Uses computer software and applications to research, investigate, and analyze data using charts, tables, graphs, or other presentation forms.
46. Collects and organizes data, determines appropriate method and scale to display data, and constructs frequency distributions; bar, line and circle graphs; tables and charts; line plots, stem-and-leaf plots, box-and-whisker plots, and scatter plots.
47. Reads, interprets, compares, and analyzes data in frequency distributions, diagrams, charts, tables, and graphs (bar, line, circle, stacked bar, double line, and multiple bar), and makes predications or conclusions based on this data.
Exploratory Technology (Grades 6-8)

6. Utilizes tools, materials, and processes to solve technical problems involving the application of science, mathematics, and inventiveness.
9. Solves a given problem using the inductive and deductive processes of the scientific method.

In general, all ten of the Georgia QCCs under Exploratory Technology support the learning of mathematics and science as integral parts of society. Specifically, two standards explicitly point out the interrelatedness of technology, mathematics, and science. The first includes the use of tools, materials, and processes to solve technical problems involving the application of science, mathematics, and inventiveness. Hands-on, minds-on science is built upon individuals observing and manipulating their environment, typically utilizing tools, materials and processes. These observations lead to inferences and meaningful learning takes place. A simple visit to any manipulative-based mathematics classroom will show how the use of materials and tools support cognitive processes in concept development.

Just as mathematics and science consider problem-solving a "foundational skill," technology educators include the idea of inductive and deductive problem-solving as essential. This manifest itself in a study of the tools, materials, and processes of science and mathematics contained in the previous standard. Typical topics of study within a weather unit might range from the history of weather measurement tools to the instruments used today from a simple rain gauge to Doppler radar. Also inherent in this standard are the effects on individual include decisions about dress or activities, effects on society include early warning for tornadoes, and man's effects on the environment -- which might include weather phenomena related to impacts of specific technology such as CFC-free air-conditioning.

A Brief Look at the Structure of a Weather Unit

The major advantage of any interdisciplinary unit -- and this weather unit in particular -- is the broader understanding inherent when the somewhat artificial boundaries of school-based subjects are rejected in favor of complete conceptual development. Five multi-day "projects" drive the study of weather. Projects are listed below with specific limited examples of WWW sites that make each project more student-directed.

(1) set-up their own weather station that monitors local weather,
   a. Description of surface weather observation techniques - http://www.nemas.net/edu/observations/index.htm
   b. An extremely large selection of weather dot com sites - http://www.weather....com/
(2) explore the history of weather measurement tools,
(3) explore the water cycle utilizing data taken at their local weather station and weather sites,
(4) determine what weather instruments are being used today to forecast weather, and
(5) analyze data using the visualization power of spreadsheets.
   a. Sources of real data include the National Oceanographic & Atmospheric Administration - http://www.noaa.gov, specifically found via the NOAA's National Geophysical Data Center (NGDC) - http://www.ngdc.noaa.gov/ngdc/ngdcsociety.html (NOTE: Data is available through multiple sources at this site, http://www.ngdc.noaa.gov/paleo/pubs/mann1998/frames.htm contains six centuries of global climatic data that could be analyzed by students, as an example.)
Additional Topics

It is important to note that not all individual concepts or objectives lend themselves to fully interdisciplinary units. However, teachers and students who are familiar and competent with interdisciplinary units will naturally be able to integrate other skills into any topic. A brief list of topics that are suitable for interdisciplinary units in the middle school follow.

1. Using Machines, simple to complex
2. Using energy
3. Using matter
4. Electronics
5. Structures, natural to manmade
6. Aerospace
7. Force and motion
8. Changes over time
9. New technologies, lasers to fiber optics
10. What things are made of, atoms to molecules to ecosystems

In conclusion, the authors believe that interdisciplinary middle school units hold special promise when attempting to simultaneously address the multiple concerns related to (1) meaningful integration of technology, (2) increased accountability, and (3) less focus on historical math, science, and technology classes that are expressed in the reform documents for mathematics, science, and technology education's. Especially when these concerns are multiplied by the concerns inherent in the middle school reform movement.

The Design of Instructional Technology to Help Students Connect Phenomena to Scientific Principles

Jerry P. Suits, Department of Chemistry, McNeese State University
Lake Charles, LA 70609
suits@muil.mcneese.edu

Abstract: When technology is used to support student inquiry, learners can develop mental models that are initially based upon their intuitive knowledge of the phenomena. Technology can support this collaborative development by giving them the opportunity to visualize the connections between their experiences with phenomena and the corresponding abstractions (e.g., mathematical equations) for a particular scientific principle. This visualization process is optimized when they interact with resources that provide the visual images and the corresponding verbal rules (i.e., heuristics) that scientists use to solve scientific problems. This process is especially effective when the level of abstraction is intermediate between the concrete instances of a phenomenon and the higher order abstractions that represent it. The author recommends that pre-service and in-service science education programs use technology to help students truly understand the connections between phenomena and the underlying scientific principles.

This paper describes how instructional technology can be designed to help students make meaningful connections between phenomena and scientific principles. Conversely, traditional science instruction separates the study of phenomena—in the laboratory—from the study of the underlying scientific principles—in the lecture room. Three types of technology can help students build procedural-to-conceptual bridges across this large curricular gap: (1) microcomputer-based laboratory (MBL) experiments give them the opportunity to predict, observe, and explore the effects of experimental parameters (e.g., pH, etc.) upon the outcome (i.e., the dependent variable); (2) computer-simulated experiments (CSE) allow extension of MBL learning opportunities to include a wider range of phenomena; and (3) multimedia learning modules (MLM) can help them apply scientific principles by practicing their problem-solving skills within a real world context. These three technologies can provide the scaffolded support that students need to design experiments and to discover scientific principles.

Visualization of Phenomena and MBL Experiments

MBL experiments have been shown to be one of the most effective types of technology used in teaching science topics (Berger et al. 94). An MBL is a system that couples a data-gathering device to a microcomputer. The microcomputer records the incoming information from a sensor (e.g., pH probe), and then organizes it into a recognizable pattern (e.g., a graph). MBL experiments can help students simultaneously visualize a phenomenon and its graphical representation (Nakhleh & Krajcik 93, Suits 00). Students need these visual experiences because scientists use visual imagery (Mathewson 99) as mental tools when they attempt to understand and solve complex problems. Technology can shift instruction away from the primacy of verbal thinking and towards the integration of visual and verbal thinking (Collins 91). Students can use it to connect multiple representations of phenomena and to enhance their understanding of principles (Kozma & Russell 97). The goal should be to help them construct meaning through the use of manipulatives, visualizations, and internalizations, which enhance mental pictures and lead to further abstractions (e.g., mathematical equations). Thus, with the support of MBL technology, students can enhance their conceptual knowledge (Nakhleh & Krajcik 93). Overall, MBL experiments can help them organize their observations of phenomena (concrete level) into a coherent set of interrelated principles (abstract level).

Intermediate Level of Abstractions and Interactive CSE

An interactive CSE can fully engage the decision-making processes of students while extending the range of phenomena that can be explored. CSE’s use models of scientific phenomena and data from real experiments to allow students to determine the experimental conditions and hence to design experiments. Upon running the experiment, they receive feedback about the experimental outcome. If the outcome does not meet their expectations,
they can change the experimental conditions and rerun the experiment. In addition, an interactive CSE enables the student to create idealized simplifications for scientific systems and to transform abstractions into concrete manipulative representations (White 93). This transformation allows them to see dynamic representations of phenomena that are connected to more abstract representations. Thus, they can relate and apply their formal knowledge to their everyday situations (White 93). This "intuitive knowledge" is a flexible and generative type of knowledge (diSessa 00) that could be used as the building blocks to construct a conceptual network of knowledge.

The instructional design of interactive CSE's is most effective when represented at an intermediate level of abstraction (ILA) (White 93). These ILA's enable students to interpret the model's behavior in terms of simple conceptual and process abstractions. They derive these abstractions from their everyday experiences. Instructional design decisions should begin with a model at a low level of complexity and then help students use causal reasoning to visualize a simple mechanism for their model. Other design decisions should make learning (White 93): (1) understandable and meaningful by building on intuitive notions of causality and mechanism; (2) transferrable by allowing the mapping of ILA's to different real world situations; and (3) linkable because their models can link different levels of abstraction (e.g., iconic and symbolic) and different perspectives (e.g., microscopic and macroscopic). These designs should feature a "vast repository of capabilities that we can tap" so that designers "have a much easier time building learning environments that capitalize on that competence (p. 98, diSessa 00)."

**Scaffolded Student Knowledge and MLM’s**

Interactive MLM’s can be designed to give students practice at solving problems in an enriched learning environment that allows visual experiences within a real-world context. Students often work quantitative problem solving exercises without understanding the underlying principles for those exercises. In addition, the feedback they receive is often delayed or uninspiring. Conversely, an MLM can show a movie of an expanding automobile air bag (Suits & Courville 99) as the “real-world feedback” that students receive based upon their calculated quantity of solid sodium azide (via the gas law equations) needed to properly inflate the bag. These enriched “drill and practice” problems can increase both student interest and “on task” attention to the problem-solving process. Initially students are given full support (e.g., feedback, help, and cues) so they can attain a particular level of competence; however, this support is faded so they can extend and apply their problem-solving skills.

Abstract Individuals are potentially capable of generating antibodies to all antigenic stimuli. Aminoacid sequencing has revealed a curious and unique fact among proteins, a high diversity (variable) amino-terminal region, responsible for antigen recognition associated to a relatively constant carboxy-terminal region responsible for biological functions. As the presence or absence of immunoglobulins during maturation will determine the fate of the lymphocyte we elaborated this game which follows some rules of Role-Playing Games. Genetic rearrangement, lymphocyte differentiation and repertoire selection are present in the game and were topics of our immunology course where students had most difficulty. Their first reaction in doing this activity was of disbelief, they were reluctant in starting and presented childish reactions, but as they did, they asked the questions we expected during classes. The game is used, with success; in continued-education programs for high-school teachers where Molecular Biology, Genetics and Immunology are the themes. This type of activity renders learning a more pleasant process.

Introduction

All individuals are potentially capable of generating antibodies to any antigenic stimuli. The antibody is a glycoprotein composed of four polypeptide chains, two light and two heavy chains, kept together by sulphate bridges forming a three-dimensional "Y" shaped structure called monomer. Each chain contains a series of repeated homologous units, each with approximately 110 amino acid residues, which fold independently into a common globular structure, called domain. The heavy chain has twice the molecular weight of the light chain, presenting four domains while the light has only two. Within a monomer, the chains are paired, each pair composed by one light and one heavy chain and chains with the same weight are identical to each other. Immunoglobulins (Ig) can also be presented in a polymeric form, joined by another glycoprotein, the J chain, synthesised by the same cell. The most common polymeric forms are the dimmers and pentamers, although other intermediary multiples exist.

Amino acid sequencing analysis of the Ig has revealed a curious and unique fact among the proteins - a high diversity at the amino-terminal region of the chains associated to a relatively constant carboxy-terminal region. The amino-terminal region, of both chains, called the variable region, is responsible for antigen recognition. The carboxy-terminal end, the constant region, is responsible for the biological functions of the Ig's - interaction with the organism's structures such as cells and enzymatic cascades. Having in mind that Igs are present on the membrane of B-lymphocytes as clonal receptors and that the presence or absence of these receptors, during maturation, will determine their fate (life or death), we explored the programmatic content of our basic Immunology course with the game "LIFE and DEATH of the Lymphocytes" which we here propose.

Genetic rearrangement, lymphocyte differentiation and repertoire selection, are the topics of the course present in the game. The game permits the comprehension of probabilities of cell survival and therefore of the repertoire selection and is based on probability calculus and combinatory analysis and follows some of the rules of Role-Playing Games (RPG), where each player participates as an actor. Before the presentation of the rules of the GAME we will make some considerations on the concepts of Ig isotypes and idiotypes. And next we will approach the problem of the generation of Ig diversity and some considerations on ontogeny of these cells.

ISOTYPES - The carboxy-terminal region, although denominated constant region, presents 5 different variants for the heavy chains and two for the light chains. The heavy chains are called mu, delta, gamma, epsilon and alpha.
while the light chains are called kappa and lambda. The variations of the heavy chains determine the classes or isotypes of the IgS giving rise to the Ig classification: IgM, IgD, IgG, IgE and IgA, respectively. Technological progress has permitted further classifications, and some isotypes are subdivided and are designated by their corresponding symbol to which a number is added, for example IgA1, IgA2. Any heavy chain can be associated to a Kappa or lambda light chain.

IDIOTYPES - The idiotype, which corresponds to the variable region, is related to the individual variation of each Ig molecule, that is to say, to the capacity that each one has in interacting to a different set of antigens. The association of any one of the estimated $10^{14}$ different idiotypes to a constant region in the same molecule rendered an interesting genetic problem formulated by Dreyer and Bennet, for the first time, in 1965:

"...The paradox results of the observation that one extremity of the chain behaves as if it was the product of an only gene while the other as if it was the product of thousands of genes..." (Tonegawa, 1983)

What type of genetic duplication would have happened during evolution that produced mutations only at one of the extremities? To solve this paradox Dreyer and Bennet proposed that the genetic material that codes the variable extremity of the polypeptide chain would combine, during the B lymphocyte differentiation, with the gene segment that codes the constant region. This visionary hypothesis came to be proven, two decades later, with the classic work of S. Tonegawa and collaborators, which rendered them a Nobel Prize in Medicine (Tonegawa, 1983)

GENERATION OF DIVERSITY - Although the V region diversity is calculated as being approximately $10^{14}$ idiotypes, sequence variability is not evenly distributed. Within the variable region there are 3 segments of higher variability designated hypervariable regions flanked by regions of lower variability denominated framework regions. During the process of molecular folding the hypervariable segments are joined and are the segments that will have direct contact with the antigen.

A cluster of multiple gene segments called VH, D, J, and C for the heavy chains, and V, J, and C for the kappa chain and V, J, and C for the lambda chain codes each chain. Each one of these three gene clusters is located on a different chromosome. Of all gene segments used to encode the variable region, the V segments participate encoding the largest number of amino acids. According to the degree of homology these gene segments are grouped in families, both in the human and mouse system. Each species presents a number of different families.

The recombination diversity is possible because of the number of germline V, D and J segments in the heavy chain and V and J segments in the light chain. The fact that the heavy chain presents an extra group of gene segments, the D segments permits a greater variability compared to the light chain. Assuming that these gene segments are rearranged in a completely random mode (which is not true), and that there are no restrictions in the rearrangements (what is, also, not true) it is possible to generate $10^9$ different variable regions. This potential repertoire can still be increased by a series of molecular events during the rearrangement process, such as nucleotide deletion, by exonuclease, and nucleotide addition by the enzyme Deoxinucleotidyl Terminal Transferase (TdT).

As the absolute number of segments of each region varies between species and have not been determined we will use figures frequently found in the literature and depicted in our game. Let us see:

Considering the rearrangements of the heavy chains

200 (segments VH) x 10 (segments D) x 12 (segments JH) = 200 x 10 x 12 = 2,4x10^4 possibilities

Considering the rearranges of the light kappa chain

200 (segments V) x 12 (segments J) = 200 x 10 = 2.4 x 10^3 possibilities

Considering that heavy and light chain recombination are independent events the combination of the heavy chain possibilities with the light chain possibilities

$2,4x10^4$ (heavy chain) x $2x10^3$ (light chain) = $(2,4 x 10^4) x (2,4 x 10^3) = 5,76 x 10^7$

Each V, D and J segment is flanked by a rearrangement signal, a special sequence which consists of three parts: a highly conserved heptamer, a non-conserved spacer sequence either 12 or 23 nucleotides long and a relatively conserved nonnammer. The spacers of the V, J, e D genes have 12 base pairs, while the spacers of the V, J, e VH, e JH genes have 23 bp. A striking feature of the spacers is that the lengths correspond either to one or two turns of the DNA double helix. The relation of 12 and 23 bp in the spacers has to be respected, so that the recombinase, can fit in the small and large groves of the DNA.

As soon as two segments have been joined by the recombinase, the endonuclease, acts on the double strand DNA. While the endonuclease cuts the DNA at the corresponding position at the beginning of the heptamers, the recombinase maintains the cut extremities juxtaposed. If the cut ends are bordering perfectly, ligase acts and makes

2741
the final repair of the DNA and the recombinase can detach. The intervening segment that was cut is lost and is
degraded. However, the cut extremities are not always juxtaposed. When this occurs it is necessary to repair the
DNA in order to become functional. The enzyme that repairs the DNA that is being maintained united by the
recombinase is TdT. This enzyme inserts nucleotides de novo at the 3' end of the junctional regions, without the need
of a complementary DNA strand. After this, polymerase, a DNA repair enzyme, which now has a template to guide
the addition of the new nucleotides, adds them starting from the 5' terminal, allowing the ligase to complete the final
repair of the double strand and recombinase may detach. These N inserts are only seen at the joining sites of the
heavy chains. The apparent absence of this type of repair of the light chains is explained by the absence of this
enzyme in the later developmental stages of the cell, when the recombination of the light chains happens.

These processes of addition and removal of nucleotides explains the presence of sequences that are not found in
the germ line gene segments as in the third hyper-variable region of the Ig which does not exist in the germinal
sequence. It is generated randomly by the V\textsubscript{H}/D and D/J\textsubscript{H} junctions. The D gene segments are Open Reading Frame
codons permitting nucleotide insertions or deletions that are not multiples of three, as any of the 3 reading frames are
allowed.

It is calculated that the diversity generated by the enzymatic activity has the same order of greatness of the
diversity generated by gene segment recombination. This means that for each possible gene combination, for
example, V\textsubscript{10}D\textsubscript{2}J\textsubscript{3} there may exist 10\textsuperscript{7} variations. Let us see how. Considering the random insert of 1 or 2 nucleotides
a general change of the molecule due to alteration of the reading frame; 3 nucleotides the addition of 1 amino acid.
Considering that 20 amino acids exist 1 amino acid insert x 20 = 20 differences while a 6 amino acid insert (20\textsuperscript{6}) will
lead to 6.4 x 10\textsuperscript{7} different molecules.

ONTOGENY OF THE LYMPHOCYTES - During ontogeny, gene rearrangements occur in a pre-determined
order. The first cluster to rearrange is the heavy chain gene segments and within it the D/J rearrangement occurs first.
Then finally the VDJ segment is rearranged to the constant region. At this point, the first polypeptide chain can be
produced and exported to the cell membrane. If a productive rearrangement has occurred and the membrane protein
receives a stimulus a series of events will be triggered simultaneously; allelic exclusion of the other heavy chain gene
cluster and the rearrangement of the first light chain gene clusters. If not then the second allele is rearranged. Now at
this point, after the rearrangement of the second allele, if the cell has not produced a functional heavy chain it dies of
apoptosis. On the other hand if a productive rearrangement has occurred and the protein is stimulated on the cell
membrane the light chain is rearranged. The cell has 4 chances to produce a light chain 2 in the kappa gene cluster
and 2 with the lambda gene cluster. The first to produce a productive rearrangement will induce an allelic exclusion
event in order not to further rearrange genes. In summary there should only be one productive rearrangement for the
light and one for the heavy chain. As soon as the cell has a full antigen receptor it leaves the bone marrow to
populate the secondary lymphnodes.

The Game - The life and death of the lymphocytes

After the lectures where we approached the themes “Lymphocyte receptors: from genes to proteins” and
"Aspects of the ontogeny of Lymphocytes.” We presented, to the students, the game we here propose. which consists
of steps where we simulate the developmental stages of a lymphocyte. To determine the several options of each stage
we propose to use dice. There are at least two possible ways of playing the game in order to demonstrate the
lymphocyte development: Individually - each student follows the rules simultaneously. After 15 rounds each player
compares the results obtained by the rest of the group. In groups - make groups of 4 or 5 students, each player waits
his/her turn to play and the group accompanies the evolution of the ontogeny of every lymphocyte (each student).

Material necessary for the game

4 RPG dice (20, 12, 10 and 4 faces, one of each) called D20, D12, D10 and D4, Scissors (representing the
exonucleases), Glue (representing the repair enzymes), models of each DNA strand, rules and Game tableau

Observations

1. Before the beginning of the game each player will have to construct the strands of the heavy chain germ line
DNA simulated in paper. To play with the light chain as well an adaptation will have to be done removing the D
segments (cyan) and substituting the heavy chain gene segments (green) to the kappa segment (due to lack of space we have not included them here. When all players have their DNA's prepared the game may begin

2. Although, in our model, we represent the five constant region gene segments of the Igs, the rules of the game don't contemplate the class switch, because it would imply in a much more complex and too long a game, which would turn it into a very tiring one. We are now elaborating a game that contemplates the interactions of the lymphocytes involved during the immunological activity.

3. For the light chains we only include one of the light chain gene clusters, there is a second group of gene segments located on a third chromosome. In other words we could still have another two chances to survive, if it were the case. Again we could continue but, to simplify the game, this rearrangement is not included.

4. It would be very complicated to include all the molecular details of the recombination in this model. When the students prepare the model of the simplified DNA strand, it already measures approximately 2 meters. To insert the details of the rearrangement signals (leader sequence, palindromic segments, spacers, etc.) these strands would be at least four times as long rendering them unworkable.

Results using this game with Students of the School of Medicine at UFF

Before we elaborated the game these were the topics in the programmatic activities of our regular immunology course where the students had most problems in learning. Their first reaction in doing this type of activity is of disbelief. They are reluctant in starting the activities, giggle and present other childish reactions but as they start to go through the steps of the game they start asking the questions we would expect during classes.

We have used the game, with great success, to work with high school teachers in continued education programs where Molecular Biology, Genetics and Immunology are the central themes. Using this type of activity renders the learning process a more pleasant one. This game can also serve as the starting point for other events where the generation of biological diversity occurs, not only at the cellular level but, also, of the organism or even of populations

The game

This game is a model of the steps (in summary) that occur during the ontogeny of lymphocytes. It is not intended to be exhaustive but a didactic model in order to make it easier to understand the lymphocyte development. The instructions of the game were planned for the B Lymphocyte but they can be applied for the T lymphocyte once they have been adapted taking into account the distinctiveness of these cells.

Rules of the game

We will consider that each participant is a lymphocyte progenitor cell committed to the development of a B cell. To survive, the indispensable condition is to have a clonal receptor on the plasma membrane. To play and try to survive, everybody will have to repeat the steps described below.

Before starting the game it is necessary to prepare a model of the DNA that you inherited from your parents. For this, get the sheets that contain the light and heavy chain strands, cut the strands and where indicated glue the ends in order to simulate the strands of germ line DNA (enlarge the models supplied here).

Have at hand the dices, scissors, glue and a pencil to accomplish the next stages and the tableau to write down the result of each stage, permitting the final analysis of the events (as a suggestion add more line to permit 15 rounds)

Let's start

1. The game starts with the recombination of the heavy chain of the B cell receptor (BCR). To know which allele will be used first used toss any dice
   - PAIR the maternal allele will be used.
   - ODD the paternal allele will be used
2. Toss the D12 dice (representing the "J" segments) and D10 (representing the "D" segments) to know which DJ combination you will have.
3. Join the selected gene segments, obtained with the dice, by making a loop in your DNA and then cut out the intervening segments and make the repair of your strand. For example, if you obtained with the dice the segments DI and J3; you will cut and drop everything that is in this interval in order to put DI next to J3.
4. Now roll your D20 and D10 dice to know what segment "V" you will have. The number obtained with the D20 represents the first two numbers, and D10, the last (i.e., D20=17 and D10=3, the chosen "V" segment is 173).
5. Make a loop in your DNA strand to join the chosen “V” segment to the “D/J” already rearranged segment. Cut out the intervening DNA and make the repair. To have a functional gene you will still need another rearrangement step (stage 8). But before let’s see if your rearrangements are functional ones.

6. Throw any dice.
   - ODD - means that your enzymes united the several segments in an appropriate way.
   - PAIR - means that some repair error has occurred and that the enzyme TdT, entered in action inserting 1 to 12 nucleotides in one of the junctions.

7. To know how many nucleotides were inserted throw your D12, and, to know in which junction, roll any other dice.
   - ODD - junction DJ
   - PAIR - junction V/D

8. And finally, to know which nucleotides were inserted use your D4, attribute a number for each of the four nucleotides and determine the sequence your TdT will provide as a template for polymerase to repair the DNA 1 - A (Adenine); 2 - C (Cytosine); 3 - G (Guanine); 4 - T (Thymine)

9. A new, non-random, rearrangement occurs at this point. Join your rearranged VDJ segment to the jδ segment of the constant chain. Make a loop in your DNA to join the respective segments and perform the repair.

Let us see if your enzymes accomplished the repair appropriately producing a functional gene. Play any dice.

**FIRST ALLELE**

- PAIR - means that your rearrangements were accomplished in an appropriate way; therefore, you (the lymphocyte) can now transcribe and translate your membrane protein. Proceed to stage 10
- ODD - means that an error happened in your rearrangements. Therefore, in order to survive, you will have to repeat the steps from 1 through 9 using this time your second allele for the heavy chain.

**SECOND ALLELE**

- ODD - you die because you have already used both alleles and didn't produce a heavy chain. Without it you won't have the clonal receptor, without which, the lymphocyte doesn't survive.
- PAIR - you now can proceed for the stage 10.

10. Having produced a heavy chain and expressing it on the cellular membrane associated to the pseudo light chain you have to receive a stimulus from the environment to continue surviving. To know if you continue to live, throw your D12.

**FIRST ALLELE**

- Numbers 1 - 4 you have to repeat steps 1-10, for insufficient stimulus;
- Numbers 5 - 12 you survive, therefore these stimuli are adequate. Go to stage 11.

**SECOND ALLELE**

- Numbers 1 - 4 you die, for insufficient stimulus;
- Numbers 5 - 12 you survive, therefore these stimuli are adequate. Go to stage 11.

11. Since you are a survivor, now you will have to rearrange your light chain, because without it you won't have the complete BCR. For this throw your D10 (representing the segments “J”) and then your D20 and D10 (representing the “V” gene segments) to know what VJ combination you will have.

12. Make a loop in your DNA and cut out the intervening sequences to join the respective gene segments obtained in the dice and make the repair.

13. Make a new loop now to join the rearranged VJ segments with the constant region of the light chain. Cut out and repair your DNA to join the gene segments.

14. Play any dice -

**FIRST ALLELE**

- ODD - means that an error occurred in your recombination. Therefore to survive, you will have to repeat the steps from 10 to 14, using this time your second allele for the light chain.
- PAIR - means that your recombination was accomplished in an appropriate way; therefore, you the lymphocyte can now transcribe and translate your membrane protein. Proceed to stage 15.

**SECOND ALLELE**

- ODD - you die, once you have already used both alleles for the light chain and didn't produce a functional gene, without which you won't have clonal receptor and, therefore, you (the lymphocyte) will not survive.
- PAIR - you now can proceed for the stage 15.

15. Having completed all rearrangements, both heavy and light chains, in a functional way, you (the lymphocyte) can now express your complete clonal receptor (BCR) and leave of the bone marrow and migrate to any secondary lymphoid tissue. You are winner!

16. To conclude, let's see how many survived. And what are the differences.
### Tableau for the game

#### Instructions

1. Write down the chosen allele in which the first recombination will occur, then the chosen V, D, J segments determined by the dice on the corresponding line.
2. If an ERROR occurred indicate at which rearrangement point and how many nucleotides were inserted by TdT.
3. In the column Final Result write down which cells leave the bone marrow and for those who die at which stage this occurred.
4. To be able to study the populations of cells produced by the bone marrow let's put together your results and those of the rest of the group or class. Now let's analyze:
   - Which is the survival rate?
   - Among the survivals how many used the same gene segments?
   - Among these, how many did not need to repair the DNA at the recombination sites?
   - How many repaired the DNA? The number of nucleotides was the same? And at the same recombination site? Are the same aminoacids be inserted?

Model of the gene segments of the heavy chain

**Bibliography**

Though recognized as a legitimate and positive aspect of teaching and learning, simulations continue to be rarely used by authors for the 2001 SITE annual. Perhaps the wide variation in defining “simulation” in education has contributed to the dearth of studies. The range in availability of hardware, courseware, and software in international locations where many of these investigations were done certainly has contributed to the variation in sophistication of data treatment. Additionally, though the global economy and international testing have moved countries closer in terms of educational goals, differences in educational philosophies have certainly contributed to the issues addressed and undertaken by this year’s contributors. These findings were cited in the 2000 SITE annual and continue to be evident by the lack of submissions in this area.

With only three submissions, the variety of definition is again seen as a strength of this technology driven teaching strategy. The way educators have chosen to define and then implement technology in the classrooms of their districts and countries is as varied as the geographic locations of the schools. Regardless of the complexity or simplicity of the technology available or the cognitive entry level of the personnel proposed for using the innovation, readers can certainly find a situation or discipline that mirrors their own. Reports of technology use for teacher-preparation as well as use with the P-12 students also increase variation.

The Papers

Dwyer and Lopez studied the effectiveness of simulations in learning cycles lessons for middle school students engaged in environmental studies. The Harper & Hedberg CD, Exploring the Nardoo, was used to enhance student performance. Upper elementary and middle school students served as a population for the study. Results of pre-instructional and post-instructional mapping showed a richer variety of concepts and increased linkage of concepts in environmental studies when simulations were included in the instructional plan.

Sarapuu and Pedaste used a simulation, Hiking Across Estonia, (http://sunsite.ee/tour/) developed in the Science Didactics Department at the University of Tartu, to develop students’ higher order thinking skills. Problem-solving and decision making were especially emphasized in the field of environmental studies. Students were assigned to hiking groups after pilot studies were run to determine the most effective simulation process. The virtual hikes in five different communities with seven different environmental problems in each community were the problems of each group. Students were able to click to links of information providing help in addressing the each of the problems. During the hikes, students also came across other problems such as the lack of food and the necessity of determining if plants encountered in a community were safe to eat. Themes of the hikes were connected to the themes present in the State Curriculum of Estonia. Another essential feature of the simulation was developing students’ communication skills in the small groups of the hiking group. Interviews before and after the virtual hikes and observations during the simulations were a part of the evaluation of the activity. Results of the study resulted in several editing changes in the design of the communities and the problems in them. However, results did suggest that the simulation program enhanced higher order thinking skills of the students, especially in the area of the ability to analyze texts and graphs.

Strang and Clark developed a Window-based simulation to assist teachers-in-training with preparation of lesson plans. LPII was designed to lead students through a decision-making process in creating lesson plans for a specific type of student. Activities appropriate for the assigned student are entered into the simulation. The final step of the simulation involves students to evaluate the effectiveness of the plan for each student. Several weeks after the initial simulation, a debriefing phase is held. This process is helpful in offering students opportunity to hone lesson planning skills with a built-in evaluative phase that improves the process.

Simulations in the Learning Cycle: A Case Study Involving "Exploring the Nardoo"

William M. Dwyer
The University of Alabama
United States
wdwyer@bama.ua.edu

Valesca E. Lopez
The Capitol School
United States
valeskka@aol.com

Abstract: This study of involved students using simulation software in all phases of the learning cycle. Middle school students used a CD-based simulation program, Exploring the Nardoo, which first provided preinstructional and exploratory activities to elicit and challenge students' alternative conceptions. Having set the context for formal instruction, simulations then were used in the invention phase of the learning cycle to help students learn new concepts. The simulations were used again to apply newly learned concepts in different contexts in the expansion phase of the learning cycle. In this study, middle school science students were observed using the simulations as they engaged in learning cycle lessons on environmental systems. The students were tested for their understanding of the concepts before and after completing the learning cycle lessons. Interviews also were made of the students and their instructor.

This study involved students using simulation software in all phases of the learning cycle. Research on the use of simulations in science education has shown that the simulations can be used effectively in preinstructional (Hargrave & Kenton, 2000; Gokhale, 1996) and exploratory activities (De Jong & van Joolingen, 1998). Preinstructional and exploratory activities elicit and challenge students' alternative conceptions. Having set the context for formal instruction, simulations then can be used to learn new concepts in the invention phase of the learning cycle. With the specific guidance in simulations such as Exploring the Nardoo (Harper, n. d.; Harper & Hedberg, 1996), students perform better (Lee, 1999). Simulations can be used again to apply newly learned concepts in different contexts in the expansion phase of the learning cycle.

In this study, 16 upper elementary and 17 middle school science students were observed using the simulations as they engaged in learning cycle lessons on environmental systems. The students were tested for their understanding of the concepts before and after completing the learning cycle lesson. Interviews also were made of the students and their instructor. Data collected included videotape transcripts, teacher journal, student field logs, student concept maps, student and teacher interviews, and products of student activities.

The use of simulations in all phases of learning cycles was shown to be an effective strategy for learning. The teacher was better able to bridge student understanding between print materials and real-world experiences. Results of pre-instructional and post-instructional concept mapping showed a richer variety of concepts and increased linkages among those concepts. This case study thus provides an example of the effective use of simulations in learning cycle lessons for middle school students engaged in environmental studies.

A Pilot Study of the Web-based Environmental Simulation

Tago Sarapuu
Science Didactics Department
University of Tartu, Estonia
tag@ut.ee

Margus Pedaste
Science Didactics Department
University of Tartu, Estonia
pedaste@ut.ee

Abstract: Nine groups of students (total 36) from three different schools participated in a three-week pilot study and passed five virtual communities of the web-based simulation “Hiking Across Estonia”. The members of hiking teams had to solve 35 different educational tasks. The analyses of students’ answers in the pre- and post-tests and also in the semi-structured group interviews proved the program to be applicable for developing students’ environmental problem solving and decision-making abilities. Students demonstrated the improvement of their skills in analyzing texts, drawings and graphs of the sub-tasks. Moreover, the participation in the virtual hike promoted students’ involvement in cooperative learning and it also increased their interest in environmental problems.

Introduction

Web-based simulation, where the authentic surrounding is transferred into virtual environment, provides learners with strong support by a variety of sources of information and rich capabilities of multimedia. Computer-based learning applications as the cognitive tools can engage learners in higher order thinking and learning providing opportunities for the acquired knowledge to be generalized to new and alternative problem spaces and contexts (Oliver & Herrington, 2000). Problem-based activity unfolds the process of learning through the application of knowledge and skills to the solution of real-world problems, often in the contexts of real practice (Bligh, 1995). Most commonly it is based on experiences and empirical findings where students learn from problem-orientated tasks rather than fact-orientated ones. Another frequently reported finding concerned with the application of problem-based learning is related to promoting students’ motivation and developing their critical thinking (Sage & Torp, 1997).

Promoting learning through problem-based activity provides considerable scope for designers of the web-based learning environment. Several approaches from cognitive theory can be used while designing web instructional pages (see Harper et al., 2000; Leflore, 2000). An essential feature issued from the appropriate guidelines is the authenticity of learning process. This could be achieved by appointing three seminal concepts: credibility, complexity, and ownership (Harper et al., 2000). All these concepts were taken into account in designing a simulation program “Hiking Across Estonia”.

Simulation Program

A web-based situational environmental simulation “Hiking Across Estonia” (http://sunsite.ee/tour/) has been programmed in the Science Didactics Department at the University of Tartu. Several features of Java and Perl have been used to make the simulation more authentic and affective.

It is proposed that groups consisting of 3-6 students might form hiking teams and participate in the virtual hike. They have to pass five different communities: heath forest, meadowland, grove, waterside meadow and bog. All the communities are provided with informational windows of supplementary texts and illustrations of about 193 species of plants, mushrooms and animals. The information presented intro-
duces the most common and interesting living objects of Estonian nature, but it also serves as a source material for solving the educational tasks. There are seven different environmental tasks in each community (totally 35) to be solved during the virtual hike. All the tasks are presented and can be solved on the web pages. Immediately after answering the questions and solving the problems students get feedback about their results – they have opportunities to get to know correct answers and their own mistakes. A certain number of points are awarded for each task. It enables to organize competitions between hiking teams.

The participants have to meet another problem during the hike – they have to find edible food from different sources. Each team may take along a certain amount of food from the virtual home at the beginning of the simulation, but afterwards the hikers must find it from the communities: they have to decide if the species of plants and mushrooms available in the simulation are edible or poisonous. All the activities of the participants on the web pages including their answers are saved in the server and can be analyzed by the organizers of the virtual hike.

The goal of the program is to develop students’ environmental literacy towards promoting higher order thinking skills, especially their problem-solving and decision-making abilities. The main target group of the simulation “Hiking Across Estonia” is suggested to be students of the upper basic and high school.

At first, the participants of the hike have to examine the virtual community provided with extra information on several aspects of it and after that, open a new window with an educational task related to the respective community. Next, they must find additional information for solving the task. The information is
usually available on the web pages of the simulation program itself or on the web sites listed on the links page. In some cases the necessary environmental facts must be looked up in different books.

Educational tasks have been composed on the basis of themes of school biology, environmental study and health education related to the themes of curricula of Estonia and other developed countries. It insures, that the questions and problems of the simulation are not only connected with Estonian local problems but might be understandable and applicable by students of other countries as well.

Students have to analyze texts, drawings and graphs for solving the environmental tasks presented in virtual communities. They can get up to 31% of the total score of 925 points on the basis of knowledge and comprehension different facts in simple questions. About 2% of the score is related to the students' ability of application of the information and 67% of points in certain problem-solving tasks can be achieved by analyzing and synthesizing presented materials and making decisions (Fig. 2.).

Another aim of the simulation program is related to developing students' cooperative involvement in groupwork, but it should also promote their interest in environmental problems.

**Pilot Study**

Nine hiking teams participated in a three-week pilot study. The main objective of the study was to carry out a formative evaluation of the simulation program and to clarify the applicability of it by the students of different age. The research design of the pilot study is shower in the figure 3.

![Diagram of the research design of the pilot study.](image)

**Figure 3**: The research design of the pilot study.

At first a pre-test questionnaire consisting of six environmental tasks was composed. The questions presented in the test had been previously pre-tested to ensure internal validity of the latter both among the students of upper basic and high school. Three classes – the 7th (aged 13-14), 9th (aged 14-15) and 12th grade (aged 17-18) – were chosen from three different schools (9 classes with 235 students in total). All the students in these classes had to solve the tasks and fill in the pre-test. According to the results of their answers a group of students with average score was clarified from each class. Next, four volunteers from each group were asked to form hiking teams. As a result of it, nine teams were selected. During a three-week period they passed all the virtual communities and solved the tasks presented on the web pages. Soon after the hiking teams had finished the simulation program, a post-test was asked to be filled in by the participants.
This consisted of similar questions as the pre-test. The answers in pre- and post-tests were statistically analyzed to evaluate the applicability of the program for developing students' problem-solving ability and, particularly, promoting their skills in analyzing texts, drawings and graphs.

Three observers made notes about teams' embarrassments in the application of the program, students' impressions and also their cooperative learning abilities. It gave the information for the formative evaluation of the program and allowed to evaluate the students' progress towards cooperative involvement.

The members of hiking teams were interviewed before and after the virtual hike. A semi-structured group interview was used to clarify students' development as to collaborative work in the problem solving process. The activity of the hiking teams was being observed during the entire virtual trip. The results of nine students' groups in solving the educational tasks in each community were carefully analyzed on the basis of log files of the server. It allowed estimating students' progress towards environmental problem-solving process and the applicability of the program by the students of different age.

A lightly modified Evaluation Scale of educational web sites (Sarapuu & Adojaan, 1998) consisting of 43 questions was presented to a group of expert teachers. The scale consists of three parts: the composition of the site, pedagogical aspects and curriculum-related aspects. A selected number of the questions from the Evaluation Scale were asked to be answered by the members of the hiking teams as well. The students' questionnaire mainly comprised the composition of the site, users' impressions and some curriculum-related aspects. Their answers gave feedback for the formative evaluation of the simulation program.

Findings

The simulation program appeared to be applicable for both basic and high school students. It became evident that only two problem-solving tasks were too complicated - no any team was able to solve them completely. These tasks were simplified and the appropriate corrections were made in the simulation program. Some other improvements in the simulation program "Hiking Across Estonia" were undertaken as a result of the formative evaluation. The majority of corrections concerned texts. A small number of suggestions were about the quality of illustrations. In some cases the text of help files was revised to be more understandable for younger students (aged 13-14).

The teams achieved 60% of total 925 points in average. Each team from the 7th grade got about 48% of total points of the problem-solving tasks, the 9th grade - 45%, and the 12th grade 65% in average. The log fail analysis allowed estimating a significant progress of the problem solving tasks towards the virtual communities (Fig. 4).
their ability to analyze texts, drawings and graphs was also under investigation. Students’ answers demonstrated a statistically significant progress towards analyzing abilities (p<0.05, in all the cases). The best results (p=0.02) were obtained in promoting the 7th grade students’ ability to analyze graphs.

The analysis of semi-structured group interviews revealed a remarkable promoting cooperative activity among the members of the hiking teams. The records of the observers demonstrated that this was due to the development of students’ communication skills and their higher motivation.

Figure 5: The average results of the 7th, 9th and 12th grade teams in problem-solving tasks presented in the pre-test (□) and post-test (■) compared with the results of the control groups achieved in answering the post-test (□) (a). The average results of the same groups on the basis of the students’ ability to analyze the graphs (b).

Conclusions

The web-based simulation “Hiking Across Estonia” is supplied with both environmental simple fact-orientated and complex problem-orientated tasks. The member of hiking teams who participated in the pilot study demonstrated the applicability of the simulation program in promoting students’ motivation and their progress towards the problem-solving activity. Authentic complex tasks provided learners with the opportunity of multiple roles and perspectives to be realizable by their collaborative construction of solutions. It encouraged learners to detect and evaluate relevant information, but also to analyze texts, drawings and graphs of the sub-tasks.

As a result of authentic activities the participants of the virtual hike revealed learning outcomes, which could be successfully applicable beyond the simulation program and environmental problems presented on the web pages. The promotion of students’ skills to analyze and evaluate texts, drawings and graphs should be relevant in solving most real-life problems. The latter will be under investigation in a quantitative study of the participants of the interschool competition that will be held in the spring-term of 2001.

The LPII Simulation: A Lesson-planning Tool for Preservice Teachers

Harold R. Strang & Ronald J. Clark
Curry School of Education
University of Virginia
United States
hrs9j@virginia.edu

Abstract: This paper describes the key features of the LPII, a Visual Basic simulation that is designed to help preservice teachers to gain insights in planning effective lessons for both motivated and unmotivated students. The tool's four-step decision-making sequence will be outlined and the post-participation debriefing phase will be discussed. Finally, initial field testing results will be presented, and projected future applications will be suggested.

Introduction

As summarized by Strang (1997), over the past two decades Curry simulations have helped preservice teachers to translate their pedagogical knowledge about teaching into realistic, enactive experiences. This paper describes the latest version of a Windows-based simulation, a tool that is designed to help our teachers-in-training to gain insights in planning effective lessons for both motivated and unmotivated students. The LPII simulation, administered via a Visual Basic software program, can be customized to address content areas including language arts, science, math, and social studies and also to address academic levels including elementary, middle school, and high school. It is intended to be used as a laboratory component in an introductory methods or theory course in teacher education. In initial applications during the fall of 2000, its administration has consisted of a participation phase followed by a debriefing phase.

The Planning Phase

Collaborating in groups of two or three, preservice teachers complete the lesson-planning simulation via mouse and keyboard actions. After entering an ID number and name registration, each teacher group begins a four-step decision-making sequence. At any point during this planning process the participants are no more than several key clicks away from reviewing and/or changing previous decision entries.

Defining the Students

The first step in the planning phase builds on a paper-and-pencil task introduced prior to the LPII simulation. During this task, group members collectively complete the Learning Pattern Assessment questionnaire (Golay, 1982) for two hypothetical students—one motivated, the other unmotivated. In discussing how to rate each of the students on the 40 items, the group develops a common impression of how these students differ. The group members complete their definitions during the first part of the simulation by deciding upon a grade level and genders for the two hypothetical students.

Defining Lesson Content

The second step involves three decisions that determine the content that the two hypothetical students will work with during the lesson. After deciding whether the lesson subject will be language arts, social science, mathematics, or science, one of three lesson subject areas is identified via the selection of a State of Virginia Standard of Learning (SOL) goal (Virginia Department of Education, 1999). Finally, one of three lesson goals linked to the SOL is selected.
Defining Lesson Activity

The third and most comprehensive step in the simulation entails the creation of a lesson for each of the previously defined students. This process evolves from first determining the number of activities that will comprise each lesson to answering questions that address five facets of each activity. These questions ask (1) what the student will do, (2) with whom the student will work, (3) what learning aids will be used, (4) what type of thinking will be encouraged, and (5) how long this activity will last. Navigation through these decisions is completely nonlinear; any decisions can be changed via a single mouse click, and attention can immediately be shifted from one student lesson plan to the other. Finally, in contrast to its predecessors, the LPII simulation expands from a "point and click" experience to one in which participants can author their own options and can also construct notes to document and/or to explain their ongoing decision-making process. Figure 1 depicts the option window that participants work with in making the five types of activity decisions for the motivated and unmotivated students.

![Option window for recording lesson activity decisions](image)

**Figure 1:** Option window for recording lesson activity decisions

Defining the Evaluation of Lesson Effectiveness

The fourth step in the LPII simulation offers a decision-making dimension not included in its predecessors—a dimension that allows participants to decide how they will evaluate the effectiveness of their planning for each student. Similar to lesson creation, opportunities are provided to tap program-defined options, to create new options, and to record personal notes. 
How will the students be evaluated?

Click the appropriate boxes below to indicate how you will evaluate the effectiveness of the lesson activities for this student. Select as many options as you wish and also use the lower boxes to define types of evaluations not included on the option list. Type notes pertaining to the evaluation in the bottom box.

- Written test
- Oral test
- Teacher oral evaluation of classroom performance
- Peer oral evaluation of classroom performance
- Teacher evaluation of the student’s project
- Teacher evaluation of a group project
- Teacher evaluation of the student’s portfolio
- Create an option here
- Create an option here

Notes

Figure 2: Option window for recording student evaluation decisions

The Debriefing Phase

Several weeks after completing the LPII simulation, participants congregate in small groups to discuss their lesson plans. This process is facilitated through the use of several printed reports that clearly depict for each collaborating group (1) the navigational path followed during the simulation, (2) the contents of the lesson plans for each of the students, and (3) a set of numerical values for key navigation and decision measures. A series of computer-projected graphical displays also allows participants to compare their navigation and decision scores with class averages or with averages generated from data collected from experienced teachers. The goals of this session are first to present these teachers-in-training with clear pictures of their lesson planning, then to stimulate them to comparison of these pictures with those of their cohort and those of an experienced teacher cohort. The preservice teachers are also encouraged to share and to discuss their plans with their colleagues beyond the debriefing session. Again, on their own initiative, participants can obtain from the Curry School Library individual lesson planning profiles of experienced teachers representing the three grade levels and the various subject areas. As the LPII simulation evolves into a vehicle that increasingly offers the opportunity for personal expression, we anticipate that its use as a satellite laboratory component in courses will be replaced by its integration into the mainstream of classroom activity.

Initial Results and Future Plans

After successfully field testing the LPII with several cohorts of experienced teachers enrolled in off-ground education courses during the summer of 2000, the simulation was included as a laboratory component in a learning and development course that all Curry preservice teachers completed early in their professional
program. Fifty-four groups of from two to three students each were constructed from the pool of 136 participants. Group assignment was based on matching two the students’ anticipated teaching goals—grade level (elementary, middle, or high school), and subject (language arts, social sciences, mathematics, or science).

Preliminary data analysis has focused on two major areas: (1) the reliability of the software, and (2) participant-rated usability of the learning tool. Regarding reliability, there were no software crashes or data losses during any of the 54 group sessions. Regarding usability, group participant ratings, obtained from a paper-and-pencil survey immediately following the completion of the lesson-planning simulation, revealed that 96% of groups found the software easy to use.

Several other ratings obtained from the post-participation survey provide additional insights as to how the simulation will be employed in the future. First, 98% of the groups believed that working together as a group on the lesson-planning task was more beneficial than working alone would have been. Second, 98% of the groups concluded that they would benefit if they had the opportunity to compare their lesson-planning decisions with those generated by groups of experienced teachers. Additional findings that address the decision-making strategies of participant groups will be drawn from two feedback instruments that map the decision path followed during the planning and the decision outcomes that define the resulting lesson. Of particular interest will be the individualized decision options and notes that the participants generate as they complete the planning task.

As findings on the newly developed simulation unfold, it is becoming increasingly clear that this tool’s use as a stand-alone laboratory task needs to be rethought. With its evolving open structure, the simulation can easily be integrated into methods coursework and can even function as a diagnostic tool.

References

Integrating technology meaningfully in social studies remains a major issue in education. Nevertheless, the papers in the social studies section represent varied, creative, thoughtful and meaningful applications of technology for powerful social studies teaching and learning. Each of the papers provide a type of case study model and ideas for meaningfully integrating technology in social studies. The papers also are broad representations allowing for adaptation at various levels.

*Teacher's Guide to the Holocaust* by Barron, Calandra, and Kemker offers an overview regarding an invaluable website developed resource for teaching the Holocaust. The papers is thorough in describing and analyzing the process for developing the project as well as the actual components of the site. The paper also provides an excellent case study and model for like projects.

The paper by Beal, *Preparing a Virtual Field Trip* focuses on constructivist approaches to technology integration such as meaningful and real world applications. The paper suggests that developing virtual field trips are engaging projects for teachers and students. Specific themes include community, service learning, and character building.

The paper by Coverdale on *Technology-rich Quest Projects* uses the thematic strand for social studies as suggested by the National Council for the Social Studies. AsiaQuest is used as the case study and model for an analysis of integrating technology, quest projects, and the NCSS themes. The paper also addresses specific issues regarding the definition, rationale, and goals of social studies.

*StarFestival* by Heistad and Miyagawa describes a multimedia project on the themes of diversity and cultural identity. The package is personalized by using one person as the case study focus for individual identity and development. The goal is to allow students to engage in self discovery of personal identity and worth.

McClelland's paper, entitled *Web-based Delivery of a Generic Research Methods Module* offers a model of a web-supported teaching and learning project. The paper describes the module and research associated with determining its effectiveness. A variety of issues related to web-based teaching and learning are analyzed including attitudes, learning styles, adaptation, and future projects.

*Multimedia Resource File* by McCoy, Milller, and Bender describes a project that is intended as a practical application resource for technology and content integration in teaching and learning. Specific components described include internet applications, analyzing effective resources, and products. This paper provides an example of the potential of the internet for powerful social studies teaching and learning.

The final paper in the section by Pye entitled *Are Middle School Social Studies Teachers in a Technological Quandary* focuses on important issues in the integration of technology in middle school social studies. The paper looks at the concept of middle school education and technology as a tool to enhance teaching and learning. The case study describes and analyzes the application of technology in sample middle school social studies classroom in Missouri.

In conclusion, these papers provide critical insight regarding the successful integration of technology in social education at various levels. The case study and model approach used by the authors provide opportunities for interested parties to adapt the ideas in meeting individual needs. The integration of technology in social studies education has made great strides as is evidenced in these papers. We still have a great distance to travel however.
Teacher's Guide to the Holocaust: 
An Extensive Online Resource for Teachers

Ann E. Barron
Brendan Calandra
John Fitzpatrick
Kate Kemker
University of South Florida
United States
barron@usf.edu

Abstract: The Teacher's Guide to the Holocaust is a large, instructional website with over 7,000 HTML pages. It was designed and developed by graduate students in the Instructional Technology program and the staff of the Florida Center for Instructional Technology, College of Education, at the University of South Florida. The program was designed to provide an overview of the Holocaust through text, original source documents, graphics, photographs, art, movies, and music.

The primary audience of the Teacher's Guide to the Holocaust is preservice and inservice teachers. The site allows them to view the Holocaust through three different "lenses"—Timeline, People, and the Arts. Additional resources are provided in the Student Activities and Teacher Resources sections. Now in its 4th year, the site receives over two million hits per month from educators and students all over the world. This paper provides background information on the evolution of the project, design considerations, and development issues.

Introduction

The Holocaust remains one of the most effective and extensively documented subjects for an examination of basic humanitarian issues; it provides a window into the understanding of the complex elements of human behavior. Through a study of the Holocaust, students and teachers alike can develop an understanding of the ramifications of prejudice and racism, and they can begin to gain insight into the meaning of responsibility for both individual and community actions.

In 1994, Florida became the first state to enact a law requiring instruction in the history of the Holocaust (Brogan, 1997). The law was championed by, among others, Stephen Spielberg, director of Schindler's List. The text of the law reads:

The history of the Holocaust (1933-1945), the systematic, planned annihilation of European Jews and other groups by Nazi Germany, a watershed event in the history of humanity, to be taught in a manner that leads to an investigation of human behavior, an understanding of the ramifications of prejudice and racism, and an examination of what it means to be a responsible and respectful person, for the purposes of encouraging tolerance of diversity in a pluralistic society and for nurturing and protecting democratic values and institutions.

Although the law mandated Holocaust education, very few of Florida's teachers were adequately prepared to teach this sensitive subject. To help meet the need for teacher preparation and curriculum resources, the Florida Center for Instructional Technology, along with the Instructional Technology program in the College of Education at the University of South Florida, created the online resource, A Teacher's Guide to the Holocaust (http://fcit.usf.edu/holocaust).
The Teacher’s Guide is designed to provide an overview of the Holocaust through text, original source documents, graphics, photographs, art, movies, and music. This website allows preservice and inservice teachers to view the Holocaust through three different "lenses"—Timeline, People, and The Arts. Additional resources are provided in the Student Activities and Teacher Resources sections.

The primary goal of the website has been to provide a "starting point" for Holocaust resources, research, and education for teachers. The site provides over 1,000 photographs, hundreds of source documents, numerous panoramas of concentration camps, traditional Jewish music, annotated bibliographies, blackline handouts, maps, and other materials. All of these resources can be used in classrooms for instructional purposes.

A secondary goal of the website has been to serve as a basis for research studies related to preservice teachers’ knowledge and attitudes of Holocaust. Several research studies are underway to assess their preparation to teach topics related to tolerance and prejudice.

Design

The initial design for the Teacher’s Guide to the Holocaust was created in 1995 by graduate students in an Advanced Design course. The graduate students spent several weeks determining the appropriate content areas and the optimal structure for the site. Existing websites were examined, and alternative instructional strategies were explored. The final composition of the Teacher’s Guide to the Holocaust presents an overview of the Holocaust from three different perspectives: Timeline, People, and The Arts. The website also includes sections related to Classroom Activities and Teacher Resources.

The Timeline section presents the story of the Holocaust chronologically along a detailed timeline of history. This section focuses on the rise of the Nazi party, Hitler’s final solution, the rescue and liberation of Nazi death camps, the Nuremberg trials, and the aftermath. Topics are supported with over 1,200 photographs of the war in Europe and copies of transcripts and documents from the Nuremberg Trials and other historical events. This section is designed to serve as a concise point of reference for teachers.

The People section exhibits the behaviorist categories of people in time of war. In this section, the focus is not only on victims, but also on bystanders, perpetrators, collaborators, resisters, rescuers, liberators, survivors, and children. People also celebrates the resisters and rescuers of the Holocaust, with a special dedication to the Righteous Gentiles who placed their lives in danger to save Jewish people. The Survivor section personalizes the Holocaust by including links to numerous first-hand stories of survivors.

The Arts section demonstrates that despite the Nazi’s attempts at dehumanization, victims and survivors of the Holocaust held onto the parts of themselves that made them most human. This section contains a gallery of the Arts—music, literature, and visual arts. In Music, teachers and students have the ability to hear traditional Jewish music and songs written during the Holocaust in both the camps and ghettos. Literature includes the works of playwrights—materials that teachers are able to incorporate into their study of the Holocaust. The Visual Arts section contains the works of David Olere, an artist who survived the Holocaust, as well as other art created by victims of the Holocaust.

The Teacher Resources section provides teachers with a wealth of reference materials, including the following (see Figure 1):

Bibliographies: General and specialized bibliographies of Holocaust works for students and teachers.
Documents: Primary source materials related to the Holocaust.
Galleries: Over 1,250 Holocaust photographs, drawings, and paintings grouped into thematic galleries.
Glossary: Terms related to the Holocaust, including the pronunciation of many foreign words.
Maps: Maps dealing with events related to World War II.
Movies: Short QuickTime movies of archival footage and survivor testimony.
Museums: Descriptions of Holocaust museums and resource centers in Florida and elsewhere.
Music: A collection of music files appropriate to a study of the Holocaust.
Plays: An annotated list of educational plays with a Holocaust theme — access to full scripts of selected plays.
Quizzes: Interactive quizzes for each of the Timeline and People sub-sections.
Software: An annotated list of educational software appropriate to a study of the Holocaust.
Videography: An annotated list of films and videos about the Holocaust.
VR Movies: Forty virtual reality panorama movies of concentration camps and other Holocaust-related sites.
Web Sites: Links to relevant Holocaust-related Web sites.

Teacher Resources

Bibliographies, General and specialized bibliographies of Holocaust works for students and teachers.
Documents: Primary source materials related to the Holocaust.
Galleries: Over 1250 Holocaust photographs, drawings, and paintings grouped into thematic galleries.
Glossary: Terms related to the Holocaust, including the pronunciation of many foreign words.
Maps: All of the maps in A Teacher's Guide to the Holocaust. Many of the maps are formatted for printing.
Movies: Short QuickTime movies of survivor testimony, Kristallnacht, extermination, transports, camps, and other Holocaust themes.
Software: An annotated list of educational software appropriate to a study of the Holocaust.
Videography: An annotated list of films and videos about the Holocaust.
Virtual Reality Movies: Forty VR panorama movies of concentration camps and other Holocaust-related sites.
Web Search: Links to relevant Holocaust-related Web search engines and directories.
Web Sites: Links to relevant Holocaust-related Web sites.

Figure 1. Teacher Resource Section

The Classroom Activities section presents a series of lesson plans, targeted glossaries, quizzes, and integrated units that can be used across the disciplines. Each lesson describes the learning objective, appropriate grade level, materials needed, and procedure. This section also contains a "Submit an Activity" area, where teachers can send their own lesson plans or submit suggestions for revisions of the lessons plans in the database.

Development

The program was developed to run with low-end browsers (version 2.0 and above) on either Macintosh or PC computers. For ease of navigation, an image-map was placed at the top and bottom of each page. These image-maps and the Site Map (which is accessible from every page) facilitate the movement from one section to another (see Figure 2). An Index is also available for easy access to relevant topics.
Several techniques were used to create the vast array of resources available on the site. For example, in order to provide immediate, client-side feedback and a mild level of interactivity, the Quizzes were created using Macromedia CourseBuilder. The software allowed items to be created using a variety of formats including, radio buttons, check boxes, drag-and-drop and more. Feedback was provided in the form of pop-up dialogue boxes with comments such as, “Good job,” or “Try again.” In some circumstances, feedback was provided in the form of correct answers. All questions were multiple-choice and their content was created and validated by a team of Holocaust and measurement experts working on The Teachers’ Guide.

All of the movie and sound files were created in QuickTime because it allows for delivery of both audio and video files over the Web and on CD-ROM. QuickTime is a universal plug-in for multimedia in Web browsers. Multimedia that is created in QuickTime will perform equally as well on Windows and Macintosh computers.

The paper manuscripts of the music were accessed from the public domain at the university library. A musician was then hired from our university to create the music on a MIDI keyboard. The MIDI file was then saved as a QuickTime file.

The Holocaust survivor movie files were originally recorded on an analog video camera at the Tampa Bay Holocaust Museum. Permission was granted from each of the survivors. The VHS videotapes were then transferred to a digital video camera, allowing the movies to be edited on a computer. Each one of the videos was then reduced to short one-minute clips. Finally, we compressed the movies to reasonable file sizes for use over the web.
Virtual Reality movies, which are a series of individual photographs combined together to create a 180 to 360 degree panoramic effect, were created for use with the Holocaust web site. Photographs were taken at actual Holocaust related sites and stitched together using Adobe Photoshop to clean image quality and VR Authoring Studio to stitch and export the panoramic image. This process involves bringing a seamless transition from one photograph to the next. From an educational perspective, the VR movie allows for the usage of virtual field trips in the classroom environment.

**Dissemination**

The primary vehicle for distribution of the project is the Web. The Florida Center for Instructional Technology maintains a Windows NT web server at USF. File management and maintenance are monitored closely, and revisions and updates can be done on a routine basis. The website currently receives over two million hits per month, and links to it have been established from hundreds of websites throughout the United States, Europe, the Middle East, and other parts of the world.

Although delivery through the Web is optimal in many circumstances, there were sufficient reasons to create a version of the program for delivery on CD-ROM. One of the major restraints of Web delivery is that not all teachers have access to the Web. Therefore, a CD-ROM-based version was created and distributed to every school in the state of Florida.

The analysis, design, development, and dissemination of a large-scale instructional project such as the *Teacher's Guide to the Holocaust* is a major undertaking. Version One was disseminated in 1997; Version Two in 1999; and Version Three in 2000. With each subsequent version, additional photographs, content, and other
resources have been added to the site. In addition to the new and updated releases on the Web (for the worldwide audience), 5,000 copies on CD (of each version) have been distributed to Florida schools.

Research

In order to pilot test the effectiveness of the website, and to determine the amount of factual knowledge preservice teachers have of historical events surrounding the Holocaust, two research instruments have been created. One instrument assesses the factual knowledge related to the Holocaust. The second instrument is an attitudinal survey that was designed to measure the subjects' attitudes towards traditionally marginalized groups. An initial study was conducted in the Spring of 2000 with 200 preservice teachers (Calandra, Fitzpatrick, Barron, 2000). Follow-up studies are scheduled for the Fall and Spring of this academic year. Answers to important questions such as the depth of knowledge related to the Holocaust and correlations between knowledge and attitudes can impact the design of teacher education and the design of future versions of the Teacher's Guide to the Holocaust.

Response

The response to A Teacher's Guide to the Holocaust has been overwhelming. Over two million hits are registered on the site each month. E-mail messages related to the site arrive daily from educators and students all over the world. Students often send questions about the Holocaust as they are working on their homework; teachers send appreciation notes and ideas for enhancement of the site. Based on the e-mail messages, educators are especially grateful for the concise information, the hundreds of photographs, and the access to the source documents. The music section, maps, lesson plans, and the virtual reality movies of the concentration camps are also features that teachers find especially useful.

The Teacher's Guide to the Holocaust has received major recognition from well respected Holocaust sites. The Cybrary of the Holocaust links to the project with these words:

Amazing...simply amazing. Student activities, timeline, links, and much more. "A Teacher's Guide to the Holocaust" offers an overview of the people and events of the Holocaust. Extensive teacher resources are included (http://remember.org/educate.htm).

The website has also received dozens of awards. The online Encyclopedia Britannica has listed it among the "Web's Best Sites" with the following citation:

Carefully designed with an extensive collection of materials, this guide provides an excellent resource not only for teachers and students but for anyone who wants to learn about the Holocaust.

Continuous updates and revisions are underway. Holocaust educators and historians throughout the world continue to contribute to the resources and information in the Teacher's Guide to the Holocaust. Through the generosity and collaboration of these Holocaust experts, this site will continue to grow and offer a major resource for Holocaust education.

Preparing a Virtual Field Trip to Teach Value of Community and Sense of Place

Dr. Candy Beal, Department of Curriculum and Instruction, North Carolina State University, USA
candy_beal@ncsu.edu

Abstract: This research paper discusses the value of engaging preservice teachers in the development of a virtual field trip. Research in psychology, sociology and education suggests the importance of engaging both teachers and students in activities that promote the development of a sense of place. Taking a field trip of the community provides students with a sense of belonging and support and gives the community a better idea about school activities. Virtual field trips may be use pre-, post- or in place of an actual field trip. During the actual field trip, students use digital cameras to record historic sites and later use HyperStudio to prepare the virtual field trip. Preservice teachers experience the field trip and prepare the virtual tour so they may know the power of this activity in building community connections and a greater sense of place.

A great deal is expected of preservice teachers today, not the least of which is proficiency in technology skills. Building a virtual field trip is one way that our teachers become familiar with technology that is easy to use and to teach to their students. Wrapped into the virtual field trip is additional value in the form of its ability to foster a sense of community and place.

Sense of place is not what it was years ago. We are a much more mobile society. This often means that there is no extended family to provide the support families need. Children may be reared by single parents or in homes where both parents work and are unable to spend a great deal of time nurturing their children. Family circumstances affect parenting skills, relationships, and may even endanger a family’s survival. Teachers are all too familiar with the effects of lack of family support.

For many children our classrooms become a sanctuary that bolsters them up and prepares them to meet the world. Rather than serving as just a safe haven, we should be helping them explore, contribute and make their mark on their immediate world. As teachers, we tend to see adolescents in our arena. Sometimes we forget that they are already part of a much larger circle. James Garbarino, a proponent of the ecology of adolescent development, explains that youth evolve in interrelated environments (Garbarino, 1985). The four areas most closely connected to them are home, peers, school and community. Adolescents develop based on their experiences and these areas are their reality. The nature and number of connections among these areas determine how fully developed and supported a person is in her life. A strong connection to the community can serve as an anchor and give a student a solid support base on which to rely. For an adolescent in the throes of an identity search, a sense of place can provide a feeling of well being and give the student the freedom to grow by taking risks that they might not have otherwise attempted. Teachers, too, need the sense of place that knowing and interacting with the community provides. They can better know the culture from which their students come if they know the cultural heritage of the different areas of the city. Studying the city helps one know its needs and opportunities that exist for your class to engage in community service (Arnold & Beal, 1995). Finally, it enables the community to know what is going on in the schools. We cannot expect unqualified support if we do not show them the worth of our students and our programs.

For the past five years preservice undergraduate teacher education students have been part of the Great Raleigh Trolley Adventure. They take a two hour guided tour of the city, complete with stories about historic sites and peoples that have been gleaned from original source documents (Beal, 1992). Some of the tales are taken from private family diaries and newspaper accounts. Throughout the tour students use digital cameras to record each of the memorable stops. One hundred and fifty preservice teachers have taken the tour and follow-up discussions and questionnaires indicate a much stronger sense of community and place and a greater commitment to doing the same thing with the students they will teach.

Students return to the university, select the site they wish to further research and prepare a fact sheet on their site. Next, they must consider the audience for the virtual field trip and prepare their text accordingly. Students are
taught HyperStudio and each prepares a card or cards with the digital image and text box. Some students are more sophisticated and can add audio, animation or quiz items that give immediate feedback. One student is usually responsible for the title card and another the city map, which is highlighted with the sites to be studied. Buttons are added to connect each of the student's cards into one stack. Those using the virtual field trip can select a specific site on the map and be taken to the student's card, which has an image and description of the site.

Preservice teachers can use the virtual field trip activity as a research hook before they take their own students on a field trip. It is useful after the trip as a follow-up and means of assessing what was learned or can be used in place of a field trip if the funding for off campus learning experiences is limited. Most schools have a computer, HyperStudio and a digital camera. If a digital camera is not available, a regular one can be used. Regular film can be developed and put on a disk or trip pictures may be scanned to a disk.

Virtual field trips work on many different levels. Service learning: When students are taking the real-life field trip they learn about their community and its needs. The community does the same. This information often leads to teacher or student suggested service learning projects to help the community. Virtual trips can be put on the web and shared with the community. Technology skills development: Students learn how to use the digital camera to record historic sites and later practice their computer skills by using HyperStudio to combine the digital images with text boxes and build the virtual field trip stack. Empowering: Trolley-told stories presented in the form of dramatic narrative show that history, often thought dry and boring, can be exciting. Students are empowered and see themselves as the Keepers of the History. Social studies takes on a whole new meaning. Students are eager to preserve and retell the stories to family and friends. Sense of Place: Students become invested in the community and see themselves as leaders in training. They make contributions that are recognized and valued and they feel confident in taking on a larger role as a community helper. Above all, they belong and have another arena in which to be successful and supported.

By using the virtual field trip activity, preservice teachers experience what they will help their own students feel someday, a growing sense of appreciation for their community and a stronger sense of place. The Raleigh Trolley has been used at all levels -- preservice teachers, community leaders, regular classroom teachers and middle school children. Most have followed the tour with the virtual field trip activity. Some have individually prepared virtual tours of a single site and donated the work to that site for their use. Connecting to the community both in a real and virtual sense has proven to be an experience students rate as memorable and the one thing they report they will replicate in their own classroom.

Abstract: This paper is a report on the experiences of a post-graduate multidisciplinary team of students attending the Cognitive Ecology and the Technologies of Intelligence Course and their Lecturer, while working in a collective text construction and using a collaborative writing tool named The EquiText. It presents the analysis of the text construction as an end of semester extra-class asynchronous work, based on Varela’s observer notion in the cognitive ecology field and in Maturana’s concepts of organization and structure. At the same time the group was testing their own ‘conivence’ environment in this tool, which had recently been available for local use.

Introduction: The Choice Of The Threads

This work is the result from the learning experience of a group of post-graduate students at the Universidade Federal do Rio Grande do Sul in the construction of a collective text, using a software of collective authorship, the EquiText. Concepts of Maturana (1999), as organization and structure, in addition to the Varela’s observer ontology notion, provide the basic theoretical support for this analysis. These concepts are also shared to a certain extent with other researchers interested in the study of the construction of the ecology of knowledge and its relation with the new technologies of the intelligence, like Pierre Lévy (1993), Gregory Bateson (1991), Francisco Varela (1997), Félix Guattari (1993), and others.

An observer as any human being, when operating in the language with other human beings, participates with them in the constitution of a domain of coordinated actions as a domain of distinctions and in this way he/she can generate descriptions and descriptions of descriptions. The relations between the components that define a compound unity as a simple unity of a certain type, constitute its organization. Thus, the organization of a compound unity constitutes its class identity, conserving itself as a whole of invariable relations. The components and the relations between the components which constitute a particular compound unity as a compound unity of a particular type, constitute its structure. The relations that constitute the organization of a compound unity takes place as a subgroup of these relations which takes
place in its structure. The structure includes more relations than those which define an organization. For this reason, the conservation of the organization does not imply the conservation of the structure. The structural transformations may come from the changing in the characteristics of the components of the compound unity or by the changing in the relations, that may produce itself in an episodic or recurrent way (Maturana, 1999).

Mazzochi (2000) mentions several sites and environments of collective constructions in the area of arts. In the area of collective construction of texts we can mention, for instance, the RCT (Remote Collaboration Tool), which represents a multidisciplinar effort to improve the interaction quality among students and among students and instructors in foreign language courses at the University of California in Davis, since 1997. (Walters, 2000)

Thus, building a text with several hands, from distinct points and different times, on a certain theme, and using a special tool to develop such a task, can be a positive, constructive, and enjoyable experience. If the team of participants are sufficiently motivated and predisposed to share their individual ideas with the whole group - on an specific theme - for the sake of constructing a significant and discursive text in a cooperative and/or collaborative mode in its lay-out.

A Virtual Environment: The Weaver's Loom

The virtual environment used to catalyze the creation of this "coexistence space", the EquiText, (Fig. 1), was first developed by a multidisciplinary group of students attending the Tele-Education Course at the Post-Graduate Program in Computer Sciences in Education (PGIE), at the Federal University of Rio Grande do Sul (UFRGS), in Porto Alegre, RS, Brazil.

The EquiText is the fruitful result of a study-project which constituted the extension course on "Tools and Techniques of Groupware". It was first designed during the 'Tele-Education' Course of the PGIE Program at UFRGS, during the second semester of 1999. It was then launched as a group contribution to the mentioned project, which initially aimed at qualifying teachers and educators to the new distance education standards set out by the Brazilian Government. The description and analysis of the results of this project and the first version of the EquiText can be find in (Rizzi et al. 2000a and 2000b).
This tool has then been conceived to give support to the production of collaborative and/or cooperative texts, and it was based on the 'paragraph' concept. This conception facilitates the display of the individual written contributions, allowing the inclusion, alteration, creation of new paragraphs, as well as the exclusion of any existing paragraph unfit to the text in progress - an important move to guarantee the coherence of the text as a significant whole (Fig.2). Besides, it also allows the inclusion of comments, as exemplified in (Fig.3), which constitute short texts in attachment.

According to Lévy, "the word 'text', in its etymology, contains the old feminine technique of weaving. It is perhaps the fact of this knitting of verbs and names through which we tried to retain the meaning, to be designated by an almost textile term, be not a coincidence". (Lévy 1999)

The paragraph concept adopted in the EquiText considers a title of a text in construction as well as one sole line as individual and identified paragraphs with a number in sequence, beginning with the number 1. That numbering is altered dynamically, according to the "movement" of the participation of its team-members.

The Experience: Weaving the Threads

The group of students who participated in the elaboration of this text-experience and in this analysis is constituted by the lecturer of the course in "Cognitive Ecology and Technologies of the Intelligence" and her students - the authors of this paper - all linked to the Post-Graduate Programs of Social and Institutional Psychology and Computer Sciences in Education at the Federal University of Rio Grande do Sul (UFRGS).

We, the authors, come from different backgrounds, such as Psychology, Mathematics, Languages, Biology, Computer Sciences, Engineering, among others, transforming this collective text writing activity a coexistence space in the 'alterity'. It is understood here that the experience of a collective writing is not constituted of a mere representation of ideas and that it follows a pre-conceived organization. It rather constitutes an updated recreation to each written interaction.

The experience under analysis had been accomplished in approximately two weeks. During this period, the group underwent two main processes: first, they were getting acquainted with the environment - by using the EquiText properly while discussing how to start the proposed task; second, the very few ones who dared to start writing their collaborations in the EquiText, by constructing their new paragraphs subject to alteration or substitution moves, not only triggered off important reflections upon the task in process but also motivated the other participants to go on in the collective text creation.

Thus, during the writing process, the text had been built resembling at times a patchwork quilt or a mere registration of ideas still not well connected. Knots were given others untied, as if an assembling of a knitting of ideas was in its way while the writing operating process took place, releasing the text which covers and illustrates the present analysis. It is important to mention that this text is one of the possible actualizations of the several roads which were opened up in the virtuality of the writings registered in the EquiText domains. We could have produced other texts if any other potential version had been actualized.

The use of a virtual environment echoed differently in the team members. The participations were of different intensities, having at every moment the observer's glance modified, pointing out this come and go of several points of view. The testing and the discovery of the environment itself, the experimentation of
unusual ways of interaction, the coupling to that other kind of authorship, all these aspects made it possible to create and recreate in this new coexistence space.

Despite the fact that this environment had not been conceived to promote personal interactions in real time, an interesting experience happened during the construction of this text. In the exact moment that the students Rose and Janete elaborated the initial paragraphs in the EquiText, the student Luciane made her contributions to the text. And such actions could be visualized in the screen, at the very movement of the occurrence of the collaborative act.

Technically, this event could be read as a deficiency of the environment, since this tool does not foresee and/or control the access competition. If this fact could generate confusion in some users, who may get surprised with a text in the screen different from that one just edited, in others, new sensations were actually felt while witnessing this irrecognition of the text in motion. That characteristic reveals the asynchronous aspect of the authorship action in the text: participants, of distant points, in different machines, cooperating collectively in the EquiText environment, in that very moment.

Another interesting fact was the oddity in relation to the entire joint of ideas placed in the text. Some participants manifested their disagreement with certain ideas and arguments. This fact proposed an instigating reflection: a collective text does not necessarily express the integrity of each author's suppositions; it may well occur a concomitant recognition/irrecognition of the text being produced. As being different from an individual text, where this process can happen in the a posteriori, it seemed to us that in a collective text that partial domain of the directions and connections of ideas, which may release this irrecognition feeling, is already present in the movements of the proper writing.

While this collective experience was taking its course, we could accompany the happening of different writing positions and styles, with different discourse levels. For the very programming of the environment the operation existed in the text itself, through the inclusion and exclusion actions, alteration of paragraphs and inclusion of comments on the text that has been created. In a meta-writing level, the movement of the auto-organization of this group, where critical comments and of positioning were done on the text; the very textual texture in action could be seen as an important component towards a construction of a hypertext.

The active participation of those involved in the 'weaving of the text' promoted significant structural alterations up to the last moment when it embodied its current form, displayed in the EquiText under the function "Final Text". It did not lose its inner organization as a good written text, though.

Thus, what may we consider for an analysis of a collaborative text production in which the individual "I" or the several individual "I" give place to another "I", this time collective? Facing this new idea of a 'cyborguian' being, the following inquiries still strike us:

- Could the individual knowledge be really disturbed by a collective mind, to the point that the individuality takes place in a multiple territory?
- Could this text written in a collaborative way be considered a product of a collective mind?

These questions reveal some evidence that the insertion of technological tools in learning environments bring about disturbances both in singular and collective levels. The interesting aspect in this experience with the EquiText is that the theoretical reflection takes place in the same happening of the collective writing. There is no anteriority of the ideas as they materialize themselves in the act of the reflexive writing when they happen to be inserted, altered, substituted or even excluded from the paragraphs in progress.

As we examine the organization of a collectively written text, where the collaboration of one participant may affect or unchain the collaboration of the other (s), we observe that there is an open, dynamic structure, virtually transformable, that works according to the flavor of the movement of the participants' thoughts. The team members get involved in finding a way to participate in accordance to their thinking, though collaboratively enough to be able to co-build a new knowledge - more enlarged and significant. It is the social cooperation, accomplished in its own activity by means of the latest technological tools, in conjunction with the old and battered verbal signs - exactly one of the more significant distinctive aspects of the human species. And associated with the use of the individuals psychological tools, it constitutes the natural phenomenon that modifies its reality.

In this sense, it can be thought then in terms of the texture concept or in a heterogeneous net of senses that is constituted in its own accomplishment, where each author has already inbuilt his/her own net:
"As each one of us was several, he/she was already a lot of people. We used everything that approximated us, the closest and more distant... Not to get to the point that it is not said 'I' anymore, but to the point in that no longer he/she has any importance to say or not to say 'I'. We are not the same ones any longer. Each one will recognize his/her "I". We were helped, aspirated, multiplied". (Deleuze & Guattari, 1995).

But, after all, which text is not collective? Are we not all participants of a polymorphic net of ecological ideas, in which each of us can only know who we are from the notion of who are we not? We are the text.

"The text is placed in movement, taken in a flow, vetorized, metamorphic. It is thus closer of the very movement of the thought, or of the image that we make of him today. The text always subsists, but the page gets hidden. The page, that is, the Latin pagus, the field, the territory located within the white of the margins, cultivated of lines and sowed by the author of letters, characters. The page, still heavy of the mesopotamian clay, always adhering to the earth of the neolithic, this very old page, hides itself slowly under the high informational surface, its disconnected signs will rejoin the numeric (digital) wave. Everything happens as if the numberization (digitalization) would establish a type of an immense semantic plan, accessible all over the place, for which each one could contribute to produce, to bend diversely, to retake, to modify, to refold..." (LEVY, 1993).

We are a collective of brains that are a collective of neurones in interaction. In this simultaneous and heterogeneous writing a kind of refolding of the text takes place, where ideas of authors formerly distant become close and because of this closeness they become irrecognizad. A topological sequential, where the ideas are clamped without necessarily producing a logical sequency.

Some Considerations: After all, What Did We Weave?

To what conclusions did we arrive with this work of co-authoring in a team and at distance, using a tool - the EquiText - exactly build for that purpose? In spite of the initial adaptation in the utilization of the EquiText, and of the inherent challenges of a collaborative writing, the accomplished results satisfied the expectations, or even overcame them, regarding the construction of a text "with several hands and brains".

Our experience configured in an existence spot, propitiating action and reflection, and to a certain extent allowing us our own transformation as well as the entire group in this coexistence episode. In this way, the EquiText domain provided resources not only for the collective construction of a text, but also for its (re)construction. In this way, its construction in a theory-practice congruence makes it possible to discuss how the coupling of the cognitive systems to the technologies can transform the manners of thinking individually and collectively.

Nevertheless, some questions continue instigating us and provoking other reflections:

- that the recognition of the knowledge built in a shared way can, ultimately, result in a larger knowledge, where the minor portions of knowledge, here seen as individual, partial, may actually aid to the constitution of the major consensual knowledge of the group;
- that new kinds of experiments may result from cognitive group productions where the participation of a larger number of people have the privilege to cooperate in the construction of science;
- that a collaborative experience of text elaboration by several people via the EquiText - a favorable environment for such an experience - where what one writes may become the substratum to what the other(s) want(s) to express, even if some part(s) previously registered is/are lost, can be an important moment of reflection over the property of knowledge, an issue on its validation after the scientific world.

From what was previously exposed, it results clear that we find ourselves in a domain where a lot of questions are left for further and deeper discussions. From what has been discussed so far, based on the 'cognitive ecology' notion of Bateson & Guattari and Maturana's concept of the 'ontology of the observer', we may already dare to insert a bridge here to link the sciences, in order to create a textual/theoretical territory, where the concepts are woven and an organization becomes a mutant structure. In other words, it is no longer possible to think in a subject-author interaction without thinking in the collective.
The notion of individual authorship is then illusory in the intertextuality process, the same as the illustrations embroidered in a rug: they give us an illusion of being separated, but if we observe them more closely, they are mere colored parts of an immense texture. And so is the text, so is the subjectivity, so are WE.

Developing an Understanding of the Social Studies Through Technology-rich Quest Projects

Gregory A. Coverdale, Ph.D.
College of Education
St. Cloud State University
United States
gcoverdale@stcloudstate.edu

Abstract: One of the difficulties of teaching and learning in K-12 social studies classrooms is the "fuzziness" of the discipline. What do we mean by social studies? The Curriculum Standards for Social Studies: Expectations of Excellence (NCSS 1994) provide a detailed framework for describing the curricular foci of the social studies by dividing the social studies into ten thematic organizational units. These themes are further delineated by performance standards for the early grades, middle grades, and high school. This paper is a qualitative document analysis of a technology-rich, interdisciplinary curriculum produced by Classroom Connect, a major producer of technology education products. This analysis focuses on the social studies themes present in one specific Quest project: AsiaQuest.

Introduction

Social studies is regarded as a major school subject and is taught in K-12 schools nationwide (NCSS 1994). However, because social studies is multidisciplinary and interdisciplinary, it is often difficult to define. The National Council for the Social Studies (NCSS) defines social studies as follows:

Social studies is the integrated study of the social sciences and humanities to promote civic competence. Within the school program, social studies provides coordinated, systematic study drawing upon such disciplines as anthropology, archaeology, economics, geography, history, law, philosophy, political science, psychology, religion, and sociology, as well as appropriate content from the humanities, mathematics, and natural sciences. The primary purpose of social studies is to help young people develop the ability to make informed and reasoned decisions for the public good as citizens of a culturally diverse, democratic society in an interdependent world.

Thousands of K-12 students worldwide participate in Classroom Connect Quest projects each semester. How does the curriculum content contained in the technology-rich projects correlate with the social studies themes and the performance expectations established by the NCSS? The purpose of this paper is to provide an overview of the AsiaQuest project and a correlation of the AsiaQuest content to the NCSS themes.

Classroom Connect Quest projects are Internet-based projects that promote active, inquiry-based learning in K-12 classrooms. Teachers subscribe to Classroom Connect and receive an extensive curriculum guide, a user id, and a password. A different Quest project is offered each semester and each Quest follows the same curricular format. Other Quest topics have included MayaQuest, AfricaQuest, GalapagosQuest, JapanQuest, AmericaQuest, and AustraliaQuest. In the spring 2001 semester, the Quest team will revisit MayaQuest. In each Quest, participants communicate with a team of scientists and explorers traveling the designated Quest region via bicycle.

Each Quest provides an inquiry question that focuses all participants' inquiries. AsiaQuest explores Venice, Italy to Beijing, China. However, there is much controversy surrounding the historical account of Polo's journey and thus AsiaQuest poses this question: "Did Marco Polo really go to China?" In Polo's writings, he fails to mention or describe many elements of Chinese culture: tea, chopsticks, Chinese calligraphy, and the Great Wall (Classroom Connect 1999). In her
book *Did Marco Polo Go to China?*, Frances Wood (1996) provides extensive evidence that questions Polo's presence in China. Particularly perplexing is how Polo could have not described the Great Wall in his writings. The first to raise the issue formerly was the secretary to Lord Macartney, the first British ambassador to China:

> The first European who published any account of that empire, Marco Polo, has made, however, no mention of the wall; tho as he travelled over land to the capital of China, it is presumed he must have passed through it from Tartary in some spot where the wall now stands. From such silence some doubts have arisen...whether the wall was really in existence in the thirteenth century (Wood 1996, p. 99).

This quote is interesting because it mentions Polo's failure to describe the wall but also suggests that perhaps the Great Wall didn't exist in the thirteenth century. However, Wood (1996) counters this possibility with evidence from her research into the wall's construction and its material composition at various points in history. Wood states:

> My feeling is that even without serious wall-building or wall-repairing efforts, there would have been much of the tamped earth wall surviving in the thirteenth century and that it would have been very difficult to have traveled into China from the West without noticing it; thus the omission of the Wall in the *Description of the World* is telling (Wood 1996, p. 101).

In researching Polo's travels, students have a chance to debunk the historical account of Polo's travels or confirm Polo's adventures based on evidence found by the Quest team in China and in documents provided in the Quest project and other resources.

The scope of this paper does not allow a detailed correlation of AsiaQuest content to all ten NCSS themes nor can the analysis extend across the full K-12 curriculum. Thus, selected NCSS themes in the middle grades will be analyzed. In the section below, each table will list the NCSS theme, selected performance expectations, and where those expectations correlate to AsiaQuest activities in the curriculum guide. Performance expectations indicate what students should know and be able to do in relation to the larger theme.

**Theme 1 – Culture**
Social studies programs should include experiences that provide for the study of *culture and cultural diversity* so that the learner can:

Table 4 – Global Connections

The NCSS themes and performance expectations above are correlated to specific AsiaQuest activities. Many of these activities recur from week-to-week. For example, Dan’s Dilemma provides a different inquiry Dilemma each week. In the section below, the weekly themes are correlated to specific inquiry questions.

Discussion

The performance expectations in the NCSS standards “should enable students to exhibit knowledge, skills, scholarly perspectives, and commitments to American democratic ideals (NCSS 1994, p. 14). Using the standards to frame social studies curricula leads to powerful social studies. “Social studies teaching and learning are powerful when they are meaningful, integrative, value-based, challenging, and active (NCSS 1994, p. 162). In the analysis below, AsiaQuest’s powerful curricular activities and themes are described.
AsiaQuest Themes and Inquiry Questions

</tbody>
</table>

Table 5 – Themes & Inquiry Questions (summarized from Classroom Connect 1999)

Table 5 above summarizes AsiaQuest's themes and a description of inquiry questions that may guide students' research. Implementation of AsiaQuest allows teachers to attend to all themes, or focus on specific themes in more detail.

AsiaQuest Activities

Interactivity: Middle level teachers and students can experience several levels of interactivity including utilizing an extensive, web-based library of resources. The AsiaQuest site allows students to submit and review original artwork, communicate with other students using the Student Message Board, and email the Quest experts and expedition team to suggest travel and exploration routes. Viewing scholarly research and inquiry as an interactive process is one of the hallmarks of Classroom Connect Quests.

History Mystery: When researching a particular issue or subject, scientists and historians often accumulate more information than they need (Classroom Connect 1999). How do they determine which information is relevant? Have students solve today's History Mystery by using the Quest Library to conduct research. Have students report their findings to the class.

Dan's Dilemma: Read today's Dan's Dilemma. Have groups of students practice the art of diplomacy by work together to reach a compromise on diverse issues. Use evidence to support positions and to amend positions.

AsiaQuest in Students' Real World

One of the most powerful aspects of Quest projects involves making connections between the concepts and issues examined in the Quest and how those same issues relate to students' real world environments. The AsiaQuest themes described in this paper are just as relevant to students in their local community as to the Quest itself, and thus make the Quest a powerful social studies experience. For example, a people's history and culture, human influence on the environment, consumption and preservation of resources, human conflict...
and cooperation, and historically-based questions and mysteries about the local community all help students conceptualize AsiaQuest issues by situating the issues locally.

Conclusion

This paper provided a qualitative document analysis of the Internet-based AsiaQuest project. Although the analysis focused on activities for the middle grades, the Quest is appropriate at some level for all students in grades K-12.

The analysis correlated selected themes from the National Council for the Social Studies standards to specific AsiaQuest activities. The analysis also highlighted the role of technology in bringing interactivity to students' research and inquiry. The high-tech, collaborative nature of AsiaQuest is best described by the AsiaQuest team leader:

Did Marco Polo ever go to China? With the help of the Internet, a remote satellite dish, and the brainpower of a million or so online participants, we hope to find the answer (Classroom Connect 1999, p. 44).

StarFestival: A Multilinear Approach to Cultural Identity

Kari Heistad, StarFestival, USA; Shigeru Miyagawa, MIT, USA

StarFestival is a multimedia K-12 educational package developed at the Massachusetts Institute of Technology that engages students and their teachers in the issues of diversity and cultural identity. It is based on the personal narrative of its developer, Shigeru Miyagawa, who returned to Japan after a 30 year absence, to answer his own personal question of Who Am I? StarFestival engages the students in answering their own questions of Who am I? Where did I come from? and Where do I fit in?

Already adopted officially by the Boston Public School district for use in K-5, this program aids teachers in developing skills and knowledge that helps them to address issues of cultural identity in the classroom with confidence. The CD-ROM introduces teachers to a multi-linear narrative, which encourages student-directed learning by making it possible to incorporate the student's own personal quest for identity and acceptance. By encouraging the students' natural curiosity and interest in relating the program's personal narrative to their own lives, the StarFestival curriculum facilitates the weaving of the threads of common experience between students and the teacher as the class explores their cultural identities and family backgrounds.

The StarFestival curriculum centers on the CD-ROM, StarFestival...a return to Japan, which was awarded Best of Show at the MacWorld Exposition. The CD-ROM is accompanied by 14 books and workbooks. These situate the technology-enabled curriculum within the technology context of today's schools. These resources also tie the entire K-12 curriculum to the National Social Studies Standards. As Dr. Michael Hartoonian, co-author of the National Social Studies Standards, notes:

"The StarFestival CD-ROM and Curriculum make a dynamic connection between the complexities of content, as envisioned by the national standards, and students' engagements with meaningful and authentic narratives and intellectual mysteries." Michael Hartoonian, Co-author of the National Social Studies Standards, Former President of The National Council for the Social Studies and Professor, University of Minnesota

The StarFestival CD-ROM is the personal narrative of "the Professor," Shigeru Miyagawa, who left Japan when he was ten years old, then returns to his homeland to find his roots. He takes with him the hi-tech Personal Digital Assistant (PDA). As the CD-ROM opens, the user finds the PDA damaged in the street. Using an electronic field trip format, the user is able to trace the journey of the Professor to the far away land. The voice of the Professor is played by Mr. George Takei, "Mr. Sulu" of Star Trek. The authenticity of the material, and its personal nature, draws the students in to identity with the Professor, and encourages them to explore their own cultural identity while learning about modern Japan.

StarFestival has been developed over an eight-year period in Shigeru Miyagawa's laboratory for technology and education at MIT. The design for these technology-based aspects of StarFestival are based on research carried out at MIT over the past 15 years, including at the Media Lab, which was the source of some of the key members of the StarFestival development team. The development of the StarFestival package was supported by the National Endowment for the Humanities and the U.S.
Department of Education, as well as Canon and NEC. The overall cost of the project was approximately $3 million.

Along with the CD-ROM, there is a website, http://sfn.mit.edu, which provides a cutting-edge, broadband interactive TV experience on the web based on some of the content from the CD-ROM. Taken together, the StarFestival package allows teachers and students to acquire skills in some of the most important areas of technology, including use of CD-ROM, web, email, and some web authoring. The StarFestival package is now available from StarFestival Inc. A detailed description of the product line is found at: www.starfestival.com.

Pilot tested by over 100 teachers across the USA, the program has received rave reviews from educators and students alike.

*The curriculum surprises you by producing work and projects that just blow you away. Those are the magical moments in teaching that all teachers live for. I was able to experience that excitement with the StarFestival curriculum. The curriculum allowed the students to be the teachers. They put their talents to work and created incredible projects and presentations. Not only did we learn more about Japan, but also we learned more about each other and ourselves.*  

Scott Clark, Educator

StarFestival is able to draw upon the skills and experiences of the teacher, to blend this with a creative use of technology and insights into the issue of cultural identity to create a program that is empowering to both the teacher and the students. It creates an environment of inclusion and exploration that brings forth the issues of cultural identity which is engaging and educational.
Using Presidential Candidate Web Sites for K-12 Lessons

James S. Lenze
College of Education and Educational Technology
Indiana University of Pennsylvania

jlenze@grove.iup.edu

Abstract: The Bush and Gore web sites offer much in the way of resources for lessons in political science. This paper reviews the information available through these web sites. Then, these resources are tied directly to state standards to demonstrate how these resources can be used to meet benchmarks.

Introduction

This year's election proved to be perhaps the most exciting election in our nation's history. Political science teachers across the country are rejoicing at the fact that many of their students, current and former, finally understand the Electoral College and the intricate workings of the U.S. republic. As if 24-hour coverage and near total media attention on politics were not enough, this year has also given civics teachers another resource for information regarding the presidential election process and the issues on which the candidates ran. The World Wide Web emerged has a tool for presidential candidates.

During the 1976 election, my teacher asked my classmates and I to visit the campaign headquarters for Governor Carter and President Ford in our hometown. We returned to class with bumper stickers, buttons, and even the occasional T-shirt. These artifacts become important resources for our lessons regarding the American political process. With the World Wide Web, teachers and students can now visit the candidates' campaign headquarters and come away with much more than buttons and bumper stickers.

The Bush and Gore web sites offer much in the way of resources for lessons in political science. This paper will review the information available through these web sites. Then, these resources will be tied directly to state standards to demonstrate how these resources can be used to meet benchmarks.

Issues and Multimedia

Both Bush and Gore used web sites during the 2000 presidential campaign. This is a relatively new technique for presidential campaigns given that the World Wide Web was in its infancy during the last presidential race in 1996. Web sites allowed the candidates to present detailed stands on issues such as gun control, abortion, the economy, and defense. For each issue, the candidates published a web page that provided a detailed overview of their respective stands. For instance, Bush's page for education included 1,561 words worth of detail summarizing his principles of reform, reform proposals, and his record on education in Texas (Bush-Cheney 2000, Inc., 2000, November). It also included links to 12 position papers and four speeches. Gore's education page provided similar details (Gore/Lieberman, 2000, November 28). His page included 1,191 words of detail summarizing his positions on standards & accountability and investing more in public schools.

In addition to issue papers, these web sites also provided links to speeches, schedules of upcoming events, means for supporting the candidates, and means for contacting the candidates via e-mail. Many of the speeches are available in text, audio, and even video formats. These multimedia files are formatted for the most commonly used streaming programs and players for the files are available for downloading from both sites.

For the most part, these pages are designed for an adult audience although the vast majority of the content is certainly designed for a general audience. As with any web site, teachers must first fully explore the site to determine if the content is appropriate for their students.
"Just for Kids" and the "Youth Zone"

Early on in the presidential race, Gore saw the need for a youth oriented section of his web site. His Just for Kids section included a crossword puzzle, a short quiz about Al Gore and his family, and a sort of treasure hunt where children are asked to look for a picture of Gore's dog, Daisy, which was hidden somewhere in the web site. Although Gore's child oriented pages had little in the way of content related to the presidential race, they did offer some fun activities related to the campaign (Just for Kids, 2000, November 28).

Later in the race, Bush decided to add a Youth Zone to his web site. These pages offered a considerable amount of content and lesson oriented material related to the process of electing a president. For instance, the first option in the Youth Zone was a description of the presidential election process related to a baseball game (Youth Zone, 2000, November 28). This description used baseball as an analogy to understanding both the primaries and elections. Not to be outdone by Gore's dog, Bush also includes the history of his cat within these pages. The Youth Zone included a streaming media file of Texas First Lady Laura Bush reading a children's book, Officer Buckle and Gloria. Most importantly, the Youth Zone offered a collection of external links including an Electoral College calculator and links to government related web sites for kids. My favorite was the Kid's Secret Zone at the Central Intelligence Agency.

Meeting the Standards and Benchmarks

More and more states are moving toward at least some standardization of curriculum accompanied by a corresponding set of exams for each grade level. To meet these standards, teachers develop lesson plans that directly address the specifics outlined by the state. For instance, Michigan has a complete set of K-12 Draft Standards and Benchmarks for all major content areas (Content Standards and Working Draft Benchmarks, 2000, November 28).

One of Michigan's standards requires students be able to explain local, state, and federal governments and how power is exercised within those frameworks. A specific benchmark from that standard requires that middle school students be able to "Evaluate information and arguments from various sources in order to evaluate candidates for public office" (SOC.III.4.MS.1). As part of a lesson plan used to meet this benchmark, students could visit a presidential candidate's web page, read the various issue papers, and then write a report that contrasts the candidates' views on specifics.

Web pages offer the ability to visit the campaign headquarters of each presidential candidate without leaving the classroom. Furthermore, students come away more than buttons and bumper stickers. They leave with detailed information regarding how each candidate proposes to govern. In a year with an exciting election, it only seems proper that educational opportunities are more exciting than ever.

How is technology using in SS methods courses?

Frequency report.

Philosophy statement...leads us to the framework

Technology and teacher education framework.

Three levels:
   For each level. We define and explain with SS examples and present frequency.

Level 3 – Teacher Educator

A Level 3 use of technology might involve a presentation by a teacher educator in a methods class. The technology in this instance could consist of several video examples of real classroom teachers teaching high school students about the Pythagorean theorem, using different instructional models (e.g., one teacher using direct instruction, a second using group work with concrete models, and a third using software). Such an approach would typically involve students in analyzing, critiquing, and contrasting the various instructional methods.

Level 2 – Teacher

An illustration of a Level 2 use might consist of a teacher educator preparing teachers to appropriately incorporate a movie about the Pythagoreans and demonstrate web-based interactive proofs of the Pythagorean theorem to enrich their teaching of the topic. Such enhancements add context and meaningful visual support to the theorem and its applications.
Level 1 – K-12 Student

An example of a Level 1 use could entail a teacher educator preparing teachers to guide their K-12 students to use dynamic geometry software (e.g., the Geometers Sketchpad) to investigate right triangles and their properties to develop the theorem in ways not possible with pencil and paper. Such an approach typically engages students in construction and exploration of figures. Students make conjectures based on observations of dynamic manipulations and measurements and verify their conjectures.

Technology and Social Studies Teacher Education – Results from a National Survey

Cheryl Mason, Univ. of Virginia, USA
Michael Berson, Univ. of South Florida, USA
Walter Heinecke, Univ. of Virginia, USA

The beliefs and practices of College and University Faculty Members (CUFA) of the National Council for the Social Studies Social technology integration into teacher education were investigated using a questionnaire. This presentation will present the survey results and highlight methods of integrating technology into social studies methods courses.

The beliefs and practices of College and University Faculty Members (CUFA) of the National Council for the Social Studies Social technology integration into teacher education were investigated using a questionnaire. Analysis of the responses indicates use of technology in instruction remains low, and faculty remained undecided as to their philosophy of education. Computer training has had little impact on faculties, who have learned most things on their own except for html and multimedia programs, which most had never learned. Faculty reported being confidence in their personal use of technology as well as confidence in their use of technology resources in education. The exception to this was the use of videoconferencing and the use of spreadsheets and databases. The presenters of this session will present the survey results and highlight methods of integrating technology into social studies methods courses.

Methods
We analyzed the data from the Likert-type format by descriptive statistics (i.e. means, standard deviations, percentages, and frequencies) and by t tests. Short-item responses were analyzed by descriptive statistics. Data from the open-ended questions were subjected to a content analysis procedure. Responses were analyzed as whole-item units, and designated a code based on the theme they represented.

Computer use
Philosophy is important in that it is related to how often faculty use technology. Computer use is higher among those who believed in providing students with technology-related instruction. The mean computer use for these respondents is 35.06 (SD = 8.6), whereas the mean for those who believe in providing students with technology skills was 31.6 (SD = 9.8). Those who believed in neither philosophy had a mean of 27.7 (SD = 8.6), which is much lower than the others. Those who believe in providing students with technology-integrated instruction were more likely to rate their general use of technology as 'intensive' (n = 17), whereas those who believe in providing students with technology skills were more likely to select 'occasional' (n = 18).
Computer use by faculty in instruction is on the medium to low side. A little more than two in five (42%) respondents claim to use computers occasionally in instruction. One in five (19.8%) used computers throughout the semester, although not every class session, and only one in seventeen (6.2%) used computers every class session. When Social Studies faculty do use technology, it is to prepare lesson plans or communicate with others via email. Videoconferencing, spreadsheets, databases and technology tools are hardly used. Faculty report that their pre-service students use technology in a similar fashion. Table 1 shows the percentage of those who reported on their own and their student's use of technology 'thoroughly' or 'every' class session. It is arranged in descending order. There is no difference in how often professors, associate professors, assistant professors and instructors use computers.

Confidence
Taken together, faculty report being confident in their use of technology. Seven in ten (69.8%) respondents agreed or strongly agreed that they were confident using computers in many settings whereas one in three (27.1%) did not feel confident. Faculty report that they have the greatest confidence in using email and the Internet to support individual or small group work. These were also the technologies that were used the most. More than half of faculty report being confident in incorporating the WWW and email in instruction, using computers in many settings, choosing effective instructional software/technology tools, teaching search strategies for use on Internet and CD-ROMs, implementing resources to support SS teacher education, teaching students to prepare lesson plans that access information via networks and modems, teaching students to select and use technology appropriate to task, teaching students to prepare lesson plans that use electronic encyclopedias and catalog, developing computer based presentations for use in instruction, teaching students to prepare lesson plans incorporating word processors, spreadsheets and databases in instruction, and working with K-12 teachers to integrate technology in local schools.

Only preparing word-processed lesson plans, communicating via email, and accessing information from the web were actually used with any frequency. There is also much reported confidence but have the greatest lack of confidence in videoconferencing. Faculty have very low confidence in preparing student's to use spreadsheets and databases, and to use videoconferencing. Faculty who believe in providing students with technology-integrated instruction (n = 4) were far less likely than those focusing on technology-skills (n = 16) to strongly disagree that they were confident using spreadsheets and databases. No other measure of confidence in the use of technology had such a large spread when philosophy is looked at.

Robert J. McClelland
Reader in Educational Technology
Liverpool Business School
Liverpool John Moores University
England
United Kingdom
b.mcclelland@livjm.ac.uk

Abstract: One educational development approach at Liverpool John Moores University (JMU) from its Business School (LBS) is that of supported web-based learning systems to complement traditional teaching. This paper focuses on recent work at LBS concerning a Masters module, which progressively developed since 1998. The module is web-based and provides a teaching, learning and support environment for academic staff and students. It is flexible in that it is variably credit rated and can be studied in full-time, part-time and distance modes. The approach used in the delivery of the module has facilitated the examination of module/programme support development possibilities on the web from academic, quality and commercial perspectives as well as the cybernetic and evolutionary nature of learning. A feedback model is developed here to inform development of a support web-site. An exploration of student attitudes and perceptions to the technology, factors related to the learning strategies adopted by students and student learning styles were used to inform an over-pinning LBS strategy of a web supported teaching and learning environment, coupled with an innovative longitudinal support mechanism for learners.

INTRODUCTION

Throughout the late 1980's towards the middle 1990's educational technology developments in the UK developed from Open Learning (text based), through to Computer Assisted Learning (CAL), which included software and hypertext on CD-ROM and file servers. This can be collectively referred to as Resource Based Flexible Learning (McClelland 1996). Traditionally one might argue that this concept considers learning to be student centred as opposed to tutor centred, where learners provide their own routes through a learning domain negotiating a set of learning events. This maximises flexibility for the learner in the way learning occurs. However, pedagogically it may not be appropriate to provide a learner with total unconstrained flexibility in a RBFL environment. This has been put concisely by (Boot & Hodgson 1990) in their discussion on constraining open learning:

“A definition [of open learning] revolves around a notion of freedom from constraints on the learning process... such constraints are grouped as administrative (time, duration, cost, etc.) and educational (objectives, methods, sequencing, entry qualifications, assessment, etc.)...The removal
of all constraints would ...leave us with no educational provision at all. The issue then is less one of openness and more one of the extent to which formal educational provision has bounded learning.”

Interest about the learning environment and the personal attributes of the learners continue to concern developers of learning environments, especially where RBFL is an issue. In the early 1990's this was particularly the case for those with interests in the resource of computer assisted learning (CAL), because the utility of CAL was sometimes a point of debate about how it could contribute to understanding, as we observe it, in a currently limited state of development. More generally, arguments about how learning environments could constrain learners in the way that they learn, or free them to explore, were seen to be as much about socio-culture and paradigms, as about pedagogy. The identification of constraints and degrees of learner freedom is something that is a concern of architects of learning environments (for example, groups of course tutors). In the mid to late 1990's studies (McClelland 1994 and McClelland & Yolles 1997), concerning CAL, demonstrated that constraints derived from a learning domain paradigm provide for that environment a set of learning “truths” that will determine overall learning strategy. It is this paradigm that will act as the set of macroscopic constraints for learners. Different paradigms operate in different levels of system, from courses; to course programmes.

Most learning theory centres on the work of (Kolb 1974 & 1984) but it is feasible to look further afield by examining learning environments as though they are systems, and move slightly away from the traditional language of learning theory. This research aims to report a systemic approach towards modelling learners and learning environments based on the ideas that derive from theories of viable systems, exposed by cybernetic learning environments (McClelland & Yolles 1997). In this case viable means able to maintain a separate (fully or partly autonomous) existence. Viable systems therefore participate in the development of their own futures through self. The idea of viable inquiry systems was identified in order to explore the nature of methodology in its relation to method, in particular with regard to the impact of the learner on the situation being inquired into. In parallel the idea of Viable Learning Systems can be developed. These can be seen as learning systems that include cybernetic learning strategy and learning style as well as approach to study (deep, surface, reproducing learning) and where change in these can be explained through ideas from the concepts of self-organisation and evolutionary theory.

APPROACH TO DELIVERY

With current developments in technology and learning supports for modules and programmes and with the rapidly changing means by which students access information, a strategy exists within LBS to develop web-sites for undergraduate, postgraduate and professional students studying modules. The strategy uses a design and template developed by (Laws 1998) which is learner friendly (to students) and addresses some of the constraints placed upon learners, such as time of study, place of study, interaction with a tutor and availability of scarce resources. Also it is design friendly (to academics), being accessible for authoring purposes in the universities campus wide information system structure. The results of a follow up study on one module, developed to the Laws template are reported here. The Research Methods module, code BUSAEM303 (see http://cwis.livjm.ac.uk/bus/busmce/l/aem303) has a web-site developed by (McClelland 1998).
This paper presents some perceptions, and attitude observations of students and staff concerning use of the web-site. In addition an evaluation of the cost benefits, pedagogical appropriateness and effectiveness as a support in developing students as researchers, is also made.

The web-site for the module contains the following supports:

*Learning supports:*
Course outline and recommended texts; A copy of the module assessment, with links and supports; Staff profile/contact details, an e-mail link; Links to other web-sites (learning & research and international); Notice board; Sources of Information and a Research glossary

*Activity based supports:*
Fifteen topic areas with hypertext links to: Lecture notes; Lecture presentations; Workshop/Case questions; Individual learning resources; Articles on-line.

The module can be 12 credits, 15 credits or 20 credits in size (120, 150 and 200 learning hours respectively) supported through 10 or 15 one-hour lectures and 10 or 15 two-hour problem based learning tutorials/workshops. The module is assessed by producing a research proposal for a Masters level dissertation (size of assessment related to credit rating).

**LEARNER PERCEPTIONS OF THE WEB-SITE**

Liverpool Business School has undertaken several studies involving students that have used the web-site template for a range of modules see (McClelland 2000a & 2000b). As part of the overall studies of web-based learning in LBS a questionnaire was developed and used as a vehicle to gauge student perceptions and qualitative information, in order to refine the design and content of subsequent sites.

A modified version of the above questionnaire was administered to a cohort of students studying the Research Methods module in semester one of the 2000/01 academic year. Of the eighteen students on the cohort twelve were full-time students on a one-year programme in European Studies and six were part-time students on a two-year programme in Leisure and Tourism Management. Some preliminary findings, as extracts, are evaluated here as contributions to developing the web-site.

In addition to the questionnaire students completed a learning styles inventory adapted from Kolb and McCarthy (Kolb 1984). The inventory is designed to explore the way people prefer to learn by indicating statements that refer to their learning predispositions. Scores are obtained and from these dominant learning abilities can be deduced. These fall into four main groupings; *Abstract Conceptualisation* (AC), *Active Experimentation* (AC), *Concrete Experience* (CE) and *Reflective Observation* (RO).
As well as being part of this research, learning style theory is included as an input to the philosophy of research on the Research Methods module [1].

Pairings of learning predispositions enables participants to be located in learning style quadrants. So, for example, if dominant learning abilities are AC and AE the student would be a Converger (practical application of ideas). CE and RO would indicate a Diverger (imaginative ability). AC and RO would indicate an Assimilator (ability to create theoretical models). CE and AE would indicate an Accommodator your greatest strength lying in doing things, in carrying out plans and experiments and involving oneself in new experiences.

Student accessibility to the site and guidance given about the site were not factors in the amount of time they spent using the sites. The cohort also indicated that necessary information provided on the sites did not suffer from problems of clarity. A series of questions presented surrounding frequency of use of the sites showed no effects from the gender; age; and current degree mean mark.

It was observed from findings that there were no differences for either of the variables gender or international category of student when tested against perceptions of ease of use of the site, clarity of design of the site, the responsibility or restriction of self-directed nature of learning and the student agreement on provision of administrative support. These observations were made using independent t-tests (p > 0.05).

However, when the variable Programme (European Studies and Tourism and Leisure Management) was tested against each of the above perception variables, no differences were observed with one exception, students on the Masters in European Studies were between Responsible and Neither responsible or restricted for self-directed learning (mean 2.17) rather than students on the Masters in Tourism and Leisure Management who were between Very responsible and Responsible (mean 1.5). Theses observations were made using an Independent t-test (p > 0.05), the latter difference was supported using the same test (p < 0.05).

The same set of perception variables were tested against the variable student learning styles and the variable age groups (21 < 24, 24 < 27, 27 < 30, > 30). No effects were observed based on learning styles or age. These observations were made using One-Way Analysis of Variance (p > 0.05).

Other observations included student perceptions on the importance of focused web-site supports, which included: Other web-sites to visit; Other web-sites to visit (international); Learning Supports; Lecture slides; Sources of Information and Glossary of terms.

No differences were observed with supports tested against the variable mode of study (Full-time, Part-time) with one exception. Other web-sites to visit (International), where part-time students perceived the facility between neutral and not very important (mean 3.17) rather than full-time who were between Very important and Important (mean 1.92). The observations were made using an independent t-test (p > 0.05), the latter difference was supported using the same test (p

[1] Lectures on the Research Methods module involves the discussion that a predisposition to particular learning styles have implications for philosophies that researchers may adopt.
No effects were observed with supports when tested against student learning styles with one exception, *Other web-sites to visit*, where students exhibiting the style of Diverger perceived the facility as of differing importance than students who exhibited styles of Accommodator, Assimilator and Converger. The observations were made using a One-Way Analysis of Variance (p > 0.05), the latter difference was supported using the same test (p < 0.05).

Extensions of these studies will ultimately allow learning strategy to be related to student learning styles and approaches to study. The model proposed here incorporates observations to support design and content developments for the module.

In terms of the cost benefits, the module has resulted in savings of approximately £4 - 5000 per delivery on resource items such as photocopying handouts and staff time per module, whilst students perceive increases in quality and support.

CONCLUSION: MEETING CHANGING NEEDS

The stated aims of the module are to plan and design research linked to certain research philosophies. The assessment for the module is to produce a Research Plan and Proposal for Masters Dissertation.

Three paradoxes are observed here:
1. The link between the aims and assessment for the module. The assessment does not focus on the learners' ability to directly undertake research, rather, the focus is on the learners' ability to plan and design research linked to certain research philosophies.
2. The teaching of the module. Due to the generic nature of this module and the diversity of student backgrounds, teaching challenges arise concerning the depth and breadth of analytical approaches to be delivered in contact sessions, the subject matter taught and the prior knowledge that is assumed from learners.
3. The relationship between the needs of students and research support for learners. This highlights that clearly there is a need for learners to use supports after the learning outcomes have been met for the module, in order to support to their actual research beyond the module.

In developing the module and the approach to delivery the above factors were incorporated as well as the following: The generic requirements for Masters level study; A range of team curriculum design inputs; Feedback from previous cohorts of LBS students using web-based supports. As the supports for the Research module are web-based, many of the above concerns are being addressed through the design platform. The web-site contains cases and links to both qualitative and quantitative articles, there are links to lower level undergraduate modules covering research methods and related disciplines, as well as on-line support materials. All supports are chosen for related content and are regularly updated; there are facilities to explore...
analytical disciplines and research approaches in depth (as well as breadth), in order to fully inform and support learners as they develop in research.

Access to the web facility is unconstrained. It is regularly updated (in terms of lecture material, links and versions of analysis tools). There are also email links for tutor consultation.

The architect of learner supports and the learner derive benefit through the tailored design of the web-site, based on learner feedback, having supports available outside of the constraints of time and place and from the facility of both subject depth and breadth beyond the lifetime of the module. This model is used to foster a medium of a more holistic multi-faceted approach to developing students as researchers.

Abstract: The Multimedia Resource File Project is used to allow students to practice and demonstrate integration of advanced technology and content skills in planning and organizing an instructional resource for high school teaching. The student will develop advanced skills in searching the web, evaluating and selecting resources, dealing with copyright issues, organizing resources, and producing a CD product.

Introduction

The National Educational Technology Standards (ISTE, 2000) consist of six general areas: (I.) Technology Operations and Concepts; (II.) Planning and Designing Learning Environments and Experiences; (III.) Teaching, Learning, and the Curriculum; (IV.) Assessment and Evaluation; (V.) Productivity and Professional Practice; and (VI.) Social, Ethical, Legal, and Human Issues. In a preservice teacher education program, there is a need for major projects that allow students to show proficiency in these areas. The following project, the Multimedia Resource File, includes experiences in all six of the goal areas. Once students have completed this project, they should easily be able to implement it in a high school setting. Thus, in planning and implementing this one major project the preservice teacher can address all six of the NETS goals. This may be a part of the Methods course, or a Technology course. Or it may be a departmental capstone requirement that is not a part of either course, but uses elements from both.

Assignment

In consultation with an advisor, the student selects a general topic as the subject of the project. The topics that will be demonstrated are “The Civil Rights Movement,” and “The Vietnam War.” Both of these topics provide a rich context for multimedia resources because they are fairly recent and primary sources are available.

The student then conducts an exhaustive Internet search for resources related to the topic. These may include text, graphics, audio (speeches, protest songs), video (news broadcasts), or links to webpages. Each resource is carefully evaluated and included only if it is judged to be of value to a high school teacher. A critical part of the project is that the student obtains permission to use all copyrighted material. The resources are then arranged by subtopics, indexed clearly, and burned to CD.
The objective of the project is not to plan a lesson or unit, but to collect resources that may be used in future lessons that may involve PowerPoint or WebPages or other media. The student will develop advanced skills in searching the web, evaluating and selecting resources, dealing with copyright issues, organizing resources, and producing a CD product.

**Assignment: Multimedia Resource File**

**Objective:** Student will design and produce a Multimedia Resource File, which utilizes expertise in technology and in content to locate and select appropriate resources for a topic in the high school curriculum. The project will involve advanced Internet searching and evaluation of resources, including copyright permissions. It will also involve advanced technology skills in organizing and producing a data CD, as well as advanced content expertise is selecting and planning instruction.

**Activities:**
1. Select a topic from your content area’s high school curriculum. Discuss topic with instructor.
2. Conduct an extensive Internet search for multimedia resources (text, graphics, audio (speeches, protest songs), video (news broadcasts), or links to webpages) that may be helpful in teaching that topic.
3. Obtain copyright permission for EACH resource.
4. Organize the file. Discuss outline with instructor.
5. Arrange resources in folders and subfolders. Create an html document that serves as an index, and includes links to resources either on the CD and to webpages on the Internet.
6. Burn the CD.
7. Include a self-evaluation, using the rubric below.

**Scoring Rubric:** (10=A, 8-9=B, 6-7=C, 5 or less=F)

- **Content** (5 points possible)
  - 5 points: Topic is appropriate for high school course. The topic is completely covered and a wide variety of types of resources are included. Resources are well organized. Copyright permissions are included.
  - 4 points: Topic is appropriate. Topic is well covered and a variety of resources are included. Resources are well organized and copyright permissions are included.
  - 3 points: Topic is appropriate. Topic is covered and some variety of resources are included. Resources are organized and copyright permissions are included.
  - 2 points: Topic is appropriate. Topic has weak areas and variety of resources is limited. Problems with organization. Some copyright permissions are not included.
  - 1 point: Topic is appropriate. Topic has many weak areas, and resources are limited in number and in variety. Organization is poor. Copyright permissions are not included.

- **Technical** (5 points possible)
  - 5 points: CD runs without error. Html table of contents includes outline and links to resources on the CD as well as links to Internet pages. All resources display without error.
  - 4 points: CD runs without error. Html table of contents links are without error. Most resources display without error.
  - 3 points: CD runs. Html table of contents has some errors. Most resources display without error.
  - 2 points: CD runs. Html table of contents has many errors. Many resources have errors.
  - 1 point: CD runs. Table of contents is missing or does not work.

The increase in the use of computer-based instruction in education and the proliferation of middle schools occurred concurrently in the 1980's. Computer-based instruction was viewed as a new learning tool, which could facilitate a variety of new teaching strategies for educators to employ in the classroom. The formation of middle level education was seen as an attempt to establish meaningful learning for the segment of schooling that encompasses early adolescence at the stage of life between the ages of ten and fifteen (National Middle School Association, 1995). The symbiotic relationship and development of these two educational entities commenced in the 1980's and continues at the moment. The purpose of this study was to determine the frequency and the nature of applications of computer-based instruction in the middle school social studies classrooms in the state of Missouri.
I recently read an article about a school for special students. Spending for these students was two to four times the average for students attending 'regular' schools in that state. The school was operated as a residential school and the students had access to many programs that the students in less funded schools did not. The test scores for these special students were, for the most part, outstanding. The state was very proud of this school for special students. However, the school, which was to be one of several in the state, was very expensive to run and maintain. The state therefore decided that this school for special students would be the only one of its type that would be funded. How is it that this one school for special students received such funding and such attention? It turns out that the school is the Illinois Math and Science Academy and these special gifted students were selected after a very rigorous admissions process.

No one denies that students who can do well in math and science (or music or art) should be penalized for their abilities. Quite the contrary, these students should be encouraged to excel through their talents. But what about the students who have been placed in 'special education' classes. Are these students, too, not special?

Each state provides guidelines as to how students who fall within their definitions of 'special education' should be assisted. However, these guidelines are often bureaucratic in tone (as is generally required when developing guidelines). The articles in this section of the Technology and Teacher Education Annual provide a varied and humanizing look at both the students and the educators who work in the area of special education. As you will see, the money is often not there. The teachers are making remarkable innovative and important uses of technology. As you read through these articles, remember that these are special teachers and researchers working with special students in special circumstances. Remind yourself that we are lucky to have such special people working with us.
Preparing Teachers To Use Assistive Technology In Inclusive Settings

"Abstract"  
With the passage of special legislation for the education of children with disabilities, educators are required to provide services to children with disabilities and consider the appropriateness of new technologies as a tool or intervention. This article considers what teacher educators can do to familiarize their preservice teachers with options in assistive technology and prepare them to work with assistive technology. Preservice teachers need minimum competencies in technology and assistive technology. Teacher educators by providing three-prong instruction may play an important role in awakening in each prospective teacher the desire and ability to be the conduit for using assistive technology to develop the potential of each student with special needs.

The Education for All Handicapped Children Act (PL94-142) was passed in 1975 to address the needs of students with disabilities. It was renamed The Individuals With Disabilities Education Act (IDEA) in 1990 and was reauthorized and amended in 1986, 1990, and 1997. Special Education programs in all states are required to fulfill the mandates of this federal legislation or face the loss of funding to local districts. IDEA requires that students with special needs be educated in the Least Restrictive Environment (LRE). Although students with special needs may be placed in self-contained classrooms, the vast majority of them are included in the regular classrooms. Inclusion refers to the placement of children with special needs in age-appropriate settings in which their needs are addressed by the regular education teachers as well as special educators.

With the passage of IDEA Amendments of 1997, Public Law 105-17 educators are required to consider the appropriateness of new technologies as a tool or intervention for every student with an Individualized Educational Programs (IEP). An increasing number of students are being prescribed assistive technology. Assistive technology can help children compensate for their disabilities, focus on their abilities, and reach their full potential. If this trend continues, an increasing number of regular education teachers and special education teachers will need to have knowledge of and experience with assistive technology.

This article considers what teacher educators can do to familiarize their preservice teachers with current options in assistive technology and prepare them to work with assistive technology. Preservice teachers need minimum competencies in technology and assistive technology. Teacher educators can provide three-prong instruction. First, preservice education programs should include an exploration of the variety of challenges students may have. Second, training should also provide familiarity with the laws and terms associate with assistive technology. Third, preservice teachers should have hands-on experience with assistive technology hardware and software. All teachers need these three kinds of information in order to assess the educational challenges and learning differences of each student and to provide assistive technology devices and services.

Section 602 of the Amendments of IDEA (1997) define the terms "assistive technology device" and "assistive technology service". The term "assistive technology device" means any item, piece of equipment, or product system, whether acquired commercially off the shelf, modified, or customized, that is used to increase, maintain, or improve functional capabilities of individuals with disability. Assistive devices allow children with special needs to access technology in the most efficient way. Educators need to be familiar with a variety of alternate keyboards, become familiar with QWERTY (standard) keyboard,
sample touch screens, trackballs and adaptive devices for students with physical disabilities. Familiarity with assistive listening devices and Braille options may be necessary as well. Examples of assistive technology devices include: adapted track ball, digital camera, IntelliKeys MIDI creator, scanner, switches, touch screens and specialized software. The term “assistive technology service” means any service that directly assists an individual with a disability in the selection, acquisition, or use of an assistive technology device. Such services include the evaluation of the needs of children, providing for the acquisition of assistive technology, selecting designing, customizing, adapting, and repairing assistive technology.

Regarding the first prong, preservice teachers can learn about special needs children from the literature and from field experiences in a variety of setting that service special needs children. The instruction can be integrated into curriculum courses or taught in separate courses designed specifically to address inclusion and assistive technology. For example, instructors teaching in the curriculum areas of language, reading and literature can consider how to identify students with language-based learning disabilities and how to use assistive technology as an intervention for these children. Instructors can consider assistive technology devices that help children who have difficulty decoding or comprehending text, writing, organizing, evaluating, remembering or generally getting their thoughts in written form onto paper. L D OnLine is a website that provides an interactive guide to learning disabilities for parents, teachers, and children (http://www.ldonline.org/).

Regarding the second prong, review of the laws that support assistive technology can be conducted. Preservice teachers can use the Internet to identify current law cases and discover more about agencies that provide services to children with special needs. Laws which should be considered are IDEA, Section 504 of the Rehabilitation Act (Rehab Act) 1973, Americans with Disabilities Act (ADA) 1990, and the Telecommunications Act of 1996. Some helpful web sites for national information include (a) Center for IT Accommodation (CITA): Provides information on legislation and policies on information systems accessibility - http://www.itpolicy.gsa.gov/cita/index.htm (b) The National Center to Improve Practice (NCIP): NCIPnet focuses on special education and technology and augmentative communication- http://www2.edc.org/NCIP/ (c) Office Of Special Education And Rehabilitative Services-United States Department Of Education: Provides an overview of schools' responsibilities toward ensuring that technology is accessible, and a listing of resources in the Federal government to assist schools- http://www.ed.gov/offices/OSERS/whatsnew/whatsnew.html. Individual states are also likely to have agencies and websites.

Regarding the third prong, preservice teachers need to be familiar with hardware and software that can assist in the inclusion of students with disabilities into the regular classroom as well as make the computer accessible to students with disabilities. They should have hands-on experience with hardware and software that support a variety of curriculum areas. For example, there is software that supports the writing process through the use of features such as auditory feedback, word prediction and organizational strategies offer a variety of applications for the classroom. Reading software may provide reading and cognitive learning strategy support through auditory feedback, enhanced visual display and customization to meet specific student needs. These include optical character recognition systems, e-text, and timesaving resources. Math software may provide organizational support, auditory feedback and additional problem solving options. Two helpful websites include ABLEDATA: A national database of information on more than 17,000 products that are currently available for people with disabilities- http://www.abledata.com/ and The Alliance for Technology Access (ATA): Provides location information for the Alliance for Technology Access regional centers. The Alliance assists individuals with disabilities access technology, mainly through computer resources- http://www.ataccess.org/.

Assistive technology requires clear planning to benefit the students involved. Preservice teachers need to have a clear understanding of the reason why it is being incorporated into the education of children with disabilities or the technology becomes just another add-on. Preservice teachers need to develop an awareness that many possibilities for assistive technology exist within an inclusion class environment. The teacher educator may play an important role in awakening in each preservice teacher the ability to be the conduit for using assistive technology to develop the potential of each student with special needs.
Academic Achievement Problems: Developing Curriculum Based Software to Help Low Achievers

Xavier Bornas

jordi.llabres@uib.es

Abstract: Low achieving children (LA) usually need a very individualized instruction. Teachers rarely can give them this kind of instruction because they have too many children in the classroom. Computer technology may be extremely helpful for those students. However, the lack of contact between developers and school teachers leads to several problems: lack of motivation, cognitive confusion, and teachers' resistance. If computer technology has to help LA, the instructional software must be based on the school curriculum. From our own experience in developing curriculum based software we can underline several guidelines. We took the curriculum materials as the base for the software we were going to develop. Teachers told us what specific contents they were going to teach, and these contents were the ones the software included. The curriculum based software we have developed proved to be useful to teach LA the selected academic contents and strategies.

Introduction

Low achieving children usually need a very individualized instruction to reach the average academic level of their classroom group (Bornas, Servera, & Llabrés 1997). Teachers, however, rarely can give them this kind of instruction because they have too many children in the classroom. Although some help is provided for disabled children (e.g. blind or developmentally retarded), by the school administration, low achievers (LA) remain underattended (Wong 1996). In fact, they often do not cause big problems to their teachers nor to the school. However, repeated failures lead them to a growing academic delay or décalage, and many of them will not finish their primary studies.

Computer technology may be extremely helpful for those students, mainly because the computer can repeat the same instructional content as many times as the student needs to master it (Burt & Ryan 1997; Torgesen & Barker 1995). Hundreds of different addition exercises, for example, can be easily presented to the student when he or she needs to master this arithmetic operation. Hundreds of pages can be shown to let the student read and to improve his or her reading skills. However, a serious problem comes up at this point: having computers in the classroom does not help LA unless an appropriate software is installed on them (Bender & Bender 1996). The quantity and the variety of the software contents are important but much more important is the coherence between its teaching style and the teaching style of the regular teacher and the school.

Instructional software is often independent of the school curriculum.

Most developers are not in contact with the specific school where the software will be used, and they make use of general, non-specific curricular or educational trends to select the software contents, to set the learning sequences, to program what feedback the user will get as a result of his or her actions on the computer, the global interactivity level between software and children, and so on, thus configuring an educational "style" for the software they are creating. The lack of contact between developers and school teachers leads to several problems. Firstly, children may wonder why they need to do the programmed tasks if these are not the ones they usually do with his or her teacher. Students can think that doing these tasks has no sense in order to learn what high achievers already learned, say reading fluently or dividing. In addition, if the computer tasks are too repetitive they can bore the student and lead him or her to avoid them. The lack of motivation can be the final result in both cases (Lewis 1998).
Secondly, since the teaching style of their teachers may be absolutely different from the educational "style" of the software, children can show cognitive confusion and they can have some trouble to learn specific concepts or strategies. It does not matter how some things are taught they will be learned by all the students (e.g. the names of the basic colors). Other things, however, have to be taught the same way to make sure that LA learn them. For example, there are several ways to teach how to subtract 17 from 20. Probably, high achievers will have no problem to learn two or more subtracting strategies simultaneously, but LA may get confused if they are taught a different subtracting strategy before they master the first one. On the other hand, however, if a specific strategy is not learned by the student then he or she has to be given the opportunity to learn another strategy to solve the same task.

Thirdly, teachers may be reluctant to use the software if (a) the software contents are not the ones they would have chosen, (b) the software instructional style is not coherent with their own teaching style, and (c) the software may cause motivational or cognitive problems to their students.

**Guidelines for Developing Curriculum Based Software**

If computer technology has to help LA, the instructional software must be based on the school curriculum. Therefore, software developers have to be in contact with the school and the teachers. Furthermore, instructional software developers need some knowledge about curriculum related aspects (what a curriculum is, why it is important, how teachers use it, and so on) to understand the teachers demands when they are planning to use computer technology in the classroom.

From our own experience in developing curriculum based software (an experimental study will be presented at the SITE2001 Conference) we can underline several guidelines that, in our opinion, have to be taken into consideration. The software we are referring to was designed to help third grade LA students to improve their performance in reading comprehension and math.

Firstly, the LA students were selected not only because of their poor performance on the evaluation tests that we administered them but also because their teachers considered them as LA. This is to say that the opinion of the teachers was an essential criteria during the students selection process. In fact, some students who performed lower than the average on the standard tests were not considered LA by their teachers, and vice versa, some average performing students were selected since their teachers considered them as LA. The knowledge a teacher has about his or her students can't be replaced by the knowledge we get when we administer them an academic performance test.

Secondly we looked at the books and other curriculum materials that students were using regularly in the school, and we took them as the base for the software we were going to develop. For example, we bought a book of the same publisher and the same level than the one the students used to improve their reading skills in the classroom. The reading software exercises and the classroom reading exercises were quite similar. This was not only true for the software contents but also for the learning strategies the software was designed to teach.

Thirdly, teachers told us what specific contents they were going to teach during the next two months, and these contents were the ones the software included. Therefore, while LA students used the computer software they learned the same contents than the other students did. In addition, although the software was not strictly linear, the learning sequence through the curriculum contents was also very similar.

Finally, it is worth to say that the software was not only based on the teachers knowledge nor on the shool curriculum. To develop the software we made use of the psychological and educational knowledge about (a) low achieving students and their cognitive problems, (b) learning strategies and metacognition, and (c) effective teaching strategies. In other words, the shool teachers and the school curriculum must be considered carefully to develop curriculum based software, but developers need knowledge about the learning and teaching processes.

**Conclusion**

The curriculum based software we have developed proved to be useful to teach LA the selected academic contents and strategies, although at the end of the computer using period LA performance was still lower than performance of high achievers. In addition, beyond the performance results we would like to underline that LA students really liked the software and they were well motivated to use the computers. Teachers got very involved in the research process since they participated from the beginning, when LA students were selected, along the whole development process: contents, strategies, feedback and reinforcement, evaluation, etc.

The Need for Assistive Technology in Educational Technology

Terence Cavanaugh Ph.D., College of Education and Human Services
University of North Florida, USA, terence@unf.edu

Abstract: This paper will address definitions, services, levels of technology and application of assistive technology concepts as they relate to education. An overview of the NCATE and ISTE guidelines concerning assistive technology, and the current elements of the graduate educational degrees concerning assistive technology is provided. Federal legislation concerns the application of assistive technology in an educational setting and its possible impact on educational technologists. A model is proposed for a course concerning assistive technology and universal design to better prepare instructional technology graduates to enhance the performance of students with disabilities and design educational material for increased accessibility. This session is intended for educators in instructional technology and exceptional education programs.

 Disabilities rights leaders have said that the application of technology will be the equalizer of the 21st century (Flippo, Inge & Barcus 1995). Through the use of assistive technology (AT) devices, many students can decrease their isolation and become an important part of a regular classroom, their least restrictive environment. Assistive technology is a basic tool in the educational process for any individual who may be experiencing a disability. Technology that is used as tool in education is the basic definition of educational technology.

What is Assistive Technology?

The Technology-Related Assistance for Individual with Disabilities Act of 1998 (PL 100-407) gave us the first legal definition of assistive technology devices and services. An assistive technology device was defined as:
any item, piece of equipment, or product system, whether acquired commercially off the shelf, modified, or customized, that is used to increase, maintain, or improve functional capabilities of individuals with disabilities.

An assistive technology service was described as:
any service that directly assists an individual with a disability in selection, acquisition or use of an assistive technology service.

What are the Levels of Assistive Technology Use?

In considering assistive technology, you must consider the environment, the individual, and the characteristics and levels of the technology (Gitlow 2000). Assistive technology may be classified as high, middle or low tech. The concept of a high technology device usually includes items that require computers, electronics or microchips to perform some function. Low technology usually does not require an outside power source. An example of high technology is a computer. The application of technology could range from having a computer read a book (high tech) to printing out material in a larger font to a student using a magnifying glass (low tech) to read material.

Along with considering the level of the technology, consider the levels of how the necessary assistive technology item will be applied. The levels in applying the assistive technology solution include whether the item is personally, developmentally, or instructionally necessary (Judd-Wall 1999). The personally necessary level is concerned with assistive technology devices that are used by an individual student, such as a pair of color blind glasses to enable a learner to more effectively interact with his/her environment. Developmentally necessary devices may be shared among individuals. These devices help meet an educational need based on a developmental delay, which ideally would be improved, eliminating the need for the item in an individual’s
future. Lastly, instructionally necessary devices are those which modify the instructional process at a course or grade level, and do not need to be moved with the user as he or she progresses to the next level in education.

What is Educational Technology?

Educational or instructional technology can be hard to define. At its simplest it can be the application of technology in teaching or education, but many feel that it is much more than that. Perhaps the most encompassing definition is from University of North Carolina Media Services (1997) which states that: “Educational technology is the application of research, learning theory, emergent technologies, and child and adult psychology to solving instructional and performance problems.” The Presidential Commission on Instructional Technology highlighted four areas in which educational technologists perform: 1) design of instruction, 2) production of instructional products and services, 3) management of instruction, and 4) evaluation of instruction.

Assistive Technology in the Graduate Educational Technology Program

The National Council for Accreditation of Teacher Education (NCATE) accreditation in association with the International Society for Technology in Education (ISTE) requires that assistive technology be addressed within such higher education programs as educational computing and technology leadership. The guidelines and standards for those programs state that a graduate of such a program should “demonstrate awareness of resources for adaptive assistive devices for students with special needs” and be able to “identify and classify adaptive assistive hardware and software for students and teachers with special needs and locate sources to assist in procurement and implementation” (NCATE 1999).

However, assistive technology is, for the most part, only discussed as a small component of technology integration classes or is thought of as being part of the “special education” section. There exists the need for the addition of a course devoted to the application of assistive technologies, awareness of the possible limitations of users, and universal design in a graduate educational or instructional technology program.

A review was conducted of instructional and educational technology programs within the colleges of education across Florida’s state university system. According to their published programs of study, none of the state colleges of education was offering a course specifying assistive technology in its title or available description. A similar limited review was conducted of universities nationwide that offered graduate programs in educational or instructional technology. From this survey, it was found that less than twenty percent of the colleges that offered an educational technology degree provide courses focusing on assistive technology.

Impact on Instructional Technologists

As part of the federal Individuals with Disabilities Act IDEA amendments of 1997 and 1999, statements now require assistive technology devices and services to be considered on an individualized basis and become a part of the individual education plan (IEP) if the child needs them to benefit from his educational program. The individualized education program (IEP) is a written statement for a child with a disability that is developed, reviewed, and revised at the child's school. The IEP’s occur each year for every child with a disability and they are developed by members of the IEP team including parents, teachers, special education teachers, administration and others. Section 508 of the Rehabilitation Act Amendments of 1998 is the most extensive new law with wide ranging effects. This ruling requires that all US federal agencies make their information technology accessible to their employees and customers with disabilities. The law gives federal employees and members of the public the right to sue if the government agency does not provide comparable access to the information and data available to people without disabilities. Section 508 applies to Web sites that are produced for government agencies. All state agencies that receive federal funds under the Assistive Technology Act of 1998 are also required to comply with Section 508 requirements. Schools seeking to comply with legal requirements regarding students with disabilities need faculty with knowledge of assistive technology.
applications. Based on NCATE accreditation requirements, it would be reasonable for a school administrator or other official to expect that an educational or instructional technology graduate from an NCATE accredited program would be able to effectively contribute to a student’s IEP team. These expectations would include that such a graduate be able to make effective judgments and recommendations concerning assistive technology and universal access.

**Assistive Technology Course Development**

With the rapidly aging population of the United States, there is also a growing need for assistive technology and universal design. To receive federal funding organizations must be IDEA and Section 508 compliant. There exists a need to provide instruction on assistive technologies and methodology to make technology products such as computer programs and web pages handicapped accessible.

Instructional and educational technology specialists require more extensive experience and education concerning assistive technology than they currently receive. Instructional/Educational Technology graduate programs should devote a course to the presentation of the basic concepts and applications of assistive technology. This course could be offered as a requirement in the current university master’s instructional technology program and as an elective in its master’s of education or exceptional education programs. The NCATE and ISTE standards state that for initial certification, a teacher should “demonstrate awareness of resources for adaptive assistive devices for students with special needs.” These standards would be well met by such a course. The technologies and strategies presented in a course concerning the application of assistive technology would also address many of the other NCATE guidelines associated with specialty programs such as educational computing and technology leadership.

An assistive technology course could be designed as an introductory or survey course in the application of technology as assistive and adaptive devices, software and strategies. This course could present strategies for students who are physically or mentally impaired, and may be in a mainstreamed situation. The purpose of the course material would be to teach about the use of technologies to overcome handicaps and improve functionality. Course topics could include: basics of assistive technology; legal/ethical issues associated with assistive technology; assistive technology and the individual education plan (IEP); levels of assistive technology; technology adaptations; Windows and Macintosh built-in accessibility tools; text-to-speech and speech-to-text; universal design and the internet; English as a second language, and physical and learning disabilities. An additional facet of such a course should also be designing web-based information to be universally accessible, covering such topics as making web pages more accessible and designing multimedia to overcome user handicaps. The assessments and activities of the course should include hands-on experiences with assistive technologies. Activities should be designed to include visitations to schools or labs to see assistive technology being used, the application and use of text-to-speech and speech-to-text programs, experiences with adaptive switches and toys, and even experimentation with environmental control hardware and software.

During discussions and interviews with inservice teachers, counselors, physical therapists, parents, and assistive technology organizations, a need for training and education in the area of assistive technologies was identified. Through continuing discussions, some basic areas of need in assistive technology education were identified. Visitations were conducted at the Assistive Technology Educational Network (ATEN), Florida Diagnostic Learning Resources (FDLRS) and Florida Instructional Materials (FIMSE) labs. The goal of the visitations was to learn about the state of the art and the programs being offered, and to understand the components of the AT community. Additional research continued through conducting a literature survey in the field, observing at schools and labs, and studying current Exceptional Student Education (ESE) and Instructional Technology (IT) programs offered at universities. In order to begin to fill the need that was perceived, a course outline was developed and components were taught at daylong hands-on workshops designed to introduce instructional technologists and teachers to assistive technology. From these preliminary discussions with professionals in the assistive technology community, it was found that an assistive technology course would be appreciated and that course delivery through distance learning would be preferred. Many of the potential students expressing interest in such a course were unable to travel to a university. As an educational technology program course, it would have an added benefit as a recertification course for ESE professionals and general education teachers.
After an initial course outline was developed, members of parent support organizations such as the Statewide Advocacy Network on Disabilities (STAND), university professionals in special education, assistive technology state organizations such as Florida Diagnostic and Learning Resources System (FDLRS) and Assistive Technology Education Network (ATEN), future students in exceptional education, and other instructional technology professionals were asked to provide feedback on the course design, goals, topics and assessments. All were extremely pleased with the idea of the material becoming available for instructional technologists, exceptional student education (ESE) and general education educators. In its current form, the AT course “Technologies for Special Populations” (see appendix) is designed as an introductory course in the application of technology as assistive and adaptive devices in education. The course itself should model effective design practices. For example web pages will be designed for universal access and course materials and multimedia will be developed to be handicapped accessible. Because of its online delivery, the course serves as a model of information presented through an assistive medium.

Learning Strategies

The Technologies for Special Populations course stresses hands-on experiences with various assistive technology approaches and devices. One of the main course goals is designing methods for a student to have actual experiences with the technology going beyond readings and looking at images about the technology. Students are expected to purchase, train, and use voice input systems, install and use an environmental control system, purchase and use a voice repeater, and use speaking software and hardware devices. Student interactions with assistive technologies fall into five areas. Students interact in an online forum, they have field experiences, and they complete technology projects, in addition to using standard materials such as tests and papers.

One of the strategies used in the Technologies for Special Populations course is the forum. Students participate for themselves and also analyze what other students have done and provide feedback to their classmates’ thoughts. Forum topics include case studies that students use in experimenting with, suggesting and explaining assistive technologies. Further forum topics encourage students to discuss and evaluate the impact that the assistive technologies have on them while they use various devices and programs such as environmental control, voice input, and text-to-speech.

Students will be required to observe the use of assistive technology as part of their field experiences. Students are asked to observe a student who uses assistive technology devices, or investigate and visit an assistive technology demonstration lab. Using an assistive technology device checklist and observation form, students would observe assistive technologies being used and then contribute in an online exchange concerning their observations.

Currently projects are being designed to give students additional experiences with assistive technology in evaluation, adaptation, and creation of assistive technology devices. Students evaluate web sites for universal access, compare various assistive technology software products, compare assistive technology hardware tools, and even complete an evaluation of a student related to the use of a specific assistive technology. Students will use software to create a communication board that augments communication within a specific class or function. Additional support is being sought for the creation of a supplemental traveling assistive technology box. Sent through the standard mail system, this box would provide students access to the more expensive technologies including touch screens, alternative keyboard inputs, talk boxes, close captioning devices, and more.

Appendix: Syllabus for Technologies for Special Populations
(an introduction to assistive educational technology)

Course Description: This course is designed to be an introductory survey course in the application of technology as assistive and adaptive devices and strategies for special population students, ESOL, learning, physically or mentally impaired, and are in a mainstreamed versus a profound situation. The basic concept of the course material is to learn about and use technologies to overcome handicaps and improve functionality. The course will be focusing mostly on integrating technology/computer based applications and adaptations. Course topics include built-in adaptations: Windows/Mac, legal issues, ethical issues, Individualized Education Plan (IEP), support agencies, English as a Second Language learners (ESOL), Exceptional Student Education (ESE), learning disability, environmental control, vision assistance, physical impairments, motion impairment, voice control, voice input, Text-to-Speech/Speech-to-Text, technology adaptive strategies: study, outline, concept mapping, toy adaptation, and universal access/design.

Topic Outline:
Introduction to assistive technology; Legal issues and the IEP; ESOL as a special population; Toys, Switches, and other adaptations; Windows & Mac built-in Accessibility tools; Text to Speech & Speech to Text; The Internet; Mobility and Physical Impairments; Hearing and Vision; Learning Disabled

Required course materials:
Internet Access, Speech to Text program, Environmental control materials & program, Voice recorder or 4-frame talker and Internet access. Texts for the class are The Internet: an inclusive magnet for teaching all students published by World Institute on Disability and Learning to Read in the Digital Age by Anne Meyer and David Rose

Assessments
Information/Research Paper:
The paper should have a focus on integrating and/or implementation of assistive technology in a school setting. What does this mean to education? How does it change the role of teachers, students and schools? How is the nature of technology changing instruction? How does change itself change what we do as teachers? This paper should examine issues, societal trends, and their effect on education. The final topic for the paper must be approved by the instructor. Paper should be three to four pages, in APA style, pay attention to format, spelling, and grammar.

Projects:
Evaluations - Using the guidelines, rubrics and forms from the website, review and provide recommendations concerning the appropriateness of use in the following areas: 1. Web site evaluation for handicap access; 2. Software evaluation; 3. Hardware evaluation and; 4. Ability evaluation
Field/Experimental Experiences - 1. Assistive hearing; 2. DVD experience; 3. Voice input/control; 4. Memo minder and; 5. Environmental control
Activities - 1. IEPs - TREE software: Use software in the process of creating an individualized education plan that incorporates assistive technology; 2. Create a communication board: Design and produce a one-page document to act as a communication board specific to subject area and grade level. The board should provide words and icons that are representative of speech necessary for discussion/communication for a class in that area; 3. Concept mapping: Using concept map software as a learning tool, develop an application for studying and learning.

Other Assessments - 1. Quiz on legal/support/IEP; 2. Forum discussions; 3. Case studies and; 4. Site experience/observation (assistive technology in a classroom or demonstration lab)
During the early part of the course, you should arrange to visit a class and observe a student using assistive technology devices. The class can be self-contained or mainstreamed. Use the assistive technology device checklist and then provide a summary of your finding concerning the student. You should make mention of how the student and teacher feels concerning the technology. If you would prefer not to visit a class or am unable to make sufficient contacts to be able to do so, the following are acceptable alternatives to classroom observations:

- Visit an ATEN lab
- Attend a ATEN workshop
- Attend a FDLRS (or equivalent) meeting or workshop
- Visit a FDLRS (or equivalent) lab displaying assistive devices

**Evaluation:** Course grades are based on quizzes, activities, projects and lab assignments.

**Target Learners:** Current and future educators, instructional technologists, and anyone interested in learning about assistive technology for the school setting. This course may be applied to recertification at all grades and subject areas.

Abstract: Our work is developing a homepage, content providers for and with people with special needs in a continuously evolving, participatory system. Our purposes are: qualifying technicians in Special Education, building, feeding and managing a site in the Web; developing a culture of the computer usage as a mediator of communication. We took into account the following directives: being flexible, modular, so that, new participants may always be integrated; looking for accessibility resources both for the production of the homepage and the qualification of the work team; decentralizing the production of the homepage form and content, and keeping a permanent channel for guidance of the participants; associating the qualification's content with its use in making the homepage; guaranteeing the work team's autonomy in keeping and improving the homepage. A preliminary graphic proposal is online to be analyzed and criticized to reach a better visual and sound promotion of the hypertext components.

Introduction

Our challenge is to develop a homepage for and with people with special needs. That means a collective work, continuously evolving, to create a participative system for preparing content providers for homepages addressed to people with special needs, as requested by the "Diretoria de Educação Especial" (Bureau of Special Education) of the "Secretaria de Educação do Estado de Pernambuco" (Department of Education of Pernambuco State).

To carry out that conception with the most positive results in number of accesses, and able to become an institutional undertaking out of the groups of participants' sphere of management, some directives have been suggested and implemented, making up a system of production. Such system of production is the project main body, and has as principle the idea of collective production of a homepage that works organically connected to the political-pedagogical conceptions of the requesting Bureau, so as to assure a real acquisition of this
instrument of work through developing conceptions and basic competence for the homepage future maintenance by the work team members.

Together with technicians and support educators, the work team defined the purposes:
1. To build a homepage addressed to people with special needs.
2. To qualify technicians in Special Education, for building, feeding and managing a site in the World Wide Web;
3. To develop a culture of the computer usage as a mediator of communication.

In order to put our work in practice we have regular meetings. This is the way we work for defining the target clients, the themes to compound the site, their nomenclature and hierarchy, have been developed, carried on through assigned tasks, discussions, records, researches on the Web, and qualification in concepts applied to the homepage production. On the [Table 1] we give an example on how the people involved in the project share the tasks.

**Table 1: Division of working tasks among personal**

Indeed, it has been established a process which does not end with the conclusion of the making of the homepage. An executive plan corresponding with the circumstances and characteristics of the group, the target public and even the requesting Bureau has been developed, taking into account the following directives:
a) To be flexible, modular, so that, new participants may always be integrated;
b) To look for accessibility resources both for the production of the homepage and the qualification of the work team;
c) To decentralize the production of the homepage form and content, and keep permanents channel for guidance of the participants;
d) To associate the qualification's content with its use in making the homepage, so as to invert the equation of outer, closed production into an inner, open one;
e) To guarantee the work team's autonomy in keeping and improving the homepage.

A process of qualification has been established, of which the practical result is the homepage development, which has been divided into six moments. Those moments consider the formalization of three component contents: 1) Web conceptions. 2) Formal Design and hypermedia, and 3) Computer and software usage. In the graphic Design and hypermedia case, the qualification has been only preliminary.

The members of the working team participate in all steps of the homepage construction.

Besides qualifying people with the necessary technical requirements to create and manage their own homepage, an important outcome is the feeling of command developed by the team, that may be understood from the methodology of work that has been built, as follows:

*Definition of a methodology of work:* collectively building this instrument, through researches, meetings, discussions, studies, use of computers.

*Break of some paradigms:* the knowledge of Informatics, seen before as a basic requirement for making a homepage, has been acquired little by little, in exchanges in the group, and according as the page contents and their form of organization are dimensioned.

*Some discoveries:* the challenge and the value of a collective construction, the possibility of approaching the school to other segments of society, the feeling of responsibility before that product that is the group's creation,
the decentralization in the management of a homepage, the acquisition of knowledge of projects, laws, entities and professionals of the area.

After organizing the site into topics from a vertical list, the group of participants built a model of organizational hierarchy [see Figure 1], in which the information could be linked through association, allowing, in a later stage, to incorporate, remove, fuse or separate the group of information, in a hierarchy discussed and defined by themselves.

![Organizational Structure Diagram](image)

**Figure 1: Organizational Structure**
The result was a substantially different division, yet keeping the characteristics of a hypertextual organization.

At present the participants have initiated their activities of exchanging e-mails, as well as collecting information to fill the page. A preliminary graphic proposal has been presented, with a purpose equivalent to that of the hierarchy proposal: to encourage the participants to develop their own interface. The model presented has been analyzed and criticized. Now, a work is in progress for a better visual and sound promotion of the hypertext components [Figure 3].

At the same time, the participants began to define a system of propagating the information: each participant will become a potential trainer of other groups.

That model proposes that interrelated associations be formed to feed not only the homepage, but also to provide content for other sites, and to continue to encourage the creation of a culture of computers' usage as mediator of communication both of people with special needs and of those who work with them.

Homepage is hypertext, representing the possibility of rapid examination of the content, of non-linear and selective access to the text, of segmentation of knowledge into modules, and of multiple connections with innumerable other hypertexts. It represents "one of the futures of the writing and reading" (Levy, 1993, p.19).
Communication will be neither the message, nor the sender, nor the receiver, but the hypertext, which "is like an ecological reserve, the ever movable system of the senses' relation that the precedent ones keep" (Levy, 1993, p.73). It is from that perspective that a new culture of communication is being created to whom is in need of special resources to get into communication.

Our role is to make people literate in Informatics, in the "Freirian" sense of the term (Jurema and O'Rourke, 1997), so assuring a real appropriation of those changes, through the development of concepts and basic competence for the future maintenance of the homepage by the participants of the working team.

Abstract: As students with disabilities are mainstreamed into general education settings, teachers need to be knowledgeable about appropriate accommodations, formats, and strategies, as well as accessibility issues. Often educators feel overwhelmed by the need to develop and deliver individually effective instructional materials for students with diverse abilities. This is particularly true in light of the current emphasis upon computer-based assistive technology as well as the need to make the Internet accessible as a learning tool for students with disabilities. There are no specific training competencies for general educators relative to assistive technology or Internet accessibility for students who require accommodations. Based on the emerging literature in this area, a qualitative study was conducted to determine the experiences and needs of teachers in this domain. A series of open-ended questions were used in an interview format. A subsequent analysis of transcribed interviews yielded patterns of teacher responses that will be discussed in terms of implications for training.

BACKGROUND

Traditionally, teachers working with students who had disabilities utilized various instructional methods to enhance student learning as well as formats that included large print or audio cassette versions of print materials for individuals with impaired vision or augmentative hearing devices for individuals with hearing impairment. However in the past five years, many of the accommodations that are necessary for students with disabilities include sophisticated computer-based assistive technology. Furthermore, teachers who utilize the Internet for class assignments must develop strategies to make this complex learning tool accessible across students who may have very different learning abilities.

THE CONTEMPORARY CHALLENGE OF COMPUTER-BASED ASSISTIVE TECHNOLOGY

Today, teachers working with students who have disabilities must expand their repertoire of accommodation formats, strategies, and accessibility issues relative to (a) computer-based assistive technology and (b) the use of the Internet as an instructional tool. Some examples of computer-based assistive technology materials for students with various abilities and disabilities include visual signals in addition to auditory signals, "Close View" screen enlargement programs, voice recognition systems for voice access to computers, adaptive software programs (including word prediction programs for word processing with limited key strokes), specialized keyboards (onscreen keyboards, large keyboards for individuals with limited motor control, or miniature keyboards for individuals with motor impairment), alternative input devices (joysticks and trackballs), and alternative output devices such as large-text or Braille printers (Lisiecki, 1999; Menlove & Hammond, 1998). For students with learning disabilities,
assistive technology accommodations may consist of reading machines, word processors, and other educational software that can compensate for reading, mathematics, writing, and spelling difficulties (Bryant, Bryant & Raskind, 1998). Finally, issues of Web accessibility for students with various disabilities remains a challenge for most classroom teachers.

TEACHER TRAINING NEEDS

A teacher's ability, training, and attitude regarding computer-based assistive technology and Web access are major contributors to a student's success. Given the emphasis upon mainstreaming of students with disabilities into general education classrooms coupled with the shortage of special educators for support and consultation, general education teachers are in need of training to support access for all of their students. Based on the emerging literature on the subject of computer-based technology and Web accessibility, a qualitative study was conducted to determine the needs and experiences of preservice and inservice general education teachers in these areas. A series of open-ended interview and survey questions were developed. Undergraduate teacher education students as well as licensed teachers and teacher education faculty responded to the questions. Questions focused upon individual attitudes, knowledge, and skills regarding assistive technology and Internet accessibility. Audiotaped interviews were transcribed and analyzed in order to develop a taxonomy of emerging patterns of practitioner experiences and training needs.

RESULTS AND IMPLICATIONS

The emerging results of this project can be broadly categorized into teachers' attitudes about special education, teachers' attitudes about technology, teachers' lack of confidence in terms of their knowledge base regarding computer-assisted accommodations, a lack of funding and resources to implement appropriate computer-based accommodations, and overall unfamiliarity with the issue of Internet accessibility for students with disabilities. As reported by McGregor & Pachuski (1996), as well as Persichitte, Caffarella & Tharp (1999), teachers in general are very concerned about the rapid pace of development of education technology coupled with new applications of classroom instruction. This concern is amplified by the reports of the teachers in this study who work with students who have disabilities. One of the ongoing goals of this study, and of this presentation, will be to expand the implications of teacher attitudes and experiences into a discussion of the specific core competencies (as initially addressed by Lahm and Nickels, 1999) that would be necessary for general education as well as special education teacher training programs.

REFERENCES

Abstract: The purpose of this project is to share the steps involved in creating and designing a specialized web site for viewers who either work with children and young adults who have special needs or those who have special needs. The web site will allow the viewers to apply the principles of bibliotherapy. Bibliotherapy is defined as healing through books, reading books to help solve and better understand personal problems, and/or mutual sharing of literature in order to structure interaction between a facilitator and a participant. The web site, designed to be interactive, becomes the facilitator and the viewers become the active participants. For example, people may log on and write reflections about their feelings toward the book listed on the web site. Participation in bibliotherapeutic intervention allows participants to hyperlink with other viewers, and therefore, make connections that encourage active problem solving related to special needs.

Project Description

The authors discovered that there is no an interactive web site on bibliotherapy that utilizes current children's and young adult books. This paper describes a project designed to help participants select books whose topics relate to the problems of people with special needs. Since the web site is interactive, participants can read a recommended selection and post their written responses to an interactive bulletin board. Initial categories were chosen based on special needs frequently reported in the literature (see Table 1), with the understanding that other categories would be added at a later date, including death and dying, less common disabilities, etc.

1LT Leo Brennan, an undergraduate in Multimedia Design at Cameron University, assisted with the creation of an interactive web site containing links to each of these special needs. These web design features were taken into consideration: background, color, imaging (animation and graphics), FAQs, links to other sites on the Internet (authors' homepages, other reviews, etc.), WebCT format, accessibility, server issues (file transfer, testing, publicizing and maintaining the site), sound clips, format for book reviews, alternative text, alignment, embedded tables. Publishers were contacted and asked to submit books that fit the specific categories presented in the following table.

Table 1: Bibliotherapy special needs books

Outcomes

Current books were identified that speak to specific special needs. Certain books were chosen repeatedly, which is indicative of the bibliotherapeutic value and literacy merit. In addition, this study also reflects the level of interest of the participants, which is considered one indication of personal need. An innovative web site has been created for use by people (professionals, librarians, empathetic readers, victims and their families) that provides healing through books.

Abstract: Although technology could have a positive impact on students with learning disabilities, it appears that special education teachers do not use these teaching and learning tools to their full potential. This paper presents the main findings of a survey on the use of technology and their needs regarding technology integration. Results from the survey show that although teachers have a favourable opinion on technology, intensive computer use in the classroom remains scarce. Lack of time, insufficient knowledge of the pedagogical uses of technology and lack of information on existing software were identified as the three major hurdles to technology integration. Considering these needs, professional development activities should aim to provide a greater knowledge of the pedagogical strategies suited to use different technologies, develop teachers' skills for technology-based activity planning and give teachers the means to share information on available educational material.

Introduction

Many studies and meta-analysis highlight the benefits of computer applications in an educational setting. Although, as pointed out by Woodward and Rieth (1997), results from such studies are not easy to interpret given the different applications, design characteristics or instructional strategy they may imply, it appears that technology can have a positive effect on learning in different contexts (Sivin-Kachala & Bialo, 1994; Johnson, Cox et Watson, 1994; Hannafin, Hannafin, Hooper, Reiber et Kini, 1996) and on student motivation (Sivin-Kachala & Bialo, 1994; Draude et Bruce, 1999).

Technology could even have a greater impact on learning for students with learning disabilities. Sitko and Sitko (1996) concluded from different studies that motivational and affective benefits derived from technology uses are more conspicuous for students with special needs. Furthermore, Bender and Bender
(1996) mentioned that certain computer attributes can help palliate some characteristics of students with learning disabilities. For instance, graphics and sound can help create interest when students show a general lack of interest towards educational material and frequent reinforcement can increase their short attention span. Green (1995), after interviewing teachers known for their extensive experience with computers and students with learning disabilities, concluded that multimedia computer software increases motivation and self-esteem for many learning disabled students and, in some cases, reduced behaviour problems.

Despite these potential benefits, there is little evidence that teachers use these technological tools on a regular basis with learning disabled students. In a report on computer use in special education, Chouinard (1996) stated that access to computers in special education classes in Quebec was limited and that special education teachers did not use technology on a regular basis with their students. Since then, very little research data have been published on the extent and nature of computer use in special education, in Quebec or elsewhere.

Special education teachers seem to use only a few of the technological tools available. Prinz and Boger-Mehal (1999) stated that the use of technology within special education classrooms is often limited to rote practices using games or to tasks such as word processing and drawing. Based on our field experience, it seems that few classroom experiences allow learning disabled students to engage in long-term projects using technology as a production tool although such projects may have a positive impact on these students. These observations lead us to believe that computers are not used to their full potential in the special education classroom.

This paper relates to a three-year collaborative research project focusing on the integration of technology in classrooms with learning disabled students and the effects of this integration on student motivation, self esteem and social abilities. The project was conducted in various schools from three distinct Quebec school boards. The main objectives of the project were as follows:
- To assess teacher use of technology in classrooms with learning disabled students and identify their needs in regard to technology integration;
- To develop, in collaboration with teachers, instructional activities where students carry out a project using technological tools;
- To assess the impact of technology integration on student motivation, self-esteem and social abilities.

This paper focuses on the first two objectives, since the impact assessment is not yet completed. After highlighting the principal uses of the computer in the classroom, it will describe teachers' needs in regard to technology integration. Then, it will make some recommendations for inservice teacher professional development, taking into account some of the survey results related to computer uses and teachers' needs. It also presents a model for classroom projects engaging learning disabled students in long-term activities.

**Method**

202 teachers from different Quebec schools working with elementary and high school students with learning disabilities or behaviour problems were asked to complete a questionnaire focusing mainly on their use of technology both inside and outside the classroom, on their attitude toward technology and on the obstacles and their needs regarding technology integration in their own classroom. Some data were also collected on teacher characteristics, experience with technology and computer access in the school. The 42 item questionnaire used a mix of Likert scale type and open-ended questions.

Interviews conducted with 43 of these teachers supplied in-depth information on the obstacles to technology integration and on the measures that could help teachers attain this integration. Interviews were conducted using a semi-structured approach.

In the second year of the project, nine elementary and high school teachers were selected to experience in their classroom different long-term projects integrating computer activities. Projects were planned jointly by research team and teachers.
Main Results

Results from the survey showed that computers are available to nearly all teachers and that more than 80% of teachers used the computer for personal and professional use outside the classroom. Teachers' attitude toward computers are also very positive, as 89% of teachers consider that technology is useful for teaching and learning and 81% of them think it should be used in the classroom. Most of them (78%) also consider that technology has a positive impact on student learning.

Despite the relative accessibility of the computer and teachers' favourable opinion toward technology, actual use in the classrooms is not very extensive: 25% of teachers don't use the computer in the classroom and no more than 29% of them use it more than two hours a week with their students. Furthermore, when computers are used in the classroom, it is usually for word processor, educational software or Internet use. These applications are the only ones used on a regular basis by more than 20% of teachers.

In order to better understand the discrepancy between teachers' positive attitude towards technology and their relatively limited use of the computer in the classroom, it is logical to investigate the obstacles identified by teachers as the main hurdles to technology integration in the classroom. Lack of time, insufficient knowledge of the pedagogical uses of technology and lack of information on existing software were identified as the three major obstacles to technology integration. A majority of teachers are satisfied with the quality of the hardware available (82%) and the technical support supplied in the school. On the other hand, 47% of teachers are not satisfied with the pedagogical support they receive to integrate technology. More than half of the teachers (55%) consider that they don't get enough information on technology relating to educational applications.

The training needs expressed by most teachers focused on the strategies to implement in order to use technology in a sound pedagogical manner. The teachers identified greater needs relating to the pedagogical aspects than the technical aspects. Over 90% of teachers consider that training on appropriate teaching strategies for technology-based classroom activities would be useful. Access to computers or suitability of the available computers did not seem to be a major obstacle for most teachers although some mentioned that they would like to have more computers in their classroom.

These results are in agreement with the opinion of Cuban (1993) who argues that logistical difficulties or lack of funds form only a partial explanation of a deeper problem related to the underuse of technology in schools. A discrepancy between sound pedagogical use of technology and core visions of teaching represent also an important issue in technology integration.

Implications of the Study

Taking these results into account, we can suggest ways to meet some of the teachers' needs, in order to facilitate technology integration in the special education classroom. Considering these needs, professional development activities should aim to provide a greater knowledge of the pedagogical strategies suited for different technology uses, develop teachers' skills for technology-based activity planning and give teachers the means to share information on available educational material. The following suggestions could help reach these goals.

- Create networks where teachers can share information and discuss different classroom technology integration experiences.

Since a majority of teachers expressed dissatisfaction toward the information available on technology applications in their school, networks where teachers can exchange information on technology-based activities seems useful. Such networks could facilitate the sharing of experiences and material well suited to the curriculum.
- Focus on the pedagogical strategies needed when using technology rather than on more technical aspects. As pointed out in our study, teachers' needs and concerns are closely related to pedagogical aspects. Consequently, teacher education programs and training should focus on the strategies to implement in technology-based activities. Proposing models for classroom activities and helping teachers develop their own activity scenarios can contribute in developing competencies in the use of sound pedagogical strategies in computer-based activities.

- Give training on a wide variety of technology uses in special education. As pinpointed by our study and by other authors such as Prinz & Boger-Mehal (1999), special education teachers only use a few of the technological tools available. As does Bailey (1992), we believe it is necessary to expand the options for computer use in special education in order to empower the teachers to use a wider variety of these tools with their students.

- Prepare teachers to guide their students towards long-term projects. As shown by our study, few special education teachers engaged their students in long-term project integrating technology. Most often, they proposed short-term activities such as instructional games. Because special education students often learn at a slower rate and have a long history of failure, long-term projects may be more suited to produce significant changes. Furthermore, engaging students in projects where computers are used as a tool to gather information and create their own productions allows the students to perform activities that are more significant.

The projects developed with nine teachers suggests different models for classroom activities engaging students in long-term projects where computers are used as a tool. For example, in one of these models teachers guide students through the following steps:

- Define a goal and topics
As learning disabled students often lack motivation toward classroom activities, it is important to let them participate in the choice of the project and the related topics. The goal should have meaning for the students.

- Get direct experience or expert testimony related to the project
Real life experience or others' testimony appears to be a good way of engaging the students in the project and heightening interest.

- Gather relevant information via electronic sources
By gathering information from different sources, students can widen the scope of their inquiry and improve the quality of the final result. Teacher supervision appears important to help students improve their inquiry strategies and guide them toward relevant materials.

- Create a collective product using electronic tools (journal, multimedia document, database or other)
Learning disabled students can take pride in authoring their own media productions. Technology as a production tool also provides some advantages for students with learning disabilities. As Woodward and Rieth (1997) mentioned, tools such as word processors eliminate the problems associated with poor writing skills encountered by a lot of learning disabled students. When used with relevant learning strategies, the computer can support the planning, writing and revision phases of product execution (MacArthur, 1997). The collective aspect of the project should take into account the strengths and weaknesses of the different students.

- Present their production in and outside the classroom
Learning disabled students' productions are rarely displayed. Assuring a distribution of their work both inside and outside the classroom can contribute to increase their self-esteem and to create a positive effect on others' perceptions.

This model can be illustrated with examples drawn from the experiences carried out during the past two years in different elementary and high school level classrooms.
More information on this project and its results is available (in French only) at the following Website: http://www.uqtr.uquebec.ca/gritas

The Integration of Assistive and Adaptive Technologies
Into the Preservice and Advanced-Level Courses of Instructional Technology and Special Education

Caroline M. Crawford
Instructional Technology
University of Houston-Clear Lake
United States of America
Crawford@cl.uh.edu

Sylvia S. Martin
Special Education
University of Houston-Clear Lake
United States of America
Martinsv@cl.uh.edu

Abstract: Instructional technology has become a tool that is integral to the preservice teacher educators' bag of tricks; however, the integration of assistive and adaptive technologies into the learning environment to meet the needs of special education learners is sometimes perceived as more cumbersome. The integration of assistive and adaptive technologies into the preservice and advanced-level instructional technology courses is discussed.

Introduction

Personnel preparation may be defined as providing the knowledge and skills related to effective educational and related services based on best practice and changing trends for educators to teach all students (Ryndak & Sirvis, 1999). Utilizing these knowledge and skills to provide a supportive learning environment has become the basis for evaluation of an educator's ability to address the individualized needs of each student. While Special Education faculty assume the role of content experts for the assessment, selection, implementation, and evaluation of assistive and adaptive technologies, Instructional Technology faculty play the role of process experts in "the design, utilization, management and evaluation of the processes and resources for learning" (Seels & Richey, 1994, p. 1).

Instructional Technology

Instructional technology is a tool that preservice teachers must begin to conceptualize throughout focused methods course work. The introductory technology course offered at numerous universities addresses knowledge and skills related to an understanding of instructional technology, theoretical implications, appropriate and successful applications within the learner-centered environment, appropriate integration of technology within lesson plan design and development as well as numerous other instances of instructional application of technology. However, situations occur that may be beyond the experiential scope of preservice teachers. For example, how does a teacher work with a student who has specific learning needs, such as a student receiving special education services? Instructional technology offers the special education learner the opportunity to work alongside other students in an on-level classroom environment. For many preservice teachers, the opportunity for early hands-on experience with assistive/adaptive technologies is not available within the traditional beginning education course work. Rather it occurs in later field experience courses.

Instructional Technology and Special Education
The teaming of Special Education faculty and Instructional Technology faculty provides an innovative formula to address the issue of assistive and adaptive technologies within preservice- and advanced-level courses associated with instructional technology and special education. While Special Education faculty have brought their knowledge of assistive and adaptive technologies to the table, Instructional Technologists have brought their expertise concerning the appropriate and successful integration of technologies into the educational learning environment. In this way, the preservice teacher educators have the opportunity not only to learn about assistive and adaptive technologies, but also to focus upon the integration of such technologies within a supportive learner-centered environment for special education PreK-12 students.

Special Education

Special Education provides technology-embedded course assignments and activities. The technology process activity provides preservice teachers with information needed to complete course assignments related to case study students. Examples of embedded technology include the use of instructional strategies requiring informational websites, e-mail, database searches and electronic libraries. Examples include the preservice teachers' use of technology to: research disability areas; develop a website "Resource Directory of Services" for young children with disabilities and their families; create on the computer original artistic interpretations and schematics; read what family members of students with disabilities say on discussion boards; participate in an interactive video workshop on assistive and adaptive technologies and universal design; visit virtual classrooms using assistive and adaptive technologies; browse vendor websites for assistive and adaptive technologies; download and use sample software programs; complete on-line surveys; create communication boards using Mayer-Johnson Inc. Boardmaker software; and design, develop and present Microsoft PowerPoint presentations.

Through the use of technology-embedded special education course work, preservice teachers become knowledgeable in the numerous ways technology can be integrated into services for special education students. Technology-embedded course work provides a link between the successful application of technology and the provision of a supportive learner-centered environment for special education students. In this way, the educator not only meets the special needs of each student but also provides the student with an opportunity for success in the general education setting. Instructional technology offers the special education student this opportunity, wherein the learning environment is not only student-centered, but centered upon student success.

Conclusions

Through the integration of assistive and adaptive technologies into the preservice and advanced-level courses of instructional technology and special education, the preservice teacher educators' bag of tricks has expanded. Such powerful tools within a learning environment offer numerous directions through which to reach special education students and to adapt the learning environment to the students' needs. The importance of appropriate, thoughtful and successful integration of technology within a special education environment must be emphasized through out the preservice teacher educators' program of study.

Designing Accessible Web Sites for People with Disabilities

Robert V. Price, Ph.D.
Instructional Technology Program, College of Education
Texas Tech University, USA
Bob.Price@ttu.edu

Abstract
In order to make the Worldwide Web accessible to individuals with disabilities and also more accessible for everyone, web developers can follow 14 guidelines provided by the W3C group. This paper summarizes these guidelines and provides suggestions for compliance. Levels of compliance, benefits of compliance, examples of accessible web sites, and an accessible web site template are described.

The Web is a democratic media that is designed to provide information not only anytime and anywhere but also for everyone. For those unfamiliar with accessibility issues pertaining to Web page design, consider that some users may be operating in contexts very different from your own. For example:

- They may not be able to see or hear.
- They may not be to process some types of information (written, visual, auditory) easily or at all.
- They may have limited ability or no ability to move or manipulate a keyboard or a mouse.
- They may have difficulty reading or comprehending text.

Individuals also sometimes use supplementary software programs and devices, called assistive technologies, which aid them using technology. Assistive technologies include specialized web browser programs and screen reader programs. Web developers should consider access for individuals with disabilities and their use of assistive technologies during site design. While there are several disabilities to consider, each accessible design choice generally benefits several disability groups at once and the Web community as a whole.

The W3C group, a nonprofit organization, has produced a set of fourteen Web Content Accessibility Guidelines which are available online (W3C, 2000). A consortium of government agencies and businesses sponsors W3C. Its goal is to increase web accessibility.

Priorities for Accessibility

The W3C guidelines provide general principles for accessible design. Each guideline has a priority level assigned to it based on its impact on accessibility. These priorities are described below:

- Priority 1: Requirements which developers must address
All sites must comply with these requirements or else one or more groups will find it impossible to access information in the document.

- Priority 2: Requirements which developers should address
All sites should satisfy these guidelines. Otherwise, one or more groups will find it difficult or impossible to access information in the document.

- Priority 3: Requirements which developers may address
These are requirements which Web developers may address to improve access to web documents.
Sites that conform to the W3C guidelines may display the image or message shown below as an indication of conformance on their web page:

The W3C Approved Web Site Image

This page conforms to W3C's "Web Content Accessibility Guidelines 1.0", available at http://www.w3.org/TR/1999/WAI-WEBCONTENT-19990505, level Double-A.

The level of compliance is indicated as A, AA, or AAA as described below:

- Conformance Level "A": all Priority 1 checkpoints are satisfied,
- Conformance Level "Double-A": all Priority 1 and 2 checkpoints are satisfied,
- Conformance Level "Triple-A": all Priority 1, 2, and 3 checkpoints are satisfied.

Guidelines for Web Accessibility

The W3C Level guidelines are summarized below.

Guideline 1: Provide equivalents to auditory and visual content.

For each graphic image, text content can be presented to the user as text. In order to be useful, the text must convey the same function or purpose as the image. For example, consider a text equivalent for a photographic image of the Earth as seen from outer space. If the purpose of the image is mostly that of decoration, then the text "Photograph of the Earth as seen from outer space" might fulfill the necessary function. If the purpose of the photograph is to illustrate specific information about world geography, then the text equivalent should convey that specific information. If the photograph has been designed to tell the user to select the image (e.g., by clicking on it) for information about the earth, equivalent text would be "Information about the Earth". Thus, if the text conveys the same function or purpose for the user with a disability as the image does for other users, then it can be considered a text equivalent. This is probably the easiest modification that can be made to most Web pages to make them more accessible. Most web authoring programs, such as Microsoft Front Page, have a function called Alternate that can be used to enter a text description for images when they are placed on a page. When the user moves the cursor over the image, a text equivalent for the image will then appear on the user's screen.

Non-text equivalents of text such as icons, pictures, pre-recorded speech, or a video of a person translating the text into sign language can make documents accessible to people who may have difficulty accessing written text, including many individuals with cognitive disabilities, learning disabilities, and deafness. Non-text equivalents of text can also be helpful to non-readers. An auditory description is an example of a non-text equivalent of visual information. Auditory descriptions of multimedia presentation's visual track benefits people who cannot see the visual information. Audio can be recorded with application programs such as RealAudio and added to the web page as an option.

Guideline 2: Don't rely on one color alone.

Ensure that text and graphics are understandable when viewed without color. If color alone is used to convey information, people who cannot differentiate between certain colors and users with devices that have non-color or non-visual displays will not receive the information. When foreground and background colors are too close to the same hue, they may not provide sufficient contrast when viewed using monochrome displays or by people with color deficits.

Guideline 3: Use markup and style sheets properly.
Using html markup improperly hinders accessibility. Misusing html markup for a presentation effect, such as using a table for a page layout or a header to change the font size, makes it difficult for users with specialized software or hardware to understand the organization of the page or to navigate through it. Constructing what looks like a table of data with an HTML PRE element makes it difficult to render a page intelligibly to other devices.

At the other extreme, Web developers should not sacrifice appropriate formatting because a certain browser or assistive technology does not process it correctly. For example, it is appropriate to use the TABLE element in HTML for tabular information even though some older screen readers may not handle side-by-side text correctly.

Guideline 4: Clarify natural language usage.

Use text enhancements, such as boldface and italic, when they facilitate pronunciation or interpretation of abbreviated or foreign text. Developers should also provide expansions of abbreviations and acronyms. Using natural language improves readability of the Web for all people, including those with learning disabilities, cognitive disabilities, or people who are deaf. When abbreviations and natural language changes are not identified, they may be indecipherable when machine-spoken or brailled.

Guideline 5: Create tables that transform gracefully.

Tables should be used for tabular information (data tables) only. Developers should avoid using them to design page layouts. Tables for any use present special problems to users of screen readers. Screen readers are software applications commonly used by visually impaired individuals to read the text on a screen aloud so that it can be heard.

Guideline 6: Ensure that pages featuring new technologies transform gracefully

Ensure that pages are accessible even when newer technologies are not supported or are turned off. Although developers are encouraged to use new technologies that solve problems raised by existing technologies, they should know how to make their pages still work for people who choose to turn off features. Ensure that pages require scripts, applets, or other programmatic objects can be turned off or not used. If this is not possible, provide equivalent information on an alternative accessible page.

Guideline 7: Ensure user control of timed content changes.

Ensure that moving, blinking, scrolling, or auto-updating objects, if used, may be paused or stopped. Some people with cognitive or visual disabilities are unable to read moving text quickly enough or at all. Movement can also cause such a distraction that the rest of the page becomes unreadable for people with cognitive disabilities. Screen reader programs are also unable to read moving text.

Guideline 8: Ensure direct accessibility of embedded user interfaces.

Objects embedded in pages, such as applets and scripts, sometimes have their own interface. In these cases, the interface should be accessible to users so that they can be adapted to work with assistive technologies if necessary. If the interface of the embedded object cannot be made accessible, an alternative accessible solution, such as an alternate version of the page, should be provided.

Guideline 9: Design for device independence.

Device-independent access means that the user may interact with the site or document with a preferred input or output device such as a mouse, keyboard, voice, head wand, or other device. If, for example, control of a form can only be activated with a mouse or other pointing device, individuals using voice input, a keyboard or some other non-pointing input device will not be able to use the form.
Guideline 10: Use interim accessibility solutions so that assistive technologies will operate correctly.

New web technologies may not be immediately available to people using assistive devices. For example, older screen readers read lists of consecutive links as one link. Active page elements such as this are therefore difficult or impossible for these users to access. Also, changing the current window or popping up new windows can be very disorienting to users who cannot see that this has happened. This guideline is classified as "interim", meaning that the Web Content Guidelines Working Group considers them to be valid and necessary to Web accessibility as of the publication of the current version of the guidelines. However, the Working Group does not expect this to be necessary in the future, once Web technologies have incorporated anticipated features or capabilities. Until all browsers allow users to turn off spawned windows, developers should not cause pop-ups or other windows to appear or change a current window without informing the user.

Guideline 11: Use W3C technologies and guidelines.

Many formats commonly used on the web such as PDF, PostScript and Shockwave, require viewing with either plug-ins or stand-alone applications. Often, these formats cannot be viewed or navigated with the assistive technologies in common use. W3C recommends that these document formats be converted to W3C supported markup languages such as HTML, XML, or plain text. When inaccessible technologies must be used, equivalent accessible pages should be provided.

Guideline 12: Provide context and orientation information to help users understand complex pages or elements.

Providing navigation tools and orientation information in pages will maximize accessibility and usability. Not all users can make use of visual clues such as image maps, proportional scroll bars, side-by-side frames, or graphics that guide sighted users of graphical desktop browsers. Orientation information is somewhat like the running head of a book and tells the user where she is in the web site. For example, a web page might include an orientation line in the footer of the page that reads something like Introduction: page 2 of 6. This tells the user what part of the web site they are viewing. Simple icons such as a home icon and forward and back arrows also improve the ease of navigation. Grouping page components and providing contextual information about their relationships can be useful for all users. Dividing large blocks of information into more manageable groups where natural and appropriate also aids in understanding page components.

Guideline 13: Provide clear navigation mechanisms.

Providing clear and consistent navigation mechanisms such as orientation information, navigation bars, and site maps, increase the likelihood that a person will find what they are looking for at a site. Clear and consistent navigation mechanisms are important to people with cognitive disabilities or blindness, and benefit all users. Link text should be meaningful enough to make sense when read out of context. For example, using a link such as Information about version 4.3 instead of click here adds to clarity.

Guideline 14: Ensure that documents are clear and simple so they may be more easily understood.

Using clear and simple language promotes effective communication. Access to written information can be difficult for people who have cognitive or learning disabilities. Using clear and simple language also benefits people whose first language differs from your own and those people who communicate primarily in sign language.

More information on these guidelines, including checkpoints and examples of techniques is available from the W3C website.

Validating Accessibility of Web Sites

A checklist which can be used for evaluating any web site for compliance with these guidelines is available online from W3C. While use of the checklist provides for a human review of web sites, the Bobby program provides an automated review of web sites (Center for Applied Special Technology, 2000). Bobby is based on the W3C guidelines. While a Bobby review can provide a good general review of potential problems on any
web site, it cannot assure compliance with all guidelines, especially those dealing with readability and

![Bobby Approved](http://www.eric.ed.gov/PDFS/ED428229.pdf)

navigation. Bobby is a Web-based tool that analyzes Web pages for their accessibility to people with
disabilities. The Center for Applied Special Technology (CAST) offers Bobby as a free public service. By
entering the URL of a page that you want Bobby to examine and clicking Submit. Bobby will display a report
indicating any accessibility and browser compatibility errors found on the page. Bobby will only test one page
at a time. If you wish to test an entire site as a batch, use the downloadable version of Bobby. Once all the pages
on a site receive a Bobby Approved rating, it is entitled to display the Bobby Approved symbol.

**Benefits of Accessible Web Sites**

I have had an opportunity to work with faculty from my university's program for training teachers of visually
impaired students by assisting them with developing accessible web sites for handicapped individuals. As I
learned about designing Web sites for universal accessibility, I came to realize that designing web sites for
handicapped individuals not only benefits those with handicaps but just about everyone else as well. For
example, use of text equivalents, while benefiting users with disabilities, can also help all users find pages more
easily, since search robots use a page's the text when indexing the page. Using good contrast between text and
background improves readability for all. Using clear and simple wording improves readability for everyone.
Following these guidelines helps improve access and usability of web sites for all, including those with
disabilities and those without them. In cases where it is not possible to incorporate all of these guidelines into a
page, creating a text based equivalent option is a fairly easy solution. This not only makes the page accessible
to many individuals with handicaps; it makes the page readable for those who lack the latest versions of
browsers and other web technologies.

For examples of accessible web sites, visit one of the following sites: The W3C Group, American Council for
the Blind, Lighthouse International, National Federation for the Blind, and The Texas School for the Blind and
Visually Impaired.

A downloadable Bobby compliant web page template, which can be used by developers, to help them get a head
start on designing a more universally acceptable site is available free on the web at the following URL:

http://www.educ.ttu.edu/templada/

This site includes tips to help visually impaired viewers change the appearance of a site with their browser, an
alternate text only page, and some useful links.

Abstract: The potential value and importance of assistive and adaptive technologies within the learning environment of special needs students must be emphasized. Students with exceptionalities can be aided through the thoughtful and successful integration of instructionally appropriate technological tools. The potential significance of instructional technologies within a special needs environment is imperative towards the success of the student learners.

Introduction

The reauthorization of IDEA recognizes the potential value and importance of assistive and adaptive technologies for students with exceptionalities. With the recent emphasis and integration of this technology into the mainstream classroom, teacher candidates must become knowledgeable and comfortable with assistive and adaptive technological tools that will aid learners with exceptionalities in the general classroom.

Instructional Technology

The instructional technology available within today's educational environment is becoming available to all levels of the PreK-12 environment at a quickening pace. Because of the diverse needs of students with exceptionalities, teacher candidates need experience with a wide range of assistive/adaptive technologies available to students with exceptionalities. Coursework and field experiences aid in the transition from preservice teacher to inservice teacher with the necessary and sufficient skills to support all learners. The experiences not only benefit teacher candidates but also the students whom they directly work with as well.

As always, instructional technology is just a tool, but a tool that can aid the special needs learner at appropriate points within the learning process. When emphasis is placed upon technology as a mere tool through which learners can access information and create products to display learning, the creativity and inspiration of the learner comes alive. Technology, when integrated into the instructional design of a learning experience, can be a positive influence within a learner's knowledge acquisition and conceptual framework of understanding. Therefore, the careful and thoughtful integration of instructional technology within a learning environment can be a positive influence for the PreK-12 learner.
Assistive and Adaptive Instructional Technologies

Instructional technologies have been integrated within the learning environment for PreK-12 learners with varying success. The emphasis for hardware and software availability is now giving way, as the pendulum swings towards the appropriate and successful integration of instructional technologies into the learning environment. However, we can not ignore the special needs of learners within the classroom environment. Assistive and adaptive technologies offer the technological efforts to not only the general education learners, but also to learners with special needs. First and foremost, we must define what is encompassed within the terms “assistive” or “adaptive” technologies:

Assistive (or adaptive) technology includes any equipment, software, service, or specialized instructional material that helps disabled persons improve their quality of life and increase their access to education, the workplace, and the community. These devices help people function more independently in nearly all aspects of life, but especially in communication, mobility, learning, and personal care (Pesta, 1994, paragraph 2).

Teacher candidates have available to them numerous types of assistive and adaptive instructional technologies that offer learner-centered, as well as teacher-centered, opportunities to develop basic knowledge of subject matter as well as strive towards higher order thinking skills. During a five-week field experience, teacher candidates select and evaluate various types of assistive/adaptive technology available to the students in their current placement. Candidates thoroughly research various technologies they have access to in the field. Candidates then draw on their research, previous coursework in Special Education and Instructional Technology, and experiences of others to apply what they have learned to the natural teaching environment. Teacher candidates document their understanding of the technology and how it is used with students with exceptionalities via videotape. That is, each candidate presents a brief overview of selected assistive/adaptive technology available in the classroom by describing the technology and its uses. Candidates then demonstrate how the technology is used with the student with an exceptionality within the context of the classroom. The experience provides the opportunity for the teacher candidate to work with the student and the technology together, rather that the technology in isolation.

Candidates and mentor teachers both express value in such opportunities. The videos created by teacher candidates are then shared with their colleagues. In addition, candidates evaluate the contributions assistive/adaptive technology adds to the quality of life of students with exceptionalities by developing an artistic advertisement of the assistive/adaptive technology available in the classroom. The advertisement reflects the value the technology has on the student’s quality of life, the skills that can be learned, and attitude of the child with an exceptionality. Teacher candidates are encouraged to use skills learned in Instructional Technology for all assignments.

Conclusions

The technologies available within today’s educational arena have the ability to not only emphasize the strengths of the exceptional learner, but also to further integrate the learner into the general classroom environment. Such opportunities for technology tools must be emphasized within the preservice teacher’s coursework to provide a supportive learning environment for all students.

Abstract: This study was initiated to investigate the technological knowledge and skill level of special education teachers and their use of technologies in self-contained and inclusive classrooms as mandated by public law. The study was conducted in two southeastern Florida school districts and included a sample of 210 teachers with a response rate of 69%. The results of this research will report the usage level of 24 technologies in the classroom and will discuss the correlation between teacher skill level and the use or non-use of computers and other technologies for instruction.

Introduction

Having daily classroom access to a variety of technological tools for special education teachers and students may soon be the norm rather than the exception. It is the hopes of many that technology will be used to improve and enhance the learning environment, but evidence has shown, "Without proper teacher training and motivation, technology can land on a shelf" (Clifford, 1998, p.34). Clifford also believes, like others, in the importance of technology in the contemporary classroom:

Simply put, its role is too important, and the hardware and software involved are too expensive and valuable to allow this to happen. As technology plans are put in place, staff development must be factored in. At the same time, educators understand that the technology is now a critical component in learning, and that staff development in this area needs to be determined, sustained, varied, calculated, supported and frequently individualized (p. 34).

Teachers of students with high incidence disabilities, educating in both regular and special education elementary classroom settings, will need guidance and assurance that possessing technological skills is consequential in the attainment of personal and career goals for themselves and their students. A professional development plan for all teachers ought to include a significant wealth of computer and other technology training programs based upon a needs assessment that will encourage personal goal attainment in technological proficiencies identified through self evaluation. If teachers are to prepare students to meet the educational and vocational plans our children pursue, then it is imperative that all teachers gain knowledge and skills necessary to acquire and maintain a full range of recognizable competencies in this fast moving technological environment.

Special education teachers are becoming much more visible in regular education classrooms during the transition to the inclusion model that is being adopted by schools as mandated in the public laws. Novice special needs
teachers are not unlike the regular education teachers who graduate from NCATE approved teacher preparation programs. They are presumed to have had at least one introductory technology course as well as numerous experiences to see how the integration of technology into the classroom could improve the teaching and learning environment. Unfortunately, during this transitional time, veteran teachers may not have had the same opportunities to acquire basic technology skills essential for today's technological expectations. The intent of this study was to ascertain the current status of the teachers' technological literacy and to identify the utilization or non-utilization of a variety of technological tools in special education programs. The results of this study may contribute helpful information to encourage the preparation of numerous technology workshops and inservice training programs to bring technologies and teachers together, to strengthen the instructional environment in special education classrooms.

Literature Review

The most recent and comprehensive analysis of special education and technology literature published in 1999 "...judged as contributing to the emerging knowledge base on special education technology research and practice," was synthesized by Edyburn, (2000, p. 7). He identified seven topics that dominated the literature: (a) assistive technology; (b) instructional technology; (c) World Wide Web; (d) implementation issues; (e) augmentative communication; (f) teacher training, and (g) accessibility. Teacher training was the focus of only 11 articles identified out of the 144 articles recorded.

Many would agree that teaching with technology in the special education classroom allows for the introduction of multiple instructional methods and modalities that may not be possible without the use of new hardware and software. Numerous research studies have reported the benefits of a diverse and multi-sensory learning environment for learners with disabilities, which also supports the argument that teachers ought to be proficient in the selection and use of computers and other technologies. According to Prinz & Boger-Mehall, (1999), "By using assistive technologies such as multimedia and hypermedia in a lesson, teachers can present information visually, audiologically, and textually" (p. 1570). Improving the technological knowledge and skills of teachers to utilize the variety of technologies would support the multi-sensory theories for instructional purposes and provide additional tools to meet individual goals as set forth by public laws governing education.

Teacher Awareness of Public Laws

There are five public laws that have a profound impact on elementary education in the teaching and learning environments that focus on implications for technology utilization specifically. Well-prepared teachers will be aware of these laws and ought to be able to distinguish the most relevant usage of numerous technological tools that may support individuals' instructional needs. Teacher training in the utilization of both low tech and high tech devices ought to be included in faculty development programs to meet the mandates of these public laws (Cronis & Ellis, 2000).

This public law addresses the need for access to technology by individuals with disabilities and their families.

This public law identifies assistive technology as a specific service to be provided to young children with disabilities, legitimizing technology as an educational tool, and mandating that all students with disabilities be considered for assistive technology as part of their Individual Educational Plans (IEPs).

This public law stipulates that classes and educational equipment must be modified to enable participation by students with disabilities.

This public law provides for greater family involvement in early intervention and states that assistive technology devices and services may be part of the Individualized Family Service Plan (IFSP).
This public law requires that states develop comprehensive programs of technology-related assistance for all persons with disabilities regardless of age.

Instructional Applications

These laws will benefit only those children with disabilities if our teachers are knowledgeable, trained, and adequately supported in the classroom to use a wide variety of technological tools appropriately. Results from a study that identified the status of assistive technology usage and special education teacher preparedness in northeastern state by McGregor & Pachuski (1996), reported that “In spite of the relatively high self-ratings of technology proficiency, teachers were substantially less satisfied with their ability to use technology in their teaching. Similarly, the largest discrepancies between teachers’ ratings of importance and availability of specific technology support involved assistance to set up and program equipment, fiscal resources, and training” (p.13). Our study focused on the identification of the technology needs of teachers and their interest in utilizing numerous technologies in their instruction to provide a more current review of the status of technology use in special education.

The Study

Research Questions

1. How do special education teachers self-rate their technological knowledge and skill level?
2. Given a list of 24 technologies (including hardware & software), do special education teachers use or not use them in their instruction?
3. Is there a correlation between the self-rated knowledge and skill level and the use or non-use of these 24 technologies?
4. What is the special education teachers' level of interest in attending demonstrations or workshops of the 24 technologies?

Participants

The participants in this study were 144 special education elementary teachers assigned in grades P-K to 5 and employed in two school districts in southeastern Florida. School district one had a total student enrollment of approximately 145,000 students and district two had a total student enrollment of 80,000 students. Teachers surveyed included: (a) specialists teaching in varying exceptionalities (cross-categorical) resource classrooms; (b) teachers instructing in self-contained emotional/behavioral disorder classrooms; (c) teachers providing instruction in classrooms implementing inclusion, and (d) teachers serving students in pre-kindergarten special education classrooms.

The mean number of years teaching experience of the respondents was 11.29. Of the 144 participants, 131 or 91% were female, 11 or 7.6% were male. Two teachers did not respond to this question. Thirteen percent of the teachers had assignments in P-K, 26 % of the participants were teaching in grades 1-3, and 29% were assigned in grades 4-5. Additionally, 25 % indicated they taught in other categories: 4% grades 1&2 only; 13% were assigned to grades 2&3 only; and 8% indicated they taught in all grades. Eight percent of the participants did not respond to the grade level teaching assignment question that was asked of the special education teachers.

Instrument Design

The instrument was developed by initially generating a list of important items based upon the researchers’ prior experiences developing surveys. Secondly, a draft of instrument was created to elicit information from teachers to determine how well the research questions might be answered. Ten special education teachers reviewed the initial draft and provided feedback and suggestions for improving the questionnaire. The second draft of the instrument was piloted with 18 special education teachers from six elementary schools. The final survey contained 19 items and required approximately fifteen minutes to complete. Quantitative data were collected using the paper and pencil method for completion of the instrument.
Data Collection

After approval from the university as well as the school districts central administration to conduct the study, a letter was sent to elementary school principals in the counties requesting permission to survey the special education teachers. A two week deadline was requested for return of completed surveys. Follow-up phone calls were made after the deadline to increase questionnaire submissions. All questionnaires were returned after eight weeks for data analysis. A total of 210 surveys were distributed and 144 completed surveys were collected for a return rate of 69%.

Data Analysis

The quantitative data from the survey items were analyzed using SPSS for Windows v. 10.0. A Microsoft Excel 2000 spreadsheet was designed to improve the reliability and ease of entering and organizing the data from the completed survey.

Results

Addressing the Research Questions

In order to answer the research questions, the participants were first surveyed on whether or not they used 24 different technologies in their instruction. These technologies included: (a) VCR; (b) Laser Disk; (c) Computer; (d) Printer; (e) CD-ROM; (f) Scanner; (g) Camcorder; (h) Digital Camera; (i) Conferencing Camera; (j) Touch Windows; (k) Switches; (l) Power Pad; (m) Intellikeys; (n) Muppet Keyboard; (o) Voice Recognition Software; (p) Word Processing Software; (q) Presentation Software; (r) Desktop Publishing Software; (s) Spreadsheets; (t) Database Software; (u) Electronic Mail; (v) Web Browsers; (w) Educational Games; and (x) Encyclopedias.

The teachers were then asked the frequency with which they believed they would use each of those technologies in their instruction. Finally the participants were surveyed on their level of interest in attending demonstrations or workshops on each of the technologies. This paper only addresses research questions one, two, and three.

Use of Technologies for Instruction

The teachers reported the use and non-use of the 24 technologies in their classrooms in the following manner: (a) VCR 88.4% used, 11.1% not used; (b) Laser Disk 25.5% used, 74.5% not used; (c) Computer 88.4% used, 11.1% not used; (d) Printer 76.1% used, 23.9% not used; (e) CD-ROM 60.6% used, 39.4% not used;

(f) Scanner 12.6% used, 87.4% not used; (g) Camcorder 24.4% used, 75.6% not used; (h) Digital Camera 11.8% used, 88.2% not used; (i) Conferencing Camera 0% used, 100% not used; (j) Touch Windows 16.2% used, 83.8% not used; (k) Switches 8.9% used, 91.1% not used; (l) Power Pad 3.7% used, 96.3% not used; (m) Intellikeys 8.9% used, 91.1% not used; (n) Muppet Keyboard 2.2% used, 97.8% not used; (o) Voice Recognition Software .7% used, 99.3% not used; (p) Word Processing Software 72.1% used, 27.9% not used;

(q) Presentation Software 17.8% used, 82.2% not used; (r) Desktop Publishing Software 35.6% used, 64.4% not used; (s) Spreadsheets 17% used, 83% not used; (t) Database Software 11.9% used, 88.1% not used; (u) Electronic Mail 15.6% used, 84.4% not used; (v) Web Browsers 14.1% used, 85.9% not used; (w) Educational Games 73.5% used, 26.5% not used; and (x) Encyclopedias 37% used, 63% not used.

Regularity of Use of Technology

An Analysis of Variance (ANOVA) procedure was used to compare the mean scores among the four skill level groups identified through the Technology Needs Survey for ESE Teachers, and to determine whether significant differences existed among these four groups in their beliefs of the regularity with which they might use various technologies in their instruction. Analysis of variance, or ANOVA, is a method of testing the null hypothesis that several group means are equal in the population by comparing the sample variance estimated from the group means to that estimated within the groups. This procedure was conducted for each of the 24 technologies included in section four on the survey.
Statistically significant differences were found among the four groups for four of the 24 technologies on the questionnaire including the perceived use of a laser disk player, scanner, camcorder, and digital camera. Table 1 presents an ANOVA summary for the questions pertaining to these four technologies. Once it was determined that differences existed among the means for these four technologies, Tukey's Honestly Significant Difference (Tukey HSD) post-hoc comparison tests were performed to determine which skill level groups among the four differed significantly in their beliefs about which technologies might be useful in their instruction. The Tukey method uses the standardized range statistic to make all of the pairwise comparisons between groups. This method is designed to compute all pairwise comparisons while maintaining the experiment-wise error rate at the pre-established alpha level, in this case 0.05. The four skill level groups of the questionnaire were used as the factor for purposes of this statistical analysis. The questions pertaining to the possible frequency of use of 24 different technologies in instruction served as the dependent list.

Questions: How regularly do you believe a laser disk player, a scanner, a camcorder, or a digital camera could be integrated into your instruction?

Statistically significant differences were found among the four skill level groups in their perceived regularity of use in instruction of a laser disk player [F (3, 92) = 3.28, p = .025], a scanner [F (3, 90) = 3.77, p = .013], a camcorder [F (3, 93) = 5.16, p = .002], and a digital camera [F (3, 90) = 6.45, p = .001]. Those participants identifying themselves as beginners responded statistically significantly different in their perceived frequency of use of a laser disk player, a scanner, and a camcorder in their instruction than those participants who identified themselves as being intermediates. No statistically significant differences were found among any other skill level groups with respect to their perceived frequency of use of these first three technologies.

Those participants identifying themselves as beginners responded statistically significantly different in their perceived frequency of use of a digital camera in their instruction than those participants who identified themselves as being intermediates or advanced users. No statistically significant differences were found among any other skill level groups with respect to their perceived regularity of use of a digital camera. In all cases, the beginners responded that they believed they would use these technologies less regularly in their instruction than the intermediates or the advanced users. It is even more interesting to note that those identifying themselves as
novice users of technology did not respond significantly different than advanced users in their perceived regularity of use of 24 technologies.

References

Everett Rogers (1995), in his renowned book, *The Diffusion of Innovations*, established a framework that helps us understand the complex process by which new ideas and practices are adopted by individuals and organizations. Simply stated, an innovation presents people with alternative ways of doing things and solving problems. Individuals and organizations must then decide whether to adopt these alternatives and change their practice or reject the innovations in favor of more “tried and true” approaches. Rogers asserts that the “diffusion of innovations is essentially a social process in which subjectively perceived information about a new idea is communicated” (p. xvii). The meaning of an innovation, he explains, “is gradually worked out through a process of social construction” (p. xvii). Under favorable conditions, a “critical mass” of users will eventually adopt the innovation and it becomes an accepted practice. In the absence of supportive conditions, however, many innovations fail to take hold and are abandoned for more established approaches.

This section consists of papers that examine efforts to promote the diffusion of technology in a variety of educational settings. The first six papers are research reports on the adoption and integration of technology in K-12 classrooms. The next four papers address efforts to infuse a technology emphasis throughout university programs. The following four papers provide descriptions of collaborative partnerships between universities and K-12 schools—followed by four reports of professional development models. A group of nine papers then examine the use of Internet-based learning environments. The next two papers focus on issues pertaining to standards for technology use, followed by four papers that give insights into the various facets of technology integration. Finally, the remaining four papers address theoretical issues involved in technology diffusion efforts.

The first set of papers examines the technology diffusion process in K-12 schools. Cavanaugh describes an online technical support database for educators. This resource provides troubleshooting tips, hardware upgrade procedures, multimedia tutorials, and links to additional resources and vendor updates. Gibson examines the effects of providing laptop computers for K-12 students in a rural community. He addresses issues such as the influence of having access to the technology on the learning process and teachers’ pedagogy. O’Rourke highlights a key element in the diffusion process in elementary schools—opinion leaders who exert influence on their peers. Implications of her findings are discussed. Rodriguez and McDonald evaluate a Web-based middle school science curriculum and identify factors that are related to effective implementation of the curriculum. Scagnoli and Willing describe efforts to integrate various subject areas via a Web-library. Topp, Doshier and Schlager’s paper focuses on the development, implementation, and impact of multidisciplinary, thematic units used within the school curriculum.

The second group of papers reports on efforts to diffuse technology components in university programs. Ferguson and Mahoney discuss issues associated with their P3 sponsored project for revising their two required preservice technology courses. Brown and Appleman describe the formation of an organization for education students who are interested in instructional design. This group, Students in Multimedia Studies (SIMMS), was created to support people interested in expanding their skills beyond those required for standard instructional design situations. Snelbecker, Slesaransky-Poe, Fitt, Miller and Gallo describe a variety of strategies to infuse technology in a large, urban teacher education program. Cerejo, Mortensen and Holcomb report on distributed learning models used in their Department of Technology and Cognition.

The papers that follow document university/K-12 collaborative partnerships. Kemker, Schullo and Fitzpatrick describe the services provided by the Florida Center for Instructional Technology Preview Center located in the College of Education, at the University of South Florida. The center offers opportunities for K-12 teachers to examine over 3000 software and multimedia titles, hardware devices like Smart Boards and digital cameras, and provides workshops for using the technologies and integrating their use into instruction. Sugar, Parke and Pedersen present details about the development of a
collaborative network that supports their university-school partnership. Wilkinson and Nel describe efforts in South Africa in which the Technicon Free State launched its Adopt-a-school program to provide professional development and other technology assistance to a secondary school in need of these services. Wolfe, Ashley, Nancy, Taylor and Wolff tell about a collaborative project in which content and teacher education faculty as well as elementary and secondary teachers redesigned curricula for implementation at their various sites.

The next cluster of papers focuses on models for professional development with technology. Jenks and Strickland describe the implementation and evaluation of a program designed to train technology mentors for rural school districts. The Technology Integration Mentors in Education (TIME) is a "train the trainers" model aimed at diffusing technology throughout a rural western state.

Bailie examined data from a survey to see how results from local educators compared with results from a nationally normed survey. One focus of the survey was professional development. Anderson and Starrett describe the process whereby a university's retention, promotion and tenure guidelines were revised to value professional development associated with professors' infusion of educational technology into their university courses.

Finally, McCurry explores inservice teacher education through the lens of two theoretical constructs—Rogers' Diffusion of Innovations theory and Vygotsky's constructivist concept of Zone of Proximal Development.

Following is a group of papers that documents the proliferation of learning environments enhanced by the Internet and related technologies. Hsu, Cheng, Chiu and Chen examined the use of the Internet in a High School in Taiwan. Teachers' attitudes and use of the Internet in instruction were compared before and after an intervention by the researchers. Findings indicate Internet use increased after the intervention, and that teachers recognized an increased need for assistance in teaching with the web as they progressed. Donohue and Ison describe how they quickly and easily get teachers to design slide shows and interactive quizzes and construct online curricula using a series of online tools. Gareau discusses how Javascript can be used to develop interactive online applications and Eckert describes a system that allows instructors and students to manipulate the same computer over a network. Pemberton, Tyler-Wood, Cereijo, Rademacher and Mortensen assess the effectiveness of the EnVision System as a tool for monitoring practicum students from a distance for their Educational Diagnostician Program. In a related paper, Pemberton, Cereijo, Tyler-Wood and Mortensen describe further efforts to use distance technologies in this program. Richardson & Felkel tell about their work with Web-based video in a business calculus class and St-Pierre focuses on practical suggestions for building and using Web sites to support teaching. Finally, Maraschin, Smith, Tamusuiunas, Costa and Rickes describe a project in Brazil in which a group of teachers used web-based collaborative writing tools in a distance learning seminar.

The next two papers focus on issues related to standards for technology use. Georgi examined similarities between California technology standards and standards developed in the ISTE NETS project. Baines and Belvin looked across a technology standards and content area standards to find areas of overlap. They hope to distill the multiple standards documents into a unified set of standards.

Technology integration is the common theme in the next cluster of papers. Dias examined the relationship between teachers' pedagogical practices and the ways that they integrated technology into their instruction. She found consistency between constructivist teaching methods and instructional uses of technology as a tool to support student learning. In his paper, Foster explored connections between integrating technology into the classroom and teachers' self-efficacy, motivation and the perceived utility of the technology. Baylor and Ritchie identified factors that influenced several issues associated with technology integration (i.e., technology's influence on developing higher order thinking skills and teachers' technological competency).

In her paper, Lim shares a framework for integrating technology in teaching and learning that she believes will guide institutions in adopting innovative educational practice.

The last set of papers all address theoretical issues pertaining to technology diffusion. Duffield, Grundmeier, Stocker and Raymond provide a review of the literature in which they examined the ISTE Essential Conditions for Implementing NETS for Teachers in light of theories of diffusion, innovation, and adoption. Knodel and Knodel discuss how developments in artificial intelligence are enabling the creation of software-based tutors and teaching assistants. Chen and Thielemann describe how a lack of technology has contributed to the digital divide and suggest ways that teachers can access resources to promote equity. Remidez, Laffey and Musser address another issue—that of open source software development and how it can benefit teacher educators. Finally, Szabo describes what he believes is a major revolution—the information communications technology revolution—and hypothesizes how educators can minimize the shock and turmoil that we are likely to face.

starrett@cstl.semo.edu

Abstract: An effort by a committee at Southeast Missouri State University to provide support to faculty infusing technology into their teaching led to the creation of a document that provided suggested guidelines for judging these efforts in merit, tenure, and promotion. This paper describes the guideline document and the efforts that were taken to develop it. This paper also outlines the technology infusion efforts of two faculty involved in training teachers at the university, one in education and one in biology, and describes how they used the document to file for merit recognition.

Teacher education institutions are being asked to respond to the changing career market faced by today’s public school students. Predictions for these students indicate that many jobs will require expertise in technology. In 1996, statistics predicted that five of the ten fastest growing jobs would require computer experience (College Planning Network, 1996). As a consequence, businesses are asking the public schools to produce students who are comfortable in the use of technology (USDL, 1991). Parents too, are demanding that their children be trained to use technology as a part of their school program (Trotter, 1997).

In response to these conditions, teacher education institutions are increasingly integrating technology into their teacher training programs in an effort to produce future teachers who are comfortable using technology in their classrooms. Both education faculty and those responsible for the arts and sciences courses that support the training of teachers are being asked to infuse technology into their university courses (NCATE, 1997). Recent research has demonstrated a correlation between the modeling of appropriate use of technology in college courses and the successful training of technology-using teachers (ISTE, 1999). Indeed, professional organizations whose job is to judge college and university teacher education programs for continued certification are now requiring the infusion of technology into teacher preparation courses (NCATE, 1999).

While the infusion of technology into teacher education is now required, the merit, tenure and promotion guidelines of many universities have failed to respond to this requirement. Though technology infusion is expected by professional organizations, many education colleges, while expecting written publications from their faculty, fail to award publication credit to the technology products of their faculty for merit, tenure and promotion (Johnson, Johnson, and Epstein, 1998). Facing the choice between traditional requirements for continued employment and using technology, faculty might opt to focus on the former...
activities over technology infusion efforts in their teacher training courses. These choices can pit the desire of the teacher education administrators to receive positive NCATE approvals that includes technology infusion requirements against the desire of the faculty to succeed in their teaching positions.

Facing this dilemma, Southeast Missouri State University made an effort to reward the infusion of technology into the university and its teacher education program. The effort began with a motion in the Faculty Senate to revise the wording of the Faculty Handbook tenure and promotion guidelines to recognize these efforts. This motion was not successful. In 1999, in order to provide recognition for the technology efforts for those who were using technology while not threatening those who were not infusing technology, the Interim Provost brought together representatives of all of the colleges of the university. This included those colleges involved in the training of teachers, the College of Education and other colleges in the arts and sciences that support teacher education. The task of this committee, the Information Technology Faculty Roles & Rewards Action Team, was to design a document that would act as a series of recommendations to the promotion and tenure-granting committees on campus, acknowledging the technology efforts of those faculty who were infusing it while still maintaining the current language of the tenure and promotion guidelines.

The committee began by researching the rationale for creating the document. Together, they collected university mission statements that focussed on the inclusion of technology within instruction at the university. In addition, the committee felt that a mission statement and charge from the provost was not adequate rationale, that substantiation of these technology efforts with successful student learning was also necessary. To collect this part of the rationale, the literature of learning with technology was researched for its instructional benefits. This information was also included in the document, providing a strong motive for the document's use when making decisions about merit, tenure and promotion. Next the committee collected examples of technology initiatives within the university. These initiatives were compiled and sorted within the three traditional areas of tenure: research, service and teaching, with a description of the interpretation for each area. The resulting document, Information Technology Faculty Roles & Rewards Action Team Information Technology Promotion, Tenure, and Merit Guidelines (manuscript in preparation), was then distributed to the Dean's Council where it was accepted. Subsequently, it was distributed to the faculty where it is currently in its first year of use.

Description of Document

The ITFRR Promotion, Tenure, and Merit Guidelines document that was produced by the committee was divided into three parts. The introduction provided the rationale that led to the creation of the document. Included in this part is a synopsis of the mission statement of the university which includes the infusion of technology. Included also is a summary of the benefits of using technology in teaching. Finally, included in this part of the document is a statement that governmental officials and parents want their students to be exposed to appropriate technology in their education program.

The second part of the document is a description of the three areas commonly judged for merit, tenure and promotion. The document describes common faculty technology uses that might fit within each of these three categories. For example, it elaborates on a description of how class Web pages might be included within the teaching category.

The final portion of the document is a listing of the common technology initiatives that faculty engage in and how they might be classified when filling out papers for merit, tenure and promotion. It provides an outline of where these initiatives best fit within the three traditional areas as described in the faculty handbook. The list can then be a guideline for faculty who use technology to develop their papers for merit, tenure, and promotion. It also acts as standards for those faculty who make judgements about merit, tenure and promotion awards. A copy of this document is available on the Internet at http://cstl.semo.edu/itfrr.
Case Study of Biology Faculty

The Department of Biology at Southeast Missouri State University prides itself on being current in educational practices and being a forerunner in acceptance of new techniques and technologies. The faculty member described here was hired into the department in the fall of 1995 as a plant physiologist. During his five years of teaching within the department, his teaching was determined to be very effective based on peer-review, student ratings of instruction, and anecdotal evidence. He also developed a successful research program involving many students. During those five years, he published five peer-reviewed journal articles, obtained a research grant from the US Department of Agriculture, and was in general active within his field as evidenced by attendance and presentations at numerous professional meetings in his area. His record in the area of service included active participation on department, college and university level committees, including two years on Faculty Senate. Also, he became heavily involved in faculty development via his collaborative work with the Center for Scholarship in Teaching and Learning. His use of technology to enhance teaching led to his being chosen to facilitate workshops that provided training in the area of technology to other faculty on campus.

The involvement in faculty development became very heavy as he continued to be involved in the planning and development of the training workshops and continued to facilitate many sessions. This quickly led to his inclusion as a Technology Associate, an advisory committee that advises the center on directions the University should take in the inclusion of instructional technology into teaching and learning at Southeast Missouri State. This heavy commitment to the use of technology led to him being appointed Director of the center at the end of his fourth year at the University, a 3/4 time position leaving him 1/4 time in the Department of Biology. Based on his achievements in Teaching and Scholarship, he was encouraged to go up for promotion and tenure a year early, during his 5th year at the University.

The Department heartily approved his Record of Service in the areas of Teaching and Scholarship with strong evidence of effective teaching and the peer-reviewed publications and outside grant funding leading the way. Interestingly, Service was rated the lowest of the 3 traditional areas. Much of the evidence documented for service related to the faculty member's involvement in faculty development in the area of integration of technology into teaching and learning. This was ironic in light of the Department's stated position on being openly accepting of new technologies and being a fair judge of faculty accomplishments, etc.

The guideline document described had not been released to the campus at the time of the promotion and tenure process described above. However, some of the justification and approach used in the document were included in the record of Service. Nonetheless, it was apparent that the heavy involvement in the integration of technology was not considered with as great a weight as other more traditional pieces of evidence were. It is hard to say what effect the document might have had had it been circulated previous to this process. The document had however been circulated when the described faculty member submitted his merit report for CY 1999; a time frame which included six months of service fulltime in the department and six months as Director of the center. In this case, the heavy involvement in technology was recognized and rewarded. It is hard to say whether the document was responsible for this in any part, but it is likely that it had some impact.

The Department of Biology serves Science Education majors as well as Secondary Education majors in other fields. The above-described faculty member has taught classes for majors and non-majors both and thereby has taught many students majoring in some form of education. Technology was integrated into many of his courses in the form of PowerPoint presentations, course-enhancing web materials, and even technology-oriented activities in biology. He has even taught a non-majors course completely on-line. Technology has also played a role in his scholarship as he has attended and presented at technology-in-education-oriented meetings and conferences and has recently submitted a book chapter on the creation and maintenance of web sites. The role of technology in service has been described above. Given that education students learn not only by content but also by example, the integration of technology into the classroom is an
important aspect of the education received by these students. In order to promote effective use and integration of new technologies, it is important to teach by example. To this end, it is essential that the use of technology by faculty be recognized and rewarded by colleges and universities. The development and use of the guideline document described is one step in moving toward a more just recognition of the use of technology in the classroom by faculty teaching the teachers of tomorrow.

Case Study of Education Faculty

In the College of Education, the document, Information Technology Faculty Roles & Rewards Action Team Information Technology Promotion, Tenure, and Merit Guidelines served as a tool for classifying technology infusion activities according to the three traditional areas of merit, tenure, and promotion. One education faculty member's technology activities were spread across the three areas of teaching, research, and service. Using the document as a guide, most of the technology activities of the education faculty member fell into the area of improvement of teaching, followed closely with the area of service. However, the efforts in both of these areas led to technology-infusion activities that fell into the area of research.

The education faculty member taught courses that included instructional methods courses in special education, educational theory courses for regular education graduate students, and instructional technology courses for both regular education and special education. The technology infusion efforts in her education courses included many uses of computer-based technology ranging from simple email assignments to demonstration of sample technology-integrated lessons for her students.

In teaching courses in special education, the education faculty member infused technology by requiring Internet searches in several areas. These searches included such things as searching for information on different disabilities, searching for communication methods to use with diverse parents, and information on different education theoreticians. The students worked in groups and were taught to use chat rooms to enable them to communicate within their groups as they searched for information on their disabilities.

Another introductory course in special education that this faculty member taught was accomplished entirely online. Students in this course were required to communicate using several technology methods. They used a bulletin board to post case study assignments, communicated via email and chat lines for group research papers on different disability areas and used instructor-created Web pages for information. These activities were identified by the guidelines paper as teaching effectiveness efforts.

In teaching educational theory courses, the education faculty member infused the use of email, searching the Internet, educational software demonstration, and production of multimedia projects. In this course, the instructor introduced a variety of cognitive educational theories and the theoreticians who developed them using PowerPoint slides. As a part of the course, the instructor required her students to develop a research paper on one of the cognitive theoreticians and to teach a lesson that reflected that theory and infused technology. The students were taught Hyperstudio to do the presentation. To accomplish these projects, the students searched the Internet for information on the theorists and emailed a draft to the instructor. As each of the theories was discussed in class, the instructor demonstrated educational software packages that reflected that particular theory, followed by the student presentation on the theory and their sample lesson that infused technology. All of these technology efforts were identified by the guidelines document as efforts to improve teaching.

Two technology emphasis areas were created by the faculty member for the elementary and secondary programs, one at the undergraduate level and one at the graduate level. In these courses, the education faculty member used many methods of technology infusion. The education faculty member demonstrated technology-infused lessons, using a variety of software packages and relevant Web sites for a variety of subject areas. For
each subject area, in addition to the software, she had the students create lessons for their students that used the Internet and then required them to find relevant Web sites to direct their students to use in their lessons. She provided hands-on use of special education technology, even requiring her special education graduate students to make a switch for their students. She used PowerPoint to present methods of making Web sites accessible for people with disabilities and then had students make accessible Web sites. She used email pen pals for her students to keep in touch with students in a K-12 classroom. Students looked up lessons on the Internet and turned them into lessons that were authentic activities using graphing software. Again the guideline document identified these as teaching improvements.

These teaching activities led to other opportunities that the guidelines document placed into the service and research categories. Several of the teachers in the courses that this faculty member taught requested her to come to their schools and provide an in-service for their faculty. She became a regular in-service provider to train their teachers to use the new technology. She served the university on several technology committees, at the departmental level, the college level, and the university level. She was asked to provide several in-services for faculty at each of these levels also.

Research and publication efforts also emanated from the technology activities that this faculty member used in her teaching. She was able to write and serve as primary investigator for several grants that used technology. She was primary investigator for an Eisenhower grant that purchased software for the regular education and special education teachers who participated in the courses she taught. These teachers developed technology-infused activities to prepare their students for state assessments. She was co-investigator and primary investigator for two grants that purchased hardware and software for regular and special education teacher candidates to use in their field experiences. The guideline paper suggested to her that these activities were properly placed into the research category.

Also in the research category, this faculty member provided several peer-reviewed state, regional and national presentations on technology use. She published five peer-reviewed articles about technology use in education, as well as a chapter in a textbook. Each of these activities were identified by the document as research activities.

Thus the guidelines document provided suggestions about the listing of technology infusion activities in this education faculty member’s record of service. This education faculty member had technology infusion activities that fell within the categories of the improvement of teaching, service to the region and university, and research activities. These technology infusion efforts allowed this faculty member to achieve the highest level of merit offered by her department in the College of Education.

Conclusion

The Information Technology Faculty Roles & Rewards Action Team Information Technology Promotion, Tenure, and Merit Guidelines document was developed to provide guidelines to faculty at Southeast Missouri State University. These guidelines were designed to serve both as recommendations for classifying technology efforts for those faculty infusing technology and as suggestions for those involved in making judgements about these efforts for merit, tenure, and promotion. Future plans for this document include the collection of data from faculty members at Southeast Missouri State University and evaluation of its impact on the merit, promotion and tenure process there.

Comparing a Local School District's Teacher Use of Computing With National Survey Results

Frances K. Bailie, Ph.D.
Department of Computer Science
Iona College
United States
fbailie@iona.edu

Abstract: Funded by the National Science Foundation and the U.S. Department of Education, the Center for Research on Information Technology and Organizations conducted a national survey of schools and teachers entitled, "Teaching, Learning, and Computing," administered to a large diverse suburban school district. The purpose of this local survey was to provide a comprehensive needs assessment focusing on the usage patterns and opinions of teachers toward computing. This paper will summarize the local survey results and then go on to compare the local results with the national survey results drawn from selected reports posted on the Internet. An outline of district plans to use the survey results in guiding the implementation of its technology plan will also be presented.

Introduction

In his State of the Union Address in 1996, President Clinton established the goal of technological literacy for all students as the nation prepared for the 21st century (Pepper 1999). Now that we have reached the new millennium, the educational community is still struggling to meet the President's challenge. Numerous surveys have been conducted to determine how schools and teachers are using computers and the Internet to advance learning. For example, surveys conducted by the U.S. Department of Education, the Office of Technology Assessment, the National Center for Education Statistics, and Education Week document the problems teachers face when trying to integrate technology into the curriculum: hardware and software that are out of date, classrooms that are not wired for the Internet, technical support that is not always available, staff development programs that are not adequate, and lack of time required to use technology effectively (Frank 1999, Oldenburg 1999, Pepper 1999).

Teaching, Learning, and Computing

Funded by the National Science Foundation and the U.S. Department of Education, the Center for Research on Information Technology and Organizations conducted a national survey of schools and teachers entitled, "Teaching, Learning, and Computing 1998." More than 4,000 teachers in grades 4 through 12 in over 1,100 schools throughout the country completed the survey questionnaire. The teacher survey posed questions on teaching philosophy, teaching practice in a single class, use of computers, general teaching experiences, and work environment. The analysis investigated the possible relationship between a constructivist philosophy of teaching and computer use. Possible correlates were computer experience, teacher responsibility and experience, educational background, and support for use of technology and constructivist practices. The survey was administered in 1998 and results were posted on the Internet starting in 1999. The availability of national results from such a comprehensive survey provided an excellent opportunity to conduct the survey on a local level and then compare the local results to the national results.
Local District Survey

The New Rochelle School District is a large diverse suburban district with a high school, two middle schools, and seven elementary schools. As is the case with most districts, New Rochelle is held accountable by its Board of Education and the New Rochelle community to develop and implement a comprehensive technology plan. The city of New Rochelle recently passed a technology bond to fund advances in computer technology in the schools, primarily in the form of improvements to the infrastructure. Looking beyond the hardware and wiring additions to their schools, district leaders felt that a comprehensive needs assessment, focusing on the usage patterns and opinions of their teachers toward computing, would be an valuable tool in guiding future technology decisions. One method of gathering data was to survey the teachers in the district to determine their use and level of expertise with technology. To that end, a modified version of the Teaching, Learning, and Computing Survey was developed that drew questions primarily from the sections on use of computers and work environment. The survey also contained other questions, including demographics (such as subjects and grades taught) and general opinions about computing and the Internet. These additional questions were based on a survey conducted by the Texas Center for Educational Technology, entitled “Teachers & Technology: A Snap-Shot Survey.” The newly designed survey was distributed in September 1999 to all teachers in the district; participants were instructed to base their responses on their teaching practices during the 1998-1999 school year. After the completed surveys were collected, the data were coded and entered into SPSS for analysis.

Local Survey Results

Responses were received from 270 teachers in the district (a little more than 50%). Demographics revealed that over one quarter of the teachers had been teaching for over twenty years. The survey revealed a moderate indication that younger teachers have a higher level of comfort with computers than their older peers; only 13% of the respondents rated themselves at the highest level of computer use. Over 80% of the teachers reported that they needed more time to use computers and the Internet, more training in technology integration, more curricular-based software, computers and Internet access and more technical support. This was a disturbingly high percentage, given the fact that the district had been very diligent in providing computers, staff development opportunities, as well as technical and instructional support to its teachers for many years. Yet, despite these efforts, teachers still appear to feel inadequately prepared when it comes to exploiting the power of computers in the classroom.

Fewer than half of the teachers reported using computers in class. The most popular objectives teachers cited for using computers in class were learning to work independently, mastering skills and remediation; word processing and games for practicing skills were the software most often assigned. It was encouraging to find that a number of teachers have a computer at home and some have Internet access. However, their competencies lie primarily in searching the Internet as opposed to more demanding tasks such as preparing a presentation or a multimedia document. Teachers reported that Internet access was the most valuable technology needed in the classroom.

Only 16% of teachers reported that they discussed computers and software on a regular basis with their colleagues; contact with teachers from other schools was rare. Despite the district’s efforts to provide staff support, only 29% of teachers believed that staff development activities were followed by support for implementation, 26% of teachers believe that teachers play an important role in defining staff development activities, and fewer than 20% of teachers report that the Internet and its use were a central topic of discussion. The lack of classroom Internet access and useful curriculum-based software were notable deficiencies. Teachers further reported a lack of instructional (77%) and technical (70%) support.

Comparison to National Results

While some of the preliminary results were encouraging, many of them appeared alarming on the surface. The question to be answered was how they compared to the results of the national survey on Teaching, Learning, and Computing. As mentioned above, the national survey results were posted on the Internet. Two reports, “Internet Use by Teachers: Conditions of Professional Use and Teacher-Directed
Use" and "Teacher and Teacher-Directed Student Use of Computers and Software" and two snapshots, "Technical and Instructional Support for Teachers" and "Professional Development" formed the basis of the comparisons described below. Since the national survey included only teachers from 4-12 grades, results from lower grades in New Rochelle were eliminated from the comparison tests. For the reports that were of particular interest to the New Rochelle School District, local data was analyzed to align as closely as possible with the national data. Not all questions of interest could be compared because in several instances questions had too few responses to formulate a valid comparison.

Internet Use

One of the major areas of concern in the New Rochelle School District is the lack of classroom Internet access, particularly at the middle and high school level. The survey shows that 95% of middle school classrooms and 90% of high school classrooms have no access as compared to 60% and 61% nationally, yet 83% of teachers rated classroom Internet access essential to their teaching. The situation at home appears to be no better, with only 11% of New Rochelle teachers having home access as opposed to 59% of teachers in the national survey. However, it is encouraging that despite their lower access rate, New Rochelle teachers report about the same (email use and posting information) or higher (lesson plans) percentage of use of the Internet.

Computer Use

New Rochelle teachers (45%) lagged behind their national counterparts (71%) in the use of computers in the classroom. One reason for this may be the higher student to computer ratio in the New Rochelle schools. The ideal ratio appears to be about one computer for every four students. Only 6% of New Rochelle teachers reported this low ratio as compared to 13% of national survey teachers. According to the national survey, the average student to classroom computer ratio is 6 to 1, whereas the average in New Rochelle is 12 to 1. It is important to note that most of the computers in the district are currently located in computer labs rather than in classrooms. While important, the number of computers is not as crucial an issue as how teachers are using them. Another area of concern for New Rochelle is that 79% of their elementary school teachers rely heavily on games and drills. A possible explanation is that most New Rochelle teachers report remediation as an important objective for computer use. In fact, 63% of New Rochelle teachers who assign games and drills value remediation as an objective, as compared to 39% nationally. Elementary school teachers in New Rochelle are to be commended for a higher mean number of computer skills (3.7 out of 7) than the national elementary school teachers (2.6 out of 7). Middle school teachers in New Rochelle, however, came in lower (2.6 out of 7) than the national middle school teachers (3.4 out of 7).

Work Environment

New Rochelle can take pride in the fact that twice as many elementary school teachers (61%) report staff development sessions in critical thinking than the national survey teachers (32%). Yet staff development sessions in computer related topics are slightly lower in New Rochelle (21%) than they are nationally (32%). Technical support in New Rochelle appears to be better than in national schools. New Rochelle teachers report that when they need support, it is available over 68% of the time, whereas national teachers report that it is available less than 23% of the time. On the other hand, instructional support in New Rochelle might be improved since it is available only 9% of the time as compared to being available 25% of the time nationally.

Discussion

It appears that the New Rochelle school district has made great strides in providing effective computer use for its teachers and students. The level of technical support that is provided is also
commendable by comparison to national survey results. Perhaps the area in which New Rochelle is most
deficient in comparison to the national survey is in the number of classroom computers and classroom
Internet access, particularly at the middle school and high school levels. There is wide agreement that
despite the fact that most students have their own computer when they go to a computer lab, having four or
five computers in the classroom significantly increases the number of computer assignments and the
number of contact hours a student receives. Moving computers from the labs into the classrooms would be
a significant improvement. Of course, wiring costs need to be addressed, especially to provide Internet
access in the classrooms. Teachers themselves need more computer access for themselves. As compared
to the national survey teachers, very few of them have computers at home to help them prepare lessons for
their students. Perhaps purchasing laptop computers that could be assigned to teachers, particularly over
the summer, would help to alleviate this problem.

Survey results seem to indicate that the elementary school teachers fare better than the middle and
high school teachers in their use of computers in the classroom. Many more of them seem to have
classroom computers so they are able to make more frequent assignments. They are also using software
that addresses higher order thinking skills, such as simulations, presentation software, and multimedia
authoring. It is unfortunate that they are also using games and drill and practice as the overwhelmingly
predominant use of computers. This could be attributed to the fact that this is the most readily available
resource that they have. Survey results indicate that teachers, particularly middle and high school teachers,
could use more training and improve their computer skills.

Conclusion

The district has already begun to address a number of the concerns the survey revealed. The
technology bond allowed the district to plan a single network that could be accessed by all schools,
providing increased Internet access that was sorely needed. Each third and fourth grade classroom has
received four computers, with a fifth computer for the teacher planned in the near future. This influx of
computers will reduce the student to computer ratio to 6-1 for the third and fourth grade. They will be
phasing out the dual platform of Macs and IBMs to standardize the interface for teachers and students. The
New Rochelle School District has recently hired two Technology Information Specialists to work on staff
development and curriculum integration in the elementary and secondary schools. Using this survey as
baseline data, the district hopes to repeat the survey at the end of the next phase of the technology plan to
show evidence of the strides students and teachers have made along the path of technological literacy. It is
hoped that the data provided by this survey and comparison analysis will assist them in moving closer
toward the goal that President Clinton proposed nearly five years ago to prepare our students with the
technology skills mandated by the twenty-first century economy.

Rage Towards the Machine: Technology and Standards in 2001

by Lawrence Baines, Berry College (lbaines@berry.edu)
and Lynnwood Belvin, Berry College (lbelvin@berry.edu)

Abstract: With the burgeoning movement to establish standards, many organizations have developed expectations for what a teacher should know and be able to accomplish through technology. We examined standards from accrediting agencies (NCATE, INTASC, and TEAC), professional organizations (NCTE, NCTM, NCSS, NAME, and ISTE), and state departments of education (Florida, Georgia, Tennessee, and Texas). We discuss and evaluate the standards promulgated through these agents in terms of clarity, complexity, coherence, adaptability, measurability, and desirability. Accordingly, the standards of NCATE, INTASC, TEAC, NCSS, NCTE, and ISTE were found wanting, while the standards of NCTM, NAME, and especially the technology standards being developed by the state of Georgia were more fully articulated, logical, and useful for teachers. In general, the more precise standards were stronger, but they were also more temporal.

Over the past twenty years, billions of dollars have been spent on computers, networks, and training. The E-rate program alone has provided America's schools with more than $3 billion worth of Internet access (Riley 2000). Concomitantly, there has been a surge of interest in national standards. Over the past decade, almost every professional organization even slightly related to teacher education has formulated, promoted, and distributed their own particular set of standards. Every state except Iowa has developed standards in at least some subject areas. Forty-four states have standards in the four core areas -- English, math, science, and social studies. Often the core standards contain explicit expectations for a teacher's technological expertise as it relates to his/her teaching field. For example, in Florida an expectation for a high school language arts teacher is that he/she be able to "select and use a variety of electronic media, such as the Internet, information services, and desktop publishing software programs, to create, revise, retrieve, and verify information" (Sunshine State Standards 2000). Forty-one states require prospective teachers to pass an exam connected to these standards (Education Week 2000).

So many standards, so little time. The array of standards vying for the attention of a teacher can lead as much to confusion as enlightenment. To what extent are the standards compatible? How do they differ? Which standards promote the "highest and best uses" of technology? To answer these questions, we examined a variety of standards as follows:

1) Teacher education accrediting agencies--the National Council for the Accreditation of Teacher Education (NCATE), Teacher Education Accrediting Council, and (although it is not an accrediting agency) Interstate New Teacher Assessment and Support Consortium (INTASC).

2) Professional subject area organizations--the National Council of Teachers of English (NCTE), the National Council of Teachers of Mathematics (NCTM), the National Council on the Social Studies (NCSS), and the National Association for Music Education (NAME).

3) Selected state standards--Texas, Georgia, Tennessee, and Florida.

In the following discussion, we will use italics to emphasize when we are citing a standards document verbatim.

Teacher education accrediting agencies

What is new about NCATE 2000 is the emphasis on candidate performance. Supposedly, no longer will a college of education be able to pass NCATE accreditation by amassing impressive volumes of data on the conceptual framework, faculty accomplishments, and sequence of courses. Instead, NCATE 2000 requires that institutions furnish the accrediting teams with information concerning the performance of candidates in
classroom settings. Although technology is not explicitly mentioned in the six broad standards, under *standard I. Candidate Knowledge, Skills, and Dispositions*, there is an indicator called *Pedagogical Content Knowledge*.

The "target behavior" for pedagogical content knowledge is a teacher who "has an in-depth understanding of subject matter that they plan to teach, allowing them to provide multiple explanations and instructional strategies so that all students learn. They present the content to students in challenging, clear, and compelling ways and integrate technology appropriately" (NCATE 2000 Standards, p. 4). With regard to the professoriate who teach prospective teachers, under *standard 5. Faculty qualifications, Performance, and Development*, the standards mandate that facilities should allow faculty to "model the use of technology...to practice its use for instructional purposes."

TEAC, which was created, in part, as a reaction against the complex, politically-correct gauntlet of NCATE, takes an understandably briefer view. According to TEAC standards, "special attention should be given to assure the technologies that ease the teacher's work and the student's learning are firmly integrated in the curriculum." The only other mention of technology in TEAC documentation is that they consider it advantageous if "graduates have acquired the basic productivity tools." One assumes that technological tools would be included in the definition of basic productivity.

INTASC, an organization formed to forge a consensus concerning model teacher behaviors across state lines (which could lead to more reciprocity among states), lists ten standards. Technology appears only under principle #4. "The teacher understands and uses a variety of instructional strategies to encourage students' development of critical thinking, problem solving, and performance skills." Unlike the similar standard in TEAC, INTASC's "instructional strategies" specify technology: The teacher knows how to enhance learning through the use of a wide variety of materials as well as human and technological resources (e.g. computers, audio-visual technologies, videotapes and discs, local experts, primary documents and artifacts, texts, reference books, literature, and other print resources. (INTASC 2000)

The technology standards promulgated by NCATE, TEAC, and INTASC are brief, vague statements that ask that a teacher use technology as part of a kind of instructional toolkit. While such breadth lends itself to adaptability, the technology standards in these accrediting organizations seem neither measurable nor particularly desirable. Technically, a teacher could fulfill each of these standards by flipping the switch on a transparency machine. Nothing wrong with a transparency machine, mind you, but it would seem to exist some distance from "highest and best use." In practice, NCATE and TEAC accrediting teams converse with faculty and students about the availability of computers on campus and peruse syllabi to determine whether or not an institution meets the indeterminate standards in technology.

**Professional Organizations**

The table below contains expectations for technological competence by organization. The table lists the total number of standards (including supporting standards), the number related to technology, and provides sample, illustrative standards. The professional organizations surveyed include the National Council on Social Studies, National Council of Teachers of English, National Council of Teachers of Mathematics, the National Association for Music Education, and the International Society for Technology in Education.

Table 1: Technology Standards in Selected Professional Organizations

In analyzing the usability of the standards of professional organizations, we were struck by the variance among subject areas. NCSS mentioned NOTHING about the competence of a teacher (let alone her/his prowess in utilizing machines in the classroom) and NCTE boasted a single standard related to technology. On the other hand, both NCTM and NAME set forth expectations that are relatively clear and precise. One could readily discern whether or not a prospective teacher of mathematics could "display a scatterplot, describe its shape, and determine regression coefficients, regression equations, and correlation coefficients using technological tools" so that he/she could teach his/her students to do this. Likewise, a music teacher...
will not be able to fake knowing "how to use MIDI sequencing, music notation software, Internet music resources, and electronic musical instruments" if these skills must be taught.

In comparison to the NCTM and NAME standards, the ISTE standards are trendy and ponderous. Would any sane teacher ever decide to go online to "identify and use technology resources that affirm diversity?" Surprisingly, the ISTE standards are warm and fuzzy, obscure, immeasurable standards that do not offer a teacher much in the way of guidance. For example, according to standard VC., a teacher should "apply technology to increase productivity." Does that mean a teacher should stop giving essay exams and put everything on SCANTRON?

State Standards for Technology

Florida's Sunshine State Standards include expectations for technology skills by grade level and subject area. In grades 9-12, language arts has 14 standards, math-6, science-4, foreign language-5, social studies-7, the arts-11, and health/physical education-4. Most of the technology skills are implicit rather than explicit. For example, in the language arts, a student should be able to "synthesize information from multiple sources to draw conclusions" (Sunshine State Standard L.A.A.2.4.8). In math a student should be able to "analyze real-world data and make predictions of larger populations by applying formulas to calculate measures of central tendency and dispersion using the sample population data, and using appropriate technology, including calculators and computers."

In addition to subject-area standards, Tennessee has created a set of Instructional Technology Standards for Teacher Education Licensure. Instructional Technology standards are to be "infused throughout the teacher preparation program." These 28 standards range from the vague, ISTE-like "ability to integrate instructional technology into the classroom to facilitate interdisciplinary teaching and learning," to the more concrete, "can load and install programs; create, find and manage files; create and use a database; create and use a spreadsheet; utilize a software presentation package to create presentations for use on a computer technology projection system."

The Texas Education Agency recently devised a comprehensive K-12 curriculum, called Technology Applications, that focuses on technology skills and the use of computers. Technology Applications specifies a grade level by which a student must attain competence in a certain technological skill. The TEA proposes eight courses in high school: Computer Science I and II, Desktop Publishing, Digital Graphics/Animation, Multimedia, Video Technology, Web Mastering, and Independent Study. In addition to the separate set of courses, technology is to be integrated across courses. However, the details of ensuring that a prospective teacher can use technology effectively have yet to ironed out. Currently, the only requirement for a prospective teacher of English is that he/she "be able to use several forms of technology without anxiety or fear." Unfortunately, fearlessness does not always equate to "highest and best use."

In Georgia, a set of Technology Integration Standards have been developed as an accompaniment to the state standards, called the QCCs (Quality Core Curriculum). The Technology Integration Standards were developed along the lines of six competencies: basic skills, productivity, communication, societal and ethical issues, research, and problem solving. Each of the competency areas lists several expectations. There are 20 standards in all with 83 supporting standards for grade 12. Basic skill, standard 1 is "Demonstrates the essential skills for understanding, using, and managing technology tools." Supporting standard 1.1 is "Demonstrates appropriate and effective uses of operating systems functions (Graphical User Interface)." Productivity standard 8 is "Creates documents using most desktop publishing functions." Supporting standard 8.5 is "Converts desktop publishing documents into html/web documents."

Unlike the wide range of expectations expressed in the standards of professional organizations, the standards of these four states are more consistently pro-technology and less prone to "educationese" and hyperbole. It is encouraging that Georgia's draft of the Technology Integration Standards attempts to spell out what is meant by "technology integration." The complex list of standards and supporting standards could be used by organizations such as NCATE or TEAC to determine whether or not a student's
performance in the classroom adequately satisfies the technology requirement. Most of Georgia's Technology Integration Standards are clear, attainable, measurable, and sufficiently adaptable.

Conclusions

Individuals who create standards face innumerable pressures and must make hard decisions based upon the best interest of students. The difficulty with formulating standards, and particularly technology standards, is that innovation never rests. As Drucker (1999) notes, "What the new industries and institutions will be, no one can say yet. No one in the 1520s anticipated secular literature, let alone the secular theater. No one in the 1820s anticipated the electric telegraph, or public health, or photography." Creators of standards must feel the impulse to formulate benchmarks that will stand the test of time, irrespective of future developments or technological breakthroughs. NCTE, NCATE, TEAC, and ISTE created broad sets of standards, ran them by innumerable focus groups, and wound up with bland, yet cryptic sets of statements. To be sure, the standards of NCTE, NCATE, TEAC, and ISTE are more akin to proclamations of the particular organization's political leanings than genuine guidance for teachers. The advantage of such mealy-mouthed standards is that teachers may interpret and achieve the standards in innumerable ways. The disadvantage is that they are so broad as to be virtually meaningless.

On the other hand, the standards of NAME, NCTM, and the developing technology standards of Georgia seem more practical, achievable, and desirable. Of course, the specificity of expectations for teachers will require that these organizations revisit and revise their standards as older technologies vanish and new products emerge. To move teachers towards "highest and best of technology," they need to be given advice beyond the edict to "integrate technology into instruction." As we continue to "rage towards the machine," it is useful to keep in mind that nothing lasts forever, most especially standards in technology.

Abstract: Based on a comprehensive study of 94 classrooms from four states in different geographic regions of the country, this quantitative study investigated the impact of seven factors related to school technology (planning, leadership, curriculum alignment, professional development, technology use, teacher openness to change, teacher non-school computer use) on five dependent measures in the areas of teacher skill (technology competency and technology integration), teacher morale, and perceived student learning (impact on student content and higher order thinking skills acquisition). Step-wise regression resulted in models to explain each of the five dependent measures. Teacher technology competency was predicted by teacher openness to change. Technology integration was predicted by teacher openness to change and the percentage of technology use with others. Teacher morale was predicted by professional development and constructivist use of technology. Technology impact on content acquisition was predicted by the strength of leadership, teacher openness to change, and negatively influenced by teacher non-school computer use. Technology impact on higher-order thinking skills was predicted by teacher openness to change, the constructivist use of technology, and negatively influenced by percentage of technology use where students work alone.

Over the past decade, many articles have appeared in popular and educational journals providing anecdotal evidence of changes that educational technology can make in schools. Even though other empirical articles have provided quantitative and qualitative evidence of these changes, most schools rarely base their technology decisions on specific published research findings. Instead, school leaders often start by thinking about the intended results that technology should provide within their school environment. Next, these leaders take certain actions regarding the attainment, allocation, use, and support of technology. Consequently, this study was framed along this line, to consider the question “What actions most effectively lead to desired results regarding the integration of technology in schools?” We considered seven factors (planning, leadership, curriculum alignment, professional development, technology use, teacher openness to change, teacher non-school computer use) and five outcomes in the areas of teacher skill (level of teacher technology competency, technology integration), teacher morale, and perceived student learning (impact on content acquisition, impact on higher order thinking skills) which will be described in the next sections. Data was collected through structured interviews with teachers and administrators, teacher surveys, and examination of school technology use plans. The following sections will describe how each variable was operationalized. For a comprehensive literature review of these variables, see Ritchie & Baylor (1999).

Operational Descriptions of Factors

In this study, technology planning was operationalized from the teacher’s perspective to include the teacher’s role in creating the technology use plan, his/her familiarity with the published vision, and the
belief that the plan considers his/her needs. From the administrator's perspective, it was operationalized to include three components: strategic, teaching/learning and operational. In terms of the strategic component, this included the extent to which the plan stated a vision and involved stakeholders, which may be the most important action regarding technology planning (Anderson, 1996). The teaching and learning component of the TUP covered instructional innovation. The operational component of the TUP included technology maintenance and support, the presence of an action plan and timeline, and facility infrastructure, configuration, and funding issues. Also included were the extent to which technology decision are based on the official TUP, the extent to which records are kept regarding the type and number of technology activities, and the extent to which purchase and use of technology has closely followed the details as described in the TUP.

Technology leadership was operationalized from the teacher's perspective to include the presence of positive technology-using role models, such as the principal, and the presence of incentives for teacher use of technology. From the administrator's perspective, it was operationalized to include the principal's ability and work with the school community to formulate, articulate, and communicate a school's vision (Dede, 1994; Raizen, Sellwood, Todd, & Vickers, 1995; Rhodes, 1994; Sergiovanni, 1995). The principal's use of technology is also included as part of the leadership component since s/he fosters credibility and respect by communicating to the staff via email, demonstrating the use of desktop presentation to the faculty, showing a student how to keep a writer's journal with a word processing program, or describing a technology-enhanced teaching strategy (Maurer & Davidson, 1998). Further, the principal's belief that technology can be integrated into teaching and learning, his/her participation of the principal in school technology training sessions, and the evaluation of faculty and/or school in reaching stated technology goals are also factors. The extent to which the school's technology knowledge and leadership is shared by a variety of faculty is important given that a successful technology leader shares leadership by empowering other school members (Maurer & Davidson, 1998). Also included in the operational definition were the vision of the technology plan to promote technology for teaching and learning, and the presence of an action plan and timeline within the technology use plan.

In this study, curriculum alignment was operationalized from the teacher's perspective to include teacher perception as to whether technology activities are covered through the curriculum documents.

Professional development was operationalized from the teacher's perspective to include the applicability of the professional development programs, incentive provided to attend programs, access to technical support, and appropriateness of technology equipment. From the administrator's perspective, it was operationalized to include the extent to which the school supports faculty to attend workshops or conferences, the listing of professional development activities in the TUP, and the support of school activities to learn to use technology. The latter is important given that teachers require prolonged exposure to new ideas and skills before classroom behaviors change; specifically, to feel in control of educational technologies and to know when and how to use them, can take five to six years (Brunner, 1992; Elmer-Dewitt, 1991). In addition, the extent to which teachers are responsible to determine in-service technology training topics is an important consideration given that to encourage faculty to embrace the concepts delivered during the workshop, it is important to involve them in the selection of the topic (Rubin, 1989). Given that there are varying abilities and knowledge of faculty in a school, seldom will there be agreement on the need for any one in-service topic; consequently, the best strategy would be to identify multiple topics and then involve only people who have needs in the specified content domain (Picciano, 1998). The presence of incentives for incorporating technology was also considered as part of professional development.

For this study, technology use was delineated according to nine subcomponents, each of which were considered separately in the regression models: 1) how often technology was used for preparing for or during classroom instruction; 2) the percentage of time that subject-matter content was the focus of the technology use; 3) the percentage of time that higher order thinking skills (HOTS) were the focus; 4) the percentage of time technology literacy was the focus; 5) the percentage of time technology was used alone by students, responding to questions, 6) the percentage of time technology was used alone by students, creating; 7) the percentage of time technology was used with others; 8) the percentage of constructivist use of technology; and, 9) the perceived success of technology use by teachers.

Based on this research, in this study teacher openness to change was operationalized from the teacher's perspective to include his/her predisposition for trying new instructional innovations, and the belief that s/he can take risks in teaching. From the administrator's perspective, teacher openness to change...
was operationalized to include whether the technology use plan promotes instructional innovation with technology implementation.

Teacher non-school computer use was operationalized in this study from the teacher’s perspective to include the number of times technology (e.g., word processing, database, spreadsheet, graphics, multimedia, telecommunications) was used at home for non-school activity.

In the previous sections, we examined the factors that may determine the success of technology in a classroom. But what are the areas that schools want to impact? The dependent measures are explained in the next sections. Note that several of the factors described previously could be considered interchangeably with the desired outcomes (e.g., it could be argued that high teacher morale should be an independent variable that affects the degree of success in using technology). However, the factors were purposely selected to serve as predictors, and the outcome measures as dependent variables.

**Description of Dependent Measures**

Impact on content acquisition was operationalized from the teacher’s perspective to include the relative impact/importance of technology in terms of the content acquisition, in other words, the extent to which the use of technology added to the class performance in content acquisition. From the administrator’s perspective, it was operationalized to include the role of the Technology Use Plan’s vision in promoting technology for teaching and learning, and the reflection of the plan in describing the use of technology by students to enhance learning based on current knowledge of cognition.

Impact on HOTS was operationalized from the teacher’s perspective to include the relative impact/importance of technology in terms of higher order thinking (i.e., thought processes); specifically, the extent to which the use of technology added to the class performance in higher order thinking. From the administrator’s perspective, it was operationalized to include the role of the technology use plan’s vision in promoting technology for teaching and learning, and the reflection of the technology use plan on current knowledge of cognition in describing the use of technology by students.

Given that the integration of technology in education should have the goal to change the nature of instruction rather than just using technology to perpetuate traditional teaching and learning methods (Hawkins & Collins, 1992), technology integration was operationalized from the teacher’s perspective to include the extent to which the use of technology fits into the overall unit of instruction, whether there are transitions before and after the activity with the rest of instruction, and the extent to which technology use is not a separate activity from other instructional activities.

In this study, teacher morale was operationalized from the teacher’s perspective to include his/her enjoyment of using technology, his/her perception of colleagues’ morale regarding technology use, opportunities for collegial sharing of technology ideas and uses, satisfaction with work environment, and extent to which s/he believes that position provides professional growth and is satisfying. From the administrator’s perspective, it was operationalized to include the extent to which faculty are rewarded for intent to use technology, the promotion of innovation/creativity within the technology use plan, specific plans for teacher technology maintenance and support, and incentives to participate in professional growth and for incorporating technology as stated in the technology use plan.

Teacher technology competency was operationalized to include teacher-perceived confidence in the following areas: using a variety of software programs (e.g., word processing, database/spreadsheet, email, internet), file management, solving general software or hardware problems, use of terms associated with computers, identifying and explaining basic computer components, operating technology equipment, selecting and implementing appropriate technology to support curriculum, incorporating technology (e.g., telecommunications, word processing, spreadsheets, computer based presentations, email, internet) in instruction, and teaching students to use technology (e.g., graphics, internet, word processing, spreadsheets/databases, electronic encyclopedia, and use of appropriate vocabulary).

Considering all of these factors and outcomes together, the primary research question is as follows: Which combination of factors best predicts each of the five desired outcomes?

**Sampling**
Through purposive sampling we selected schools that were known to be effective users of technology in four areas of the country. A set of schools was nominated from each of four regions of the country that researchers believed to represent highly technology-integrative schools. From this process, twelve schools were selected: five from California, two from Florida, three from Virginia, and two from the state of Washington. In return for their assistance, the schools were provided with a grant for the purchase of instructional materials and a report of the data collected from the school.

Of the twelve schools, five were urban, four were suburban, and three were in rural settings. The percentage range of white to non-white students ranged from 5% to 95% with the mean percentage of non-white students as 32%. Five of the schools were elementary, five were middle schools, and two were high schools. Once the schools were selected, the principal of the school provided the researchers with list of “classrooms” meeting the three following requirements: 1) the teacher is the primary provider of instruction (not part of a teaching team); 2) the teacher is using technology in his/her teaching; and, 3) the teacher has been teaching the class since at least the prior school year and is intending to teach at the school through the next year. From this list of classrooms, we selected at random ten to twelve classrooms for each school. Following this, the principal asked each of the randomly selected teachers whether they would be willing to participate. If a teacher declined to participate, a replacement from the pool was randomly selected, until there were at least ten participating teachers per school.

The resulting sample included a total of ninety-four teachers and correspondingly ninety-four classrooms from the twelve schools, with the classroom as the unit of study.

Instrumentation

Given that there were no existing instruments that matched the sources of the data with the independent and dependent variables, we developed four new instruments to collect school, classroom, teacher, and administrator information. The four instruments included the following: administrator structured interview, teacher structured interview, technology use plan evaluation, and teacher survey. Each instrument was created to consist primarily of Likert items on a five-point scale. As appropriate, each instrument was evaluated by a panel of experts for content validity, reliability, and usability, as will be described below. Triangulation was an important component to gather data from multiple sources to gain multiple perspectives. Data was collected according to the following schedule: Administrator interview (Spring, Summer), Technology use plan analysis (Spring, Summer), Teacher survey (Fall), and Teacher interviews (Fall). The instruments were implemented by researchers in each of the four geographic regions.

A structured administrator interview was conducted and tape recorded with each chief school administrator to gather information regarding the following variables, as shown in Table 1: technology planning, leadership, professional development, and teacher morale. The transcripts of all of the interviews were then analyzed and scored by one researcher. A sample question from the scoring instrument was as follows: "The principal believes technology has the potential to be transparently infused and integrated into the entire spectrum of teaching and learning. (1- strongly disagree; 2-disagree; 3-neutral; 4-agree; and 5-strongly agree)"

A structured teacher interview was conducted with each of the 94 teachers to identify the teacher’s perception of technology in the classroom regarding the following variables, as shown in Table 1: curriculum alignment, technology use, impact on content acquisition, impact on HOTs, and technology integration. Part of the interview required the teacher to list all activities in the prior school year that involved technology. From this list, three activities were randomly selected to focus upon and were scored according to Likert-scaled items. All researchers in the four geographic areas were trained via video together with detailed structured interview questions, all on a Likert 1-5 scale. The interviewer’s guidelines for assessing the level of technology integration for an activity is as follows: "To determine the level of integration of the activity, ask questions such as the following: In a typical day in which this activity was conducted, what would normally be taught right before and right after this activity? How did the activity fit into the unit of instruction? What are transitions like between the different components of the activity with the rest of instruction? Is the activity separate from other instructional activities?" Following the interview questions, the interviewer would then rate the activity according to the following scale: "The technology-related aspects of this activity are integrated into classroom instruction. (1-strongly disagree; 2-disagree; 3-neutral; 4-agree; 5-strongly agree)."

Technology use plans from each of the 12 schools were obtained and evaluated according to how well the plan established a vision for the incorporation and integration of technology by the school’s
faculty. Analysis of the plan contributed to the following variables, as shown in Table 1: planning, leadership, professional development, teacher openness to change, technology use, integration, content acquisition, HOTS acquisition, and teacher morale. The TUPs were scored by a trained team including one researcher in each of the four geographic areas. Inter-rater reliability was conducted by evaluating sample TUPs until the researchers scored reached a reliability coefficient of .85. At that point the researchers each independently evaluated the technology use plans in their geographic areas. A sample rating question regarding instructional innovation is as follows: "The plan promotes instructional innovation and/or creativity with technology implementation. (1-strongly disagree; 2-disagree; 3-neutral; 4-agree; 5-strongly agree)."

A take-home teacher survey was given to each teacher to collect information on the following variables, as shown in Table 1: planning, leadership, professional development, teacher openness to change, teacher non-school computer use, technology use, teacher technology competency, and teacher morale. A sample question regarding teacher morale is as follows: "My teaching position is satisfying. (1-strongly disagree; 2-disagree; 3-neutral; 4-agree; 5-strongly agree)"

Results

Using the four instruments described above (with a combined total of 148 items), data was collected from 94 classrooms. A total of 15 independent variables (technology use was broken down into 9 subcomponents) were considered as predictors for regression models for each of the 5 dependent variables.

Given that nearly all of the items were on a 1-5 Likert scale, a process of aggregation was used to average the scores and provide one score ranging from 1-5 for each classroom, where 1=low and 5=high for a given variable. Aggregation was performed by averaging all related item values so that each variable was reduced to one score per variable per class. For example, Mr. Lang's classroom could be rated 1.24 on technology planning, 2.45 on leadership, 4.56 on curriculum alignment, etc. A strength of this method was that multiple sources of information (via the four instruments) contributed to the overall variable scores. Variables that were not on a 1-5 Likert scale (e.g., the technology use subcomponents) were not aggregated, but entered into the model separately as-is. Descriptive statistics are listed in Table 2.

The primary means for analyzing the data was through step-wise regression analyses to identify what combination (if any) of the independent variable(s) predicted the results of the dependent variables. A statistically significant model of independent variable(s) predicted each of the five dependent variables via a forward step-wise regression.

Technology impact on student content acquisition was predicted by 1) the strength of technology leadership at a school; 2) openness to change; and 3) (negatively influenced by) teacher non-school computer use. (R² = .589). All independent variables were entered in a forward stepwise regression model. See Table 3.

Technology impact on higher-order thinking skills was predicted by 1) the degree of teacher openness to change; 2) (negatively influenced by) the amount of technology use by students working individually in situations where they were "creating"; and 3) the level of constructivist modes of technology use (R² = .608). All independent variables were entered in a forward stepwise regression model. See Table 4.

Teacher morale was predicted by professional development and constructivist use of technology. (R² = .559). All independent variables were entered in a forward stepwise regression model. See Table 5.

Teacher technology competency was predicted by teacher openness to change. (R² = .164). All independent variables were entered in a forward stepwise regression model. See Table 6.

Technology integration was predicted by teacher openness to change and technology use with others. (R² = .391). All independent variables were entered in a forward stepwise regression model. See Table 7.

Conclusion

The degree of teacher openness to change was repeatedly found to be a critical variable as a predictor in our study. Teachers who are open to change, whether this change is imposed by administrators or as a result of
self-exploration, appear to easily adopt technologies to help students learn content and increase their higher-level thinking skills. It also appears that as these teachers incorporate these technologies, their own level of technical competence increases as does their morale. Because this one variable has such an important influence on how well technology and its subsequent influences are embraced in a classroom, administrators and policymakers may wish to encourage further development in this area. Unfortunately, given that it is a personal trait, it is difficult to influence.

Another variable with high predictive influence was the level of technology leadership and support for professional development. It appears that administrators who promote the use of technology, not only in words but also in action, lend credence to a technology culture. Our interview was designed to look beyond administrators who superficially endorse technology, and identify those who actively use, model, and reward teachers who infuse technology into their classroom. The bottom line appears to be that administrators who wish to nurture a technology culture need to figuratively "roll up their sleeves and join in" rather than sitting by the side.

Although we found that administrators contribute to the positive interactions of technology in a school, of greater importance were teacher attributes. Long-range planning for software developers and schools of education should include a vision that nurtures decision-making and development by teachers, rather than implementing systems solely from the level of policymakers. Currently many technology initiatives rely upon policymakers to communicate the value of technology to teachers, instead of involving teachers from the start. By helping teachers find ways to actively infuse technology, investments in time and money will pay off in greater content acquisition and higher-order thinking skills for students and greater teacher competence and morale.

Abstract: In a department or school of education, how does one set up an environment that acknowledges the importance of developing simple instructional design solutions, while simultaneously offering students opportunities to experiment with cutting-edge technologies? One approach is the creation of an extra-curricular organization that focuses on exploring technological innovations and the development of a supportive atmosphere for people interested in expanding their skills beyond those required for standard instructional design situations. The organization of Students in Multimedia Studies (SIMMS) at Indiana University is one example of this approach; the recent creation of the SIMMS 'be Washington State University is a second example. Both groups face interesting challenges in administration of the organization, and developing and maintaining activities of interest to the membership.

Introduction

Instructional Design program coordinators are often faced with a dilemma. How does one promote an attitude of parsimonious and judicious design and development, following adages like “less is more” and “form must follow function,” while at the same time promoting and fostering an atmosphere of enthusiasm for experimenting with new and innovative computing technologies? How does one set up an environment that acknowledges the importance of developing instructional design solutions in the least obtrusive manner, while simultaneously offering students the opportunity to experiment with cutting-edge technologies where “obtrusiveness” may be an acceptable starting point? Schon writes,

In the varied topography of professional practice, there is a high, hard ground overlooking a swamp. On the high ground, manageable problems defy technical solution. The irony of this situation is that the problems of the high ground tend to be relatively unimportant to individuals or society at large, however great their technical interest may be, while in the swamp lie the problems of greatest human concern. The practitioner must choose. Shall he remain on the high ground where he can solve relatively unimportant problems according to prevailing standards or rigor, or shall he descend to the swamp of important problems and nonrigorous inquiry? (Schon, 1987. p.3)

Indiana University’s graduate programs in Instructional Systems Technology and Education, and Washington State University’s undergraduate and graduate programs in Education focus on the theory and practice of instructional design and delivery. The programs offer students course work on the history and current practice of instruction in corporate, K-12 and higher education settings, curriculum development and theory, and opportunities to pursue research in these areas. Classes within these programs include basic
instruction in innovative technologies and multimedia production. Courses with titles such as “Educational Technology Used in the Schools” and “Instructional Development and Production Process” ensure that upon completion of the program, students will have had some basic training in multimedia production (e.g. making simple websites).

A small but significant portion of students involved in these programs would like to find opportunities to go beyond the basics of multimedia production. Currently in vogue is digital multimedia development, (using software to create computer-based experiences with graphics and sound). In other words, they would like to go mucking about in the swamp, to which Schon refers, but using new tools to do it. Responding to this need, Indiana University's Department of Instructional Systems Technology developed an extra-curricular organization that offers students an opportunity to explore multimedia development well beyond the essential requirements of their degree program.

The following sections articulate the types of activities appropriate for developing increased skill in media production and the development; the subsequent dissemination of a student organization designed to explore possibilities in multimedia production; the administrative challenges these organizations face; and concluding remarks.

**Developing Media Production Skills**

Experienced and competent instructional design (ID) professionals recognize a difference between the instructional design process and the production process (Brown, 1999 p.1). While the instructional design process involves the identification and development of objectives, activities and evaluation protocols in order to promote learning, the production process is a phase within the instructional design development process (Appelman, 2000); it focuses on the creation and design of tangible products identified as necessary to the overall instructional design. Research conducted at Indiana University suggests that incorporating the following activities into an instructional design program helps facilitate students’ development of media production skills (Brown, 1999 pp 201-202).

1. Offer a number of production experiences, allowing learning to occur through a set of iterations. This gives students an opportunity to learn from their own mistakes as well as a chance to apply good general practices to a variety of production situations. This should help particularly with the goal of generating increased respect for what should and should not be accomplished given specific materials, time, and skill.

2. Hold critique sessions. These allow students to focus on function and design issues in a formal setting that allows for greater focus on the project itself, de-emphasizing distractions like course grading.

3. Offer opportunities to “Show and tell.” Students get to see how others have met specific production challenges and can share ideas on how best to approach similar challenges. There is also a “level element within this activity that is beneficial to those students who may fear that they are not performing up to the standards of their peers as well as students who may mistakenly believe they are more advanced. In order to capitalize on this leveling effect, care must be taken when choosing sample work for show and tell sessions in order to show a reasonable range of products, not just a sampling of the very best or very worst.

These activities can be incorporated into a course of study, if media production courses are offered. What happens, though, when few (or no) advanced media production courses are offered within a program of study? How can students with an interest in advanced media production receive departmental, faculty and peer support?

**An Extra-Curricular Solution**

Indiana University's Department of Instructional Systems Technology (IST) developed an extra-curricular organization that focuses on exploring technological innovations and the development of a
supportive atmosphere for people interested in expanding their skills beyond those required for standard instructional design situations. The organization of Students in Multimedia Studies (SIMMS) at Indiana University has an active membership of students not only from IST, but from other departments and programs around the Bloomington campus as well. SIMMS members meet multiple times during the academic year to share projects individuals and groups on working on or completing; to share information about new or updated media development hardware and software and to socialize with people who share their interest in multimedia production. The recent creation of the SIMMS ‘beta chapter’ at Washington State University performs the same function in Pullman, Washington. Washington State University has no Instructional Systems Technology programs presently, but it does have a number of students on campus who take an active interest in multimedia development and instructional design.

There is an element of fun to all of this, which can be more easily addressed since SIMMS is an extra-curricular organization. As Landauer writes:

> Here is the hypothesis. We have taken to computers not because they made us more productive, not because they bring us better products or services, but because we like them. Being able to charge my groceries by swishing a card through a machine that automatically debits my bank account is neat. I get a kick out of it. The store manager does too. We are a world of people who like the new, the cute, and the ingenious. (Landauer. 1995. p. 193)

There is nothing wrong with enjoying “the new, the cute and the ingenious,” especially if taking some pleasure in this promotes students’ keeping a watchful eye on the horizon of technological innovation. It is plausible that even the recipient of this “innovation”, the learner, might find this novel form of instruction motivational, engaging, and even fun.

Administrative Challenges

Both SIMMS groups face interesting challenges in administration of the organization, developing and maintaining activities of interest to the membership and bridging the gap between group members who are highly technologically proficient and those who aspire to greater technological proficiency.

At Indiana University (IU), Dr. Appelman of the Instructional Systems Technology Department, initially conceived of the SIMMS organization in 1995 as functioning similarly to the Medieval Craftsmanship Guilds. Just as those early practitioners focused on quality and growth in the execution of their craft, so was SIMMS to focus on quality and professional development with multimedia. Through the submission of a portfolio, students were classified into apprentices, journeymen, and masters of a specific aspect of multimedia such as video, imaging, audio, or graphic design. By delineating such a hierarchy, leadership for each group was made clear, and growth objectives for apprentices and journeymen were targeted at becoming a master within a group.

This rigid structure worked well to create a positive esprit de corps among the students, but the administrative overhead was considerable. Extensive faculty involvement was necessary to set standards, provide support for missing skills, and to keep meetings and workshops happening on a regular basis. Following a couple years of rapid growth, the “charter members” graduated and a decline in membership prompted a redefinition of SIMMS. It was clear that the goal of reaching a mastery level in the hierarchy of SIMMS was not desirable for most students, but what they wanted instead was simply exposure and guidance into new media domains.

The current iteration of the SIMMS organization at IU is almost entirely student run. The IST Department, along with generous alumni, have invested in a high-end digital space called the SIMMS Lab. Equipped with sophisticated Macintosh, PC, SGI, video, scanning, and audio tools, this lab is only accessible by SIMMS members and their trainees (called SIMMlets). Each semester focus groups are formed around leaders within SIMMS who then send out a call to the entire IST body for anyone interested in a particular focus of study. The foci may be 3D modeling, digital video editing, authoring, media research, and in general anything that the IST Department is limited in attending to in depth within its curriculum. A goal for each focus group is to put together a “SIMMinar” for the IST student body that describes what they have learned and discovered. The development of tutorials and job aides are very much encouraged, such that learning curves may be shortened for others that follow in their footsteps.
Finally, it is worth mentioning the view of SIMMS from the standpoint of faculty. At IU, the Alpha chapter of SIMMS provides an avenue for faculty to find resources for projects, both individual and departmental. Countless media elements need to be created for the web and other products, and many of these needs have been met within the SIMMS organization. As the faculty find out that things can happen in both areas of production and research by simply saying “find a SIMMS member and see if you can work something out”, the SIMMS organization becomes strengthened. Care should be taken NOT to look at SIMMS as a production unit unless considerable faculty mentorship and funds are available to compensate students. SIMMS members must feel free to follow their own directions for multimedia development since the time commitment is considerable. Imposing pressures of time and faculty rank have proven to cause loss of interest and the sense of experimentation that is at the heart of the SIMMS concept.

At Washington State University (WSU), Dr. Brown of the Department of Teaching & Learning has taken a lead role in contacting other professors around campus to develop interest in a “beta chapter” of SIMMS. Responses from faculty members in a variety of departments, including Fine Arts, Architecture and Management Information Science have expressed interest. Initial meetings with professors and graduate students has indicated there is an enthusiasm for developing and maintaining a SIMMS organization at WSU.

One means of maintaining SIMMS activity is to develop within the organization a network that provides information about professional development opportunities for its members. At WSU, Dr. Brown and Dr. Darcy Miller have received funding from The Arc of Washington to support the development of three “knowledge objects” designed to teach essential concepts. The concepts are to be determined by service special education teachers; the target learning audience is students with mild mental retardation. In offering significant funding as well as an opportunity to develop a computer-based knowledge object, the SIMMS organization finds a very compelling reason to meet with regularity.

Conclusion

The focus of any education or instructional design program must remain the judicious application of both “soft” and “hard” educational technologies. It is easy for students to get sidetracked by glamorous new technologies that may or may not be used to create effective instruction. However, in stressing the importance of simple technologies that have proven effective, it is possible to create a situation that limits students’ abilities to experiment with the new and different.

Offering students opportunities to work with advanced media; to share their efforts with peers and mentors; and to critique each others’ work can be accomplished through organized extra-curricular efforts. The SIMMS organization at Indiana University has enjoyed multiple years of success, the nascent beta chapter of SIMMS at Washington State University is enjoying a similar success as the organization begins to coalesce into a working entity of students and faculty from around the campus. Projects like The Arc of Washington knowledge objects initiative help to support the organization by providing both projects to focus upon and funding to complete those projects.

**Acknowledgements**

The Indiana University SIMMS chapter is supported in part by the IST Department, technology fees assessed from IST Students, and donations from IST Alumni. Special thanks to Elizabeth Boling who was instrumental in the initial development of SIMMS and Jalin Huang who designed the SIMMS Logo.

The Washington State University SIMMS chapter and instructional multimedia development activities are made possible in part by the financial support received by the U.S. Department of Education for its funding of “teach.edu,” a PT3 (Preparing Tomorrow’s Teachers to use Technology) initiative at Washington State University. Multimedia development facilities at Washington State University are also supported by CO-TEACH, a project underwritten by the U.S. Department of Education.

Funding for the knowledge objects, currently in production at Washington State University is made possible by The Arc of Washington Trust Fund.

Dr. Brown would also like to acknowledge and thank Ian Quitadamo for his help with the organization of SIMMS WSU.
Online Technical Support Database for Educators #61

Cathy Cavanaugh, Curriculum and Instruction, College of Education and Human Resources, University of North Florida, Jacksonville, FL USA. ccavanaugh@unf.edu

Abstract: As educators depend more on technology, demand has grown for school technical support. Timely, convenient support is needed for schools to most effectively use technology. An online database was developed to provide immediate easy access to technical assistance. Developed for Florida educators, TLC: Tech Links for Classrooms, is a searchable web archive of assistance. TLC offers troubleshooting tips for hardware, software, operating systems and networking; steps for performing hardware upgrades; multimedia tutorials; and access to updates from vendors. Existing web resources were linked from the database and additional materials such as tip sheets and help files were created. Presentations related to using school computer networks, and tools to streamline the work of school technology coordinators were developed. Users may view all resources, or search the database by selecting from a list of six broad categories of resources: hardware, software, networks, general technology information, technology management, or technology training. Keyword searching locates specific topics. Search results list the resources with a link to the full resource, and a link to more detail about the resource. Resources are available as web pages, PDF files, PowerPoint presentations, database files, spreadsheets, word processing files, or multimedia SMIL presentations.

As students and teachers depend more on computers as teaching and learning tools, demand will grow for school technical support. Schools continually deploy additional classroom, lab, and research computer stations to allow greater access to computer resources by students. Not all users and school technology coordinators have skills in troubleshooting, problem-solving, maintaining, or upgrading computers. In order for the computers in schools to be maximally effective, they must be maximally operational. Keeping computer operating well requires access to instructions, hints, and techniques applying to a wide variety of hardware, software, operating systems, and infrastructure.

An effective educational technology technical support resource must have a specific combination of features. It must support the array of legacy and cutting edge technologies in use in schools, and it must be updated to reflect the constant changes in school technology. The technical support service must be available to schools at low cost, preferably in each location where technology is present. The resource must offer rapid access to the knowledge needed to address the situation, and the information must be useful to audiences with a range of technology experience and ability.

Current technical support resources tend to fall into two main categories: niche, vendor or product related information; and information tailored to the systems found in a particular school or district. Neither category constitutes a convenient one-stop clearinghouse for users. The resources are generally distributed as books, CD-ROMS, or web sites. Books and CD-ROMs have the highest cost to the user due to the physical nature of the media, and due to the distribution process the information tends to lag behind the most recent technology in use. Web sites tend to be less expensive to develop and distribute, are very comprehensive, and can be very current, but few address the needs of education.

To begin to address the growing need for educational technology technical support, one of Florida's instructional technology centers created an online database of information designed to provide immediate and easy access to assistance. The center worked with state grant funds to design, develop, and publish a searchable web archive of resources called “TLC: Tech Links for Classrooms.” The center collaborated with area school district technology specialists to identify the highest priorities for the types of resources to make available in the database. Priorities included troubleshooting tips for the most commonly used hardware, software, networking; steps for performing simple hardware upgrades; multimedia tutorials; and access to updates from vendors.

The next stage in the development of TLC involved creating and gathering the resources for the database. The project staff performed web searches to locate and evaluate existing resources that could be linked from the database. About 100 such web resources were included in the initial database. An evaluation of the selected resources revealed incomplete areas of need, including troubleshooting, hardware upgrading procedures, and tools specific to school technology management. To fill in these gaps of knowledge, the project staff wrote tip sheets and help files as web pages to add to the database. University graduate instructional technology classes
agreed to do their semester projects to contribute to the database. The students in the classes, Advanced Multimedia and Advanced Design, teamed up to create multimedia tutorial job aids. The job aids illustrated the steps in hardware installations and upgrades. Two additional university classes in School Networks provided materials to the database. These materials were presentations about procedures and practices related to using school computer networks, and tools to streamline and organize the work of school technology coordinators. Almost 100 additional original database resources were added from these activities.

As the scope and content of the TLC database was developed, the options for placing the information online were evaluated. The web database involved three main decisions: choosing the database application; selecting a server configuration; and selecting a web based user interface. The database options included Filemaker Pro or Microsoft Access databases. The databases could be accessed from a server using FrontPage extensions, a server set up for Filemaker Pro, or a Cold Fusion server. The tools available for writing the user interface for the database were HTML, FrontPage, Macromedia Dreamweaver, Cold Fusion Studio, and Claris Homepage. The skills and interests of the project team led to the selection of an Access database residing on a Cold Fusion server queried from a Dreamweaver web page.

The interface web page was deliberately kept simple, open, and light, with a few clear options. Users may click a button that shows the entire list of resources in alphabetical order by title. Users are able to search the database by selecting from a list of six broad categories of resources: hardware, software, networks, general technology information, technology management, or technology training. Keyword searching was also made available to enable users to search for resources related to specific topics. After launching a search, a new page appears listing the resources in digest form: the title, a short description, a link to the full resource, and a link to more detail about the resource. The full URLs of resources are included to facilitate printing a useful results list. Resources that are not available as web pages are provided in alternative formats such as PDF files, PowerPoint presentations, database files, spreadsheets, word processing files, or multimedia SMIL presentations.

The TLC database has received very favorable responses from educators in its first year of use, and it is subject to regular review and update. The possibility of having work included in the database has been a motivational factor for students in the contributing university courses, and they’ve appreciated having access to samples of work from previous classes for their own learning. The maintenance of the database includes checking that existing web links are valid and still useful, adding newly discovered web links, adding newly created original university projects, and updating the corresponding project contributors list. The contributors’ list shows all project developers and materials developers by name accompanied by the link to their resources.
Modeling and Implementing Effective Technology Practices

Abstract: Faculty in the department of Technology and Cognition at the University of North Texas have identified several strategies to enhance students' use of technology and students' level of technology proficiency. In our instructional technology classes, future teachers are being introduced to the effective use of old and new technologies to deliver their lessons. In other courses in the department, innovations in the faster delivery of video on the Internet have allowed department faculty to store portions of videotaped class lectures on the department's server and make a sample of these available to prospective students. Thus, students may read about a class and also view a lecture before deciding whether or not to enroll in a course. Distributed learning models being used in the department make use of multiple platforms. One approach the department has developed is a program for the delivery of asynchronous and synchronous class-lecture videos with the use of streaming media and the Internet.

Infusing Technology in Our Teacher Education Courses

Students interested in the technology aspects of being a classroom teacher have several course options available in the College of Education at the University of North Texas. There is an assumption that most students will bring some level of computer proficiency with them into their coursework. For those whose skills are weak an introductory course on computer literacy and basic computer applications (in this, Microsoft Office) is suggested. This course can be taken on-line in an independent study mode supported via technology such as email, on-line testing, and discussion forums. A traditional, on-campus classroom section of this course is also offered for those that require more structure and guided instruction. Outcomes of this course, either distance delivered or the on-campus offering, meet the necessary prerequisites for other courses in the technology sequence. In addition, this course provides many students their first exposure to distance delivered instruction and technology-based instruction.

Instructional Technology

In our Introduction to Instructional Technology classes future teachers are being introduced to the effective use of old and new technologies to deliver their lessons. Within the first weeks of the semester, students are introduced not only to different learning theories and teaching models but also to hands-on modules integrated with each new chapter. These hands-on modules demonstrate real world technology applications and provide the connection to appropriate uses and inclusion of both old and new technologies of instruction. As soon as learning theory is reviewed, the classes concentrate on several book and multimedia modules that overview the system's process (instructional design, etc)... then progress to non projected and projected media elements that are demonstrated and then reinforced via subsequent lab experiences (i.e. a chance to learn how to dry mount, rubber cement, and create non-computer transparencies...) for a taste of the old which is still in use today. But immediately, students are also taught how to create and enhance transparencies with the use of a flat bed scanner, computer, drawing software and a color printer. In order to create these transparencies students exchange the old cardboard frames for the word processor or the power point program, and the scissors and glue for the new cut and paste features found in both programs. Students are taught the basic uses of both software packages and the features that
could help them enhance a presentation and a handout. The scanner and features of graphics software are also demonstrated to teach students how to include pictures when the clipart library found in the software is not enough. The use of a digital photo camera provides the students skills at obtaining additional illustrations. In subsequent modules students are given a chance to understand and use digital video cameras and create a "how to" team video, use the Internet for specialized searches, evaluate educational software and web sites given a criteria, create a web page, attend and participate in a hands-on videoconferencing demonstration, learn about filtering software, virus scanning, web based courses and much more. Although each skill is addressed at only an introductory level, students' awareness of all these tools and teaching methods gives our future teachers enough guidance on the use of the tools and inclusion methodology, thereby enhancing and enriching their skills as a teacher. The hands-on approach seeks to prove that, although complex in their inner workings, the tools themselves are easy to use and have a very short learning curve. Familiarity should result in a relaxed understanding and eventual use of technology mated with creative ideas.

**Other Technology Courses**

Also in the sequence of preservice technology courses is Computers in Education. This course stresses the use of technology in the classroom with an eye toward integration of technology into the curriculum. Students in the course increase their knowledge of technology and its impact on teaching and learning. In addition, topics such as development of student portfolios, evaluating software, creative activities using the Internet by students are investigated. If students follow the entire sequence, they place well on a "Teachers Using Technology" continuum developed by the Technology & Cognition faculty. That is, they demonstrate the skills necessary to meet the standards of ISTE/NCATE.

We also try to offer a diversity of learning systems for our students to use in the acquisition of the course materials. Although we do believe that the sage still needs to be on the stage for some of the class materials, we also strive for interactivity through a variety of delivery systems. Our courses range from standard class schedules that are approximately ½ lecture and ½ lab work... to fully asynchronous, web delivered sections. Our most popular model (with both teachers and faculty) is a combined class during which the students come to campus 6-8 times a semester for high tech labs, specialty lectures, and teacher-learner/learner-learner interactions. The other 8-10 classes have all materials delivered via the web (both our own server/web sites and a university-based WebCT system). Most testing is web based. We feel that this model gives us opportunities to serve both as 'sage' and as

**Delivery of Courses via Distributed Learning Models**

In the Department of Technology and Cognition at the University of North Texas, new technologies are being used and tested to deliver class instruction across the Internet. Each program area in the Department maintains a comprehensive Web site (i.e. www.cecs.unt.edu) that provides course syllabi, degree requirements, course objectives, faculty information, etc. Streaming media (discussed later) is used to give prospective students a brief sample of the course before they register. In addition, students get a brief introduction of what taking a course via the Internet may entail. For instance, in order to take advantage of some of the extras on the Web site, they have to download players and plug-ins. This serves as an example of the types of skills necessary to receive a course delivered via streaming media.

WebCT is supported at the university level as a deployment tool for distributed learning. The software is used in several different models of delivery in the department. Some courses only use the on-line testing, email and chat functions. Other courses utilize the entire functionality of WebCT. Most of the distributed learning courses are at the graduate level. As mentioned earlier, several course delivery models have been developed. For instance, several VTEL equipped classrooms are available for traditional, synchronous distribution of two-way audio and video. While optimal for delivery of courses at satellite university locations, the equipment is in high demand resulting in a waiting list for use. Due to this limitation, faculty gravitated towards Internet distribution as an alternative. This has also proven to be problematic as discussed later.

The use of streaming media was an early attraction to faculty delivering instruction via the Internet. As a result, we have developed several models of delivery based on streaming media technology. As an aside, we have found the software solutions offered by Real Networks best meet our requirements.
Course Delivery Models Using Streaming Media

Several models of course delivery via streaming media have been developed with the department. The next section describes those models. As will be seen, some of the models deliver content synchronously and some were designed to deliver content asynchronously. While not the focus of this paper, the creation of streaming media requires some audio and video production hardware in addition to the related software (in our case, Real Producer Plus by Real Networks). We have found this hardware to be inexpensive and readily available. Figure 1 shows a mobile cart developed to record video and audio, convert to streaming media and deliver "live" via the Internet. Files can be stored immediately on a local hard drive or a streaming media server. While a convenience, a high-speed or powerful computer is not a necessity to capture, store and play streaming media.

![Figure 1 – Portable Streaming Media Production Cart](image)

Streaming Audio

Two graduate level courses have been taught using streaming audio. The instructor lectures to an on-campus section of a course and streams the audio live. Students can listen to the lecture in real time. Viewing web pages as directed enhances the audio portion. This method of instruction requires a microphone, computer with sound card and encoding software. Each lecture is also archived on a server so that students can review it at a later date. This is also a great convenience for those that could not attend the on-campus lecture or "tune in" to the live streaming lecture. The faculty member using this technique has also recorded the live lecture on videotape, converted it to streaming video and archived it for future use.

Live Streaming Audio and Video

This approach uses streaming audio and video to deliver instruction in real time via the Internet. Students access a website and view the live broadcast. Basically, the course content is captured using a video camera and microphone, digitized, converted to streaming media, transferred to a streaming media server and delivered to the end user. There is a very brief lag, measured in seconds, between the time the content is actually created and when the user finally receives it. This approach is the most elaborate implementation from a hardware and software perspective. Typically, the live course content is also archived for later use by students. The advantage to this technique is obvious.

Archive Streaming Media

Faculty members have found that recording course content (audio, video or audio and video) and converting to streaming media for future use is a viable approach to distributed learning. This technique allows for content editing. As is often the case, the first several minutes of a course are devoted to local business, conversation, or other mundane topics. There is little or no benefit to this information for a student not attending the on-campus class. In essence, postproduction editing and archiving creates an efficient module. Using this approach, a faculty member typically has all of their on-campus meetings videotaped. These sessions are then edited for content and prepared for distribution at a later date. This, in essence, is the equivalent of preparing a telecourse. The only difference is the mode of distribution. In lieu of broadcasting each session on a schedule basis, the student accesses
the course lectures at their convenience. Faculty using this technique also has to be attentive to updating the content each time it is offered.

**Archive Streaming Media with Graphics**

One of the advantages of the Real Networks software is the ability to synchronize graphics with the audio or video stream. This technique requires post-production work in order to create and synchronize the graphic elements with the streaming content. Figure 2 shows an example of what the student sees while viewing the archived content. This technique is somewhat time consuming but the effort results in an efficient delivery of the content. Again, editing allows for the removal of any activity that is not directly related to the content of the lecture.

Real Networks refers to this technique as SMIL Technology. Graphics are synchronized with the streaming media using time. For instance, simple code is used to instruct the software to show a graphic so many minutes and seconds into the file.

![Figure 2 - Sample SMIL screen. Video plays in black box upper left in the frame.](image)

**Streaming Audio with 3rd Party Software**

Several faculty members have found Screen Watch by Optx (www.Optx.com) to be a unique tool for the delivery of instruction. Screen Watch is a screen capture program similar to Lotus Screen Cam. The Optx product has great advantage because of the large amount of compression applied to the capture resulting in files that easily stream over the Internet. Procedurally, the user narrates his/her on screen activity. The audio portion is recorded and the screen movements, mouse movements, etc. are synchronized to the audio track. This is an ideal platform for teaching computer related topics, how-to’s etc. The student can hear the instructor reciting the procedures and see the result of those procedures on screen at the same time. Similar to Real media, this software requires the user to download a browser plug-in in order to view the presentation.

**Issues Related to Streaming Media**

As can be seen from above, we have extensively used streaming media in various implementations as alternatives to traditional on-campus instruction. Being a high tech, high touch department, students have come to expect technological approaches to course content. There are graduate courses in the creation of digital audio and video and creation of streaming media. Students enrolled in those courses have the advantage of both taking a course in this fashion and learning how to create streaming media and other delivery approaches at the same time. In addition, undergraduate courses using the technology are also in various stages of development. Again, students will learn how to create streaming media while taking courses delivered by streaming media. We feel this represents the highest possible form of modeling technology.

With the advances in streaming technology, a user can view an audio and video clip on the computer within seconds of clicking on its link. The video and/or audio files no longer need to be completely downloaded before viewing can begin. Now only a small portion of the media file is downloaded, buffered into the user’s PC RAM. When an approximately 20 second buffer has been created, the streaming media starts playing. The rest of the content is buffered and readied for playing “on the fly.”

Buffering speeds are mostly limited by the students’ modem or other connection. While the majority of the users may have a 28.8Kb or 56Kb modem, the students with a DSL, T1 or higher connections will experience more
continuous viewing. Also, the advent of Sure Stream Technology by Real Networks, allows for the server and student's computer to negotiate what speed to use for playback depending on the highest available bandwidth at connection time. This process is transparent to the student. While offering courseware via the Internet is, the biggest advantage of streaming media (whether live or archived), the Internet itself is the biggest disadvantage. Graduate courses in the department are offered in the evenings during peak Internet traffic times. Streaming media requires a large (but not outrageous) amount of bandwidth. Problems have been reported at both ends of the distribution. Students report that streaming media continually pauses and buffers during peak Internet usage times. As a result, an archived file that should play smoothly for perhaps 45 minutes may take over an hour to stream. Another problem also exists at the origination end. In our case, the bandwidth of our connectivity at the university is "maxed out" except between two and 6 am. This builds in a delay before the signal leaves the facility. Oddly enough, most of the bandwidth allocation has been traced to the dorms where students are downloading files from Napster.Com! The magnitude of this phenomenon is great we have the equivalent of seven T-1's running at full capacity. To circumvent this problem, a faculty member that originates live streaming video each week, has moved to a satellite campus to teach. This location has available bandwidth. In addition, production equipment and a server also were relocated. As a result of problems related to bandwidth, many faculty members have abandoned streaming media. Unfortunately, this reduces the amount of distributed learning courses offered by the department. It also reduces student's exposure to this technology.

Other Approaches to Implementing Technology Delivered Instruction

As mentioned earlier, the "high tech" nature of the faculty in the Department of Technology and Cognition results in many approaches to course delivery. As streaming media proved to be problematic, hybrid approaches have been developed as solutions. For instance, the instructor of a Cognitive Psychology course and an Instructional Design course decided to asynchronously distribute streaming media files via CD-ROM instead of the Internet. This approach provided the same content using streaming media with none of the limitations of the limited bandwidth of the Internet. In addition, on-campus sessions are offered on several weekends for those students that prefer some contact with the instructor or other class members. Web enhanced activities are offered with the help of WebCT software which has proved to be viable for providing online testing, email, chats, download sites, etc. for these course models. This hybrid approach has been well received by students enrolled in those courses.

Since the Internet has posed some problems with distribution, other faculty members have rediscovered multimedia technology as a method of creating distributed learning courseware. One project under development will use multimedia (from CD-ROM) to help preservice special education teachers to understand the concepts of gifted and talented students. The project uses video-based case studies, information pages and web links to create an information source for students. The value of this project is that it will provide an alternative to on-campus instruction.

Synchronous and Asynchronous Class Formats

Web based courses are being offered synchronous and asynchronously. In the synchronous setting, the student attends classes live but in the space independent setting of their own choosing (home, office, library, other) wherever a computer with an Internet browser and Real Player client software is available. Students in this setting can hear and see the lecture, follow the power point slides released by the teacher, and interact with other students through a chat room (see Figure 3). Also, using the chat room the students can ask the teacher questions live during the lecture. Synchronous Web based lectures are recorded and saved in the school's server for later viewing. Students are then given the URL and password of the server to access these and other class materials (syllabus, schedule, assignments, handouts, class slides, bulletin board and email) at a later time.

The asynchronous setting of "attending" classes on the Internet is not only space independent but also time independent. Students from anywhere and at anytime can access the University's server and view any of the pre-recorded classes, saved and labeled by chapter number and topic. After choosing a video clip, students can hear and see the class lecture, and follow the power point slides much like in the synchronous setting, except for two variants. First, and most obviously, there is no one to interact with in the chat room while viewing the lectures. And second, while viewing the video the student can pause, rewind and view over and over any or all of it as needed, using the VCR like controls on the screen (see Figure 3). Also, since the live lectures are recorded in the classroom with the teacher and students present, part of the teacher-student interaction such as questions and anecdotes, can be "experienced" by the students Web viewing the class in synchronous and/or asynchronous mode.
While many advantages and disadvantages maybe cited for the asynchronous class format, two characteristics are indisputable. Asynchronous classes are time and space independent. Students may “attend” classes at any time from anywhere. On the other hand, synchronously delivered courses are live and so students are time dependent. Those students may also benefit from the live interaction with the instructor and other peers as the lecture is taking place. Because Web based courses are the new instructional phenomena, new research is being conducted to determine its effectiveness and new methodology is still being tested to determine adjustments in the pedagogy of such courses. These areas of research have been intriguing to faculty using distributed learning technologies. In addition, graduate students have been exposed to research and research methodologies related to distributed learning.

Conclusion

Presently, studies indicate that students with very busy lives that hold full time jobs, have a family, live over 30 minutes from the university campus, travel in job related assignments and have many commitments, like to “attend” classes in some fashion other than coming to the main campus of the University of North Texas. As is often heard, students say “anything is better than driving to Denton!” Certainly, more research is needed to determine if the virtual classroom, or whatever hybrid approach is used, is as effective as our traditional classrooms.

In the Department of Technology and Cognition not only are teachers being trained to appropriately use technology, but also technology is being tested in new ways in the delivery of these courses. Technological innovations are being introduced and tested from our classrooms’ podiums while research is conducted to establish their effectiveness. As long as this continues, faculty will benefit professionally by investigating different distributed learning approaches. Students will certainly benefit by being exposed to the techniques. And new viable ways of instruction may in the very near future allow educational institutions to adapt to the changing life style characteristics of the student population they serve.
Understanding the “Digital Divide” - the increasing technological disparity in America; Implications for Educators

713-221-8143

Abstract: Within the past decade, a growing body of evidence supports the ever-widening technological gap among American school children (U.S. Department of Commerce, 1998). The “Digital Divide,” a leading economic and civil rights issue, is defined as the divide between those with access to new technologies and those without. Disparity in computer use can be found among rural, urban and suburban students, with the division drawn upon socio-economic lines. This trend indicates that the “haves” possess increasingly more information and economic opportunity, -nots” are lagging even further behind. Groups that lack access to information resources include: minorities, low-income people, less education people, children of single parents, and residents of rural areas or inner-cities. Since many people do not have knowledge of technology to pass onto their children, schools will serve as the catalyst for preparing America’s youth for the age of technology. Data indicate that outside of work, schools are the second most frequent place where people access the Internet, 33% of access is made from schools (http://www.digitaldivide.gov). Since schools are so important for technological education and access, the U.S. Department of Commerce has arranged for additional funds to aid American schools in purchasing technology. These funds are now available for nonprofit educational organizations and public school districts. Educators must recognize the manifestations of the technical inequality as it affects the lives of America’s school children and must become aware of initiatives, both federal and private, that will provide the means and methods to narrow this gap. The purpose of this paper is to describe the “Digital Divide” and explain the steps needed to be taken by America’s educators to close this gap.

Introduction

Two hundred years ago “The Great Divide” that threatened the destiny of many Americans was the geographical challenge of crossing The Continental Divide. Only by crossing the treacherous Rocky Mountains could the desperate pioneers partake in the economic benefits westward expansion offered. Two centuries later, “The Great Divide” for Americans is no longer geographical, but technological. Many Americans find themselves unable to meet the challenge of the technological demands of the 21st Century and feel left behind. This "Digital Divide" for modern-day Americans divides those with access to new technologies and those without. Data suggest that the “haves” possess increasingly more information -nots” are lagging further behind (http://www.digitaldivide.gov). The “Digital Divide” has become a critical issue for America; one that if left unchecked, threatens to increase economic inequality and sharpen social division. America’s educators must recognize the manifestations of this technical inequality as it affects the lives of America’s
youth and must become aware of initiatives, both federal and private, that will provide the means and
methods to narrow this gap.

Federal Initiatives

To determine means for reaching out to people at risk of falling behind in the Information Age,
President Clinton called upon both the government and the private sector to support policies and
initiatives that will work to bridge the divide. During the "Digital Divide" discussion in President Clinton
(2000) stated:

... No one has to be bypassed this time around. The choice is in our hands. We can use new
technology to extend opportunity to more Americans than ever before; we can truly move more
people out of poverty more rapidly than ever before, or we can allow access to new technology to
heighten economic inequality and sharpen social division. (http://www.pub.whitehouse.gov/uri-

During a recent "Digital Divide Summit" Secretary of Commerce William M. Daley introduced a
new federally sponsored web site. This web site, digitaldivide.gov was developed by the National
Telecommunications and Information Administration of U.S. Department of Commerce (NTIA) to inform
American citizens of federal programs designed to close the "Digital Divide" (see Figure 1, Source:
http://www.digitaldivide.gov). This web site also provides information on a range of grant and loan
programs including private sector educational and funding initiatives.

Private Sector / Corporate / Higher Education Initiatives

The public media has tried to raise public awareness of the issues manifested by the "Digital
Divide". PBS has aired a series of programs, the Digital Divide Series, that address the "Digital Divide"
and how technology affects classroom, gender, race and work issues (http://www.pbs.org/digitaldivide/).
Several universities across the country have formed partnerships with corporations, private
educational foundations, and non-profit organizations to seek solutions to the growing problems presented
by the "Digital Divide". A recent conference hosted by Delaware State University focused exclusively on
how to bridge the "Digital Divide" in spite of growing limitations (http://www.bridgingthedivide.org/).
Non-profit organizations such as Alliance for Technology Access have also been formed to make sure
small groups, such as children and individuals with disabilities were not left out in the efforts to bridge the “Digital Divide” (http://www.ataccess.org/).

In the campaign for public awareness and support in seeking solutions to the “Digital Divide”, corporate level participants play an important role. Many hi-tech companies devote products, service, and grants to give back to the local communities. Specifically, Microsoft and Sun Microsystems have teamed with the Black Family Network in order to host activities such as Black Family Technology Awareness Week. During the meetings, participants sought solutions to the “Digital Divide” dilemma (http://www.blackfamilynet.net/soon/). 3Com, one of the leaders in network technology, has established initiatives to help the nation’s public schools bridge the growing “Digital Divide” among urban communities. In July 1999, 3Com, in partnership with The United States Conference of Mayors, created the Urban Challenge program, which is a partnership that rewards forward-thinking cities with $100,000 grants in 3Com systems and services for technology initiatives designed to improve residents' lives (http://www.3com.com/government/urbanchallenge/).

The “Have-nots” of the Digital Divide

America’s educators must recognize the technical inequality as it exists in the lives of students both inside and outside of school. This inequality is tied to several important factors in the student’s life, the region in which the student resides, available economic resources, family structure, and level of education of family members. According to the NTIA in the U.S. Department of Commerce (1999), the groups that lack access to information resources in the United States are minorities, low-income people, less educated people, children of single-parent households, and residents of rural areas or inner-cities (http://www.ntia.doc.gov/ntiahome/fttn99/contents.html).

One important determinant of computer and Internet use can be linked to a student’s region of residence. The following chart (see Figure 2) describes the usage of computers in U.S. households (42.1% overall) by region: rural (39.9%), urban (42.9%) and central city (38% in 1998) (http://www.ntia.doc.gov/ntiahome/fttn99/FTTN UChart-I-11.html).

![Figure 2: Computer Penetration Rates in different areas](image_url)

Another important determinant of computer and Internet use can be linked to family income. The U.S. Department of Commerce (see Figure 3) reports that economic advantages in the form of family income increases a student’s access and use of computers in schools (http://nces.ed.gov/pubs98/condition98/c9803e03.html).

2878
Figure 3: Family income increases a student's access and use of computers in schools

Recent data indicates that the penetration rates of telephone, computers, and Internet among the U.S. households are 94 percent, 42 percent, and 26 percent respectively (see Figure 4). A large discrepancy exists between the 94 percent telephone penetration rate and the 26 percent Internet use penetration rate (http://www.ntia.doc.gov/ntiahome/fttn99/Chart-I-1.html). Most households receive their Internet access through local or national Internet Service Providers (ISP) by paying a flat monthly fee. Figure 4 indicates that in 1998, among the U.S. households with Internet service, 69 percent obtained the connection through national service providers such as American Online or Microsoft Network, 14 percent from local phone companies and local service providers such as PDQ and Flash in the greater Houston area, and 4 percent from long distance companies such as Sprint and AT &T (http://www.ntia.doc.gov/ntiahome/fttn99/InternetUse_II/Chart-II-24ab.html).

Figure 4: Penetration rates of phones, computers, and Internet in US Households

In response to the question of why households with a Computer/Web TV do not use the Internet at home (see Figure 5), 25 percent answered they simply didn't want the service, 9.7 percent answered the monthly Internet Charge was the reason, 9.6 answered they can use other Internet connections available elsewhere, 8.3 percent answered their computers are not capable of the connection, 6 percent answered concern for children was the reason, 4.8 percent didn't want to pay the toll call fee to the ISP, and 2.3 percent didn't want to pay the other cost involved. In total, at least 25 percent of the reasons for not
connecting to the Internet were cost related; yet 7.5 percent of the surveyed population were planning for future Internet access (http://www.ntia.doc.gov/ntiahome/ftn99/InternetUse III/Chart-III-25.html).

Figure 5: Reasons of households with computer/WebTV not using the Internet at home

Household structure is another important determinant of computer and Internet usage (see Figure 6). While 61.8% of households composed of married couples with children own computers, only 31.7% of female-headed households own a computer. Black families with two parents are nearly four times as likely to have Internet access as single-parent Black households. Married couples with children under 18 exhibit the highest rates of Internet penetration (inside and outside the home Internet access (37.6%) http://www.ntia.doc.gov/ntiahome/ftn99/InternetUse III/Chart-III-24d.html).

Figure 6: Percents of US households with a computer/WebTV using the Internet at home by household type

Education level appears to be another important determinant for computer and Internet usage (see Figure 7). Among the U.S. households using the Internet in 1998, 45 percent held a BA or higher
degree, 30 percent had some college education, 15 percent had a High School diploma or GED, 6 percent had some high school experience, and 4 percent had only an elementary education (http://www.ntia.doc.gov/ntiahome/fttn99/FTTN_I/Chart-I-25.html).

Figure 7: Percent of US households using the Internet by Education

The Importance of School in Closing the Digital Divide

Since many people do not have knowledge of technology to pass onto their children, schools are destined to serve as the catalyst for preparing America's youth for the age of technology. In 1998, in U.S., 35 percent of Hispanic, 27 percent of Black, 20 percent of White, and 19 percent of Asian/Pacific Islanders used the Internet outside the home and gained access at K-12 schools (see Figure 8, source: (http://www.ntia.doc.gov/ntiahome/fttn99/InternetUse_II/Chart-III-15a.html). The data reveal that school is the single most crucial entity for someone who cannot afford to have Internet at home gain access to the Web. Data indicate that outside of work, schools are the second most frequent place where people access the Internet, 33% of access is made from schools (see Figure 9).
Applications of a Best Practice Study:
Implications for Technology Integration in the Elementary Classroom

Laurie B. Dias
Middle/Secondary & Instructional Technology
Georgia State University
United States
lbdias@gsu.edu

Abstract: This paper presents the results of a study on four elementary teachers' technology integration practices. Boyatzis' (1998) thematic analysis technique was used to examine interview transcripts, observation notes, and teacher-produced documents for pedagogical practices that accompanied uses of computer technology in these teachers' classrooms. Emergent patterns borne out by the data resulted in a general conclusion that best teaching practices and best technology integration practices go hand-in-hand. Educators should not be overly impressed by the mere use of technology in instruction. They need to be discerning about the pedagogy that accompanies its use.

Introduction

An emerging consensus in the current educational reform effort suggests that teaching methods based on constructivist principles promote learning in a way that teaching-by-telling cannot do. The social aspect of learning by collaboration and an individual's need to explore and experiment are best directed through pedagogies based on constructivist theory. Some of these strategies identified as “best practice” include student-centered instruction, experiential and holistic learning, authentic experiences, reflective exercises, social interactions that scaffold learning, collaborative grouping, problem-oriented activities, and integrated thematic units (Daniels & Bizar, 1998; Zemelman, Daniels, & Hyde, 1998). Many in the field of instructional technology (Grabinger, 1996; Jonassen, Peck, & Wilson, 1999; Wilson & Cole, 1996) also recognize that an instructional context based on these principles has significant implications for uses of technology that promote meaningful learning. As Clark (1983) indicates, "Media are mere vehicles that deliver instruction but do not influence student achievement any more than the truck that delivers our groceries causes changes in our nutrition" (p. 445). It is not the media that influences learning; rather, it is the instructional design utilizing effective teaching strategies that makes an impact. Good teaching combined with appropriate and effective uses of technology makes for a dynamic, rich learning environment.

So, what might you expect from an elementary teacher who is using best practices as they relate to technology integration? From my observations and discussions with four elementary teachers who infuse technology into their instructional practices, it has less to do with the pizzazz of a PowerPoint presentation or graphics whizzing onto a web page and more to do with the lesson design and teaching methods selected when technology is being used (Dias, 2000).

The Study

The study began in the Fall of 1999 and concluded in the Spring of 2000. I used qualitative inquiry since this study sought to provide a “picture” of teachers' technology integration practices as they naturally occurred (Bickman, Rog, & Hedrick, 1998). Using the reputation case selection sampling technique (Miles & Huberman, 1994), 4 elementary teachers from a large metropolitan school district in the Atlanta, Georgia area were chosen. They were identified as “technology integrators.” All were female. One taught third grade, another fourth grade, and two taught fifth grade. Two of the four teachers taught in the same elementary school. The participants’ teaching experience ranged from 4 to 23 years. Their ages ranged from 34 to 45 years old. Their earned degrees included one Bachelor of Arts and three Master of Education degrees.
The schools in which the teachers worked served between 700 and 1,100 students. The average class size for these four teachers was 24 students. Two teachers had five networked, multimedia classroom computers with Internet access and the other two teachers had only one. A variety of computer-related technologies were available at these schools such as digital cameras, scanners, and various display devices. Each school had a computer lab with a fixed rotation schedule. The schedules varied at each site. Time allotments ranged from 25 minutes to 50 minutes approximately every 6 days.

I gathered data from multiple sources: interviews, participant observations, and documents such as lesson plans and web pages. Each teacher participated in four informal interviews with foci based on Seidman's (1998) interview protocol. Interviews followed observations, except in the case of the initial interview. I observed the teachers for four observations periods ranging in length from 40 minutes to six hours. On several occasions, observation periods continued into a second day depending on the activity that I was observing. Since the purpose of the study was to identify best teaching practices as they related to technology integration, I scheduled observations with the teachers so as to coincide with technology-connected lessons. The teachers provided me with lesson plans reflecting the activities I observed as well as others previously used along with artifacts such as web pages that they had created.

Through inductive analysis, categories, themes, and patterns emerge from the data (Janesick, 1994; Patton, 1990). Boyatzis' (1998) thematic analysis was employed as a means to interpret the data collected. This began as data was first collected and ran throughout the study. Triangulation was evident after a review of observation field notes and documents confirmed the trustworthiness (Lincoln & Guba, 1985) of the interview data.

Results

Emergent patterns borne out by the data resulted in a general conclusion that best teaching practices and best technology integration practices go hand-in-hand. It is sufficient to say that effective teachers adjust instruction to meet the needs of their students. In addition, they typically use a broad repertoire of approaches skillfully (Darling-Hammond, 2000). The participants in this study used a variety of methods while diffusing technology into the curriculum throughout the school year in order to achieve a balance of activities for their students. Their approaches to technology integration helped to foster a supportive classroom climate: one in which students made choices, took responsibility, expressed themselves and their knowledge in a variety of ways, and created a community of learners. The following are five best practices that emerged from my analysis of interview transcripts, observation field notes, and documents.

1. Multidisciplinary and Problem-based Units

Elementary teachers use technology best when it is done in conjunction with multidisciplinary, problem-based units. These units are typically contextualized for the students so as to simulate a problem that they might encounter outside of the school setting. Teachers in this study facilitated only one or two such units a year because of their in-depth and time-intensive nature. For example, one teacher created a stock market unit in which her fifth grade students collaborated with ninth grade students for a six-month look at how the stock market worked. Both classes researched a variety of stocks and used e-mail to exchange information once a week. With the fifth graders acting as stockbrokers and the ninth graders taking the role of investors, students worked in "firms" buying, selling, and trading shares. They computed costs, losses, and gains, prepared stock reports, and created investment portfolios. Using word processing tools, graphing software and Internet tools during this project helped to increase students' understanding and extend the learning environment.

2. The Ends Drive the Means

Teachers who are integrating technology are purposeful when using it. One of the best practices of teaching is focusing on what the students should have learned when the lesson is over. This is true of technology integration. Teachers in this study determined the objectives first and then decided when and if to use technology to help meet these objectives. In addition, they used technology with their students in a variety of places in the lesson: to introduce material, to extend understanding, to provide additional practice, to enrich
learning, to provide closure, and to assess learning. Technology should play different roles in instruction depending on curriculum objectives and lesson design. Teachers who integrate are flexible and not single-minded in their placement of technology within a lesson.

Teachers also realize that the design of the lesson may cause their role to change. Both direct instruction and teacher-as-facilitator were instructional strategies used when integrating technology. Direct instruction was generally used to introduce material, clarify content-based misconceptions, or teach technology skills. Teachers I observed tried to keep these segments short, between 15-30 minutes. They also acted as facilitators of learning while students were engaged in cooperative group work or even during individual assignments. These teachers' end goals for their students help to determine the means needed to reach them.

3. Collaboration and a Community of Learners

I also observed these teachers building a community of learners. The Internet and e-mail make it possible to extend the classroom beyond its four walls. Students can participate in data gathering activities with schools locally and nationally. The third and fourth grade teachers in my study worked side-by-side in the same school and team-taught many units. In a unit focused on regions and the impact of people’s needs and wants on the environment, they created surveys to find out the “ecological footprint” of other elementary classrooms in various regions across the United States. They e-mailed their surveys to schools throughout the country. After compiling the data using graphing software, the students constructed different scenarios depicting the potential impact of supply and demand on the environment of these regions.

Adopting “e-pals” was another way several of these teachers expanded their community of learners. One fifth-grade teacher and her class joined nine other classes across the United States for a “Cyber Quilt” project. Using e-mail and “snail mail,” the classes exchanged information about themselves including the culture, lifestyles and climate of the area in which they lived along with fabric squares that they felt represented this information. Each class created a quilt with material that students brought in as well as the fabric squares from their e-pals. Through this project, students gained a greater understanding of the power of the Internet and e-mail as communication tools, made new “cyber friends,” and considered the similarities and differences between themselves and people living in other parts of the United States.

The community of learners is not just about activities external to the classroom, but also about the teacher being a learner in the process and helping students to recognize each other as experts. Due to the limited number of computers frequently found in classrooms, collaborative activities are a natural fit as an effective instructional method. Problem-based activities or multidisciplinary units provide the perfect context for students to work together. Technology integrators use this best practice to capitalize on students’ strengths, develop teamwork skills, and to scaffold learning. For example, groups of three or four students may gather around a computer to use Inspiration for a brainstorming session prior to starting on their group project. They also share and divide the work in such a way that all group members have task responsibilities so that each student has some individual time on the computer. While this works best in classrooms with three to five computers, I also saw it work in classrooms with only one.

4. Scaffolding For Understanding

During technology-connected lessons, technology-integrating teachers regularly and systematically scaffold learning for their students. Using this method, the teacher provides the student with some type of assistance to complete a task or learn a concept. Gradually, the “scaffold” is removed until the student is doing this on his or her own. The scaffolding strategies used in conjunction with technology by the elementary teachers in this study included the following: bookmarking websites, providing written directions for computer-related tasks, graphic organizers, note-taking guides to use while gathering information from on-line resources, verbal reminders, and peer tutoring. Pre-selecting appropriate sites allowed the students to begin developing information access skills in a somewhat controlled environment. It helped to eliminate potential problems that can result from inadequate search strategies, misspelled words, or poor keyboarding skills. Graphic organizers guided students as they gathered and recorded data from on-line sources as well as helped them organize ideas prior to using the computer to generate graphs, charts, reports and presentations. Written directions, demonstrations, verbal reminders and peer tutoring all served to assist students as they learned to use technology in the classroom.
5. Using Multiple Hard and Soft Technologies

Another best practice related to integrating technology is the use of multiple hard and soft technologies. These teachers who used technology effectively did not limit integration to a narrow set of technology tools, but rather chose from a variety in relation to their teaching goals. These included soft technologies such as the Internet, e-mail, word processors, graphing programs, databases, cognitive mapping programs and multimedia software. Of these, the availability and versatility of word processing and Internet tools resulted in more frequent use.

They also included hard technologies such as flex-cams, digital camera, scanners, and some type of display device (which is critical to whole class instruction). One of the fifth-grade teachers I observed used the digital camera throughout the year as a way to record the “class history.” She and her students used the digital pictures in multi-media presentations that reflected what students had learned from a recent fieldtrip. They imported pictures into classroom newsletters as a way to communicate with parents about special events, and students printed out pictures to use in classroom art projects.

Conclusions

Computers and the Internet are more available now to teachers and students than ever before (Williams, 2000). In a recent study (Smerdon, Cronen, Lanahan, Anderson, & Angeles, 2000), 99% of teachers reported having computer access somewhere in their schools. Of these, approximately half used them for classroom instruction. 84% indicated that they had computers available in their classrooms. Accompanying this trend, is an increasing demand for teachers to make computers an integral part of their instructional activities. They are expected to integrate technology in ways that ensure that their students achieve success in learning, communications, and life skills as well as becoming technology literate in the process. Within the last few years, the International Society for Technology in Education (ISTE) and its partners have developed both the National Educational Technology Standards for Students (2000) and the National Educational Technology Standards for Teachers (2000). These documents clearly indicate expectations for effective computer usage in teaching and learning. Standards, competencies, assessment, and accountability for technology usage are upon us. It is important for school administrators and others in leadership roles to understand what constitutes best practice in technology integration. When administrators evaluate teachers using technology, it is imperative that they know what to look for. They should not be overly impressed by the mere use of technology. They should be discerning about the pedagogy that accompanies its integration. Based upon my research, and that of others, some of the questions that should be addressed when evaluating teachers’ effective integration of technology into the school curriculum are the following:

- To what extent does technology bring additional value to multidisciplinary units?
- To what extent is the integration of technology driven by instructional objectives?
- To what extent does technology cut across different events within a unit or lesson?
- To what extent does the teacher adapt flexible roles and teaching/learning strategies in order to maximize learning outcomes through the integration of technology?
- To what extent does the teacher utilize the integration of technology to build a community of learners?
- To what extent does the teacher utilize various scaffolding strategies in order to maximize learning outcomes through the integration of technology?
- To what extent does the teacher utilize multiple hard and soft technologies in order to maximize learning outcomes through the integration of technology?

Computers in the classrooms are here to stay. Already a variety of assessments tools exist that help teachers determine their technical skill level, such as those based on the Mankato Scale (Computer Use Self-Assessment, 2000). There are others that attempt to measure teachers’ instructional use of technology (Moersch, 1997). These self-reporting tools are valuable sources of information that can help teachers and administrators plan for staff development. However, as teachers become more proficient at integrating technology into their curriculum, we must begin to move beyond self-assessments. New evaluation models that include looking at pedagogical practices in relation to technology integration are necessary.

National educational technology standards for teachers (2000). Eugene, OR: ISTE.

Abstract  This paper explores the feasibility of an Internet software known as “iMatrix” to enhance learning opportunities within the virtual environment of the NatureShift/Linking Learning to Life web world. The NatureShift project, a US Department of Education Technology Innovation Challenge Grant, seeks to investigate the impact on learning when informal (free-choice) education methods are applied through technology to formal education curriculum. To build an effective technology delivery system, NatureShift chose iMatrix, an image and audio database software developed by Surweb (a TICG project), to provide instructional tools for users that allow on-line construction of slide shows, tests, and learning units. By adapting iMatrix tools to its NatureShift Exploration Model, an inquiry-based, constructivist learning model, learners gain creative control over their learning environment. They may create digital presentations or instructional media with minimal understanding of the technology. NatureShift is evaluating the iMatrix effectiveness in assisting learners to make learning meaningful.

Background

NatureShift/Linking Learning to Life (NS) is a five-year Technology Innovation Challenge Grant (TICG) funded through the US Department of Education and awarded in 1997 to the partnership of Dakota Science Center and Grand Forks Public Schools. Two primary objectives of the grant are the creation of an instructional web-based environment that reflects and evaluates the effectiveness of the NS Exploration Model as a learning strategy, and incorporation of appropriate and innovative instructional technologies throughout the learning process. In spring 2000, NatureShift accepted an offer from Surweb, another TICG project, to join a consortium of projects testing and adopting Surweb’s software innovation known as “iMatrix.” It was determined that iMatrix software might enhance NatureShift’s instructional capabilities, contributing a database to house informational resources and an on-line set of tools for creating custom learning events from those resources. One immediate instructional advantage was clear – iMatrix provided opportunity for users to collect resources from their world and then turn those resources into custom instruction. This advantage meant that a user (learner) could create meaningful learning events by studying information from the world they already understood (Brynes 96, Negroponte 94, Solis 97a, Papert 93) the prime goal of the NS Exploration Model. The iMatrix offered a second advantage to users, whether educators or learners – the opportunity to create a complete instructional sequence, including resource, instructional presentation, assessment and context, live on the web in real-time (Bills et al. 95). The advantage offered immediacy, feedback, and personalization of instruction, all critical elements of effective learning strategies. The critical and decisive choice was then made to integrate iMatrix tools seamlessly through the NatureShift construct rather than establish a standalone iMatrix web site as the consortium envisioned without educational application to member projects. Under this design, iMatrix and NatureShift each gained enhanced capability to utilize the powers inherent in the other.
Nature Shift! Scope and Innovation

The Nature Shift grant seeks to impact learning outcomes through integrating informal (free-choice) education approaches into the formal education experience (Sanford & Uyehara 97). In so doing, the grant calls upon innovative technology to aid instructional application and stimulate creative uses of technology throughout the learning environment.

Innovations of the Grant

Innovation 1

The grant developed an educational model, the NS Exploration Model, which culls best practices from free-choice education and formal education strategies and applies those strategies to both formal education classrooms and informal education settings. The goal of the model is to stimulate critical thinking and interpret meaning from personal discovery and understanding. The model has four structural elements which, together, are designed to bring the learner to the goal. (1) Engagement – stimulates inquiry and puts the learner in charge of the learning path. (2) A Web Adventure – provides free exploration through a defined instructional path and teaches research using new technologies. (3) A Real World Adventure – brings instruction into the learner's world and offers a path for knowledge application and understanding. (4) A NS Project – constructs a summative presentation or demonstration of knowledge gained, requiring the learner to interpret the meaning of the principles and/or skills acquired. Solis (Solis 98) explains, "a learning environment requires the development of two components: (a) a guiding philosophy and (b) a system that supports the philosophy in practice." Establishing a supportive system to deliver the Nature Shift philosophy led to the second grant innovation.

Innovation 2

Nature Shift disseminates its model, its curriculum framework, its resources, and its instructional practices through a robust networking system and a web site that uses advanced technologies to construct a learner-centered instructional environment. The NS world is a simulated exploration through five cross-disciplinary, integrated microcosms. It engages learners through inquiry and it gives them content for study, investigative methods, and tools for engaging content, critical components for motivating learners in project-based learning approaches (Blumenfeld et al. 91).

Innovation 3

Creative partnerships empowered an innovative educational program that linked information resource providers and expertise with schools, universities, and non-formal education providers. An unbroken learning line was established that could deliver information from an original source through instructional designers to educators and pre-service teacher training programs and into the hands of learners for construction of knowledge and meaning. The partnerships created a meaningful instructional medium and context for learning so that higher order thinking skills could be stimulated in target learner populations (Solis 97b).

Curriculum and Technology Contributions

Curriculum

Nature Shift is unique in its approach to content development. It had opportunity through its partnerships to develop content contributed by first source providers. Grant administrators sought out the primary
educational resources necessary for development of NatureShift-applicable curriculum. North Dakota is a state challenged by sparse population, rural isolated communities, and a limited economic base (Sanford & Uyehara 97). One key need that drove development of the grant was the lack of resources for the State's North Dakota Studies curriculum framework. NS resource partners were selected for their ability to add substantial resources to the project to meet that need. One of the first findings of the grant was that collection of original source material from partners for creating curriculum turned out to be an effective fuel for firing-up interest in learning, even though those resources were delivered through a virtual medium. Because learners could study information that came from their home environment, they became interested in the content under study -- even when that content was delivered via the web. It was, in fact, critical to student interest that that original material was in the virtual presentation. It had the effect of "making it real" (NatureShift Progress Report 2000, Solis 97b). Learners no longer simply investigated the application of knowledge to their world in a Real World Adventure, but they now had the "real thing" available on-line for exploring the curriculum they were learning.

Technology

Midway into the NatureShift project, it became clear that a robust technology architecture would be needed which could serve a comprehensive web site to learners. It would need to deliver a highly interactive web environment and offer communication and collaboration tools that would ensure appropriate on-line teaching and learning methods. The elements added to the NatureShift web site included a model NS Exploration for each of the five modules, on-line pre-post evaluations, knowledge checks with feedback, authentic content delivered engagingly, a functional operation that stimulates inquiry and exploration, plus communication and collaboration technologies to encourage learner interactions. The addition of the iMatrix software brought necessary enhancements to these functions and contributed a new layer of user controls.

iMatrix Contributions

Development of the original iMatrix software was the project of SURWEB (State of Utah Resources WEB), a Technology Innovation Challenge Grant formed by a statewide consortium of public and private agencies, led by Southeaster Education Service Center. The project was intended to address educational opportunities for disenfranchised communities, provide authentic, locally-created resources to enhance educational opportunity for all of Utah's elementary and secondary students, provide quality education resources via technology, build connectivity to access information, and develop curriculum applications for the Internet (Bills et al. 95). At the conclusion of the project, the software was turned into a consortium of Challenge Grant web sites and renamed iMatrix.

Capabilities of the Software to Deliver NatureShift Objectives

The iMatrix software is structured upon searchable digital Collections of images, sounds, movies, and PDF documents that are accessible for the creation of HTML-generated Media Shows, Tests, and Learning Segments. This four-part package of tools is easily learned by teachers and students (Nelson 2000). The power of the user tools to create instructional materials over the web in real-time gave to NatureShift, as to other consortium members, the ability to generate an archive of instructional resources which users could manipulate for generating new instructional content. What NatureShift recognized was that iMatrix provided several answers that could prove effective for the project. It was a database with a web interface that could house all of NatureShift's partner developed resources. It could make those resources available to school partners and Dakota communities. More importantly, the software functionality matched NatureShift instructional strategies for putting interpretation of learning into the hands of learners and giving learners the ability to follow their own lines of inquiry. It also offered NatureShift users the option to create summative projects on-line for their NS Explorations. What development staff discovered, once they
began using iMatrix software, was that, given further development to meld the two webwares, iMatrix could lead to more innovative offerings for both web sites.

**Merging Application Powers for Curriculum Development**

*NatureShift* web innovations included the creation of simulation-style learning environments whereby users could enter, watch, interact, listen and explore a specific world of inquiry. iMatrix innovations gave users a web site archive that could be manipulated into instructional products of the user's choice. *NatureShift* staff determined that they could merge the two innovations. By embedding iMatrix tools inside the *NatureShift* world and making them available to NS Explorers, it allowed learners to remain in the learning experience and yet have creative power to manipulate it. This tactic offers learners an option for drawing meaning from their *NS Explorations* and a way to prepare an interpretive presentation of what they have learned, without leaving *NatureShift*. iMatrix thereby gains curriculum and/or content focus for its user while *NatureShift* gains tools for the learner to use with curriculum content. *NatureShift* recreated the design of its web operations to enable iMatrix tools to be used within the *NatureShift* curriculum. This feature meets *NatureShift*’s primary goal of stimulating creative thinking by providing content and giving the learner freedom and power to interpret and formulate meaning from his or her engagement with the content (Pirie & Kieren 92).

*NatureShift* developers have reviewed the advantages of the merged functions of both web technologies. As a result, curriculum writing teams are now developing coursework for specific curriculum frameworks that can be delivered almost anywhere through this enhanced medium.

**Professional Development**

Both *NatureShift* and iMatrix goals include the proven instructional strategy of modeling learning methods when drafting professional development plans. If the merged technologies work well for teaching students, they should work equally well for training educators and professionals. iMatrix is designed for use as a training tool as much as a learning tool. When combined with *NatureShift* web tools, it functions admirably for demonstrating *NatureShift* teaching strategies. iMatrix has been used exceptionally well to demonstrate the twin values of instructional *immediacy* and learner interactivity (Montgomery 2000). With only an Internet connection, iMatrix can be accessed and immediately put to use when giving a presentation. It has obligingly provided its tools for uploading pictures in real time during workshops and demonstrated to participants the power of creating an instructional event in real time to a multitude of learners. A Media Show can be created in less than 10 minutes. iMatrix has the unique capability of providing instruction, demonstration, and training at the same time. It is ubiquitously portable, sending its lessons and media shows anywhere there is an Internet connection to receive it.

**Conclusions**

iMatrix has proven a powerful tool for putting creative power into the hands of learners. In combination with a curriculum- or content-rich site, it gains power exponentially to help learners interact with the objects of learning. Because the same authoring platform is used by teachers and students, students gain the opportunity to become teachers, thereby demonstrating what they have learned and enhancing their own learning. This ability for users to author instruction matches one of *NatureShift*’s core principles — to give

---

* Webware refers to a package of web programming that delivers a "software-like" application over the web.
* NatureShift teaching strategies include: (1) "Each one teach one" (i.e., teacher creates lesson in iMatrix from which students create their own lessons for other students, or class presentations); (2) Use of technology to deliver instruction; (3) Personalizing learning inquiry (using digital cameras to gather information, uploading it into iMatrix, presenting it).
* "Authoring platform" refers to a software tool that allows the user to create (author) new software applications. In this case, iMatrix gives users the ability to generate new HTML-based instructional materials.
learners a way to sum up the knowledge they have gained by constructing their own meaning from it. This functionality, however it might be used, will undoubtedly enhance the NatureShift web site by allowing it to grow openly and through unlimited user contributions.

The Interactive Classroom

Richard R. Eckert
Computer Science Department
State University of New York at Binghamton
United States
reckert@binghamton.edu.edu

Abstract: Computer programs have been developed that enable students in a classroom to interact with and take control of the computer the instructor is using to present the class material. From their seats students can request to connect their laptop computers over the network to the main computer that is being used to project the course material. Once connected, any student can, at any time, send messages to the instructor and ask to take control of the main computer’s mouse and/or keyboard. This enables students to perform actions such as: unobtrusively ask questions, move to another slide in the presentation, make annotations on the main screen to help clarify their questions, participate actively in online simulations, type in answers to questions, and an almost endless number of other tasks that require remote manipulation of the computer the instructor is using. At all times the instructor determines whether a student is permitted to take control of the system and can override that control as needed. The server program running on the main computer also allows the instructor to perform administrative tasks such as maintaining a list of authorized students, their logon IDs and passwords, as well as the IP network addresses to be used.

Introduction

In most universities and colleges large lecture sections have become very common. Unfortunately that kind of environment is not very conducive to meaningful interaction between students and the instructor. Ideally the instructor of a large lecture section should be able to move freely about the room to interact as needed with students as he or she is presenting the material to be learned. In addition it would be beneficial if students could have the possibility of interacting directly with the material being presented without having to leave their seats. We have developed a relatively inexpensive, Windows/PC-based “virtual blackboard” system that can be controlled at a distance by a classroom instructor and/or students in the class. [1] One component of our system is a wireless mouse emulator that is implemented using a software-controlled standard red laser pointer. With this system the instructor is no longer tethered to the computer, but is free instead to roam the classroom and interact with students as needed. The second component is an electronic system of communications between students and instructor. With this system any student can temporarily take control of the mouse and/or keyboard of the instructor’s computer. This is a tested, full-featured implementation of the prototype communications system described in the paper “The Classroom of the 21st Century.” [2] Figure 1 is a diagram illustrating conceptually how the system is used in a classroom. Figure 2 shows how it can be set up.
The Electronic Communication System

In this paper an electronic communication system between students and instructor is described. It is assumed that the instructor is using a computer projection system as the main mechanism for presenting the educational material. The instructor may, for example, be delivering a PowerPoint™ presentation, showing material from the World Wide Web, running a simulation that he or she wants students to be able to use, or executing any number of different programs on the main computer. With recent advances in networking technology it is becoming very common to have Internet connections available at every seat in the lecture hall. So quite commonly many students bring their own laptop computers to class. Our system enables any student in the classroom to use his or her laptop computer to send an electronic message to the instructor, and, with the instructor's permission, take control of the mouse and/or keyboard of the instructor's computer. This allows students to perform actions such as: unobtrusively ask questions, move to another slide in the presentation, make annotations on the main screen to help clarify their questions, participate actively in an online simulation, type in answers to questions, and an almost endless number of other tasks that require remote manipulation of the computer the instructor is using.

The keys to the system are two Microsoft Visual C++ programs that we have developed and tested. One of them (ClickServer) runs on the instructor's computer, and the other (ClickClient) runs on each student's computer. The instructor is assumed that all computers are connected to some sort of a TCP/IP-based network. This could be a wired or wireless LAN.

The user of the ClickServer program (the instructor) is presented with a window that has, among others, an "Options" menu item containing "Accept Connections", "User Management", and "Configuration" submenu items. Within "User Management" the instructor, acting as administrator, can add users (user name, password, IP addresses from which the student can connect) and indicate whether or not the user is authorized to request taking control of the mouse and/or keyboard. Within this same dialog the administrator can edit the current list of users or delete users from the list. Figure 3 shows the initial ClickServer screen, Figure 4 the "Options | User Management" Window, and Figure 5 the "Add User Information" dialog box.
ClickServer defaults to rejecting connections when first executed. To allow connections from student clients the instructor selects the "Options | Accept Connections" menu item, which puts the program into "Active Connection" mode. From that point on students can connect to the server program. A list of students who have connected appears within a large "Connections" window. Any messages sent by any student will appear along side that student's name, in addition to a "status" flag that indicates whether or not a given student has taken control of the main computer's keyboard and/or mouse. The instructor can, at any time, click on a button that will "activate" or "deactivate" a student, thereby enabling or disabling that student from taking control. In addition there is a "Kill Connection" button in which a selected student can be disconnected from the server. It should be pointed out that at all times, regardless of whether or not a student is controlling the main computer's mouse and/or keyboard, the instructor also has the capability of local mouse/keyboard control. Furthermore, at any time the instructor can override student control of the system.

ClickServer's "Options | Configuration" menu item allows the instructor (administrator) to set certain system parameters such as the TCP/IP port to be used, to configure "hot key" combinations, and to set or alter other system parameters. In most cases the instructor will not need to invoke this menu item.

When students run the ClickClient program on their laptop computers, they are presented with a window that allows them to enter their user ID, password, and the IP address of the ClickServer. Figure 6 shows the ClickClient screen that appears on a student's laptop when he or she starts the program.

Figure 4. The “User Management Window”.  
Figure 5. The “Add User Information” dialog box.

Figure 6. The initial screen that appears on a student's laptop when ClickClient is run.
When students want to connect to the instructor's computer, they can click on the "Make Connection Active" button. Then, on the instructor's screen, the "Status" of the student who has been given control changes from "INACTIVE" to "ACTIVE". The student's "Log" box will reflect the fact that the student has assumed control by displaying a "Mode set ACTIVE" message. That student can then click on a "Show Pad" button to actually take control. At that point a large rectangular "mouse pad" area will appear on the student's laptop screen, and subsequent mouse movements and clicks while the cursor is over the pad area will cause the corresponding mouse actions to occur on the instructor's computer and be reflected on the projection screen. In addition, any student keyboard actions will also be directed to the main computer. Figure 10 shows the mouse pad that is displayed on the student's screen when...
he or she has taken control.

![Mouse Pad](image)

**Figure 10.** The “mouse pad” that appears on a student’s laptop after taking control of the instructor’s computer.

If the student tries to use the main computer’s mouse and/or keyboard and is not the current active user (i.e., has not been given control by the instructor), messages to the effect that mouse and keyboard control are unauthorized will appear in the log window. At any time, in the program’s main window, the student can click on a “Disconnect” button, in which case the server will close the connection of that student’s computer to the server.

A demonstration of the ClickServer and ClickClient communication system will now be given.

**Conclusions**

The ClickClient and ClickServer software has been tested in several university settings. Both students and instructors have commented that the system is relatively easy to use and that it really does enhance interactivity in the classroom. It can be especially useful in those kinds of classes where it is important that students be active participants — for example in situations where the student actually needs to use the instructor’s computer to do something. It has been ideal for allowing student manipulation of simulations. One example is a computer graphics ray tracing algorithm animation program that was developed by the author and one of his students. [3] The instructor explains and demonstrates the system at the main computer’s projection screen, and then, from their seats, individual students are allowed to work with the ray tracer animator, while the professor guides them and explains what is happening in the animation.

Abstract: In June of 2000, the Department of Educational Technology at the University of Northern Colorado (UNC) received a PT3 grant. One of the most difficult, crucial, and comprehensive aspects for implementing the PT3 grant at this university pivots on how well both the university’s and the state’s standards have been integrated into the two technology courses pre-service teachers are required to take before becoming licensed; more importantly, however, is how well these concepts have been integrated into the thoughts and practices of these pre-service teachers once they find jobs and begin creating courses and curricula. To put it another way, the challenge is how well the pre-service teachers have been taught the fundamental concepts of technology and how to apply that technology not only to both the university and the governmentally-mandated standards, but also to the course they will create and teach. This presentation will encompass three elements of the redesign process of the introduction to technology course that all pre-service teachers at UNC are required to take: first, various aspects of the data collection and evaluation will be explored; second, the integration of Colorado Department of Education’s (CDE’s) Standard 7 into the course’s curriculum will be explained; and finally, one aspect of the PT3 grant implementation process will be evaluated. This presentation will illuminate the trials and tribulations of all aspects of the evaluation, course redesign, implementation, and field-testing processes.

Introduction

In June of 2000, the Department of Educational Technology at the University of Northern Colorado (UNC) received a PT3 grant (Preparing Tomorrow's Teacher to use Technology). This university's grant has three overarching goals: graduates of the UNC teacher education programs will effectively utilize technology for instruction in their classrooms when employed as full-time teachers; two, UNC student teachers will effectively utilize technology for instruction in the partner school classrooms; and three, UNC faculty members will effectively utilize technology for instruction and model appropriate technology use for the preservice teacher education students. This paper will focus on how the PT3 grant team at the UNC will implement and integrate the best practices of technology use (both as a set of teaching tools, and as a model of how to use those teaching tools effectively in classrooms) into the second overarching goal of teaching pre-service teachers to use and to teach the use of technology in the classroom.

In 1996, Persichitte, Tharp, and Caffarella completed a study commissioned by the American Association of Colleges of Teacher Education, which investigated student and faculty use of technology by colleges and departments of education. The authors found that the 744 institutions surveyed generally had extensive infrastructure already in place, but the faculty were either not using it at all, or they were only using it for personal productivity, rather than for instructional activities. The data also showed that students were not being asked or required to utilize technology for class projects beyond basic word processing.

In a year-long research study, Lohr, Javeri, Mahoney, Strongin, and Gall, (2000) utilized a rapid application development (RAD) model to integrate various technologies into curriculum that could be used both
as a self-paced instruction (SPI) format, and as an in-class instructional model. Qualitative data gathered and analyzed by Lohr et al., that is significant to this project, found students felt the following about the introductory educational technology class: (a) the self-paced format was not only convenient, but gave freedom and flexibility; (b) the projects and rubrics were not as challenging as they could have been; (c) more examples and non-examples of each project would have been beneficial; and (d) fewer open laboratories would be preferable. The graduate-level teaching assistants (TAs) felt that students who chose to take the course online and thus did not attend many, if any, of the classes turned in less sophisticated projects than those who participated in the weekly class sessions. The TAs further felt that students tended to copy the project example rather than create unique solutions of their own. The project team as a whole was disappointed that the rapid application development (RAD) process did not allow time for learner-based (rather than teacher-based) beta testing—a problem that proved to be a stumbling block during instructional delivery.

As a result of this study, the PT3 team decided that self-paced instruction should be created using a template that has been originally designed to deliver learner-friendly instruction. This template would allow for continuity and uniformity of language and format. In the process of the Lohr et al., research study, the two educational technology courses it encompassed (a 200-level course for freshmen and sophomores, and a 300-level course for juniors and seniors) were brought current not only in the knowledge and skills they taught and developed, but also in the utilization and implementation of latest in computer hard and software.

In preparing to redesign the courses yet again, not only to incorporate the aims of the PT3 grant, the improvements in technology, the more demanding standards of the university, and the CDE’s governmentally-mandated standards into the curriculum, but also to meet the needs of partner schools as those needs related to the PT3 grant, UNC’s PT3 team visited 21 partner schools (K-12) to speak with principals, teachers, and technology coordinators as well as observe each school’s classroom uses of technology. For each of these visits, two to three team members visited each of the partner schools. Each member of every visitation took notes and wrote up a summary of their findings both from the principal’s and technology coordinator’s interviews, and from the classroom observations. The initial evaluation of the data collected have highlighted several key issues which need to be addressed in this, latest redesign of the 200- and 300-level courses: (a) all schools visited have a fairly extensive infrastructure, both new and old machinery that is not being used to its fullest potential; (b) networks and file servers are playing a much greater role than could have been imagined; (c) the balance between platforms is shifting away from MAC and toward PC machines running the MS Windows platform and this is true across all grade levels; (d) teachers are not able to generalize how to use software outside of the way they have been originally instructed to either use it, or utilize it; (e) K-12 faculty want and need activities that they can integrate into their curriculum successfully; (f) student information management systems have become a critical component both in the individual schools, and in those schools’ districts because state regulatory agencies demand extensive and comprehensive student data every year; and (g) with standards and assessments demanding more and more physical (time and energy) and financial (budgetary resource) support, technology facilitators (technology support personnel) have, as of late, become one of the lowest priorities on the K-12 personnel/time-allocation matrix.

In order to integrate into this university’s required technology courses not only the applicable overarching goals of the PT3 grant, but the latest parameters of governmentally-mandated (CDE) standards (Standard 7, see Appendix 2), conclusions gleaned from the Lohr et al. (2000) study, data collected from the PT3 grant-facilitated school visitations, and information gained from the Persichitte, et al. (1999) study, were woven together to create a tapestry of what the latest redesign of this university’s required technology courses. The second goal of this paper and the presentation is to outline the processes involved in revamping the introductory (200-level) technology course. Because the two courses (the 200- and the 300-level courses) are so dependent on each other, the redesign of one cannot be investigated without discussing the other; as a result, during this presentation the redesign of both courses will be discussed even though as this paper is being written, only the 200-level course redesign is nearing completion.

**Redesign Process**

Each of the PT3 grant’s three overarching goals are interconnected, and the key element—the common keystone, if you will—in each of those three arches relies on, depends on, how well the university’s pre-service teachers are taught; in other words, how well the fundamental concepts of technology have been integrated into these pre-service teacher’s thoughts and practices. The pre-service teachers now enrolled in the university and those to come must be taught the best practices of technology use by their teachers. Preservice teachers must be
able to recognize and address the technology-integration needs of schools into which they are ultimately placed, and they must be able to model the various technology's usages to and for the teachers with whom they will be working. The goal and process of revamping the other courses (as well as the teaching philosophies of those course's professors) in which these pre-service teachers will be taught is ongoing, as is the design of the 200- and 300-level technology courses.

To best achieve the goal of integrating the knowledge, usage, understanding, and dissemination of technology into the consciousness of these pre-service teachers, it was important to create not only comprehensive, effective course material and exercises, but to make the instructions efficient and projects appearing as well. At the same time, the amount of material that needs to be covered to appease the needs and goals of the many interested parties (the PT³ grant, this university's and the CDE's concerns and mandates, and the needs of the 21 partner schools, as well as addressing the findings from school visitations, Lohr et al. (2000), and Persichitte et al. (1999) was almost overwhelmingly extensive.

The first step in the process was to identify the ‘optimals’ (the skills necessary in order to meet the -service teacher standard 7, see Appendix 1). This required skills and knowledge base was then matched to the curriculum content of current 24x and 34x courses (the ‘actuals’ what we were teaching). The difference between the optimals and actuals illuminated for the team the gaps that needed to be addressed in the redesign process. Of the components identified in the optimals list, some were deemed so universally understood that they were dropped completely from consideration for the course material; others were categorized as basic enough to be listed as prerequisite skills for the course; and some were not presently being addressed, so were added to the required instruction for the course. Thetasks, skills, and knowledge-base requirements which remained were either left unchanged, redesigned, or combined with other tasks. Templates were then created for both the self-paced tutorials, and the rubrics used for assessing projects. The templates were designed to ensure that there was uniform wording and formatting both within the instructional content, and in the tools used to assess the students' skills acquisition and knowledge retention. From these templates, the new course's syllabus was created.

The next step, once the course syllabus had been created, was to assign the instructional design/redesign tasks to members of the team (see 24x Schedule Redesign). In the initial step in this redesign process, each instructional designer (ID) identified the critical components of skills and knowledge needed by the learner for the understanding and use of the tool for which the ID would be creating instruction. These components were placed in the rubric that eventually formed the structure from which the creation of the self-paced instruction would come. This process identified the specific tasks required of the learner to show proficiency in the understanding and use of the tools, and from which the learners' grade will be dependent. After each of these rubrics was created, it was presented to the whole PT³ team for evaluation, feedback, and revision. The ID then implemented the agreed upon revisions and finalized the self-paced instruction module. Once the self-paced instruction was created, the entire team critiqued it for clarity, giving constructive criticism for its improvement. Each module was then beta tested by both the PT³ grant/design team, and appropriate skill-level learners. Revisions based on feedback from these beta-testing sessions were also implemented into the self-paced instruction modules. This analysis/beta-testing/revision process will be ongoing over the next several months to ensure the most effective, efficient, and appealing courseware possible.

The 200-level course will be piloted during spring term 2001 as part of the formative evaluation process. As unexpected problems arise, they will be addressed by reworking the instructional content. Data will be collected from the learners during and at the end of each piloted class, so their input can be integrated into the final product. The team hopes to have the new courseware in its final form for summer semester of 2001.

At present, the redesign effort of the 300-level courses is in its initial stage, but it will follow the same process as the 200-level courses. The team understands that, due to the constantly changing hardware, software, and market requirements, any course that attempts to teach technology is a work in progress; as a result, this design team's efforts will continually be focusing on an illusive moving target.

Conclusion

At this time, the PT³ team is in the middle of revamping the two-courses. This phase of the PT³ grant implementation project will be completed by May 2001 for 24x and August 2001 for 34x. The data collection and evaluation phase turned up some fairly startling facts. First, there was much usable hardware and software already in place in the schools. Second, that while there were a few isolated individuals who were utilizing those tools to good and lasting effect, there still remains a huge gap in the schools' teachers and administrators'
desire and ability to integrate those tools. Third, one of the most surprising (and negative) side effects of education's latest push for the integration of intrastate and cross-discipline standards is that the personnel needed to help integrate the technology that can only help expedite the implementation of those well-meaning and well-thought-out standards are being, of necessity, pulled away from what, in the long run, would be advantageous, so that more short-term and short-sighted goals can be met. Finally, even though these courses were extensively redesigned a short time ago, anew redesign is required in order to meet new standards, the changing needs of the market, and the changing complexion of the available hard and software.

Standard 7, the technology standard of CDE's curriculum-wide K-12 listing of standards, has been well-thought-out and is very comprehensive in nature. Integrating all those standards into two one-credit courses created a challenge almost too great to be overcome, especially given the many, varied, and often conflicting requirements of the various entities that warranted influence on this redesign process. Evaluating which of those many and varied demands could be subjugated to the myriad of others that absolutely had to be addressed by the two courses, proved to be a very powerful teaching tool and learning experience for the IDs on the PT3 team. The result, thus far, has been well worth the efforts, and in the end, all of the crucial goals and requirements have been addressed.

Because of the two studies previously conducted and evaluated for this project, Lohr et al. (2000), and Persichitte, Caffarella, & Tharp (1999), this redesign has gone surprisingly well. There have been very few hitches, problems, or complaints. The redesign process has required an extraordinary amount of work by the PT3 team, but the results have, thus far, shown that RAD does have a place in academia; however, using a proven template in conjunction with that RAD helps immensely to not only speed up the design process, but to eliminate some of the more frustrating foibles and hurdles the Lohr et al. redesign encountered. Time will tell if the highest of the overarching goals will be met by the efforts of the PT3 grant team. We will have to wait for four slow-to-take-effect changes to occur before any real success or failure of that goal can be evaluated. Those changes include the revamping of university-wide curricula that affect pre-service teachers; the revisioning of the teaching philosophies of those professors who have applied to the grant for assistance in redesigning the courses they teach; the ability of the course redesigns to reach the students with both new information and with better and more comprehensive tools; and finally, how well those pre-service teachers integrate not only the technology they learned at UNC, but also the technology yet to come. Ultimately, realistically, any valid and reliable assessment of the PT3 grant team's success or failure may prove unattainable. The success may have to lie in the efforts, aspirations, and desires of the individuals within that team.

Why Technology is Being Integrated into the Classroom at Such a Slow Rate: A Discussion of Self-Efficacy, Motivation, and Utility.

Jesse J. Foster, II
University of Alabama
College of Education, USA
jfoster@bamaed.ua.edu

Introduction
In the past fifteen years, there has been much attention paid to the issue of integrating computers into the classrooms. The CEO Forum on Education Technology in Washington, D.C., polled nearly 80,000 public schools and found that only about 3 percent of the schools are successfully integrating technology into the curriculum. Why is the technology not being integrated at a faster pace? Researchers have seemingly asked every question but one; "Are teachers motivated to use technology in their classrooms?" I contend that the integration of technology is not an issue of the availability of resources or information. It is an issue of whether or not teachers motivation, and their belief that the integration of the technology into the curriculum will bring about a level of instruction and learning greater than otherwise possible. This is an issue about some teachers' need to avoid negative images. Consequently, too many teachers are struggling everyday, not to master the technology, but instead to invent ways to avoid failing at using the technology.

Perceived Self-Efficacy
Generally defined, self-efficacy is the degree to which one believes that she is able to achieve a given task. A teacher's self-efficacy can be described as the belief that he or she is an effective teacher. More importantly, research supports the idea that a teacher's self-efficacy is significantly positively correlated with student achievement. Teachers' perceptions of how effective they are as teachers is based on how well their students perform the task they have taught. Teachers who do not possess the necessary skills to perceive themselves as proficient with technology will not believe that they can help a student achieve at the task. They will not foresee the students succeeding because of their efforts. The predicted failure of the student leads to the teacher's anticipation of a lower self-efficacy at the task of teaching technology. This anticipation of low self-efficacy presents a special problem for the teacher. Dweck (1988) suggests that self-efficacy at a given task, given certain conditions, can often give rise to negative affect and a significantly lowered perception of self-worth. This is more likely to happen when the individual attributes the failure to forces that are internal, uncontrollable, and stable. These are precisely the attributions that teachers generally make about their "failed" efforts to teach any given subject. The ability to teach the subject is within them. It is not viewed as an environmental or situational force. Where the failure is associated with information that the teacher does not possess, the forces are often viewed as uncontrollable. The final attribution that most teachers make is that the results are stable. They believe that every time they attempt to teach technology with the knowledge that they have, the results will be the same...failure. These factors combine to put the teacher in a position where failure has a negative affect on their perceived self-worth. Consequently, to avoid the negative affect associated with lowered self-worth, teachers develop some mechanism to protect their self-worth. Either they can increase their knowledge of the technology, subsequently raising their self-efficacy about teaching it, or they can avoid the task all together.

Motivation to Achieve
For an explanation as to why so few teachers choose the former of these two options, I consider Atkinson's early theory of achievement motivation. Atkinson (1964) states that "the motive to achieve success (Ms), which the individual carries about with him from one situation to another, combines multiplicatively with the two specific situational influences, the strength of expectancy or probability of success (Ps) and incentive value of success at a particular activity (Is), to produce the tendency to approach success that is overtly expressed in the direction, magnitude, and persistence of achievement-oriented performance." In simple terms, the individuals tendency to approach success is equal to Ms x Ps x Is. The motivation to achieve success is generally accepted as a constant characteristic of the individual. This variable is the same for learning technology, as it would be for learning mathematics, science, etc. The other two variables are where the degree of flux appears from task to task. Atkinson notes that these two variables depend upon the individuals experience in specific situations that are not unlike the one she now confronts. The difficulty of a task as it appears to an individual is represented in terms of the strength of the expectancy of success. Where the task is perceived as very difficult, the Ps is very low. The inverse is true as
well. The probability of success (Ps) is, somewhat, subjective for tasks that fall between the impossible and the overtly easy. For most teachers, the Ps in mastering technology is very low. This is because of the perceived difficulty of the task. Atkinson's theory is that this perception is the result of previous experiences with like tasks. In the case of technology, I assert that these past experiences are not all computer specific. Since most of the teachers that are in the classroom do not use personal computers, the difficulty of this task must be generalized from other technology-oriented tasks. It is more likely that these past experiences include such tasks as programming VCRs, bouts with the school copy machine, and setting the clocks on microwaves and televisions. Because of the difficulties with this technology, and the perception that mastering computer technology is even more difficult then these "simple" tasks, the Ps for computer-oriented tasks is perceived as being very low.

The Utility Factor

Now the question becomes, "Why aren't we seeing teachers with high degrees of Ms for technology?" It is easy to see that if the Ms is high then the Ts will be high regardless of the Ps and the Is. This is where Atkinson's model is too simple in its approach. Atkinson fails to account for an individual's utility or value of the task. I propose that Ms is not constant from task to task, but in fact is dependent upon the individual's value of the specific task. An alternate writing of the equation would possibly be Ts = (Ms +/- Vs) X Ps X Is, where Vs represents the individuals value of the specific task. When the task is greatly valued, the individual is inclined to devote more energy toward the task, invoke the use of more volitional strategies to accomplish the task and work toward the task over a longer period. Consequently, the Vs is added to Ms proportionally. When the task is not valued, on the other hand, the Vs is not high, and in fact may even serve to detract from Ms (Ms - Vs). In this case, the individual does not care if failure comes. The failure does not effect the individual's self-efficacy as much as a valued task, and causes little of no negative affect. A further assumption is that if the Ps is small (a very difficult task) and the Vs is small (a relatively unvalued task), then Vs more readily becomes a negative figure. This is the case with many teachers and technology. The Author's personal research has attempted to examine this idea of teachers valuing technology. Middle and Secondary teachers were given a survey that questioned their beliefs about and usage of technology in the classroom. The study found that seventy percent of the teachers surveyed did not believe technology could make them better teachers. Teachers, in general, do not value the usage of computers within their classroom, and so they do not willingly attempt to tackle the task. The effect on their self-efficacy is not rooted in their valuing the task of teaching computers so much as it is in the task of teaching.

Intelligence Types

Dweck's research illustrates why teachers that do not believe that technology can make them better teachers often choose to avoid the task of integrating technology. Dweck suggests that there are two primary types of intelligence, Entity and Incremental. The Entity theory of intelligence is that intelligence is fixed and no matter how much effort you put into developing it, intelligence and performance are generally constant. The other type is an incremental orientation. This theory suggests that intelligence is malleable. These individuals believe that if one works hard and puts a lot of effort into a task, one can improve intelligence and subsequently performance. I assert that teachers that do not believe that technology can make them better teachers are more entity oriented, and those that do believe that their teaching skills can be enhanced with computers are often incremental thinkers. These two types of individuals have specific goal orientations and behavior patterns they display when they perceive their ability as high or low. Individuals that are incremental-oriented are more likely to seek challenges that foster learning. They have a high degree of persistence, and are mastery oriented. These individuals will display this behavior pattern despite their perception of their ability to perform a given task. Their goal is to increase competence. This is not the case for entity-oriented individuals. Entity-oriented individuals strive to gain positive judgments and avoid negative judgments of competence. When an entity-oriented individual perceives her ability as being high, that individual will be mastery oriented. They will seek challenge and be very persistent in their pursuit of excellence. This individual does not fair so well, however, when their perceived ability is as low. In this condition, the individual avoids the challenge and has a low degree of persistence. This is what happens entity-oriented teachers that have low perceptions of their ability to teach technology. They avoid the task because of their need to avoid negative judgments of competence...even when these judgments are primarily internal.

Discussion

For too long, we have been struggling with this problem. We have sacrificed teacher time and energy, in our efforts to conquer it. What we have not done is, gotten to the root of the problem: some teachers do not believe the technology can make them better, and are not motivated to integrate the technology. They are afraid of failing in front of their students and afraid of failing their students. Consequently, they have not invested themselves into the integration of the technology.
JavaScript for Teachers

Stephen Gareau
Department of Curriculum and Instruction
North Carolina A&T State University
United States
sgareau@ncat.edu

Abstract: Increasingly, teachers at all levels are making use of the Internet—both as a source of instructional information, as well as a medium for instructional delivery. Some instructors develop their own Web pages, which are typically written in HyperText Markup Language (HTML). JavaScript™, a browser scripting language originally developed by Netscape Communications, is a valuable tool that can enhance the functionality of any Web page. This paper examines the nature of JavaScript, and investigates how it can be used to enhance education-oriented Web sites of today's teachers.

Introduction

Increasingly, teachers at all levels are making use of the Internet—both as a source of instructional information, as well as a medium for instructional delivery. According to Technology Counts '99, an education technology survey conducted by Education Week magazine and funded by the Milken Exchange on Education Technology, most teachers across the United States currently have access to a computer, either at home or at school. Almost all teachers who have access to a computer use it for some kind of professional activity, and 61 percent use the Web to enhance instruction in their classrooms (Education Week on the Web, 1999).

Taylor (1980) provided a useful model of how computers can be applied to instructional purposes. His "tutor, tutee, and tool" model describes three different approaches to computer use: (1) computer as teacher (i.e., providing information and instruction); (2) computer as learner (i.e., learning tasks via computer scripting and programming); and (3) computer as classroom assistant (i.e., assisting in the completion of classroom projects) (Newby, Stepich, Lehman, & Russell, 2000). Each of these approaches can be applied to the use of the Web in the classroom as well.

JavaScript™, a browser scripting language originally developed by Netscape Communications, is a valuable tool that can enhance the functionality of any Web page. The purpose of this paper is to examine the nature of JavaScript™, and investigate how it can be used to enhance education-oriented Web sites of today's teachers.

What is JavaScript?

JavaScript is an interpreted, cross-platform, object-based scripting language that was designed for the development client- and server-based Internet applications. JavaScript commands can be embedded directly in HTML pages to allow for greater Web page interactivity and intelligence. JavaScript commands can recognize and respond to user actions such as mouse clicks, form input, and page navigation.

For example, a JavaScript-based script can be used to verify that users enter valid information into an online form. And, since a JavaScript script runs on a user's computer without any network transmission required (and the accompanying time delay), an HTML page with embedded JavaScript can immediately interpret the entered text and alert the user via a message window if the input is invalid. A JavaScript can also be used to perform an action (such as playing an audio file or communicating with a plug-in) in response to a user opening or exiting from a Web page.

JavaScript has a rich set of built-in functions and commands and, using JavaScript, even less-experienced developers are able to direct responses to and from a variety of events, objects, and actions. In
learning to control and handle events using JavaScript, a teacher can develop Web pages that are dynamic, interactive, and three-dimensional, rather than static and two-dimensional. JavaScript provides anyone who can compose HTML scripts with the ability to change images; play different sounds; and output different information in response to specified events, such as a user's mouse click or screen exit and entry.

As Weiss (1999) pointed out, JavaScript was introduced "to make it easier for Web pages to 'process' information; that is, rather than merely display static information, JavaScript could be used to perform calculations, output results to the page, and so on. Typically, this power is best employed when triggered by the user who is, after all, the primary agent in a Web page."

JavaScript and Java

JavaScript™ is also useful for working in conjunction with, and complementing the many benefits-based applets. Applets are small intelligent programs written in Java™ programming language, that can be used increase a Web page's level of interactivity. JavaScript can be used to execute; modify the settings; and control the appearance and behavior of Java applets. Java applets can be developed for such things as Web page animations and Web page databases. One such example is a Web page database applet called finditgrid™ that was developed by DoubleOLogic™ Software Corporation (Double0Logic Software Corporation, 2000). This applet will sort information that is provided in a text-delimited format, and then allow a Web page user to search through the information interactively.

Whereas JavaScript is a scripting language that can enhance the functionality of HTML-based Web pages, Java is a general purpose, cross-platform, compiled, application development language that can be used to develop full-blown applications—both for Internet-based or non-Internet-based, standalone information systems. Java was originally developed by Sun Microsystems Inc.

Like JavaScript-based scripts, Java applets execute client-side (i.e., on a user's desktop computer using the browser software), instead of server-side (i.e., on a Web server). As previously mentioned, this feature allows for fewer network transmissions, and much faster processing of information.

Web Page Enhancements Via JavaScript

Below is a list of some of the many features that can be added to a Web site and enhance it, through the inclusion of appropriate JavaScript-based scripts. Many of these features can be applied to educational purposes, both by teachers and students. And, for many of these features, there are Web sites that offer free downloadable (shareware) JavaScript-based scripts that will perform these functions. The Web site entitled The JavaScript Source™ (http://javascript.internet.com), developed and maintained by internet.com Corporation, is one such site.

Web page features possible through the inclusion of appropriate JavaScript code include:

- Web page input form functions: Field validation, checkbox changer, copy fields, etc.;
- Web page utilities: HTML page builder, print page, e-mail buttons, show link info, list of links, calculator, calendar, clock, etc.;
- Web page search features: Search engine, site search page, etc.;
- Web page dictionary features: Definition of unfamiliar terms, help popup, information box, etc.;
- E-mail: E-mail button, e-mail this page feature;
- Web page menus: Menu bar, pull-down menu, portable menu, midi menu (background music), etc.;
- Web page windows: Popup window, exit message window, etc.;
- Web page navigation: Remote control navigation, thumbnail navigation, page scrollbar, etc.;
- Web page security features: Password protection, text encryption, etc.;
- Web page graphical image display functions: Image slideshow, image previewing, photo/image album, drag-n-drop images, etc.;
- Web page messages: Animated headline messages, banner ads, exit messages, time-based greeting, visitor alert messages, etc.;
- Web page quiz features: User quiz, Math quiz, etc.;
- Web page games: Math Quiz, Maze, Buzzwords, Bridge, Insight Generator, Force Memory, Connect 4, Concentration, Catch a Spy, etc.;
Conclusion

The Internet and the World Wide Web, when used appropriately, hold great promise for improving the quality of educational content and delivery; for empowering students and teachers in their educational activities; for providing access to educational resources not previously available; and for making education more readily accessible to learners at a distance who might not otherwise have access. JavaScript is a simple, readily available, low cost technology that can help to support students and teachers in these endeavors.

Operationalizing a Technology Standard with Proficiency Skill Sets

David Georgi
Teacher Education Department
California State University, Bakersfield
USA
dgeorgi@csusb.edu

Abstract: The presentation of this interactive session will begin with an overview of the existing program which operationalizes the California technology standard for K-12 teachers with the California Technology Assistance Program (CTAP) Region 8 technology proficiencies. Lecture will be supplemented by a PowerPoint presentation and demonstrations of the following web sites: 1) the CTAP Region 8 site (http://www.ctap.org/ctc/) includes a rubric for three levels of certification and digitized video examples of exhibits at Levels 1 and 2; 2) the California technology standard (http://www.csub.edu/~dgeorgi/contents/techstand.htm); 3) the PT3 grant that helped coordinate these efforts (www.uroiecitnt.com). Next, a description of the process involved in coordinating this certification process with K-12 districts and teacher credential programs. To date, over 500 teachers have been certified including growing a cadre of Level 3 leader/mentors. An interactive discussion on implications for those present will conclude the session.

Introduction

In 1997, the California legislature passed a law mandating the development of a technology standard for K-12 teachers that would be used in the credentialing of new teachers and in the review of teacher credential programs. The Technology Education Advisory Committee (TEAC) was selected from among diverse constituencies to research the topic and develop recommendations for the Commission on Teacher Credentialing (CTC). The TEAC met many times over the next year and engaged the services of the State Librarian to research the efficacy of technology on the teaching and learning process (Umbach Report). A preliminary set of recommendations was sent to all pertinent institutions and individuals for field review. Taking the feedback from the field, the TEAC proceeded to develop language for a technology standard with a number of “factors to consider” that would be used to accredit teacher preparation programs (http://www.csub.edu/~dgeorgi/contents/techstand.htm). The recommendations were presented to the CTC in December, 1998 and were accepted. At first, the new standard was to be made effective in January, 2000, but a number of institutions requested more time and currently the standard will be effective in January 2002. All teacher preparation programs in California have been requested to submit plans for implementation of the standard and a number of methods have been proposed and were accepted.

Meanwhile, the California Technology Assistance Program (CTAP), a consortium of regional offices coordinated by the California Office of Education, was working on developing its own technology standards for teachers. Region 8, consisting of four central California counties, decided to build on the work of the CEAP by taking the technology standard’s factors to consider and using them as skill sets for technology proficiencies. The CTAP Region 8 Advisory Committee met several times and developed a rubric for assessing technology skills (http://www.ctap.org/ctc). The rubric has been used by K-12 districts to organize professional development activities and by teacher preparation programs at CSU Bakersfield. A federal PT3 project included a task force on Technology Proficiencies and helped coordinate the effort (www.uroiecitnt.com).

The CTC technology standard divided its levels of proficiency to articulate with the system for obtaining a teacher credential in California, which is a two level system. Meeting level 1 is a requirement for a candidate must be recommended for a preliminary credential. Meeting level 2 is required for recommendation for a professional clear credential. Level 1 is primarily personal computer skills with some application to teaching responsibilities; level 2 involves the integration of computer skills into teaching responsibilities.
CTAP Region 8 proficiencies have been organized into a rubric based on the two tiers described above and added a level 3 for advanced certification. All certification is done on the basis of portfolios assembled by the teachers. Teachers can be certified at level 3 as either mentors, whose main responsibility is training other teachers, and leaders, who serve as tech coordinators or administrators. Level 3 teachers can certify level 1 and 2 teachers.

Results

As a result of implementing a coherent approach to certifying teachers at various proficiency levels, a number of positive results have occurred.

First, technology skill training is directed toward meeting the levels of certification. This ensures that teachers attending training sessions are at an appropriate skill level and for specified skill development; avoiding some teachers being lost and others bored. This also allows all training at K-12 schools and university teacher credential programs to be articulated on the factors underlying the technology standard.

Second, teachers are encouraged to attain certification at all levels. Some schools offer a bonus for attaining level 2. Level 3 teachers often receive stipends for the training and administrative tasks they perform.

Third, by having level 3 teachers certify levels 1 and 2, the presence of expertise has been greatly expanded. Most local schools have at least one level 3 teacher and many schools are including the attainment of specified percentages of faculty attaining each level by specified deadlines. A strong cadre of level 3 teachers is being developed and will soon be adequate to provide technical support for local schools.

Fourth, by having a common certification system, unprecedented collaboration is occurring among schools and university teacher credential programs. Level 3 teachers are participating in the writing and implementation of a variety of grants and projects involving technology. One example is the Preparing Tomorrow’s Teachers to Use Technology Implementation federal grant, which includes a Technology Proficiencies Task Force. CTAP Region 8, local teachers and university professors have collaborated in developing a web site that includes the technology proficiencies rubric, application for certification, and examples exhibits that meet most proficiencies. In addition, a list of certified teachers is maintained at the CTAP Region 8 office and is posted on its web site. This is a further incentive for teachers to attain certification as it indicates that all teachers are expected to have demonstrated technology skills.

In addition to the positive results of this system, a number of problems have emerged.

First, articulation between CTAP Region 8 and instructors in the university teacher credential programs has had difficulties. University professors have been slow to get certified to level 3. CTAP Region 8 has offered to provide such professors with level 3 teachers so students in university classes can have their portfolios certified officially.

Second, it is difficult to ensure that all candidates will have access to certification. The university credential programs have submitted a plan to the CTC stating that by June, 2001, all credential candidates will be required to attain levels 1 and 2 in order to be recommended for the preliminary and then the professional clear credential. Because of the large number of credential candidates, an independent study course in Technology Portfolio Certification is being developed to meet the needs of out of state teachers and others who fall through the cracks. In addition, the state of California has contracted with National Evaluation Systems to develop a test our procedure for level 1, primarily for out of state teachers.

Third, some universities in the region refuse to participate in the system, citing turf issues. They will be required by the state to meet the technology standard in their own ways.

Fourth, other regions and the state level CTAP are developing their own systems, which may have a future impact on the Region 8 system. Similarly, the ISTE standards are seen by some as a model on which to base training. In response, a correlation chart has been developed, which indicates where specific skills are located in each system.

Conclusion
The implementation of a technology proficiency skill sets certification system based on a state technology standard has had dramatic positive effects on the development of technology skills in local schools. The certification of hundreds of teachers at levels 1 and 2 has encouraged many teachers, including those with life credentials, to develop technology skills that enhance the teaching-learning process. The increasing presence of level 3 teachers is providing that most commonly missing element in technology professional development: adequate and accessible technical support. As an added benefit, the awareness of the importance of technology in schools among level 3 teachers has produced that second most commonly missing element: equipment and training as a result of grant writing activities. As the new technology standard goes into effect, the system described in this paper can be expected to continue to promote the development of technology fluent teachers in local schools.
Educational leadership, community partnerships and 24/7 access to educational technology: Bridging the technology gap in small, rural communities with anytime, anywhere learning.

Ian W. Gibson
Department of Administration, Counseling, Educational, and School Psychology
Wichita State University
United States
igibson@twsu.edu

Abstract: This paper describes a project providing school children with 24/7 access to laptop computer technology in a small rural school community in western Kansas. Based upon the visionary leadership of school and community figures, this collaborative venture incorporates creative approaches to financing the project, a focus on actively changing approaches to pedagogy and the learning process, and an analysis of the impact of the project upon the school community. Key features of the project incorporate a focus on educational leadership; community partnerships; anytime, anywhere learning; the digital divide in rural communities; 24/7 access to computers; and constructivist learning in a technology dependent learning environment.

Introduction

The tenor of much of the recent literature on the use of educational technology in classrooms is predicated on the belief that the effective introduction of technologies into learning environments creates circumstances and opportunities under which there is a positive effect on student achievement (Honey, McMillan, Culp, & Spielvogel, 1999). Early claims suggested that using technology effectively in classrooms enabled teachers to be more successful and assisted students in learning what they needed to know to be effective citizens (Bialo & Sivin, 1990; Cotton, 1991; Means & Olson, 1993; Sheingold & Hadley, 1990). More recently however, it has been suggested that technology in and of itself, did not directly change teaching or learning. Rather, the critical element was how technology was incorporated into instruction (Office of Technology Assessment, 1995, p. 57).

Longitudinal data from the Apple Classrooms of Tomorrow (ACOT) studies indicated that technology was an engaging medium for student thought and collaboration and that "technology pay[ed] a catalytic role in opening the minds of teachers to new ideas about children, about learning and about their own role in the education process" (Dwyer, 1996, p.29). In the words of ACOT teachers: "ACOT has revitalized the teaching process tremendously. It has been a catalyst for a transition from blackboards and textbooks to a method of instruction where students can explore, discover and construct their own knowledge" (p.25).

Others have described similar significant changes to the teaching environment brought on by the presence of computer technology. Sheingold and Hadley (1990) surveyed 608 computer-using teachers. Findings indicated that teachers expected more creative and edited work from their students and that they spent more time with individual students. Further, this research suggested that the presence of computers improved the teacher's ability to present more complex instruction and that the associated amount of time spent lecturing was reduced. Sheingold and Hadley (1990) suggested that data such as these indicate that the presence of information technology had the potential to modify certain practices in classrooms.

Parallel to this focus on technology use in the literature is an equal emphasis upon the incorporation of a constructivist approach to teaching. In stark contrast to the prevailing, traditional, teacher-centered classrooms, constructivist teaching practices do not focus on regurgitating newly presented information, but rather on helping learners to internalize or transform, new information (Brooks & Brooks, 1993). Deep understanding and not imitative behavior appeared to be the goal of these learning environments. According to Perkins (1999), considerable research showed that active engagement in learning often lead to better retention, understanding and use of knowledge. He suggested that "constructivism generally casts learners in an active role" (p.8). Further, Daggett (1999) and Schlechty (1997) have suggested that the skills needed for success today include
the ability to access, analyze and apply information to solve predictable and unpredictable real life problems, the ability to manage information and to work in groups to solve problems.

The predominant form of schooling today looks quite different to these images however. For example, despite the fact that Gibson (2000) and Schlechty (1997) have made clear that the way people access, work with, and communicate information is fundamentally different than a decade ago, for the most part, the way learning is structured today appears to be much as it was five or more decades ago. Most teachers use a variation of a teacher-centered model of instruction where the emphasis is upon the presentation of a body of knowledge or a set of skills that students are required to learn (Glenn, 1996; Goodlad, 1984). The focus of power in these classrooms remained with the teacher and students were generally passive listeners. According to Dwyer (1996), in settings such as these, learning was viewed as the transfer of thoughts from one who is knowledgeable to one who is not, and where the work of the teacher was perceived as direct instruction. Common teaching methods include lecture, whole class or small group instruction, drill and practice exercises from workbooks or sheets with a dependence upon facts, rote learning and structured, clearly defined activities.

With the contradictions presented by juxtaposing constructivist and traditional approaches to teaching, and keeping in mind the often recognized potential represented by technology in classrooms, the question of the day then becomes, "How do we engage students in meaningful learning opportunities, and how can schools embrace information age technologies to better prepare students for the world in which they are living?"

The Project

The project described below attempts to address this question by exploring the impact of technology on a small, rural school community in western Kansas. Through creative partnerships and collaboration, educational and business leaders in this community have provided access to laptop learning technologies for students on a 24/7 basis. This working model is attempting to establish the viability of infusing cutting edge technology in all schools, for all students, despite limited school district resources. Conceived as a vehicle for transforming and improving existing pedagogy and curriculum as well as a bridge spanning the digital divide so common in poor rural communities, this project creates an arena for analyzing many of the questions common to school districts nationwide concerned about the impact of increased access to technology on student learning.

Designed to impact the delivery of education and improve access to technology for students, this multi-year project began in the fall semester of 2000, although collaboration, preparation, planning and conceptualizing preceded this beginning by many months. The concept driving the project describes a long term vision that includes a district-wide, wireless network complemented by internet access in students’ homes. As the project develops, all 6-12 students in this district, and their teachers, will carry a laptop computer as core equipment for their daily learning activities. In this vision, learning will not be constrained by the arbitrary time divisions of the traditional school day. By redefining the basic building blocks of the traditional conception of ‘school’ and t expect to see significant positive changes in teaching and learning. These changes are expected to be directly related to expanded access to information and learning technologies and the associated changes in where and when learning actually occurs. In the conception of this project, these significant changes are accompanied by a focus on learning which has individual learners constructing their own knowledge sets, and creating an emphasis upon student-centered learning in the context of authentic and situated activities. Clearly, in these situations, the role of the teacher is expected to undergo significant transformation. Delivery of instruction is expected to give way to a supportive and collaborative role where team work and shared responsibility feature prominently.

Lest the reader be mislead into conceiving of this project as one focusing solely on the school-based learning process in isolation, an understanding of the entire context of this project is necessary. An analysis of the proposed plan of implementation reveals further possibilities of the expected impact on this small, rural community and the business partners supporting the endeavor.

The Implementation Plan

In the first phase of this project a district-wide, wireless network has been installed, capable of supporting the laptop computers provided to all middle school teachers and those leased by all sixth grade students. Ongoing staff development designed to prepare teachers to teach in this new environment has become a regular
feature of school life. A charging station and a spare battery for each computer has been purchased to ensure reduced downtime and strain on the power grid of the school buildings. Internet access has been secured at a reasonable rate for all sixth grade families to guarantee continual access to the internet and district resources. Evening computer training opportunities are being provided for all parents to support the concept of parents as partners in the learning process. Teachers are designing and posting appropriate lessons, units of study, and associated activities for delivery over the internet. Subsequent years of this project will see additional grade levels of students and teachers involved in this rural attempt at anytime, anywhere learning. By the year 2007, the initial phase of the project will be fully implemented and all teachers and students 6-12 of this small, rural district will be involved.

The plan is dependent upon a unique set of partnerships and agreements between school district leaders and teachers, parents, and cooperating business partners. In the first instance, families will lease a computer over a four-year period for $200 per year. Families unable to meet this requirement (i.e. families eligible for free or reduced lunches) will contribute according to their circumstances. Agreements have been reached with community benefactors to cover the cost of these arrangements. At the end of the initial four year leasing period, families will be able to purchase the computer for $50. Arrangements have been made for these students to lease new computers for the remainder of their school careers for $300 per year with a purchase price of $50 at the end of 3 years. Insurance has been arranged by the district to cover damage or needed repairs for a cost of $14 per unit per year and the district will insure against loss or theft at $14 per unit per year. Internet access has been secured for families who cannot afford the monthly rate through the local ISP. This partnership has pledged 10 free Internet accounts for the first year and has potential for an increase in this number as the project grows.

A project of this scope cannot survive without the strong commitment and real involvement of community groups. For example, in this context, the local educational foundation agreed to serve as the fiscal agent for the project, responsible for managing all funds, in addition to conducting appropriate fundraising activities. Further, local benefactors agreed to subsidize a variety of costs during the pilot year. The local bank has established low interest leases for each family, and a local insurance agent has agreed to establish low cost and effective insurance. A further key component of the project is the support of the families involved. While all families will contribute some financial resources to the project, their active involvement was important in other areas preceding project implementation.

Simple in its conception, this project originated with a series of pre-implementation steps designed to create community involvement, buy-in, and increase chances for success over the period of the project. All interested parties were included in conceptualizing and planning: students, parents, teachers, school and district administrators, business partners, members of the board of education, and community members. Productive and active partnerships were established with business organizations and community groups capable of sharing appropriate experience and willing to contribute towards filling each identified project goal. Support from a local, community-based educational foundation was secured and school district personnel were active in revising the district technology curriculum during the previous year in preparation for this new direction. The intent of this curriculum revision was to ensure minimum competencies and the basic technology skills needed for students to function successfully in the new learning environment. In addition, teachers who were involved in the planning process recognized that changing their roles from ‘purveyors of all knowledge’ to ‘facilitators of learning’ was a dramatic change that would not happen easily or instantly. Consequently they have created a focus on continual and contextualized staff development as an integral component of the project implementation and maintenance plan.

Such dramatic adjustments to the traditional expectations of schools, teachers, and learners requires careful monitoring to ensure continual success and continual support from the community of contributors and participants of the project. In fact, it has been suggested elsewhere, that education will likely undergo many changes as a result of the incorporation of technology into everyday activities. Jukes (2000) has suggested that education will not be confined to a single place, a specific time, a single person, human teachers, paper-based information, memorization, linear learning, or controlling learners. With such dramatic changes occurring in education, it is part of the responsibility of educational innovators to describe the impact of such innovations on the learning process. The introduction of cutting edge conceptions of education, supported by appropriate technology in this small, rural community demands a serious attempt to gauge the success of this working model of anytime, anywhere learning.
Project Evaluation

To accommodate the need for thoroughly evaluating the impact of this project on the educational community of this small rural school district, and to widely disseminate the results, the project incorporates an evaluation component. The initial evaluation will be conducted by external investigators and will focus on three broad questions.

1. What impact has the introduction of full-time technology access had on the learning process?
2. What impact has the project had on the way teachers teach?
3. What impact has the project had on the school and community?

This activity will be an evaluation in progress. As a result of the longitudinal nature of the study, the possibility of variations in approaches to the research design and to data collection is possible in order to accommodate variations in the project as it evolves through time. During the initial phase of the project, the rationale, design, data collection strategies, and data analysis procedures for this proposed evaluation have been taken from the qualitative paradigm of research and represents a naturalistic approach to educational inquiry (Erlandson, Harris, Skipper, & Allen, 1993; Lincoln & Guba, 1985; Patton, 1990). Naturalistic inquiry was defined by Patton (1990) as a "discovery-oriented approach that minimizes investigator manipulation" (p. 41).

As the intent of the evaluation is to determine the reaction of participants to the intent, impact, process and potential of the project, the need to describe their perceptions, expectations and attitudes forms the basis of the data collection process. Erlandson et al. (1993) suggested that although "both qualitative and quantitative methods can be used, qualitative methods are generally preferred, primarily because they allow for thick data to be collected that demonstrate their interrelationship with their context" (p. 16). Further, Babbie (1998) described qualitative analysis as "the non-numerical examination and interpretation of observations, for the purpose of discovering underlying meanings and patterns of relationships" (p. G5).
