A variety of qualitative methodologies are proposed for use in this evaluation: interviews, focus groups, observations and document reviews. The evaluators considered that such an array of data collection strategies would provide the richness of data and the variety of perspectives necessary to understand the complexities of the situation under study (Erlandson et. al., 1993). Such a multi-source approach to data collection also provides a further element necessary in building the trustworthiness of the data collected: triangulation (Lincoln & Guba, 1985). Participants in these data collection strategies will include students who have leased a computer; teachers who are involved in teaching in the project, as well as those not involved; parents of students involved in the project; school and district administrators involved in the project, as well as those not involved; and community members who have been actively involved in the project.

Data will be analyzed using the constant comparative analysis methodology advocated by Lincoln and Guba (1985). Constant comparative analysis requires data to be unitized. Erlandson et al. (1993) defined unitizing "as disaggregating data into the smallest pieces of information that may stand alone as independent thoughts in the absence of additional information other than a broad understanding of the context" (p. 117). Once data from each data collection strategy are unitized they will be merged into one datafile in a relational database. A process of inductively grouping and regrouping the data will allow categories to naturally emerge from the units of data. In considering the common attributes among the data, common themes will be developed, and will lead to the production of conclusions based on the evaluation findings. The evaluators will use this information to form recommendations related to the guiding questions of the evaluation. The results of these analyses are formative in nature and will be used to modify and re-conceptualize the project as it progresses.

Conclusion

As educational reform is too often equated with "plugging students into anything that happens to plug in." (Stager, 1995, p.78), the goal of this collaborative community effort, unlike many technology initiatives, was not simply to purchase the technology and put it in place. Rather, the intent was to use the technology to positively impact the traditional teaching and learning processes that were prevalent in the district. In addition, this project provided the time teachers needed "to grow in their use of technology"(Miller & Olson, 1995, p. 75). There is no instant solution expected here. As Miller and Olsen suggested, "Educators who believe that technology automatically fosters effective learning styles and instructional patterns need to think seriously about such issues ... the real progress computers can stimulate comes from a healthy debate about what we
really care about in classrooms and whether that is happening" (p. 77). This project not only provides a timely analysis of data regarding the merits of teaching and learning using laptop technology, but will also provide a model of community collaboration for public schools to consult when the issue of limited school/community financial resources appears to stifle technological initiatives.

This innovative, community based project also provided an opportunity to evaluate the effectiveness of the partnerships and community collaboration designed to remove the discrimination factor that variable access to technology often generates across subgroups of a population. By making technology accessible to all in this small, rural community, this goal has been partially addressed. Lemke and Coughlin (1998) suggested that emerging trends in research indicate "that under the right conditions, technology accelerates, enriches, and deepens basic skills; motivates and engages students in learning; helps relate academics to the practices of today's work force; increases economic viability of tomorrow's workers; strengthens teaching; contributes to change in schools; and connects schools to the world (p.14-15)." The approach to leveling the technological playing field, described in this project, has the potential to create an environment capable of providing longitudinal data over the next seven years to verify these claims. This project meets the challenge of the digital divide head-on, and provides patrons of this small, rural community with the tools to define their own educational futures and bridge the technology gap with their version of anytime, anywhere learning.

Abstract

This research project employs the case study method to investigate the effects of instruction and learning with the Internet at the senior high school level. In the first year of this study, the main focus is to explore the current status of integrating the Internet into school management, teaching and learning. Some teachers were selected in six subjects, Chinese, Geology, English, Mathematics, Biology and Earth sciences, to use the Internet for their professional activities. The data collection instruments included the 'Teachers' Professional Use questionnaire and The Students' Computer Use questionnaire. The survey data showed that (a) more teachers and students knew how to access the Internet for instructional or learning purposes after the researchers intervened, and that (b) more teachers reported that they needed assistance for designing a web-based database and Instructional strategies for their Internet use.

Keywords: Computer Networks, Internet-aided Instruction, Internet-based Learning

Introduction

Over 90% of schools in America can access to the Internet (Becker, 1999). From statistics (Becker, 1999), 24% of teachers in American access Internet both at home and in their classroom, 35% of them access Internet in classroom only, and 15% of them access Internet at home only. This reveals the Internet begun to be habitual as an information and communications resource in the working and home environment of most teachers. However, most teachers are trained to teach from their textbook. Most teachers devote the majority of class time to presenting information, demonstrating how to solve problems, and assigning tasks to their students who usually have a single, short right answer. Few teachers are skilled integrating the Internet into their teaching. The teacher role is an important issue in the integration of technology into instruction.

Teaching is an active task of inculcating learners with the skills and cognitive processes to "direct" and on the Internet (Gilliver et. al., 1999). Current teacher education programs have not prepared preservice teachers to integrate the Internet and computers into classroom teaching. The necessary skills, such as computer skills, instructional strategies, and search skills were not taught, so most teachers feel anxious when computers and the Internet technology come into their classroom. Without support from teachers, students cannot learn effectively. Therefore, researchers not only need to evaluate the students' learning in a web-based environment but also investigate the teachers' adoption of technology including the changes in instructional strategies, the changes in learning activity design and changes in assessments (Beaudoin, 1990; Brophy & Good, 1986; Mc Kenzie, Mims, Davidson, Hurt & Clay, 1996; Thatch & Murphy, 1995; Verduin &
Clark, 1991). Other teaching skills also needed in effectively using the Internet for education are, searching for information, web-page design and socially interactive skills on the web. It is important that teachers know how to choose suitable learning activities and instructional strategies when they integrate new technology into teaching and learning in order to promote students' conceptual development and thinking skills (Mc Kenzie, Mims, Davidson, Hurt & Clay, 1996). Therefore, this study conducted questionnaires to investigate teacher Internet uses at a senior high school.

Method

This research project employs the case study method to investigate the effects of instruction and learning with the Internet at the senior high school level. In the first year of this study, the main focus is to explore the current status of integrating the Internet into school management, teaching and learning. Some teachers were selected in six subjects, Chinese, Geology, English, Mathematics, Biology and Earth sciences, to use the Internet for their professional activities.

Participants

The teachers and students at Luodong Senior High School were selected as the participants for this case study. Luodong Senior High School is located in the northern region of Taiwan. The Internet access at Luodong Senior High School was convenient. Most computers were located in three computer labs and some were in the teacher offices. Teachers and students could use the campus Internet and T1 for Internet access since 1998. There were 59 teachers participating in this study in 1998 and 31 teachers in 2000. Only 23 teachers participated in both 1998 and 2000. The data from these 23 teachers were used for teacher measurement comparisons between 1998 and 2000.

Instrumentation

The instruments used in this study included measurements of teacher computer use and teacher attitudes toward computers. We constructed the Teachers' Professional Use questionnaire to survey teachers' computer use, teachers' access to the Internet, teachers' Internet use for instructional purposes, attitudes toward computers and the Internet, and teachers' anxiety concerning computers. The attitudes toward computers and the Internet consisted of 15 items with five subscales measuring class involvement. The instrument contained selected items from the tests developed by the following authors: Liu & Johnson (1998), Knezek & Christensen (1996) and Moroz & Nash (1997). A panel of experts, including nine professors from National Taiwan Normal University, established the content validity of the questionnaire.

Procedure

This study included three stages: (a) The preparation stage (from June 1998 to July 1998): According to research purposes, we selected a typical case or an available case. Luodong Senior High School was selected because of its available Internet access and full support from the principal. (b)
The baseline-building stage (from August 1998 to July 1999): In the first year, we conducted questionnaires to survey teacher computer use and teacher attitude toward computers. Informal interviews and observations were also used to gain more information on teacher computer use and Internet access. (c) The intervention stage (from August 1999 to June 2000): Teachers in six subjects, Chinese, Geology, English, Mathematics, Biology and Earth Sciences, integrated the Internet into their class during the second year. At the end of the year, we surveyed teacher computer use and teacher attitude toward computers. Informal interviews and observations were also used to gain more information on teacher adaptation to computers and the Internet for instructional purposes.

Data Collection and Analysis

The independent variable was the intervention; the dependent variables were teacher professional use and teacher attitude toward computers and the Internet. The survey data was shown as descriptive statistics to illustrate the impact of the Internet on teaching. Additionally, we conducted paired t-tests on one of these dependent variables (teacher attitude toward computers) between pre-intervention measures and post-intervention measures. The collected data was analyzed for teacher Internet use using SPSS (Statistical Package for Social Science, version 7.0).

Results and Discussions

Teachers' Changes Before and After the Intervention

1. Teachers' Computer Use

Most teachers reported making some use of computers in their daily life. Our survey asked about five uses in particular: accessing the Internet, playing games, editing documents, graphing or analyzing data, and using e-mail. A majority of teachers used computers for editing documents: 91% in 1998 and 78% in 2000. Teacher Internet access increased after the intervention from 46% to 78% (see Table 1).

Teachers used computers at home, in the office, in the classroom or the computer lab. The computer was seldom used either at home or in school before the intervention. There were increase uses in the second year (see Table 2). We surveyed teachers' computer-software use including MS word, PowerPoint, Excel, FrontPage and FTP relative software. The most popular software was Word for editing (about 87% of the teachers used it). The next most popular software was Excel for calculating student scores (about 60% of the teachers used it) (see Table 3).

2. Teachers' Access to the Internet

Seventy-four percent of the teachers knew how to access the Internet and 91% did after the intervention (see Table 4). More teachers knew how to access the Internet after the researchers intervened with teacher instruction and student learning with the Internet. A majority of the teachers (60% in 1998 and 74% in 2000) (see Table 5) accessed the Internet below five hours a week and most used it for browsing web pages (65% in 1998 and 87% in 2000) (see Table 6). The percent of teachers
using e-mail and FTP through the Internet increased 17% and 9% after the intervention (see Table 6).

3. Teachers’ Internet Use for Instructional Purposes

Overall, few teachers made use of the Internet for instructional purposes before this study. Our survey asked about four professional uses in particular: student work on the World Wide Web, demonstrating web-based materials in the classroom, developing instructional materials using Internet resources, and requiring students to find information on the Internet. After the researchers intervened with teacher instruction and student learning on the Internet, more teachers used the Internet for instructional purposes; especially, for student work on the World Wide Web (from 9% to 17%), developing instructional materials using Internet resources (from 13% to 26%), and requiring students to find information on the Internet (from 13% to 30%) (see Table 7).

4. Teacher Needs for integrating the Internet into instruction

Since relatively few teachers reported using the Internet for instructional purposes, what capabilities do teachers need for using the Internet in the classroom? Our survey asked about six skills needed by teachers in particular: computer skills, skills for Internet access, skills for the use of editing software, skills for the use of graphic or image-processing software, skills for designing web-based database and Instructional strategies. Most teachers reported that teachers need training in computer and instructional skills. More teachers perceived that they lacked enough skills after the researchers intervened in their teaching with the Internet (see Table 8). Skills for the use of graphic or
image-processing software (61%) and the skills for designing web-based database (73%) were needed most by teachers before the intervention. After the intervention, teachers reported that skills for designing a web-based database (70%) and Instructional strategies (65%) were needed most when they made use of the Internet for instructional purposes (see Table 8). With experience to use the Internet in the classroom, teachers perceived Instructional strategies were as important as the necessary computer skills.

Table 8: Teachers’ Needs

5. Attitudes Toward Computers and the Internet

There was no statistically significant difference in teachers’ attitudes toward computers and the Internet before and after the intervention. The pretest mean was 52.95 with a standard deviation of 5.30. In contrast, the posttest mean was 51.77 with a standard deviation of 8.44. The paired t-test results show that there was no significant difference between the teacher pretest and posttest on computer attitude (t= 0.68, p>.05; The data was shown in Table 9). This means that teacher computer attitudes did not show a significant change before and after the intervention.

Table 9: Summary Table for Paired t-test: Teacher Attitudes toward the Computer and the Internet

<td>8.44</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Conclusions

The findings in this study demonstrated that more teachers knew how to access the Internet and use the Internet for instructional or learning purposes after the researchers intervened. However, more teachers also reported that they needed assistance in developing skills for designing a web-based database and instructional strategies when they used the Internet for professional purposes.

Abstract: This study examines the strengths and difficulties of the Technology Integration Mentors in Education (T.I.M.E.) program through accounts given by participants. The T.I.M.E. program, at its peak in 97-98, included approximately 400 inservice teachers from 55 school districts in eastern Idaho. Several inservice teachers who have successfully completed two years of the program were asked to participate in an extensive online interview and survey format (via WebCt) designed to pinpoint major characteristics of the program as well as attitudes. This research explores three areas of the T.I.M.E. participants' experiences: Workshop training experience, implementation of technology into their own curriculum, and peer mentoring activities. The detailed perspectives of these participants are critical to understanding the successes and difficulties of the program. The results of this current research will inform improvements in the implementation of the T.I.M.E. program.

Introduction

This study examines the strengths and difficulties of the Technology Integration Mentors in Education (T.I.M.E.) program through accounts given by participants. Several inservice teachers who had successfully completed two years of the program were asked to participate in an online interview and survey format (via WebCt) designed to pinpoint major characteristics of the program as well as attitudes. This is a pilot study for more comprehensive research into the T.I.M.E. Mentor program. Also, the results will inform proximal instructional decisions for the program.

About the T.I.M.E. Mentor Program

In 1996, the College of Education's Support for Integration of Technology in Education (SITE) team developed the T.I.M.E. inservice program. The T.I.M.E. program serves a mostly rural area that includes 55 school districts that cover about 40,000 square miles of eastern Idaho. At its peak in 1997-98, there were about 400 participants. This teacher-mentor program trains teachers to utilize tool and multimedia software in real-time classroom instruction. Then the teachers are required to perform peer-to-peer mentoring and formal training of teachers in their building/s. The program can be expressed in the following flow model: Technology Trainer → Mentor → Peer Teachers. This mentor model is tiered, in that there are three years of incremental instruction and mentoring requirements. Upon completion of the program, each mentor has had opportunity to become proficient at using computer technology in the classroom and at training peers to do the same.

Formal mentor programs are common in the business world, but recent examples can also be found in educational institutions. Knight and Albaugh (1997) report success in the "Teaching Software
Institute" (TSI) mentoring program, a one year model similar to the T.I.M.E. program. Teachers were trained in specific software applications and then required to train groups of teachers. The T.I.M.E. program is distinctive from the TSI program in that it is tiered in content and time. In other words, the teacher-mentors learn a progression of softwares (e.g., tool software basics to multimedia software) over a period of three years, and are expected to "ramp up" their mentoring opportunities from peer-to-peer contacts to also include the formal training of groups within their schools.

Research Design

This research explores three areas (constructs) of the T.I.M.E. participants' experiences: Workshop training experience, implementation of technology into their own curriculum, and peer mentoring activities. Participants, through survey (online), semi-structured interview (online) and submitted journals of mentoring activities, offer a participant perspective critical to understanding the successes and difficulties of the program.

The survey and interview are given in a WebCt environment. The participants are given an orientation to the WebCt site, and then allowed to take the survey and the interview when they wish. An important characteristic of both survey and interview instruments is their asynchronous design. Though the survey can be completed in as little as 10 minutes and the interview in about 20 minutes of continuous work, participants do not have to complete either in a single sitting. Within the basic time limits of this research, they can complete all instruments at their convenience.

During the orientation to the site, participants are also introduced to an open bulletin board forum with participant anonymity. The forum is seeded with two leading questions designed to grow a conversation among the participants. The bulletin board will always remain unstructured; the three constructs that guide every survey and interview stem will be absent. Potential dialogue may bring out aspects of the T.I.M.E. Mentor Program that have not been asked about in either the survey or interview instruments.

Results

At the time of acceptance of this research paper, the survey and interview processes were still underway. Completion by all participants and the analysis of the data is expected to be complete in early January. The full results will be presented at the time appointed for this paper.

Preliminary results show that this small selection of participants has had a qualified good experience as T.I.M.E. Mentors. Attitudes toward the program and its effectiveness appear to be related to attitudes toward the technology instructors and toward the handling of workshop and mentoring assignments by the technology instructors. More definitive results are forthcoming.

Summary and Conclusion

The current research examines the implementation of the T.I.M.E. Mentor program from the perspective of successful participants. The program is tiered in that there are three years of incremental instruction and mentoring requirements. The participants in this current research have successfully completed the second year of the program and are asked their views on the workshop training, their own implementation of technology into their curriculum, and their own peer mentoring activities. By examining the responses of the participants, the strengths and difficulties of the program will be clearer and will help elucidate the effectiveness of the program.

The Florida Center for Instructional Technology

Kate Kemker katek@tempest.coedu.usf.edu
Shauna Schullo shauna@usf.edu
John Fitzpatrick jfitzpat@tempest.coedu.usf.edu

Abstract: The Florida Center for Instructional Technology (FCIT) is located in the College of Education, University of South Florida, at Tampa, Florida. The Florida Department of Education funds FCIT, Office of Educational Technology and the Florida Information Resource Network, to provide leadership and support services to educational institutions with regard to the integration of technology in education. A primary focus of FCIT is the development of instructional materials and databases for telecommunications. The faculty members and graduate students in the USF Instructional Technology program contribute to many of the products created by FCIT.

Purpose

Established in 1982, the Florida Center for Instructional Technology (FCIT) has been a leader in working with educators to integrate technology into the curriculum. With its location in the College of Education at the University of South Florida, Tampa, FCIT is available to assist over 1,200 pre-service teachers who graduate from USF each year as well as thousands of in-service teachers in Florida. With funding from the Florida Department of Education, Bureau of Educational Technology, and the Florida Information Resource Network, FCIT provides many resources for Florida teachers, including training materials for telecommunications, interactive instruction on technology, and maintenance of online database resources. FCIT offers a wide variety of services and materials for Florida's educators.

VITAL

FCIT offers extensive support for the University of South Florida faculty through its membership in VITAL (Virtual Instructional Team for the Advancement of Learning). VITAL (USF's Virtual Instructional Team for the Advancement of Learning) was established in 1997 to assist faculty at the University of South Florida in the use of technology for the enhancement of teaching, learning and research. When VITAL began on campus, the instructional technology expertise of FCIT was tapped as a resource for USF faculty as well. Hence, a new "division" of FCIT was created to offer services to faculty in the College of Education and the University.

At the University of South Florida, several collaborative initiatives are addressing the challenge of integrating technology into the teaching and learning model. VITAL is not an entity with a physical location on our campus, rather it is a consortium of units housed in separate pre-existing areas, working together as a team to provide the best support for the most faculty possible. It is a virtual one-stop-shopping support unit. The majority of organizations that belong to VITAL have been providing these services and support to faculty as part of their overall mission for many years. VITAL combines the expertise and resources of these seven existing units to better support the development of technology enhanced education. Members include Academic Computing, the Center for Teaching Enhancement, Educational Outreach, the Florida Center for Instructional Technology, the Health Sciences Center for Information Services, the Tampa Campus Library, and WUSF-TV.

Faculty are encouraged to seek individual mentoring and assistance as well as attend workshops designed for small groups. Faculty who want individual assistance with technology issues can call upon a specific VITAL member, or they can reach a "generic" VITAL contact through multiple means. The many services that are offered by each VITAL member can be viewed on the VITAL Web site.

ERIC 2927
http://www.usf.edu/vital (see Figure 1). In addition, VITAL has an email list (vital@usf.edu) that reaches all members, any of which are able to answer support questions. Support is also offered to the “Learn from a Distance” program in the College of Education for those faculty teaching via distance.

VITAL is a network of support to assist USF faculty integrate technology to advance teaching and learning. VITAL provides many skill building and informative workshops on the uses of technology for teaching and learning. This past semester, VITAL facilitated 23 skill-building workshops in which faculty and graduate teaching assistants were able to improve their level of comfort and skills with technology. The workshops cover a wide range of technology topics, but many are related to enhancing teaching using the Internet. Some examples include; “Making the Right Choice: A Comparison of WebCT and CourseInfo”, “Developing and Learning with Online Communication Tools”, “Creating Web Pages: A One Day Workshop”, “Improving Teaching and Learning with WebCT Version 3.0: A Two-Day Intensive Workshop” and Discovering Options: Using Streaming Media to Enhance Online Teaching and Learning”.

Recently, VITAL began providing additional support personnel in a lab environment for use by the College of Education faculty and staff. The College of Education and Technical Services and Resources provide the lab to all employees of the College of Education yet was being underutilized. This lab is now staffed for 30 hours to assist those who need to use technology but may feel uncomfortable doing it alone or do not have the resources necessary in their offices. This has increased the number of faculty who take advantage of the technologies provided in the media lab as well as technology usage in general.

**FCIT**

FCIT provides leadership and support services to educational institutions, such as local schools, districts, museums and other educational agencies. Through these partnerships, FCIT has designed distance education tools, conducted research, provided technology assistance and staff development, assisted in grant writing, and produced multimedia instructional programs. FCIT booklets, brochures, and electronic media are distributed free-of-charge to Florida educators. Printed publications may be duplicated for educational purposes and online materials may be downloaded from the Center’s Web site.

The FCIT Preview Center provides educators with an effective source of integrative technology for the classroom. The Preview Center maintains a library of over 3,000 educational software and multimedia titles to provide K-12 educators, faculty, and staff with the opportunity to preview the latest in educational software. The Preview Center also provides valuable services for preservice teachers at USF. The students are
given the opportunity to use the software and to learn methods for integrating technology into the classroom. The Preview Center is equipped with a lab of 40 networked Macintosh and Windows computers so those educators can preview the software on the platform of their choice. Other featured technologies include telecommunications, Smart Boards, digital cameras, video conferencing, flatbed and film scanners, assistive/adaptive devices, digital video cameras, and MIDI keyboards.

Throughout the year, FCIT offers one and two-day hands-on workshops for K-12 educators. Many workshops focus on technology integration in a specific teaching such as reading, science, math, music, art, or foreign language. Other workshops cover topics such as Web page publishing, networking for Windows and Macintosh, digital video, digital imaging, computer graphics, the one-computer classroom, desktop publishing, internet for education, digital photography, basics of MIDI sequencing and mini-grants for technology. It is during these workshops, that the diverse software and hardware is featured, allowing teachers to experience what is available for integration of technology into their classroom.

FCIT has been given the opportunity to collaborate with the school district of Pinellas County on a variety of projects. One project is the Pinellas County Schools' Student Expectations Database, an educator's resource and reference tool to identify what students should know and be able to do at the pre-K through grade 12 level in ten subject areas. This guide relates the Pinellas County Student Expectations to the Sunshine State Standards, benchmarks, competencies, lesson plans, assessments, and resources. The Student Expectations Database was developed in partnership with Pinellas County Schools through the Goals 2000 Student Achievement Grant.

Another project is a television show called Digital Learning, is broadcast on a local cable channel. Digital Learning is a cooperative venture covering a wide variety of topics relating to the use of computer programs and networking facilities. The television shows provide teachers with the opportunity to have training at home or at school. Topics have included QuickTime, Inspiration, HyperStudio, MovieWorks, and how to scan.

Other projects included assistance to fellow departments at USF to realize some of the benefits of instructional technology. The first project was to develop a Web site for the International School Connection. This project underwent some change in scope as the project developed, but throughout had a focus on better enabling educators to have a global perspective on student learning and achievement. FCIT was responsible for creating the Web site for this program. This project also illustrated nicely the collaboration between the K-12 and the higher education components of FCIT. While the K-12 side was building the Web site, the higher education component was working on creating the Web-CT side of the program.

A second project that FCIT has worked on is "Thinking Like a Marketer". This was a grant from the National Training Collaborative for Social Marketing, funded through the Center for Disease Control. The grant focused on taking the center's existing in-person training modules and provides them on both the World Wide Web and CD-ROM based format. This project was exciting in that in incorporated a number of different technologies. Transcriptions were created of the different sessions and recorded using a professional narrator. Those recordings were then compressed using and saved as QuickTime movie files. The sound files were then used allowing each session to have the real time feel that it does. Finally, Macromedia Coursebuilder was used to create the engagement questions that participants would be asked about content as they listened to the presentation. Combined, these different components came together extremely well and produced a viable way for health professional to easily receive training on marketing strategies.

Teaching N' Technology is a database of technology-related lesson plans developed by Florida educators. Search 400 lesson plans to easily find activities to enhance your curriculum. Each TNT lesson plan contains technological and subject information, as well as its correlation to Sunshine State Standards. Each lesson provides detailed instructions on how to implement the activity in your classroom. TNT enables you to search by subject area, by grade level, and by keyword. Select lesson plans from the TNT database were distributed to Florida schools on the "FCIT Teaching Tools 2000" CD-ROM, fall 2000.

Currently, FCIT is working with the Childhood/Language Arts/Reading Education department on a project called InterLnk. This project is being funded from a grant with the Corporation for National Service. The project will include working with one school in Miami, Florida, two schools in Tampa, Florida and one school in Memphis, Tennessee to develop model literacy classrooms with technology integration.

The print publications cover a variety of topics for educators. An Educator's Guide to School Networks provides an overview of computer networks and their integration into the school setting; The Internet: Ideas, Activities, and Resources provides an overview of the Internet and includes curriculum
integration ideas for Florida educators. A Teacher's Guide to Distance Learning provides an introduction to distance learning technologies and applications in K-12 education. Getting Started With Telecommunications offers information on obtaining and using a Florida Information Resource Network (FIRN) account. Language of the Internet is a convenient guide to Internet terms and acronyms. Searching the Web is a beginner's guide to using Web search tools; and HTML Quick Reference Guide is a summary chart of basic HTML code.

In addition to all of the booklets and brochures available on the FCIT Web site, there are simulations. Cruising the Information Super-Highway Simulation provides information on the various features and components of the Internet and World Wide Web including Internet connections, Telnet, FTP, Gopher, WWW browsers and more. It also provides hands-on practice with Web page creation and video and audio conferencing. Interactive HTML Tutorial is a student project by David Tai. Learn basic HTML commands by typing text directly into boxes on the tutorial and see the results immediately. Interactive HTML Tables Tutorial is a student project by Lara Labastie. Practice constructing HTML tables and sees the results in pop-up windows.

CD-ROM products are distributed to Florida schools as a part of a Technology Literacy Challenge Grant. The Teacher's Guide to the Holocaust version two and the Fourth Grade Reading FCAT Staff Development Tool were distributed in late fall of 1999. Public school copies were shipped to the district Superintendent's office for distribution. Private school copies were mailed directly to the school address.

FCAT Reading 4 Staff Development Tool (See Figure 2) is designed to help teachers prepare students for the fourth grade reading Florida Comprehensive Assessment Test. Sections include teaching strategies, rubric scoring, practice tests, and references. This CD-ROM was distributed to Florida schools in the fall 1999.

Figure 2: FCAT Reading 4

FCAT Reading 8 Staff Development Tool (Figure 3) is designed to help teachers prepare students for the eighth grade reading Florida Comprehensive Assessment Test. Sections include short and extended response rubrics, a self-test using scoring rubrics, two FCAT practice tests, teaching strategies, and related Web sites. Distributed to Florida schools on the "FCIT Teaching Tools 2000" CD-ROM, fall 2000.
A Teacher’s Guide to the Holocaust (Figure 4) is an overview of the people and events of the Holocaust through photographs, documents, art, music, movies, and literature. Version 3.0 adds thousands of new files to the Teacher's Guide including 600 new photographs, 25 virtual reality movies, 75 movie clips of survivor testimony, and a complete site index.

Currently, FCIT is working on projects to be distributed in the fall of 2001. A Teacher's Guide to Florida History will include both a fourth grade unit and a set of resources suitable for use at any grade level. FCAT Reading 10 Staff Development Tool is being designed to help teachers prepare students for the tenth grade reading Florida Comprehensive Assessment Test. FCAT Math 5 Staff Development Tool is being designed to help teachers prepare students for the fifth grade math Florida Comprehensive Assessment Test.

FCIT has collaborated with the Research and Measurement department at USF to conduct a variety of research studies. The first research study was A Holocaust Web Site: Effects on Preservice Teachers’ Factual Knowledge and Attitudes Toward Traditionally Marginalized Groups. This study reported is an initial investigation of the impact of the Teacher's Guide to the Holocaust Web site on preservice teachers’
knowledge of the Holocaust and attitudes towards traditionally marginalized groups. In addition, this research provides evidence of the extent of pre-service teachers' knowledge related to the Holocaust. Ultimately, this research should lead to further development and improvement of Holocaust instructional materials, as well as improvement of Holocaust education in Florida.

A separate study was Preparing 4th Grade Students for the FCAT Reading Test. The purposes of this study were (a) to determine how 4th grade teachers in a large Florida school district prepare themselves and their students for the FCAT reading test, (b) to investigate relationships between preparation practices and school characteristics, and (c) to estimate correlation between preparation methods and subsequent student performance on the test.

The final study is Computers in the Classroom: Teachers' Attitudes and Uses targeting their attitudes toward and use of computers in instruction. A special emphasis was placed on classroom uses consistent with the proposed NETS for teachers and students. The data for this study were obtained from a survey administered to all teachers in a large Florida school district. Surveys were distributed to each school site with instructions that all classroom teachers were to be provided the opportunity to participate.
Using Intelligent Agent Tutors

Abstract
Intelligent agents are, in simplest terms, software programs built to perform certain specific tasks for the user. They are “autonomous” in the sense that they operate without specific user intervention. One form of intelligent agents, “chatterbots”, is beginning to provide the capability to have intelligent tutors available to students at all times.

Many of these chatterbot software packages can be customized to provide content appropriate for individual lessons and can perform other tasks automatically, such as opening web pages, reading text, running other programs, answering questions and providing instruction. Further, they can even solicit information and distribute information. Several low-cost, easy-to-use packages have emerged, with useful features, such as anthropomorphic features and speech recognition. Soon, chatterbot agents will be providing useful information in many classrooms and over the web via distance education.

This demonstration will showcase several of these packages, including examples of how they are being used and can be created. One agent, Sylvie, will assist in the presentation of material.

Introduction and Background

One of the most interesting, and potentially important, aspects of the information technology revolution might be the rapid integration of intelligent agent tutors into the classroom environment. “Intelligent software agents”, also known as “knowbots” or just “bots” have recently become more than just a better way to search or to find bargains on the internet. Moreover, these second and third generation agents are taking on aspects of human intelligence, allowing them to assist educators with classroom functions. Interactive anthropomorphic agents are beginning to actually provide instruction, explain answers, grade exams, answer questions,
give references, provide underlying theoretical logic, link to websites, and, in general, guide and instruct students—all functions heretofore were done by humans. The list of tasks that intelligent agents are already performing and might someday perform is rather extensive.

Intelligent agents (a.k.a. software agents and/or knowbots) are, in simplest terms, software programs built to autonomously perform certain specific tasks for the user. Intelligent Agents combine elements of Artificial Intelligence from other subsets (e.g., expert systems, object-oriented technology, neural networks, genetic algorithms, case-based reasoning, speech recognition, natural language processing, etc.) into an interface that has great applicability and appeal. Behind the agent front end is more often than not some simple rule-based programming which triggers actions when certain conditions are met. Some of the agents even have a crude capability to adjust their “reasoning” and “learn” from the user.

Current incarnations of intelligent agents can perform such useful tasks as retrieving information from the web, assisting in shopping for items by automatically finding the best price, monitoring auctions for specific items, gathering stock quotations and building customized newspapers. The latest generation of software agents moves closer to the ideal—an agent which can function autonomously to assist the user or the learner by providing help in dealing with what has become an information hyperabundance.

**Today**

Today, an important use of intelligent agents is providing features that can guide, advise, teach, critique and explain in an intelligent tutor or classroom instructor role. Although these early applications are often just prototypes, more importantly for educators is that the rapid development of intelligent agent tutors is becoming both a practicality and a necessity. Being able to provide students with just-in-time learning, customized for what they need at the moment they need it is not possible with human instructors. Agents can also assist instructors in finding, filtering, and fusing the vast amounts of information now available. Due to the massive data explosion and the limited time and availability of human instructors, more often than not instruction is provided at a level which accommodates the majority in mostly a same time, same place environment. Now, however, the potential exists to tailor lessons specifically for each individual.

Soon it will be possible to have a personal tutor for each student. This intelligent agent tutor will be customized to not only provide the instruction that the student seeks at the time he or she seeks it, but the tutor will do so in a very effective manner. Several low cost, easy-to-use packages have begun to emerge, with useful features, such as impressive anthropomorphic features and speech recognition. Indeed, they could soon even become mentors for faculty as well as tutors for students. An interesting example in development is the agent Virtual Steve that can provide tailored instruction for training. Virtual Steve has a virtual reality front end and an intelligent agent engine combined with speech recognition and speech synthesis. Unattended Steve is able to guide students, react to their actions, correct them if they make a mistake and
admonish them if they ignore procedures. Although only a research effort at the moment, Virtual Steve is an example of the type of customized personalized instruction that is possible with intelligent agent tutors.

Many of these new software packages can be customized to provide content appropriate for individual lessons and can perform other tasks automatically, such as opening web pages, reading text, running other programs and answering questions. Further, they can even solicit and distribute information. Already they can provide answers to questions, instruct on how to perform actions and provide feedback to queries. Soon, agents will be providing useful information in many classrooms and over the web via distance education. Providing these services in a 24/7 environment makes them an attractive method for the delivery of customized instruction.

Agents can also provide great assistance to teachers and students by automatically finding and organizing data available over the world wide web. Using such agents leverages the valuable time and energy of teachers and students. Autonomous agents can function as assistants (someday even colleagues) and look for information relevant to the lesson at hand. Some agents can even assist in the knowledge management function, so necessary as the amount of information becomes overwhelming.

**Future**

The future is even brighter for the use of intelligent agents, both as software tutors and as Learner Relationship Management (LRM) assistants. Indeed, the use of intelligent agents for these purposes will soon be seen in several venues. So far, several articles have profiled the development of intelligent agent tutors, but few academics and faculty have begun to use them. In a recent issue of *Educause Review*, an article by Alfred Bork gives a vision of providing instruction via intelligent computer tutors to everyone at an affordable cost. The inexpensive use of software expert tutors means that superb instruction can be available at any time for anyone. Further, the instruction can be tailored to be different for every student. Just now beginning, the rise of intelligent agent tutors will become a flood as the technology matures. Their potential to provide valuable assistance not only in the traditional classroom but also over the web (e.g., distance education) is tremendous.

As the technology rapidly matures, the limiting factor will no longer be the technology itself, but the development of a new paradigm for teaching. Instead of “one size fits all” lectures, for example, lectures will be customized for each student and provide information at a pace appropriate for each student. This mass customization feature has been taking place in other areas, but, so far, has been limited in education. Intelligent Agents will provide the means to have a personal tutor or instructor tailored for each student. Instead of having to rely on one instructor, students will have the ability to tap the information reservoir through their intelligent agents who can link to virtually all information. Instead of having to wait for feedback on an exam or private counseling session, students will instantly know what they have done right and
wrong. Instead of having to meet at a particular time and place, students will be able to meet anywhere, anytime with their personal agent tutor and still enjoy the richness of a face-to-face session.

Additionally, there will be an increased growth in the ability of the agents to learn for themselves rather than being constantly reprogrammed with new information. Increasing ability to “learn” from experiences, increased improvements in anthropomorphic features, increased friendliness, increased ability to collaborate and increased ease-of-use will no doubt boost the use of intelligent classroom agents. Already, some collaborative agents which can meet and share information are beginning to emerge. Gossip, for example is one such collaborative agent which can meet with other agents with similar interests, exchange web links (gossip) and ideas and return more knowledgeable about a subject. It is not much of a stretch to envision these agents acquiring additional knowledge on a particular subject of interest, incorporating this new knowledge into the subject matter database, and updating their material for lectures or presentation automatically!

Likewise, the use of intelligent agents in the area of LRM appears to be likely. Imagine having an online assistant to aid students in answering their administrative questions. Unlike the tutoring use of agents, the LRM involvement of agents might take on a slightly different tenor. These LRM agents will, perhaps, have to examine the student database to answer queries about courses to take; they might have to calculate grade point averages and suggest remedies or future studies; they will have to be more conversational in nature to be able to interact with students on a more equal basis versus providing instruction. The growth in LRM agents, however, seems likely as already such agents are providing similar assistance in the business world (see: www.extempo.com, for examples).

Summary

The development of intelligent agent tutors and LRM assistants has begun and will continue at a rapid pace, greatly expanding the ability to provide excellent instruction, tailored specifically for individuals at any place and time. Continued technology improvements will make the use of such “intelligent tutors” and LRM agents not only possible, but probable. Educational institutions will need to become involved with these developments since they will alter the way in which educational instruction is provided for many future students.

A Framework for Integrating Technologies in Teaching & Learning

Grace Lim
Temasek Engineering School
Temasek Polytechnic, SINGAPORE
kehbuoy@tp.edu.sg

Abstract: Convergence of IT & communication technologies brings about greater potentials & possibilities in using technologies as a powerful medium of delivery, instruction & communication. Changes in student demographics generate a strong demand for international higher education which can provide life-long, flexible learning programmes. Compelling change of skills needed at workplace drives education communities in all over the world to re-think about education requirements & processes. Combination of these factors set a scene of transformation in education causing a paradigm shift in teaching & learning, which poses new challenges to educators in acquiring skills & competencies not only in technology literacy but also in pedagogy. This paper aims at presenting a practical framework for integrating technologies in teaching and learning. The collective findings based on the author’s experience and that of other institutions of higher education can serve as a general roadmap for an educational institution in adopting innovative educational practice supported by technologies.

Introduction

Integrating technologies in teaching & learning goes beyond setting up system infrastructure. The emphasis of integration is on curriculum re-design for using technologies to support student-centred, process-oriented curriculum & building learning communities in cyberspace. This paper seeks to offer insights into a range of issues confronting educators on deployment of technologies in teaching and learning. As with the case of any innovation, effective & successful integration of technologies in teaching and learning is best described within a framework. The framework comprises six components namely, institutional support, training & development, designing for integration, approach to integration of technologies, paradigm shifts in education & technological development, cultural change among educators.

Institutional Support

Research has shown that institutional support can exert both direct and indirect influence on the outcomes of staff in adopting innovations, therefore it plays a critical role influencing the success of integrating technologies in teaching and learning (Hart et al. 2000; Bottomley, 1999; Collis, 1997; Mogey, 1997). Some form of top-down management decision and support is necessary in providing the initial ‘push’ and in maintaining the momentum of any innovation adoption. Hence, an institutional needs to establish a suitable climate or environment for change before any significant change can take place. The support includes a combination of the following:

- Establishing relevant institution-wide policy on the use of technologies
- Commitment of resource in terms of
  - Building a stable and robust IT infrastructure
  - Providing human resource in technical support at all levels
- Providing adequate computing access and facilities for both staff and students
- Providing recognition and reward to staff on teaching excellence and effective use of technologies in teaching and learning
- Providing time release for teaching staff who are involved in developing interactive technology.
based instruction

- Establishing academic support centers or units for providing on-going staff training as well as for assisting staff in developing technology-based courseware
- Inculcating sharing culture corporately so that experience, skills and knowledge on any innovation and the adoption of innovation will be shared among the staff. This practice provides a mechanism for enhancing knowledge of the staff via peer-teaching as well as prevents duplication and "re-inventing of wheels" of known innovations within the institution

Training and Development

A good classroom teacher is not necessary a good online teacher. Training plays the most critical role in the successful integration of technologies in teaching and learning (Hart et al. 2000; McCarton et al. 2000; Roger, 2000; Lim, 1999a; Littlejohn & Stefani, 1999; Collis, 1998; Canole & Oliver, 1998; Mogey, 1997).

Staff training and development is essential, both in terms of learning and handling the technologies and in terms of how to use technologies in a learning environment. Therefore, successful training goes beyond software skills training. It is important to develop cohesive training programmes with emphasis on learning which encompass an understanding of how people learn, course design and teaching strategies (Rogers, 2000; Verneil & Berge, 2000; Littlejohn et. al, 1999).

While staff training provides the initial familialisation of various teaching methods and selected software, the actual learning is effected during implementation of integrating technologies in teaching and learning. It is during the implementation phase that the staff can experience the synergy of pedagogy and technology.

A one-off training event such as a workshop, a demonstration, or a seminar, will achieve little without proper follow-up in staff development. It is therefore, apparent that during staff development, which constitutes the post-training phase, the staff require a continuation of technical support and "hands-hold" sessions before they can gain confidence and competence in deploying innovative teaching which are supported by technologies.

Adoption of innovation with technology entails a learning curve for both staff and students. Therefore, students also need to be trained in technology literacy before they can use technologies effectively in their learning (Lim, 1999a; Mogey, 1997).

Designing for integration

It is very common for staff to have a conception that going online equates to no more than presenting lecture material, in traditional print format, onto a Website so that students can access them easily, without due thinking through the process for student learning (Littlejohn et.al, 1999). The consequence of poorly designed technology-based courseware is that students find the materials unclear, confusing, difficult to navigate, boring and non-engaging.

Another common practice among staff is to treat technology-based instruction as a separate entity from traditional teaching without proper integration with the rest of the curriculum. Consequently, students cannot relate the technology-based learning materials with the rest of the curriculum in terms of lectures, tutorials, lab session and assessment. Therefore, technologies in teaching and learning will not be effectively used unless it is properly and thoughtfully integrated into the existing curriculum (Lim, 1998b, 1999a, 2000a).

Approach to integration of technologies

Traditionally emphasis has been placed on technologies without regard to teaching and learning aspects. It is
important to avoid this pitfall by ensuring that the adoption of innovative teaching is educationally sound (Littlejohn et al., 1999; Mogey, 1997; Lim, 1999a, 2000a).

Technologies alone cannot provide solutions to teaching and learning problems and needs. Neither can technologies themselves transform teaching, learning and assessment. Transformation comes from re-structuring or re-designing of existing teaching and learning practice with incorporation of technologies. Various findings from the research strongly indicate that deployment of technologies in teaching and learning goes beyond acquisition and set-up of technical infrastructure. Hence, the integration of technologies should not be technically-driven.

Pedagogical-driven approach begins with considering teaching and learning problems, needs and learning styles. Technology will be relied on when there is a need to accomplish desired learning outcomes (Lim, 2000a; Bottomley et al., 1999; Littlejohn & Stefani, 1999; Collis, 1998; Mogey, 1997).

With this approach, adopting innovative instruction requires raising awareness of alternative teaching methods (e.g., active learning, problem-based learning) necessary in addressing paradigm shifts in education, developing new skills with the methods, and know when to apply those methods to optimize student learning.

Paradigm shifts in education and technological development

How do the two diverse disciplines: education and technology synergize in the deployment of technologies in teaching and learning?

This section of the paper examines contributing factors of paradigm shifts in education in the light of globalisation, contemporary learning theory and technology-supported instruction and learning.

Globalisation via flexible learning programmes

Benefits brought about by using Internet as a medium of delivery are well-documented. Internet-based education has been providing means of delivering education in ways not possible by traditional delivery methods. It is able to reach out to diverse groups of students in diverse geographical locations. Learning becomes borderless, stretching beyond the physical boundaries of "real" colleges and universities thereby greatly extending and enhancing learning experience beyond traditional classroom-based instruction can provide.

Shifting from teacher-centred instruction to student-centred learning

Traditional mode of instruction treating students as passive recipients of information is deemed as ineffective and inadequate in preparing students for the workplace of the new millennium.

A wealth of literature suggests the shift of teacher-centred instruction to student-centred learning in which active involvement of students in their learning is deemed as critical for effective learning (Felder et al., 2000; Lim, 2000a, 2000d, 1999a; Rogers, 2000; Ritter & Lemke, 2000). The role of the teacher or instructor is shifted from being a sole information-provider to that of a facilitator for guiding students with different learning styles in attaining desired learning goals.

By capitalizing on interactivity, bringing together resources of different media (text, graphics, audio and video), and converging of IT and communication technologies, technology-supported flexible learning environment is capable of providing various pedagogical interventions necessary for active learning. These include provision of learner-control over pace, time, place of accessing materials as well as selecting or
skipping of materials as required, student engagement in carrying out various online learning tasks and activities, self-reflection, and self-evaluation with the archived transcript of online conferencing (Lim, 2000d; Ritter & Lemke, 2000; Verneil & Berge, 2000).

**Shifting from content-based to more process-oriented curriculum**

A truly content-based approach to instruction and learning can no longer cope with the proliferation of information and with the rate of change in technologies. Hence, students preparing for the workplace of tomorrow need to acquire a range of process skills besides having a firm grasp of discipline fundamentals. As defined by Wood et al. (2000), process skills are 'soft' skills used in application of knowledge. These include skills in construction of new knowledge, multidisciplinary problem solving, communication, writing, learning to learn, self-assessment, change-management skills. Well-designed Internet-based instructions are capable of supporting active construction of knowledge via information retrieval, evaluating, analyzing and synthesizing of information.

**Shifting from individualistic learning to more collaborative learning**

Group work plays an important role in promoting team-working skills which are greatly valued by employers (Rugarcia et al., 2000; Felder et al., 2000; Wood et al., 2000; Rena et al., 1999; Kear & Heap, 1999). Underpinning team-building skills is the notion that learning is a social process characterized by the exchange and sharing of ideas, thoughts, opinions among people, resulting in new ways of understanding the materials via multiple perspectives. Through team-building, members are able to appreciate diversity in views and respect views of others enabling them to work interdependently during problem solving. By working on real-world problems in problem-based learning helps students work collaboratively. Technologies can be deployed to facilitate problem-based learning (Lim, 2000c). Computer-mediated communication (CMC) has been shown capable of supporting and promoting collaborative learning (Verneil & Berge, 2000; Lim, 1998a, 1999a, 1999b, 2000a; Ritter & Lemke, 2000; Salmon, 2000) via group communication and work. The online collaborative tools used include e-mails, bulletin-board systems, newsgroups, chat, audio conferencing and desktop video conferencing.

**Cultural change among educators**

Cultural change among educators encompasses “buy-in”, preparedness, commitment and engagement in adopting innovative teaching. Research has shown that educators are often unconvinced about effectiveness of technology-based instruction. Hence, one of the challenges for implementing an institution-wide deployment of technologies in teaching and learning is to determine the motivating factors which drive the educators to “buy-in”.

Adoption of new teaching practice supported with technologies will call for major curriculum and course structure reviews, re-design, development and delivery as well as implementing of alternative teaching methods and assessment. The initiative and the effort of change will greatly rely on willingness and commitment on the part of educators to adopt innovative teaching practice and to expect and endure initial implementation hiccups. They also need time for adaptation and adjustment of their instruction in response to the changes in the practice (McCarton et al. 2000; Hart et al. 2000; Lim, 1999a; Bottomley et al., 1999).

As integration of technologies cannot function based on the initiative of an isolated educator, the commitment and engagement of all educators for any particular course are recommended for an effective adoption of technologies in teaching and learning. This will ensure a coherent use of technologies across a course and not in isolated topics and subjects.
Conclusion

While institutional support provides the climate for adopting innovations in teaching and learning, true culture change will only materialize from the widespread adoption by many individual educators (Littlejohn & Stefani, 1999, Collis, 1999; Mogey, 1997). Therefore, a successful integration of teaching and learning requires a mixture of initiative i.e., firstly from a top-down component via management support and decision and secondly, a bottom-up component via commitment and willingness of educators to change in adopting innovative teaching practice.

While there are sufficient and mature technologies capable of supporting student-centred, process-oriented curriculum and collaborative learning, the driving motivator of a successful institution-wide deployment of technologies in teaching and learning should be pedagogy rather than technology. Technologies are tools for complementing and facilitating teaching and learning. The initiative requires educators to re-structure their instruction to take advantage of the interactive capabilities of technologies. For an effective deployment, technology-based instruction should form part of the mainstream teaching and learning (Lim, 1998b, 1999a, 2000a).

Findings at Temasek Polytechnic and other institutions of higher education suggest that successful integration of technologies requires close attention be paid to pedagogical, institutional, cultural and technical issues (Rogers, 2000; Verneil & Berge, 2000; Lim, 1999a, 2000a; Bottomley, 1999; Littlejohn & Stefani, 1999; Littlejohn et al., 1999; Mogey, 1997). The collective findings can serve as a general road-map for an educational institution in adopting innovative educational practice supported by technologies.

Zones of comfort, proximal development and technology skills diffusion: A critical reflection on a curriculum-based approach to inservice teacher training.

dmccurry@monmouth.edu

Abstract: This paper explores the current practice of inservice teacher technology training through the lens of two theoretical constructs; Roger's Diffusion of Innovations theory as it relates to technology diffusion among select groups and Vygotsky's constructivist concept of Zones of Proximal Development as applied to practicing teacher's exposure to new tools in their working environment. The approach to training teachers in the context of their own workspace is directed at exploring situated experiences with new technological tools. The relationship between these tools and their patterns and habits of pedagogical practice are described through ethnographic and quantitative data collected during an inservice technology training for K-8 teachers.

Introduction:

An acknowledged problem with the infusion of technology into the classroom environment is the relative lack of skills-training current and new teachers receive both as part of their initial preparation for certification and during inservice training provided for professional development (OTA, 1995; NCATE, 1997). Information and communication technology (ICT) is positioned in close proximity to the working environment of teachers but these practitioners may not have the necessary skills (Cuban, 2000) nor the theoretical orientation to fully utilize it. A situation exists where investments in technology (hardware and software) are not providing the benefit sought by educational policy makers and planners, either as a lever for massive, systemic transformation of learning environments or simply as a means to raising achievement scores (Becker, 1994).

While government and private sector efforts currently emphasize preservice technology training as a way of insuring that new teachers are proficient users of technology, inservice training for practicing teachers is also encouraged and local school districts invest many resources towards this effort. Various models are used in this latter area of activity. Common among these is a model where teachers are invited or encouraged to attend summer, inservice workshops which typically concentrate on a few selected skills, often focused on specific software applications. The transfer of relatively complex skills into classroom practice using this model has proven to be inefficient and problematic. Teachers may, for example, demonstrate competence in using the new skills in the workshop itself but fail to implement the new skills with technology in their classrooms. Moursund and Bielefeldt (1999) also describe the problems associated with isolated technology courses for pre-service teachers advocating an integrative approach where skills are transparently meshed with the teaching of content or pedagogical methods. Technology training programs which utilize traditional instructional design methods (broad overview followed by component skills introduction and practice) in hopes of seeding the "revolutionary" change towards socially constructive, problem-based pedagogy, would seem illogical. It is the author's view that much of this type of training is conducted in the absence of any (intentionally) applied theory. This paper describes a theory and practice based approach to teacher inservice technology training which, following Byrom's (1998) suggestions, builds on known advantages to considering curriculum practices first, communicating technology transfer through peer or practitioner relationships, and through considering the levels of complexity of the target technology. In this latter regard, proponents of technology integration into preservice and inservice education have consistently overestimated time and resources (Conte, 1997), and professional "space" needed to develop the desired levels of technology infusion. There is no unifying theory guiding the practice of using technology in education. Traditional instructional systems models are often placed alongside sociocultural practices with each proposed as an effective means for achieving the same outcome; Technology integration. Multiple theories are used in rationalizing the cost and purpose of linking certain pedagogical practices with specific information and communications technologies.

In hopes of illuminating conditions which will offer alternative considerations, this paper will explore two disassociated yet related and well known theories, applied here to a single instance of teacher inservice...
technology training: Vygotsky's Zone of Proximal Development and Roger's Diffusion of Innovations in technology transfer. Several characteristics of these two theories, both related to how individuals construct new perceptions and skills related to tools and practices in their immediate environment, are explored under the rubric of a "curriculum-based approach". This approach situates the skills acquisition and development within a physical and socio-cognitive proximity to the practitioners.

Even though the zone of proximal development generally refers to an early developmental and sociocognitive concept, this paper posits that it has value in exploring socially constructed knowledge among adult learners as well and is generally compatible with works by Dewey and Kolb in relation to adult learning theory. In this sense, teacher/practitioners, as adult learners, have specific learning needs related to their highly individualized and established behavior patterns and constructed knowledge. The Curriculum-Based Inservice training model used in this case first sought to capture a "snapshot" of each participant's integrated technology skills as foreground and their approach to curriculum (as practiced in their classroom) as background. This was done through the application of a self-survey instrument and individual interviews prior to the training program.

In this paper, each of these perspectives are used as a way of understanding the emerging processes of the teacher's exploration of technology skills. In particular, the concepts of "zone of comfort and proximal development" are applied to the issue of complexity (diffusion theory) in learning new technology skills in relation to existing practice. The focus of this combined theory analysis is an inservice training in central New Jersey of 18, K-8 classroom teachers, one administrator and the school's technology coordinator.

The Training Design:

The general design of the training called for a three-phase modular approach. First, teacher/participants conducted (guided by the facilitator) a pre-assessment of their own teaching with technology skills including an inventory of existing technology skills. The inventory is a detailed, incremental list of skill categories and listed sub-skills with a 5 level, self-scoring rubric. Many skills assessment tools are usually directed at identifying frequency of use in basic categories of technology such as word processing, spreadsheet software or presentation software. The use of a detailed, self-scoring rubric allowed for a higher level of analysis of each participant's zone of comfort with specific sub-routines such as "manipulating an email filter to sort and organize email messages". The self scoring rubric used is represented by the following table.

<table>
<thead>
<tr>
<th>Level 1</th>
<th>Level 2</th>
<th>Level 3</th>
<th>Level 4</th>
<th>Level 5</th>
</tr>
</thead>
<tbody>
<tr>
<td>I am a complete novice in this area. I do not really understand the terminology or what this function/software is about.</td>
<td>I have heard of this function/software or I have seen it used and know something of its potential, but I have not actually used it or learned it myself.</td>
<td>I understand what this is and I have used the function/software occasionally with limited success. I feel I could learn much more about this.</td>
<td>I understand what this function/software is and what it can be used for. I use the basic features on a regular basis in my work but I am uncomfortable explaining it to others.</td>
<td>I am fully familiar with this function/software and I am able to explain it to others so they may use it also. I know and use many of the more advanced features associated with this.</td>
</tr>
</tbody>
</table>

This was followed by a simple questionnaire which elicited information for participant profiles. An additional part of the first phase of the training was an in-depth interview between the skills trainer (the author) and the participant. In this interview, a general sense of the participant's level of comfort and prior use of technology was elicited along with anecdotal information on successful curriculum design and implementation experiences. These latter examples did not need to contain any relationship to applied technology in the classroom and were generated for purposes of establishing the participant's own orientation towards creative and constructive curriculum practices.

As a second stage to this process, teacher/participants engaged in an intensive one-week exploration of skills related to their own individualized (and shared) curriculum goals. This workshop was designed to first introduce a variety of optional uses of technology in the classroom, including modeled examples of WebQuests, PowerPoint presentation software and uses of spreadsheet software for classroom organization and assessment.
The introduction of any one of numerous “kiddie software” (as the technology coordinator called them) programs was eliminated as the teachers already had numerous opportunities in the school to review the plethora of various “learning software” packages available. The initial list of available technologies were drawn then from the office productivity package used at the school and web-based classroom activities (WebQuests). As each of the identified technologies were introduced, their component skills were demonstrated and participants were “allowed” to interrupt the presentation and seek more detailed explanation. This process led to an emerging set of skills which became the focus of small dyads and triads of teachers, working collaboratively to explore a targeted technology tool. The movement of participants from the computer lab to their own classrooms in the week prior to the beginning of the new teaching year also proved to be an essential part of exploring new skills and knowledge within these zones. This allowed for the trainer to visit with and observe the transfer of newly acquired skills in the laboratory setting into the classroom where the teacher would likely employ.

In the third and final part of the training, (which as of this writing is in the planning stage) the teachers will re-convene during the school year for a half-day consolidation workshop. Finally, follow-up assessment activities for evaluating the effectiveness of the model will include a presentation mini-conference where teachers share their progress and experiences with parents, colleagues and community members.

**Applied Theory in Technology Inservice Training**

Two features dominate our thinking about technology as an integrated part of the teaching process. First, current forms of ICT being promoted in classroom use are relatively new, and not generally widespread as commonly observable and accepted routines of practice, and are therefore defined as an innovation in practice. This fact should not be minimized in the overall discussion. Whatever theories are used to dissect and study the process of how innovations interact with current states of practice, one common feature holds that all innovations, as changes in patterns of behavior and culture, are difficult to instigate and direct as an intentional outcome. Secondly, teachers need to be both comfortable with and “convinced” of the adaptability of the skills being introduced to current practice as a starting point for eventual transformation of the culture of teaching and learning in their own workspace. Technology training, therefore, carries the dual burden of presenting a highly complex array of new behaviors with challenges to the basic assumptions and underlying approaches to classroom practice conducted by the teacher. Given this, it is a wonder that teachers learn any new skills at all.

Technology transfer theory has informed us that new skills and practices are best utilized when a natural process of adaptation occurs. Adaptation is described here as a process of first receiving new information, transforming the modeled practice and information to form the best “fit” between existing patterns of behavior and those previously described which then results in new forms. This process of adaptation is crucial to teachers being able to use new skills in their teaching. It requires a maximum flexibility in defining the expectations for skills development as pre-defined learning outcomes may not match the resulting experiences. Rogers, in *Diffusion of Innovations* (1995) supplied 5 essential characteristics of successful innovation adoption, based on numerous studies of how various technology innovations have been introduced, accepted and become widely used among select population groups. In regards to technology in the classroom, these 5 characteristics can be used as a framework to discuss how teachers view technology in the applied inservice training example:

**Relative advantage over what it replaces:**
The new technology and associated skills, at the very least, must provide some clear advantage, such as saving time, minimizing redundancy, providing a better defined product, than performing the same task without the technology. This is an often overlooked characteristic in technology inservice training. The introduction of spreadsheet applications in organizing assessment records and class lists provides a useful example. These teacher tasks are common practice which traditionally involve pencil, paper and inexpensive and readily available materials. The advantage of using grade book software (specifically designed for this function) or spreadsheets (which require teacher input into basic formatting) must be demonstrated as easily “doable” and providing an advantage over traditional methods. Several teacher/participants who, once shown how a simple spreadsheet could be used to merge information with a form letter, quickly identified this as the most relevant and desired technology skill to focus on in the first part of the intensive workshop. The reflexive process allowed them to pursue this as a small group while others worked on different skills. The teachers looking at the
spreadsheet example saw an immediate advantage to more laborious methods in communicating letters to parents which typically need to be individualized for the learner yet containing much redundant information.

**Compatibility**

In a similar way, the technology needs to exhibit some degree of compatibility with the existing tasks facing teachers in the classroom (in their own work) or with the perceived structure of the individual teacher's classroom practice. This is a particularly difficult area for technology proponents and educators since in the most fundamental sense, the "new technology" being promoted is actually a demand for profound changes in the most personal and basic activity of the teacher’s professional performance. It follows that new technology practices which are furthest from the existing practice of the teacher are the least likely to be seen as compatible.

**Complexity**

This perhaps is the most important of these considerations. Rogers (and other “diffusionists”) identified many instances where even though a new technology had many demonstrable advantages over existing practices, the acquisition of skills needed to manipulate and work the new technology were too complex and required a higher level of effort which made continuing with existing practice more desirable. Complexity, however, is also directly related to Vygotsky’s theory in that distant actions, currently out of the reach of one’s proximal development zone, appear too complex and unattainable. The gradual scaffolding of new skill acquisition can reduce the perception of complexity.

**Trialability**

In a linear diffusion model, trialability has to do with a prospective adopter (of new technology) being able to test or to “try out” new skills in a safe and comfortable environment. This also has interesting connotations in the present discussion for understanding a teacher’s own “zone of comfort” in encountering new skills. The training model employed here allowed for a safe and non-judgmental approach to testing out new skills in an un-pressured, loosely structured training environment. The extension of the training experience from the laboratory to the classroom and further, to the demonstration of use in practice after some period of time, allows for the much needed practice, modify and reapplication cycle promoted.

**Observability (of results)**

Related to the perceived advantages of using a new technology is the ability to see changes and positive outcomes to adopting the new skills and technology. If the positive results of the training process were not visible, little impact would be expected.

The short training program offered teachers a technology skills training tailored to their own classroom practice. The actual training itself was first preceded by defining the participant’s existing comfort level, skills and classroom practice approach and then followed by activities planned to further build on the new skills. The acquisition of new, advanced technology skills is therefore fully integrated with their teaching styles, goals, learner outcomes and curriculum standards. The expectation is that as these new skills are acquired, the teacher’s own practice will undergo a transformation both to accommodate the technology and to reflect the types of instructional activities the new technology can make possible. It is further possible that the transformation of teaching will occur through the development of technology skills which lead to a more constructivist-based approach to curriculum in the classroom.

**Discussion and Conclusion:**

Emergent preferences for personal productivity skills which resulted from the workshop activity could reflect a desire to gain control over the technology and associated skills prior to, rather than as part of, the integration of technology use in pedagogical activity. In this way, teacher’s desire to be comfortable around their computers, in the face of colleague interaction and observation by the school administration, parents and the students themselves, would be a motivational factor in the acquisition of the newly introduced skills. Teachers’ own level of comfort and self-assessment allowed for clear definition of individual zones of proximal development. From this, skills training could be targeted for high levels of efficiency, with the trainer serving to help identify the closest proximal relationship between the teacher’s existing patterns of classroom activity and extended uses of technology with new associated behaviors.
Even though the described training model provided for an expanded and flexible orientation to individualized training needs, the continual support and monitoring to enhance a scaffold approach developing the teacher’s use of the technology is difficult to sustain. The on-site technology coordinator, who participated in the training, provides additional assistance to the teachers but must also attend to maintaining the network system, software installation, equipment maintenance and provide services to other faculty at the school. While the training design allowed for individual exploration of specific technologies, workshop participants expressed in the workshop evaluation a desire for more directed, “step by step” training. This was an unexpected outcome, where teachers who are used to traditional models of direct instruction need to be provided with a highly-structured training targeted to very specific sets of skills and technology use. Identifying key technology skills related to personal goals would seem to be verified as an effective strategy for determining training needs but then should be followed by a highly individualized module which matches a specific technology use to the teacher’s self-defined training goal. Such just-in-time training can be delivered through a variety of methods but must be established in the routine of teacher’s expected professional development.

Finally, by designing a workshop training is such a way as to reflect both a diffusion of innovation and constructivist approach, the success and likelihood of technology skill transfer from the training experience to the classroom in the form of adaptable, sustained practices would seem more likely. Additional study of this particular group will yield further information related to the design.

The Identification of Opinion Leaders in the Elementary School

Susan L. O'Rourke EdD
Education Division
Carlow College
USA
sorourke@carlow.edu

Abstract This study focused on the identification of opinion leaders by administrators and teachers in the elementary school. The intent was to determine the extent to which opinion leaders exist in the elementary school. Three methods were utilized to identify opinion leaders within the school social network; self-designation, key-informant and sociometric. Three areas of opinion leadership: (a) school policy issues, (b) curriculum issues and, (c) technology related issues, were analyzed. Results of these methods were combined to identify teachers viewed as opinion leaders by their teacher peers. The findings reveal that teacher opinion leaders exist in the elementary schools included in this study. Fifteen of the 117 teachers included in this study were identified as opinion leaders.

Introduction

Effective school systems make adjustments to meet the changing demands of society. Changes are continually necessary in both curriculum and pedagogy. A variety of forces are responsible for driving these changes. One such force is advancement in the area of technology. Microcomputers and networking capability affect the way we communicate, store and retrieve information, and the way we learn. Consequently, many educators recognize this time of rapid technological introduction and change as pivotal in public education (Poole, 1997).

Recent school reform efforts have a rich history from the introduction of programmed readers to the implementation of 'new' math. And, although schools would seemingly appear to have vast experience in adapting to and promoting change, attempts at change have often been unsuccessful (Futrell, 1994; Zaltman, Florio, & Sikorski, 1977). Many factors contribute to this inability of our school systems to effectively make changes. Some analysts believe that a portion of the difficulty lies in the fact that key teachers within the school system have been found to stop the change process (Webster, 1994). Webster's,
A 1994 study in a secondary school found that a group of senior staff members prevented the adoption of a new curriculum because they did not 'buy into' the product.

Some researchers believe that the leadership model based on a top-down approach has impeded the change process (Hofstede, 1994; Lieberman & McLaughlin, 1992). Teachers who are not consulted when planning a change often have difficulty adopting the change (Lieberman & McLaughlin, 1992). Research suggests that the organization of our educational system can be more effective when the structure permits information to flow from the bottom-up (Mehlinger, 1996; Fessler & Ungaretti, 1994; Yarger & Lee, 1994; Kelly, 1994). This allows for teacher involvement when formulating school policies and procedure. Some teachers are influential in the school system and ultimately can either promote change or prevent it (Webster, 1994).

Diffusion of innovations research examines the manner in which a change, whether a product, procedure or a way of thinking is adopted. Rogers (1995), defines diffusion as 'the process by which an innovation is communicated through certain channels over time among the members of a social system.' Communication, and particularly two-way communication of ideas is necessary for the adoption of innovation or change initiatives. When planning for change in the elementary school, it is important to understand the school social structure and the school environment (Lieberman & Miller, 1992; Hall & Hord, 1987). These two factors significantly impact the communication that occurs. Social network analysis methods allow us to examine relationships or 'ties' connecting members of a society (Scott, 1991). By examining these social structures, we can better understand the processes affected by the communication of ideas (Rogers, 1995). This understanding can then be applied to efforts for planned change in the elementary school (Harzing & Hofstede, 1996; Han, 1996; Lieberman & Miller, 1992).

One area of diffusion research analyzes the impact that certain individuals have on the adoption of a change initiative. This research indicates that some actors within a social system have a greater influence than others to promote or halt the adoption process (Rogers, 1995). Individuals who are able to influence others’ behaviors on a consistent basis are identified as ‘opinion leaders’. Top down, bureaucratic leadership models assume the opinion leaders to be school administrators. However, opinion leaders may be either school administrators or classroom teachers. The entity promoting a change may solicit support from these opinion leaders to facilitate the change process and aid in the improvement of our schools.

This study focused on the identification of opinion leaders by administrators and teachers in the elementary school. A comparison of the formal leadership structure (principals, vice-principals, department heads) to the informal leadership structure, that includes opinion leaders was analyzed. The study also examined relationships between opinion leadership and the specific areas of: 1) technology, 2) curriculum, and 3) school policy.

Results
It is beyond the scope of this paper to include all of the data and findings generated from this study, therefore, general information and data related to technology will be reported. For more detailed information, refer to O'Rourke (1999).

The networks (i.e., elementary school) ranged in size from 16 to 29 teachers. The average size of the networks contained 23.6 teachers. These networks included regular classroom teachers, ancillary teachers and special education teachers. The schools in this study maintained computers in the classrooms or in the library and did not have computer labs. Therefore computer resource room teachers were not part of these elementary school networks. Grades kindergarten through fifth were represented in each school. One hundred and seventeen teachers in the five schools were invited to participate in this study. Ninety-five teachers (81%) returned the questionnaire.

The results of the three different techniques used to identify opinion leadership; (1) self-designating, (2) key informant, and (3) sociometric were combined to identify teacher opinion leaders in each of the five elementary schools included in this study. Table 1. Provides an example of the data utilized to determine opinion leadership. Teachers identified by all three techniques were considered to be opinion leaders. In addition those teachers identified by two of the three techniques and to a lesser degree the third were considered to be opinion leaders.

Table 1. School A: Opinion leader identification
The findings revealed that teacher opinion leaders exist in the elementary schools included in this study. Two of the fifteen teacher opinion leaders were part of the school’s formal structure (department heads, head teachers). Conversely, thirteen of the fifteen teacher opinion leaders did not carry formal designation as a leader in the school system. These teachers seem to constitute an informal leadership structure within the elementary schools studied. The study revealed that only one teacher identified as an opinion leader was viewed as an expert in the area of technology, in the elementary schools in this study.

Implications

An opinion leader becomes valuable to any individual promoting change within a specific environment (Krassa, 1988; Hall & Hord, 1987; Harzing & Hofstede, 1996; Rogers, 1995). Studies have found that their influence is related to the success of the adoption of a new product, a new methodology or a new technology (Beal & Rogers, 1957; Coleman, 1957). Their influence on the members of a social system can assist or hinder the efforts of a change agent (Rogers, 1995).

The integration of technology into a school’s curriculum involves the adoption of such technologies by teachers. Schools choosing to incorporate instructional technologies by utilizing a top-down approach may be impeding the change process. Research suggests that the organization of our educational system can be more effective when the structure permits the information to flow from the bottom, up (Mehlinger, 1996; Fessler & Ungaretti, 1994; Yarger & Lee, 1994; Kelly, 1994). This allows teacher involvement in instructional technology decision making. Some teachers are influential in the school system and ultimately can either promote change or prevent it (Webster, 1994).

Surry and Farquhar, (1997) suggest that analysis of social factors be incorporated into the instructional development process in order to increase an innovation’s use. They believe that, "instructional developers should consider the potential adoption and implementation of their products as carefully as they consider the instructional outcomes." Other researchers have also included consideration of social factors in the adoption of educational innovation process. An Environmental Analysis (Tessmer, 1991), where factors within the school setting are analyzed and considered by the instructional designer, provides information that may increase the adoption rate. When teachers and other members of a school social network involve themselves in the adoption process, the integration of the innovation is more successful (Hall and Hord, 1987; Mehlinger, 1995).

Summary

The intent of this study was to generate information concerning opinion leadership within the elementary school. The opinion leaders in this study were influential in the area of curriculum and to a
lesser degree school policy issues. Leadership within the area of technology seems to be quite different from those teachers whose opinion is sought out in regard to curriculum. The administrative educational technologist was cited as most frequently sought out regarding technological issues. Some teachers were also identified as opinion leaders in this area. However, only one teacher identified as a leader in technology was identified as an opinion leader in this study. Additional research in this area could provide further explanation for the cited difficulties in educational technology integration. An examination of communication patterns and influence as they relate to the diffusion of technological innovations in schools may yield information towards an explanation of the seeming failure of many teachers to fully utilize the potential of computer technology in the classroom.

These findings suggest that the diffusion of innovation process or teachers' willingness to adopt new technologies may be promoted or impeded by the school's social structure. An individual attempting to drive change in such a school system could benefit from understanding this structure and developing a formal plan for the adoption of innovations into the classroom by teachers. They may consider seeking out the teacher opinion leaders and soliciting their support. In addition, schools may want to offer additional training to teacher opinion leaders in the area of technology. If other teachers observe these respected teachers utilizing the technology and integrating it into the curriculum, they may recognize its value.

In summary, a school's social network should be analyzed and this information applied to a plan for the diffusion of technologies into the classroom curriculum. This may help to enable individuals responsible for promoting change in schools to facilitate the adoption process.

Abstract: One of the challenges of course delivery at a distance is determining an effective method to conduct practicum supervision. In the past, educators have used a variety of strategies to observe practicum students completing their field work. On-site supervision often required extensive travel for faculty or hiring adjuncts to conduct supervision. The University of North Texas Educational Diagnostician Program is involved in a research study using EnVision, desktop conferencing software developed by Sorenson, Inc., to supervise graduate students enrolled in an advanced practicum. This paper assesses the effectiveness of the EnVison System as a tool for monitoring practicum students in the Educational Diagnostician Program.

Using Technology to Enhance Practicum Supervision

Supervision of students during a practicum is often a major challenge in distance education. On-site supervision may required extensive travel for faculty or hiring adjuncts to conduct supervision. Earlier attempts at using technology to reduce faculty travel time included video taping practicum experiences and reviewing the video tapes to provide educators with feedback. Although this practice can reduce faculty travel time, very often it is difficult to provide timely feedback to students. The technology is now available to use desktop conferencing software as a tool for practicum supervision.

The University of North Texas Educational Diagnostician Program is involved in a research study to supervise graduate students enrolled in an advanced practicum using EnVision, a desktop conferencing software developed by Sorenson, Inc. We are interested in determining the accuracy of using the two-way audio video technology for supervision purposes. Students need to pass a check out procedure for using standardized assessments. This check out involves the university student administering the standardized test using correct procedures with the instructor scoring the assessment procedure and providing feedback. Travel and time are issues for both students and faculty. Therefore, using the EnVision software, we proposed the following research questions: Does the EnVision two-way conferencing technology provide the opportunity to observe students at a distance with the accuracy required for supervision? What are the perceived benefits and limitations to using two-way conferencing technology for supervision of a practicum at a distance?
Research Project

This study involved observing thirty students enrolled in three graduate level assessment classes using EnVision software. All students participating in this study were observed administering a standardized test (Woodcock Johnson R, PIAT, or WISC III). Protocols for check out on the tests was developed by two instructors in the Educational Diagnostician Program and checked for reliability prior to beginning the study. Each student participant was observed while administering an assessment instrument by two evaluators communicating through EnVision. One evaluator was on-site with the university student administering the assessment and one evaluator was observing at a distance. Reliability was determined by comparing scores with the on-site rater and the distance rater. In addition, a questionnaire was given to all participating students prior to and following the observation to determine perceived strengths and limitations of using two-way conferencing technology.

Desktop Videoconferencing Practicum Supervision

In order to maintain the same high quality supervision during the practicum component of the assessment course through distance education, affordable technology that provides audio and video connections point-to-point is required. The EnVision software uses compressed voice and video and runs via the Internet or ordinary phone lines. For this study one computer is located at the main campus in a faculty office and one computer is located at the student's practicum site. The system includes an audio video connection and a chat function with a save and print function. While supervision is taking place, the two observers type observation notes for each other's viewing without interrupting the student's performance in the practicum experience. Using application share software the two observers are able to complete the observation simultaneously.

The pre/post questionnaire given to students helped to assess the following advantages: ease of use of the system for supervision at a distance, accuracy of observation notes, and frequency and ease of use of the EnVision System. Possible disadvantages to be assessed of the use of this technology included: cost, ease of installation and subsequent use of the Envision Software, student confidentiality, and the effect that the Envision System may have on the reliability and validity of the practicum observation.

Program Assessment Procedures

A major part of field experiences for the educational diagnostician program centers on assessment procedures. Assessment is the process of collecting data for the purpose of decision making (Salvia & Ysseldyke, 1998). Aligning the assessment procedures to provide continuous monitoring of individual progress is required for teachers to meet the definition for special education as specialized instruction (Dyck, Pemberton, Woods, & Sundbye, 1999). In order to provide students with disabilities an appropriate education, teachers need information about student progress in a timely, systematic fashion that can be used to make instructional decisions on a per student basis. Educational diagnosticians provide expertise in the area of assessment to individuals working with students.

Students in the program master the competencies for norm-referenced assessments, which can provide information on an individual's performance compared with the performance of many peers (Taylor, 2000). These assessments provide information ranging from academic achievement to intelligence scores, depending upon the test selected. There is a need for students to master the correct procedures required for various norm-reference assessments. The EnVision software is one way for the instructor to observe the testing situation at a distance. The chat and document share functions on the EnVision software are both available as a vehicle to provide feedback that is not interruptive of the assessment process.

Parents, teachers, medical staff and students in a day treatment center are interviewed over the EnVision system as a part of the process for conducting a Functional Behavior Assessment. The goal of the functional assessment is to provide information to use in the redesign of environments and selection of new skills to be taught. A Functional Behavior Assessment to develop a positive behavior plan is now required by the Individuals with Disabilities Education Act of 1997. Part of this assessment is gathering information from interviews, questionnaires, and direct observation.
Advantages and Challenges of the Remote Supervision Technology

There are many advantages of using technology for supervision at a distance. First, it makes it possible to observe and supervise students in remote locations. Second, because travel time is eliminated, more frequent observations and more extensive feedback can be provided. Third, the potential for interaction between the student at a distance and the faculty member is unlimited. Faculty members can see and hear the students, understand the directions, and directly view the assessment procedures and provide feedback. Fourth, this technology provides an opportunity for students and faculty to observe quality assessments. Fifth, number of opportunities to interact through interviews with others during the assessment process has increased.

Challenges to the use of remote supervision technology include amount of technical support to set up, debug, and maintain equipment. The cost to equip each site limits the number of sites available. Issues of confidentiality and protocol used during conferences must be addressed for each use of the technology.

Abstract: The University of North Texas Educational Diagnostician Program has implemented effective uses of technology to help address the critical need for diagnosticians in the Dallas/Ft. Worth Metroplex and surrounding rural areas. Students in the Metroplex often deal with traffic back-ups that require a huge investment of time. Accidents or road construction on key highways can significantly impact travel. Students in rural areas often must drive long distances to access university classes. Technology can assist in meeting the needs of these two distinct student populations. The challenge for instructors in the program became how to use technology to support student learning without compromising the requirements of a certification program that includes a rigorous state exit examination and a high level of expertise on the job.

Program Overview

The College of Education at the University of North Texas (UNT) offers a Master’s in Special Education and/or certification as an Educational Diagnostician. This degree program is designed for students who want to be employed as an Education Diagnostician or for teachers who are interested in assessment issues in the classroom. A focus of this program is directed towards Curriculum Based Assessment and the implications it holds for teachers in making curricular decisions. In addition, students will be certified to administer standardized tests including the WISC-III. The curriculum is divided between didactic courses that provide knowledge in critical areas of special education and field-based practica that address assessment skills. Upon completion of the program, students must successfully pass an ExCET examination for certification in the state of Texas. Graduates are expected to demonstrate a high level of expertise in the area of special education and assessment for employment. UNT currently has a pass rate of 98% on the ExCET examination and 100% placement of graduates of the program.

Importance of Technology for Course Delivery

There is a critical shortage of educational diagnosticians in the Dallas/Ft. Worth Metroplex and surrounding rural areas. Students in the Metroplex often deal with traffic back-ups that require a huge investment of time. Accidents or road construction on key highways can significantly impact travel. Students in rural areas often must drive long distances to access university classes. Technology can assist in meeting the needs of these diverse student populations. The challenge for instructors in the program became two-fold: Use technology to provide easy access of content for students and support student learning without compromising the requirements of a certification program. In addition, the need to supervise students during assessment procedures to ensure accuracy was critical. The entire program is now structured for course delivery in a distant education format through the use of technology. Thus, the content becomes accessible to our diverse population of students.
Program Features

The goal of the program is to develop distance education technology that enhances and supports the delivery of a quality educational diagnostician program. The main features of the distance education program are:

1. Didactic classes are delivered through an electronic, microwave-based, interactive, closed circuit two-way television system. Our program is currently using five sites, with the option of adding more as the program expands. The program time slot is from 5:30 PM to 8:30 PM on two evenings a week. Broadcasts typically originate from the UNT System Center, but most professors broadcast from each site at least once during the semester. There is a support person at each site to address technology needs. During broadcasts, the instructors may lecture, conduct a class discussion, show a video, or present information on an overhead. Faculty present lectures using PowerPoint slides. Students give presentations, discuss and ask questions, and work in small groups. There are two large television screens at each site. The instructor and students are viewed live on television screens and that image is transmitted to all sites. The camera is voice activated and projects the image of the person speaking at the time. Students and instructors interact in much the same way as they do in on-site classes.

2. A program Web site provides general information about the program, application forms, and faculty to contact for additional information. In addition, each faculty member maintains his/her own web page for courses offered. Extended syllabus, assignments, class notes, announcements, and tests are transmitted through the Web site. In addition, students' work/projects may be posted in certain classes for other students' viewing and learning. Potential students can open the Web site and view information about the program prior to enrolling.

3. Email is used to communicate with students on advising issues, assignments and updates. Assignments are often sent in as attachments. Students are encouraged to email and share information with each other as they move through the program.

4. Practicum courses are supported through EnVision, a two-way audio/video desktop conferencing software developed by Sorenson, Inc. EnVision is available on the main campus and in one of the centers of the university. Students in their final year of study can check out an EnVision software system to use on their school computer. Faculty can observe students during assessment with standardized tests through EnVision and provide immediate feedback to the student. The chat function on EnVision is used to coach the student during the assessment process, if needed. The protocol currently used for assessment supervision provides information directly to the student through the document share function. Students can also discuss data collected on Curriculum Based Assessment projects with their university faculty member in a timely manner.

Students use EnVision in a connection with a day treatment school located away from the main campus. The day treatment school is for students with emotional/behavioral disorders or other health impairments. Part of the assessment process is gathering information from interviews, questionnaires, and direct observations. Students' assignments include interviewing teachers, parents and grandparents raising students with disabilities.

Advising students, and often students' peers that are interested in university work, can also take place over the EnVision system. This face-to-face contact and the demonstration of technology are both exciting and available to current and potential students.
5. Software programs to support diagnostic report writing assignments are located in two of the main computer labs for the university: one on the main campus and one in a university center located ninety minutes away. Students also can purchase a copy of the software for home or school use. This software provides students with an opportunity to learn best practices in completing reports following diagnostic evaluations. A partnership with Ewing Solutions has provided ReportWriter software to assist students with preparing appropriate psycho-educational reports in a time efficient manner. Additional software has been purchased to score various tests and rating scales. The use of scoring software greatly reduces scorer error. With the use of technology, scoring tests and writing effective psycho-educational reports can be accomplished in a time efficient, accurate manner.

Technology is an important component of the Educational Diagnostician Program. Needs of the students, instructors, and overall program dictate the technology used. Technology serves as a tool to make a highly successful program convenient for commuter students while enhancing the learning opportunities.
Open Source and the Diffusion of Teacher Education Software

Abstract: Three recent reports, one from the U.S. government and two from European Union related groups, indicate that the open-source software development model is gaining worldwide acceptance. This model provides a means for teacher educators to create software that is sustainable, continuously improving, and sharable. As a result, it can reduce duplicated efforts among PT3 grant recipients and reduce the risk that a project’s work efforts will go unutilized when a grant’s funding ends. The paper gives a brief overview of what the open-source model is, explains how it can be used to benefit the different stakeholders in a grant funded project, and discusses how it can support the diffusion of technology innovations. The paper concludes with the recommendation that the U.S. Department of Education should encourage the use of the open-source model in all department-funded projects that have a software development component.

Introduction

“The PITAC believes the open source development model represents a viable strategy for producing high quality software through a mixture of public, private, and academic partnerships. This open source approach permits new software to be openly shared, possibly under certain conditions determined by a licensing agreement, and allows users to modify, study, or augment the software’s functionality, and then redistribute the modified software under similar licensing restrictions. By its very nature, this approach offers government the additional promise of leveraging its software research investments with expertise in academia and the private sector” (President’s Information Technology Advisory, 2000).

These opening comments were part of the transmittal letter for a report by the President’s Information Technology Advisory Committee titled “Recommendations of the Panel on Open Source Software For High End Computing.” Although the Committee chose to focus its efforts on high-performance computing, the report provided some general observations about the open-source software development model that are applicable to all types of software, including educational software. In a similar report about the open source development model, the Working Group on Libre Software, created at the initiative of the Information Society Directorate General of the European Commission, reported that:
"The impact of open source technology is expected to be quite noticeable in the software industry, and in society as a whole. It allows for novel development models, which have already been demonstrated to be especially well suited to efficiently take advantage of the work of developers spread across all corners of the planet" (Working group on Libre Software, 2000).

Another European initiative, the Information Society Technologies theme in the 5th Framework Programme of EU RTD (IST), a division of the European Commission with a budget of 3.6 billion Euro, has specified two objectives in a draft version of its 2001 Work programme that support free and open-source software. The first objective is "to foster in Europe a critical mass of development of free software released under GPL [General Public License] compatible licenses." The second objective is "to make available European based support services for free software projects" (Information Society Technologies, 2000). These objectives are not likely to change before they are adopted and will be used to guide the selection of projects that the IST will fund. One can read more about GPL compatible licenses at http://www.gnu.org/.

These three reports are clear indicators that the open-source software development model is gaining worldwide acceptance. This model provides a means for teacher educators, and educational software developers in general, to create software that is sustainable, continuously improving, and sharable. An immediate benefit is that this model can reduce duplicated efforts among PT3 grant recipients and reduce the risk that a project's work efforts will be under or unutilized when a grant's funding ends. The paper gives a brief overview of what the open-source model is, explains how it can benefit the different stakeholders in a grant-funded project, and discusses how it can support the diffusion of technology innovations. The paper concludes with the recommendation that the U.S. Department of Education actively encourage the development of open-source software in future requests for proposals.

Open Source

There are two forms that every computer program is stored in. The first and most commonly experienced form is as a binary executable file made up of 1s and 0s that only the computer can read and cannot be modified by anyone. The second form is as human readable computer code, source code, which can be modified at any time and used to create a binary version of the program. The open-source model facilitates the sharing of source code and the binary files. Currently, the field of teacher education, and instructional technology in general, does not have a method to facilitate sharing and building on the building blocks/source code that other community members used to create an intervention/computer program. Software development is the only area in these fields that is confronting this limitation. Unlike academic research reports, there are no established protocols and outlets for creators of educational software to share their work with others in a way that allows for it to be critiqued and built upon. Imagine a system where professors conducted research but no one could critique their research design, data collection, or data analysis methods and statistical procedures. Researchers would not have the option of selecting which parts of the study they found useful and reusing those parts. A researcher's choices would be to use the resulting intervention as is, or start from scratch. They would also be completely dependent on someone else to update and modify the procedure used as the environment changed. There is little doubt that researchers would recognize that each environment is unique and that they needed to be in control of the tools that they use and would choose to redevelop the intervention for their target environment. This scenario is very analogous to the one that teacher educators and instructional technologists who develop software applications currently face. Researchers working in these fields lose all of the advantages of the scholarly journal system that most other fields take for granted. The benefits of the scholarly journal system are what an open-source software development model brings to the field of software development for teacher education and instructional technology in general.

The open-source model is not a set model or procedure for developing software. It is closer to a philosophy than a process. However, the development process used by most open source projects is very similar to the rapid-prototype methodologies. The biggest difference between the rapid prototype model and the model used by most open source projects is that when the first prototype is released the source code is also released for other developers and potential users to examine and offer feedback on. Opensource.org (www.opensource.org/osd.html), a leading Web site in the open source community, provides a definition of what types of software should be considered open source. According to this definition, software should be considered open source if its associated license provides for (1) free distribution, (2) a means to easily access the program's source code, (3) the ability to distribute derivative works, (4) non discrimination against any person, group, or field, (5) distribution outside of the original product, (6) a means for not contaminating the licenses of other software that work with it, and (7) equal treatment for everyone
who wishes to license the software. A more complete description of these criteria and a list of associated software licenses can be found on the site.

Open Source and Stakeholders

Some of the principles embedded in the definition of what qualifies as an open-source license are probably foreign to the stakeholders involved in a grant funded software development effort. This section will briefly explain the benefits to each major stakeholder of using this model. These are some of the arguments used when members of the Shadow netWorkspace (TM) project (http://sns.internetschools.org) successfully convinced the University of Missouri-Columbia to allow them to distribute software using an open-source license.

Funding agencies

Funding agencies often have the goal of each project have as large an impact on the targeted audience as possible (e.g. getting the most bang for their buck). Because software developed using the open-source model has all of its source code freely available, any organization that might have a use for the program can acquire a copy of it at little or no cost to them. Established online communities such as the one at www.sourceforge.net provide a means to publicize and distribute an open source program to a worldwide audience at no cost to the author.

In addition to knowing that the resulting software will be free, the process of publishing the source code ensures that other researchers can build on and modify the original product. This in effect embeds the ability for the program to be sustainable and continuously improving as versions of operating system or Web browsers change. In effect, this open approach to software development allows a funding agency to lower their exposure to risk. Even if the project can't support itself when the funding discontinues and the researcher moves onto another project, the open-source model allows anyone who finds value in any piece of the work to continue building on it. The result is that the risk of a funding agencies' investment going underutilized is greatly reduced.

Universities

Most universities have a goal of increasing their name recognition to support recruiting and fundraising efforts. Because the open-source model facilitates the widest possible distribution of a software program, an organization that sponsors the development of an open-source project, vs. a closed source project, receives the widest possible exposure. A university does not give up the copyright when they license the software under an open source license. This ensures that their name will be associated will all of the project's work.

The goal of generating revenue from the work efforts of its researchers has recently gained increased attention from universities. Giving away software that a researcher produces may seem contradictory to this goal. However, this simplistic view ignores the trend in the software industry to view the industry less as a manufacturing industry and more as a service industry. Universities that promote open-source projects are in the best position to capitalize on revenue generated from the services associated with these programs. Who is someone more like to turn to for service with a product, a name that has been associated with the product from its inception or a third party? There are multiple business models that are based on selling services associated with open-source software. The most notable of these is Red Hat, a company that supplies a version of the GNU/Linux operating system and associated services.

Developers/Researchers

From a developer's perspective, the open-source model offers a means to bring the time-tested model of sharing via journals and conferences presentations to educational software development. Just as is the case with traditional publishing, mistakes (bugs) in the work are easier to identify when more people review the methods used. Solutions, modifications, and workarounds to the limitation/bugs can be openly discussed so that others can confidently build on the work effort. This allows each researcher to evaluate, select, and reuse the pieces of a work effort that are appropriate for his/her context. None of these activities are adequately facilitated by the current system of close source programs. The result is unnecessary duplicated effort among developers because they can't

As described above, by appealing to a funding agency's desire to maximize results while at the same time reducing their exposure to risk, a researcher can gain a competitive advantage when applying for funding. Proposals that commit to using an open source approach embed the concept that the project maximize the number of users while allowing others to build on the resulting work. Researchers can use these points to their advantage when competing against others who propose to develop closed source program. There is a great difference between a
researcher who simply promises to make a program freely available and one who proposes to provides a means to allows others to build on every aspect of what is produced. Researchers can highlight this in their funding proposals.

By using an open-source model, developers can also take advantage of online community sites such as wwwslashdotorg and wwwsourceforge net to raise awareness of their project, recruit developers, and in effect multiply their development and user testing teams. Also, because using an open-source license and taking advantage of the existing online communities will likely result in a wider distribution of a software program, researchers will likely have a larger group of users and as a result have a larger pool of potential research subjects to draw from.

Supporting Diffusion

The nature of the open-source software development model encourages and, because of the associated licenses, almost requires users to form communities to support the use of the software. Because of this, encouraging the development of the open-source software would help form communities of educational software developers filled with educators communicating and sharing reusable software programs. Communities such as this have already developed around other open-source projects such as the GNU/Linux operating system, the Apache Web server, and the Perl programming language.

Everett Rogers has identified a set of attributes, as perceived by potential users, that affect an innovation's adoption rate. The five most important attributes that Rogers identified are relative advantage, compatibility, complexity, trialability, and observability (Rogers, 1995). A short comparison between the attributes of open-source software and these attributes reveal that the open-source model holds several advantages over the currently employed closed-source model of software development. Relative advantage is the degree to which an innovation is perceived as being better than the idea it supersedes. Because the open-source model invites comments and developer contributions throughout the process, it is reasonable to expect that a more attractive product (e.g. less bugs, more desirable features, etc.) will result. "Compatibility is the degree to which an innovation is perceived as consistent with the existing values, past experiences, and needs of potential adopters" (Rogers, 1995). By opening up the development process and gaining increased input and possibly increased work effort, the open-source model is more likely to be compatible with the needs of a larger number of users than if it was designed and developed by only a few individuals. "Complexity is the degree to which an innovation is perceived as relatively difficult to understand and use" (Rogers, 1995). Because potential users are exposed to more options for using and participating in the development of an open-source project than a closed-source project, projects using an open-source model do run the risk of seeming more complex than closed-source projects. Developers who are aware of this can take precautions to not overwhelm potential novice users with too many options. However, because of the increased opportunity for user and developer input, a project developed using an open-source model should be able to identify any potential perceptions of complexity early on. "Trialability is the degree to which an innovation may be experimented with on a limited basis" (Rogers, 1995). Because, using the opensourceorg definition described above, all open-source projects are free, they hold a clear advantage over closed-source projects in the amount of trialability they offer the user. Anyone can download an open-source project, try it out and continue to use it for as long as they like without any limitations. Although this easy trialability can be true for a closed-source program, open-source licenses allow third parties to make copies of a program and distribute it. Unlike closed source programs, it is perfectly legal for teacher "A" to make a copy of a program for teacher "B" to try out. The last major attribute that affects an innovation's rate of adoption is observability. "Observability is the degree to which the results of an innovation are visible to others" (Rogers, 1995). Rogers states, "The observability of an innovation, as perceived by members of a social system, is positively related to its rate of adoption" (Rogers, 1995). Observability is one variable that both closed and open-source projects struggle with. Because software programs in general are relatively hard to observe being used, neither open nor closed-source projects have a clear advantage in observability. However, as this paper mentioned earlier, because users of open-source software are encouraged to join a community of users, open-source software could be seen as having an advantage in observability. Although this is a very short review of the attributes that Rogers identified as affecting an innovation's rate of adoption, it is intended to raise overall awareness of the attributes of the open-source model and hopefully initiate a discussion within the research community about the merits of this approach.

Conclusion

This paper briefly reviews reports by the President's Information Technology Advisory Committee, the Working Group on Libre Software, and the Information Society Technologies theme in the 5th Framework Programme of EU
RTD all supporting the open-source model of software development. It then gives a brief overview of what the open-source model is, explains how it can benefit the stakeholders in a grant-funded project, and how it can support the diffusion of technology innovations. In light of these reports and the arguments presented in this paper, we argue that the U.S. Department of Education should encourage the development of open-source software in all department-funded projects that have a software development component.

Abstract: The authors have been using Excel and Maple in their Business Calculus courses, and they have also been using WebCT for managing the class and the students. This paper discusses WebCT and the idea of producing compressed videos of class work that are made available to the students through the Internet. The videos show the students how to use the technology (for example Excel and/or Maple) within the course. The students can view the videos as often as needed and then practice the concepts while watching the video. The advantages to students, course content, and time management are obvious.

Introduction

How does one integrate technology into the classroom without neglecting the subject matter of the course? This is an area of concern when trying to include Excel and Maple into a Business Calculus class. Using Excel and Maple would afford the opportunity to discuss more "real world" type examples without getting bogged down in mountains of algebra. This would also allow students to focus on what answers and calculus concepts mean instead of focusing on algebra and rote memorization of formulas. The challenge is that students must be taught how to use Excel and Maple, as well as the class concepts, in a very finite amount of time. Students may miss class or fail to immediately understand the "how to's" of the technology. Thus the authors have introduced compressed video into their Business Calculus classroom in order to help alleviate this problem.

The authors are currently using WebCT to manage the class and the students. This allows the students to have unlimited access to grades and class announcements. The authors have also recently started the production of compressed videos of class work that are made available to the students through the Internet. This affords the opportunity of unlimited access to class work as well as class announcements. The videos must show the students how to use the technology (for example Excel and/or Maple) within the course. The students can view the videos as often as they wish and then practice the concepts on their own. The advantages to students, course content, and time management are obvious.

WebCT

WebCT is a web tool that allows the instructor to create an intricate web-based course without having to design everything "from the ground up." It allows the instructor to create, with relative ease, learning and communication tools for students within the web-site, as well as providing class management options for the instructor. The authors use it for Business Calculus and a discussion of how they use it follows; however, it is not just a web tool for mathematics classes, and one may visit the WebCT web-site at http://www.webct.com/ to obtain more general information.
The homepage can be created quite easily and the instructor controls its organization. The following is a sample of icons on the homepage:

The icons labeled "conditional" are not generally seen by the students. The instructor can program settings that specify when and how long the icon is available and also specify which students or sections are allowed to see the icon. The programming can be done through a point and click fashion within WebCT.

The calendar of course events is always available to the students. The instructor can provide messages, downloadable files, and homework assignments to the students and also include his or her own private schedule within the calendar. To view the day's assignments, the students need only to log into their WebCT account, click on the calendar icon, and then click the day of interest. The day's messages for the students are then displayed. Html code can be embedded within the calendar messages, permitting the instructor to provide downloadable files. The following is a sample of what can be seen by a student:

<table>

  **Click here to download**

- homework:
  - Numbers 1-3 on the 4.6 handout.

Figure 2: A sample of the Calendar of Course Events.
The instructor also has many options in managing a course or students within WebCT. Student names and grades can be stored in column format. Each column can be programmed to be viewable or hidden from student view. Each student can view, if the instructor allows it, his or her grades only and not the grades of other students. The order of student information and what is available to students is completely at the instructor’s discretion. All settings can be programmed with ease. The following two figures show the point and click options for programming column settings:

**Modify Columns**
- Add column
- Delete columns
- Convert column type

**Organize Columns**
- Move item left
- Move item right

![Figure 3: Column modification options.](image)

![Figure 4: Column layout options](image)

Tests can also be created within WebCT and graded by the instructor or by WebCT. Test questions can be categorized according to the instructor’s desires. The test questions can be formatted as multiple choice, paragraph, short answer, matching, or calculated. Once a test bank has been established, an instructor can create a test within minutes, and grading can be done in seconds. In fact, it is possible to have final averages computed and available to the students within one second after the last student submits his or her exam.

Calculated questions allow the instructor to ask the same type of question, but WebCT randomly assigns different inputs, numbers for a math class, according to the instructor’s specifications. All other question formats deliver the same question to each student. The following two figures show the students view of a calculated question and the instructor’s editable version of the question:
Suppose you take out a loan of $53174 at an annual rate of 8.7% and decide to pay it back monthly over a period of n years. If the payments are $353.16 per month, what will the balance on the loan be after the third payment is made?

**Answer**

Figure 5: The student view of a calculated question

The question and formula are entered. The instructor clicks on “Analyze variables” and then enters upper and lower bounds on the variables. One then needs only click on a button labeled “Generate random answer set” and the question is complete.

Figure 7: Variable set for a calculated question
Videos

The authors' Business Calculus course required extensive use of Excel, Maple, and WebCT. This afforded the opportunity of discussing more interesting "real world" problems; however, some class time had to be used to teach the use of the technology. Of course, at least one student would inevitably be absent, and others would not grasp the instructions immediately. The goal would be to maximize class time for the discussion of Business Calculus concepts while providing enough instruction on technology use for every student. With this goal in mind, the authors considered producing videos that explained class concepts and technology use.

Some problems do immediately arise. Production medium, availability, and file size are some of the major considerations. The production medium could be simply videocassettes of the class presentation; however, this seems impractical. The point is to make the movies accessible over the Internet. One could use a digital camera to create a video, but this creates a rather large file that would hamper accessibility. The video must be quickly viewable, downloadable, and contain all pertinent information for the concept.

The authors decided to use Snapz Pro, which can capture from 1 to 30 frames per second and can capture audio as it records the computer screen. Most of the videos were made on a Macintosh PowerBook G3 with color settings of 256 and a resolution setting of 640x480. Snapz Pro was set to record microphone input and record five frames per second. This produced videos of computer screen activity with audio and achieved a file size of approximately 500K per minute. Better color and resolution settings could be used to view the videos, and most of the videos required less than eight minutes. The videos were then hinted and made available on WebCT through either streaming video, or the student could download the video to his or her home computer and view it. In either case QuickTime Player was used to view the videos.

As long as students viewed the streaming video on computers with high speed Internet connections, the hinted videos worked well, unless students wanted to rewind the video. If one tried to view it with a 56K-modem connection, the results were troublesome. However, the video could be downloaded and viewed without any troubles. At present, only downloadable versions are made available so that all students can access them through any computer with an Internet connection.

The advantages of this approach are clear. The file size is not huge, so students can download and view the videos in a reasonable amount of time. Students can play, pause, rewind, fast forward, progress one frame at a time, and view the video as much as necessary.

![Figure 8: View of the QuickTime Player](image)

From Figure 7 above one can see that the student has a great deal of control over the video. The students immediately see the cause and effect relationship of Excel and Maple commands and can practice them. In fact, students can work along with the video as it plays. Finally, if a student must miss class, then he or she can access the videos and keep up to date with the rest of the class.
Conclusion

By using Excel and Maple in Business Calculus, more useful examples and problems can be discussed. However, students can often have problems understanding the concepts or understanding how to use the technology. The goal is to provide plenty of instruction on how to use the technology in order to analyze the problems in the class.

WebCT is useful in helping to accomplish this goal. It is a wonderful tool for managing the students' grades as well as course content. The students can log into their accounts at any time and receive class updates. Any students that must miss class can still keep up to date with the class schedule. However, the student that misses class also misses valuable instructions that may not be communicated as well with the written word.

The present generation of students is well acquainted with computers and video of many types. Producing these class videos provide a useful tool to students in a medium to which they are accustomed. The student that must miss class can now keep up to date much better than before. The authors' students have been watching the videos, and student feedback thus far has been positive.
Implementing a Web-based Middle School Science Curriculum: An Evaluation Report

Stephen Rodriguez & JoAnn McDonald
Texas A&M University D Corpus Christi

The Internet and its associated World Wide Web (WWW) have been marked by phenomenal growth and use in seemingly every aspect of life. The WWW has emerged as an area ripe for development of products that can support educational efforts at all levels. As a case in point, Active Ink Incorporated—a Texas-based firm specializing in development of web-based learning materials—has developed the eeZone Project. This project is a Science/Technology/Society (STS) on-line, web-based interdisciplinary curriculum. The intended audience is middle-school students.

Our primary purpose here is to report findings and related recommendations resulting from a year-long evaluation study of the eeZone Project. We sought to determine how teachers and students at a single South Texas middle school used the eeZone materials; what factors supported teachers’ use of eeZone; and finally, what skills, knowledge, or attitudes students and teachers may have acquired along the way.

In this report, we include a review of literature, description of our method and findings, discussion, conclusions, and recommendations for the future.

Review of Literature

Criticality of Planning

Many educators agree that instructional technologies hold high potential for improving learning in the schools. However, like any major social innovation, adoption of IT by teachers is a complex, multifaceted, and lengthy evolutionary process.

One is also cautioned to remember that technology is a means—a tool which must be used thoughtfully and in planned ways. Providing hardware or using technology are not end results in and of themselves:

Technology alone cannot improve teaching and learning. . . Technology use must be grounded firmly in curriculum goals, incorporated in sound instructional process, and deeply integrated with subject-matter content. Absent this grounding, which too often is neglected in the rush to glittery application, changes in student performance are unlikely (Baker, E.L., Herman, J.L., & Gearhart, M., 1996, p. 200).

Clearly, planning how to integrate uses of technology such as the eeZone Project into the school curriculum has emerged as one of the most critical issues facing educators and instructional technologists today. Growth of the Internet and the World Wide Web, advances in digital video technology, and the introduction of alternative, affordable storage media such as “write-able” CD-ROMs all add to the challenge of successfully integrating technology in today’s school curricula.

Technology Standards for Texas Students

The Texas Education Agency (TEA) has developed a set of technology standards which closely parallel established national standards. These standards—placed as elements within the Texas Essential Knowledge and Skills (TEKS) standards—are known as TEKS for Technology Applications.

The TEKS address the acquisition of technology application skills as a continuum, progressing from the elementary to the grade twelve level. The technology TEKS are organized by benchmarks, not by grade level, so as to provide schools with flexibility in how to achieve them. Students are expected to demonstrate targeted proficiency levels before exiting second, fifth and eighth grades, respectively. Embedded within the grade clusters are four strands, or levels, with appropriate student expectations in skills and knowledge for each strand.

The first strand is the Foundation Level. Students are expected to demonstrate knowledge of hardware components. Specific skills at this level include using the correct and appropriate input and output devices, demonstrating keyboarding skills, navigating successfully within the desktop, saving files, and using peripherals.

The second strand—the Information Acquisition Level—requires that students gather varieties of information from electronic sources. This involves performing keyboard searches and navigating successfully to access information in text, audio, video, graphical, or combined modes. Students are expected to both gather the information and to evaluate the relative success of the search along with the credibility and usefulness of the acquired information.

The third area targets problem solving. Here, students are expected to create and modify problem solutions, using software to incorporate audio, video or graphic components. At this level, students also conduct research using electronic tools in order to be able to justify the recommended solution. The student should generally be able to use word processing and multimedia software to explain ideas and to solve problems.

The fourth strand is the Communication Level. Students should be able to present audiovisual information, selecting appropriate fonts, graphics, and color, all of which are geared to enhance communication. Other communication skills and knowledge include suitable printed output, consideration of monitor displays, video presentations, and use of electronic mail. The expectation is that the student should select appropriate applications in order to facilitate and evaluate communication.
Constructivism and Technology Use

Constructivist conceptions about human learning have also emerged in the literature and at professional conferences as a central theme associated with technology use in the schools. The constructivist view holds that learning and knowledge construction are grounded in meaningful experience and individual meaning making. Again, we see that the design of the eeZone on-line curriculum is consistent with such a view. Jonassen (2000) asserts that students do not learn anything, per se, from computers. Rather, he argues that teachers should use computers to engage students in thinking meaningfully and representing their knowledge. Under this view, "... the most effective uses of computers in classrooms are for accessing information and interpreting, organizing, and representing personal knowledge" (p.4) rather than for studying traditional instructional software. The learning activities included in the eeZone curriculum are structured in a manner that is consistent with this view.

While the constructivist view holds appeal for many, most educators recognize that constructivist approaches must be used in balance with more traditional instructional strategies, including direct instruction.

A brief review of some of the tenets of constructivism is in order, as they serve to remind us of the need to engage students in meaningful uses of technology which foster knowledge construction. Jonassen, Peck, and Wilson (1999) provide an excellent summary of key, related views. Their views and related commentary follow:

1. Knowledge is constructed rather than transmitted: that is, knowledge cannot simply be handed off or passed from the teacher to the student. Rather, learners construct meaning and knowledge from experience. Technological assists here insofar as it is used to broaden students’ base of experience. For instance, computer-based simulations allow students to experience a modified version of some reality such as planning a city that may not otherwise be possible. E-mail can increase students’ experience in communicating with others across the country and world.

2. Knowledge is acquired through activity: accordingly, learners acquire knowledge by actively interacting with elements of the world around them. Instructional technologies are also consistent with this view insofar as they foster active engagement on the part of the student. It should be noted, however, that instructional software titles vary in the degree to which they require active learning.

3. Knowledge is grounded in the learning context: when a student interacts with phenomena in the world, acquired knowledge includes information about the context where the interaction occurred. This view suggests that teachers should be careful to help students see the linkages between computer-based learning experiences and the real world. Further, as students use technology for traditional curricular purposes, they are likely to gain separate skills and knowledge related to use of technology tools—specifically, computing skills.

4. Meaning is subjective: In the mind of the individual: there is no absolute external meaning; people can hold common views or share meaning through the process known as social negotiation. The end result is that multiple perspectives of phenomena exist across individuals. Computers can foster shared meaning and social negotiation by bring individuals together to work on technology-based products such as multimedia presentations or web pages. Of course, e-mail and online chatting or discussion groups directly facilitate communication among individuals, which is at the heart of the matter.

5. A student’s interest in solving a problem or resolving some type of perceived dissonance will prompt that student’s ownership of the learning task and increase relevance and meaningfulness. Many students find the very use of computers or other types of technology such as video equipment inherently interesting. Many teachers report that this increased interest increases students’ ownership of the learning task. For instance, a student might have greater ownership of producing a computer-based presentation than of producing a traditional essay.

6. To truly learn and generate knowledge, the learner must articulate and reflect upon relevant learning experiences. When used as a communication tool—whether for word processing or developing a multimedia presentation—the computer supports articulation of experience.

7. Meaning may be shared with others: learning is often a social process, and conversation can prompt meaning making. So called knowledge-building and conversation communities are natural extensions of this view. Technology supports the sharing of meaning when students use the computer to communicate with others. Engaging students in group projects also fosters conversation.

8. Meaning is distributed within communities. Our interaction with other members of a community influence our beliefs and knowledge. Again, technology can bring students together and further communication, thereby supporting interaction with others.

9. Not all meanings are equally valid: The viability of knowledge is determined by its acceptance and the degree to which it is acted upon. Technology can assist teachers and students in determining the validity of given meaning because it allows for the amplification and sharing of ideas.

Constructivist views remind us to place the learner at the heart of the schooling enterprise and to plan for learning experiences that will be meaningful and engaging to students. However, the views should be kept in balance. Fisher, Dwyer, and Yocum (1996), in discussing the Apple Classroom of Tomorrow (ACOT) project, offer related commentary: “Mature ACOT sites tend to balance use of direct instruction with a collaborative and inquiry-driven knowledge-construction approach to teaching and learning” (p. 8).

Educators should thus keep in mind that using computers to deliver test preparation software or other inflexible, commercially produced instructional software is insufficient. Rather, these uses should be balanced with more constructive activities involving analysis and display of...
data, communication between people, and development of multimedia and web-based products. It seems clear that the design of the eeZone Project is consistent with the conceptions about constructivism just described.

Purpose of the Study

Although leaders in the field of instructional technology have urged educators to include multimedia and instructional software as integral components of teaching and learning in schools, many teachers still struggle to meet the challenge.

The purpose of this study was to examine the implementation of a Science/Technology/Society (STS) on-line, web-based interdisciplinary curriculum to learn how its use affected teaching and learning at one South Texas middle school. The following research questions guided this investigation.

1. How do teachers use the eeZone materials to support student learning?
2. What conditions or factors support teachers' use of the eeZone online curriculum?
3. What knowledge, skills, and/or attitudes have students and teachers acquired through their participation in the eeZone online project?

Method

Participants

Participant informants in this qualitative case study included all of the eighth-grade teachers at one suburban South Texas middle school campus, their students, and the media specialist who also acted as a mentor for the project. The fifteen eighth-grade teachers were arranged in three teaching teams. Each team consisted of five teachers: two language arts teachers, one science, one math, and one social studies teacher. The teachers represented a variety of experience levels ranging from two to 38 years with the average years of teaching experience being 13. There were 12 female and three male teachers. Although one team had piloted the eeZone materials the previous year, the other two teams had never used the on-line eeZone curriculum prior to the 1999-2000 school year.

Data Collection

Data were collected through interviews, conversations, observations, and analysis of program documents and products. The use of multiple data sources allowed us to compare and cross check the consistency and validity of the data collected. Triangulation of data was also utilized to limit the effects of researcher bias.

Interviews

Interviews were conducted with both teachers and students regarding their use of the eeZone curriculum. While formal interviews were scheduled with individual teachers, we also met with teams of teachers in focus groups. Interviews with students were never scheduled, but were conducted randomly during site visits. A generalized interview guide approach (Patton, 1990) was utilized. Prior to conducting interviews, we identified a few key questions we wanted to explore with each respondent, but allowed the conversations with teachers and students to unfold based on their comments and interests. This allowed us to elicit certain information from every participant without rigidly structuring the conversation. Such an approach was found to be more responsive to individual participants expectations and concerns. The open-ended nature of the questions allowed respondents to share their unique perspectives without being limited by boundaries imposed by a rigid interview protocol. All of the interviews were conducted at the middle school. Formal interviews were audiotaped and transcribed.

Observations

In addition to interviews, we observed teachers and students engaged in eeZone activities. In September of 1999, we joined the eighth grade teachers for the initial training on the implementation of the eeZone curriculum. Throughout the year, we observed classes working on eeZone projects in the computer lab and in their classrooms. Field notes were recorded during site visits.

Documents and Products

Document and product analysis also contributed to our understanding of how the eeZone curriculum affected teaching and learning. We first reviewed the eeZone on line curriculum and even registered as users so that we were able to monitor the Activelnk web site. We also monitored teachers entries to the Working Circles, an on-line reflective journal allowing teachers to log comments or responses to key learning questions. Some of the questions posed included:

1. How do technical problems affect student learning?
2. Does eeZone address our curriculum?
3. How does the technology of eeZone help students gain real-world skills?

Student products reviewed included maps, graphs, charts, and Power Point presentations. We also reviewed teacher products such as lesson plans and teacher-generated teaching materials.

Data Analysis

In order to bring structure and meaning to the mass of collected data, inductive processes of data analysis were employed. The use of inductive analysis allowed patterns, themes, and categories to emerge from the data. After each site visit, audiotaped interviews were transcribed and field notes reviewed. Interpretations and emerging patterns and themes related to the data were noted and recorded in quarterly reports.
Three major themes emerged from the data.

THEME 1: Implementation of the eeZone Online curriculum was inconsistent and hampered by unavailability of computing equipment, experience levels of team members, and other internal and external factors.

Calallen teachers and students got a late start on eeZone projects due to external factors such as lack of computers and the lateness of some projects coming on-line. Although teachers participated in the initial eeZone training in September 1999, implementation of the curriculum began in January 2000. The late start was due primarily to unavailability of classroom computers for some of the participating teachers. Although some teachers had classroom computers, teams delayed implementation until all team members were equipped with the necessary computer hardware. Unfortunately the computers were not received until late in the fall semester. In addition, some of the eeZone projects were not posted on-line until January. Many teachers reported that the lack of equipment and slow posting of some eeZone projects on-line significantly delayed their efforts to implement eeZone projects earlier in the school year.

Internal factors such as lack of time and experience and stress due to TAAS testing also contributed to the late start. Many teachers reported that even after the computers were delivered and all of the eeZone projects were on-line, they delayed implementation of projects so that they could prepare their students for the February administration of the Texas Assessment of Academic Skills. Even though math, science, and social studies teachers were not directly involved in the February testing, teams delayed projects while language arts teachers were focused on TAAS testing. As a result, all three of the eighth grade teams got late starts on eeZone projects. Once projects were initiated, many teachers temporarily abandoned their projects to prepare for the April administration of the TAAS. Overall, it seemed that the emphasis on high-stakes testing drew teachers' and students' attention away from eeZone.

Teachers' level of experience also affected their implementation of eeZone projects. The value of related prior experience was evident. For example, the Eagles team, composed almost entirely of teachers who worked with the eeZone Project last year, completed more eeZone project activities and exhibited a higher level of confidence. Teachers also reported that it took a great deal of preparation to integrate eeZone into their existing curriculum and identify related TEKS. Most teachers suggested that it would save them a great deal of time if Activelnk would clearly identify TEKS related to eeZone project activities. However, by the end of the school year, all teams had initiated a project related to their discipline and aligned with state mandated TEKS.

Overall, teachers' comfort levels with eeZone projects varied based upon their prior experiences. However, teachers viewed the 1999-2000 academic year as a learning experience and felt that they would be more proficient in using the eeZone Online curriculum next year. One teacher summed it up this way:

I don't feel like we've accomplished our objectives this year because of the late start. Next year I'd like to see better coordination between the teachers on my team. But next year we will be ready because we have developed more skills. I think we did pretty good this year. You know, the first year, you get your feet wet. The second year you do better, but the third year, we will have great coordination and it should be terrific (Lowe, 5-11-00).

THEME 2: Critical support for teachers implementing the eeZone Online curriculum came from other teachers on their campus.

As is common with any instructional innovation, the teachers often felt uncomfortable and incompetent during initial attempts at implementation. Most of the teachers were unfamiliar with the use of eeZones web-based software and initially weren't sure that the eeZone curriculum would help them meet the instructional standards mandated by the Texas Essential Knowledge and Skills (TEKS). In addition, some teachers expressed difficulty understanding how the inquiry-based environmental eeZone projects fit into their existing curriculum. Several teachers described themselves as technology illiterate. Although they used computers for word processing, they had little experience with utilizing technology and multimedia in their instructional practices. As a result, they initially expressed anxiety and frustration about their abilities to utilize the eeZone program.

The technology specialist on the campus who also served as the eeZone project mentor provided critical support for the teachers. The project mentor acted as the liaison between Activelnk and the pilot teachers. She reported concerns and difficulties to the software designers and provided trouble-shooting expertise when teachers experienced problems with hardware or software. She also assisted teachers in the computer lab and made classroom visits. The specialist also provided training for the teachers in the use of digital cameras and software programs such as Excel and Power Point.

The technology specialist also assisted teachers in their efforts to relate the online projects to local environmental concerns. For example, when the teachers chose the eeZone graffiti and landfill projects for their classes, she copied related articles from the newspaper and regularly distributed them to the teachers. She even participated in a field trip to the local landfill with one of the teams.

On the whole, the teachers expressed much appreciation for the support that the technology specialist provided. Teachers indicated that her support was instrumental in their successful implementation of the eeZone projects.

Teachers also reported that their peers provided valuable support. Since teachers planned as teams, they had opportunities to share successful strategies or materials with other team members. This was particularly evident on the team that piloted the eeZone materials the previous school year. One of the language arts teachers on the team was new to the campus. She was very positive about her participation in the eeZone project. We found this surprising since many of the other teachers who had never previously used eeZone seemed much more uncomfortable than she did. When we questioned her more closely, she credited the other members of her team with giving her the support and encouragement she needed to feel successful. She reported:

We started with the waste project because we felt we would have an advantage going in that direction since the other teachers on my team used it last year. They know where they had problems and they have new ideas about what they want to do this year. So I am
Overall, teachers shared materials and ideas with one another and tried to provide assistance to team members who were experiencing difficulty. They indicated that teaming provided support mechanisms that were readily available and trustworthy.

THEME 3: Teachers enhanced their technology skills as a result of their participation in the eeZone projects.

Both teachers and students perceived that their personal technology skills improved as a result of their participation in the eeZone project. While improving students' technology skills was an anticipated outcome of the schools' participation in the program, improving teachers' technology skills was an added benefit. During interviews, teachers often reported increased competence and confidence with regard to the use of computers and multimedia in planning and delivering instruction. Their new found competence and confidence went beyond the use of eeZone software, extending into other computer uses and applications.

The teachers reported that one factor significantly contributing to their enhanced technology skills was increased access to computers. Many of the teachers had never had a computer available in their classrooms prior to receiving one through the eeZone pilot program. Teachers noted that once they had a computer in their classrooms, they began to experiment with new software, to review web sites that could be used to enhance instructional units, and to generally increase the use of technology in classroom instruction.

At the end of the 1999-2000 school year, one of the participating math teachers decided to leave the school district to pursue a Masters degree in educational technology. He credited his experiences with the eeZone project as the catalyst that sparked his decision. He reported:

Before the computer was put in my room, before I was made to do eeZone, I had been through some computer workshops. But I didn't feel confident. Now I feel confident that I can do computer work, that I can do research. I can do downloading; I can converse with others through e-mail. I can get on the computer, go to sites, answer questions. I feel a lot more confident. On a scale of one to ten (10 being the highest level of competence), I was about a three at the beginning of the school year, now I'm about a six. Yeah, I'm much better, more confident. That's why I applied for the technology/math program in San Antonio (Villarreal, 5-11-00).

Even teachers who described themselves as technology illiterate or anxious at the beginning of the year, perceived that their computer skills had improved. The social studies teacher on the Patriots team provided one such example:

At first, I wasn't real sure what to do with it [eeZone Online materials]. I was pretty technology illiterate. I began to play around with it, learning how to do new things. As a result, I've improved my computer skills. It has made my planning much easier. I've started using a computer grade book and, boy, that has really been great. I'm doing projects I haven't been capable of before, but there's a lot more I'd like to learn. On a scale of one to ten, I was about a two in using computers, now I think I'm about a six. I like it. I've always been a book, pencil, paper kind of teacher. I don't like to play games. I don't think kids benefit from that when they go to high school. But computers are different. That will be something that will help kids when they go to high school (Lowe, 5-11-00).

On the whole, teachers credited their enhanced computer knowledge and skills to the increased availability of computers. They also perceived that their classroom instruction improved as a result of their enhanced technology skills.

Discussion and Conclusions

Our evaluation produced some positive findings while also revealing some pitfalls associated with implementation of an on-line curriculum project such as eeZone.

On the positive side, our study revealed that the project empowered some teachers in the use of the computer for instruction. Many teachers reported a gain in skills and confidence in computer use. Teachers also expressed how much a skilled technology mentor can contribute to successful project implementation by providing instructional and technical support and general encouragement. These findings suggest that use of a project such as eeZone can have positive effects on development of teachers' computing skills. They also support the view that a strong on-campus technology leader and mentor can have a powerful influence on teacher behavior relative to implementing a project such as eeZone.

Students also expressed positive views concerning use of the eeZone curriculum. They were generally enthusiastic about their on-line learning experiences, seeing them as a favorable, more active alternative to traditional classroom instruction. Some students who worked on the waste project indicated that their awareness of how much trash they generate increased. Others stated that they had learned how to use electronic mail in conjunction with their eeZone work in order to receive directions from a teacher. Some developed multimedia presentations on their eeZone research. Clearly, the majority of students enjoyed using the materials and found the experience to be fun. This suggests that students are likely to find future interactive web-based science curricula such as the eeZone project both appealing and motivating.

While positive outcomes resulted from use of eeZone in the school, certain problems related to implementation also emerged. Foremost among these was uneven implementation. In some cases, teachers waited until the last two months of the school year to begin using eeZone with their students. Such a delay in using the on-line materials certainly undermines the likelihood of providing students with a rich, deep, and meaningful learning experience. Problems obtaining computing-equipment for the project no doubt hampered things at the start; however, as time wore on, lack of motivation on the part of some teachers to "get to it" seems another major cause of the weak implementation. Teams which lacked a member with eeZone experience or strong technology skills were also hindered when it came to implementing.

Teachers also delayed use of eeZone due to concern about preparing students for the Texas Assessment of Academic Skills (TAAS). Others expressed uncertainty as to possible linkages between eeZone and the Texas Essential Knowledge and Skills (TEKS). Addressing teachers' concerns in these areas would do much to foster more timely, sustained implementation of the project.
Recommendations for the Future

Based upon the findings of our study, we offer the following recommendations:

1. Establish time-certain milestones for project implementation: rather than providing teachers with free reign as to when they will complete project activities, establish a timeline for achieving milestones and try to monitor and hold them accountable.

2. Ensure that each eeZone team includes an experienced user whenever possible: encourage formation of teams to include an experienced eeZone or technology user as a support mechanism for the less experienced teachers. In this regard, a general strategy would be to build on teachers' previous successes using eeZone.

3. Provide additional, accessible teacher support materials to foster stronger implementation: in many cases, teachers failed to see how eeZone might contribute to students preparation for TAAS or how it correlated with the TEKS. Support materials—possibly in print format—providing explicit guidance in these two areas might do much to encourage greater and more timely implementation.

Closing Thoughts

The development and implementation of the eeZone Project represented a massive undertaking. As with most human endeavors, the effort at the school we focused upon produced positive results along with ideas for “how to do it better” in the future. For some involved teachers, lack of follow-through emerged as a prime cause of poor and less than timely implementation of the project. On the positive side, students expressed appreciation for eeZone as an interesting and fun alternative to more typical learning activities. Teachers too indicated that their technology skills improved due to their involvement with the project.

In sum, the evolution of projects such as eeZone holds great promise for engaging students in powerful on-line learning activities that relate to the real world.

Abstract: This paper presents an effective use of the World Wide Web by schools. This is a multidisciplinary proposal intended to integrate disciplines from the school curriculum in a common project. A description of the steps to develop this virtual school library for its use as a tool in the everyday process of teaching and learning is provided. School teachers have tested this Web-library and their comments greatly contributed to the paper.

Introduction

It is difficult and challenging to find new ways of teaching and organizing information. Any learning experience today involves not only the mastering of the fundamental concepts in the field but also, the use of technologies (Bruce, & Levin, 1997). Nowadays, the improvements in educational technology help educators to deal with completely different methods of teaching and organizing knowledge (Nicaise, 1998). Computers and the Internet open the door to thousands of possibilities, hence a lot of ways of exploiting those possibilities.

The Benefits of the Internet

A recent study of uses and impacts of the Internet, WWW, and related technologies in community colleges found that library and learning resources are seen as the application with the most potential positive impact on students’ outcomes and institutional effectiveness (Layton, 1997). The Internet has become the least expensive method for communicating and distributing information (Friedman, McGrath, & Barron, 1997).

Projects that include technology help in improving people's fluency with information technology. This fluency is defined as the key to survive in the current and future world by the Committee on Information Literacy (1999).
The Purpose and Advantages of the Web-library

Our proposal is to build a library according to the school needs and not just to explore somebody else's creation. It differs from others in the sense that it points to the creation of the site by those who will be the potential users.

This library source will cover the areas required in the curriculum, because the teachers of those areas will be involved in the organization and design of the site.

The material will be considered as owned because teachers will feel they are not adopting something imposed, as software. The difference is marked by the relationship of what teachers and students are doing in the process of exploring learning: Either following somebody else's agenda, or following their own (Papert, 1993).

The material will be customizable since the users will be able to edit or add things as they use it, so it will be framed to their needs; it will answer to the needs of that school and for the time it is created, but with the potentiality of updating and customizing.

Our purpose is to encourage schoolteachers, staff, students, and parents to create a space on the WWW that will function as a source of information, a non-linear library made by hyperlink connections, for their use as a tool in the everyday process of teaching and learning.

This cyberspace would be unique to each school, though it will contain documents, which are shared with all the Internet community. The sense of uniqueness is given by the way this documents are selected and organized from a huge amount of possibilities.

The implementation of this virtual library will save the time spent in exploring sites at random, and will allow teachers and students to make immediate use of the information already evaluated, selected and appropriately listed in the web library.

This project can equip educators with a new dynamic teaching tool and addresses the national science education standards since the students can apply the information that they gather with the Internet to solve real-world problems. The data that students can collect can be obtained for real sources of scientific research, then making the learning experience an absolutely real scientific work.

Project Development

The actions proposed to carry on this project can be synthesized in these terms: engaging, building, using, maintaining, and the cycle will be constantly looping.

Now that the advantages of this approach have been considered, the stages to develop the project will be described. First the basic requirements to start the project will be mentioned, and next detailed steps to carry it on.

Assuming that schools will be provided with Internet connections, the ideal situation for carrying on this project would be several computers in the classroom where the users can access and retrieve the data on demand.

This project will need the involvement of member of the school personnel (or PTA) with Internet skills, that is with the ability to communicate using e-mail, browse the Internet, develop a web site, and be able to solve the basic problems encountered in the process from browsing to publishing. A person aware not only of the advantages that the information super highway can bring to the class, but also the danger of the misuse or irresponsible use of it, if necessary and agreement on the possibility of a previous training should be considered. This is a very important point that shouldn't be disregarded. Eastwood et al. (1998) affirm that unless staff development is properly addressed, infrastructure per se will do little to improve teaching and learning.

Then it is necessary to group those that will be in charge of starting to develop the project, taking into consideration computer skills, areas of study, and position in the school.

The number of individuals that have to compose the team should be determined by the scope that the school want to bring to the project, a minimum of one teacher and student per area of study should be involved, though more
people in the same area make more sense because in the process of selection of the information various criteria would help a better result.

Once the school is engaged in this project, the starting point will be developing a productive and time-efficient search approach. The process that goes from collecting data to using that data as knowledge base resource will follow these steps:

1- **Determining the Needs**: The first step will be to decide what are the most important topics that will be included in this bank of information. To decide about the topics the team will have to consider items that are shared by various disciplines, are taught in various grades at different levels, and are still subject of study in many areas so they are constantly updated.

2- **Collection of Data**: There are several factors to consider in data collection to make it more efficient and organized: a- Who will look for the information? b- How long will be devoted to the collection of data within the whole duration of the project? c- What amount and what type of information shall be considered?, d- How will the information be stored?

3- **Search Strategies**: Learning about the Internet search tools and some of their strengths and weaknesses should be included in an outline to follow a search plan.

4- **Assessing the quality of information**: Because the web is available to almost anyone with access to a computer, teachers must assess the quality and trustworthiness of the information they have accessed. This task can be accomplished having in mind the following aspects: The scope of the information, the audience form whom it is intended, the author, the publishing body, the currency and treatment of the information, and the ease of use (Fenton & Repass, 1999).

5- **Documenting the search**: The final outcome of the preceding work is a list or database that will document the search. This list will be the one that the school will use as a knowledge base resource. This will not differ much from an ordinary library card or a catalog.

6- **Development of the web-library site**: The team will design and create a website which will host the selected information resulting from the search process. This will be the visible outcome of the project.

7- **Maintenance**: The group must be in charge of keeping the library web pages updated.

---

**Online Test Version of the Web Library**

The web site developed as a result of this project can be found on the Internet at http://www.students.uiuc.edu/~scagnoli/weblibrary/. This is a version that we developed for the schools that we invited to test and explore its usability. The site consists of:

- **A Front Page**: This introduces the idea of the project and explains how to use it.
- **A Search Page**: That will allow users to type in the topic and search by category, topic, name of the site or keywords.
- **Results for their search**: The results will be displayed in order of relevance with the topic.
- **List by Categories**: Users can select any of the categories displayed on the menu and a complete list of all sites in that category is showed on the screen. They can access to the site by clicking on the URL (Fig. 1).
- **Add a Site page**: A form that allows users to add new sites to the library (Fig. 2).
- **Edit a Site page**: With the same procedure that the sites are added they can be updated or deleted.
- **Add/Edit a Category page**: The sites are indexed according to disciplines or categories. In this case the categories correspond to the main areas in the school curriculum. They can be added/edited or deleted from the web library when necessary.
- **Add/Edit a Sub-Category page**: Categories can be divided into sub-topics.
Conclusions

Most schools are in the technology game. This web library proposes a customized guide achieved by the collaborative work of the school people, which will ensure saving time, sharing expertise and encouraging involvement. This project has been presented in schools in Urbana, Illinois, USA (Urbana Middle School and Martin Luther King Elementary School) and their feedback has been used to improve the project. Since we believe in the usability of the project we plan to expand its scope making it available to larger audiences and other school settings.

Planning Makes “Perfect?” - A Comprehensive Look at Successful Implementation of Technology and Teaching at a Major University

Abstract: Temple University has demonstrated success at infusing technology and at implementing innovative approaches to teacher education. This presentation is comprised in five segments that address successful strategies and programs at different university levels: university, college, department, course, and community/school district collaboration. Each segment will address specific topics such as Preservice Teacher Education, technology diffusion, faculty development, and diversity. One of the primary goals of this presentation is to connect strategic planning at the university and college levels with successful implementation of innovative programming at the program, course, and community/school district levels. Presenters include faculty, professional staff, and graduate students.

University Level: Temple University Instructional Technology Planning

Glenn E. Snelbecker, Ph.D.
Educational Psychology Program
Temple University

Major comprehensive changes in technology planning began in 1994 in conjunction with the establishment of a “Teaching-Learning Technology Roundtable” (TLTR) at Temple University -- (the first developed in accordance with American Association for Higher Education (AAHE) guidelines). This resulted in University-wide emphasis on the theme that “curriculum and instruction should drive technology” (instead of having technology drive curriculum and instruction).

This paper is written from one faculty member’s perspective, based on TLTR and TLTR Academic Planning Committee (TLTR-APC) membership since 1995. Much information reported previously was presented in TLTR-APC or TLTR documents. Many people collaborated in developing ideas and procedures that serve as the foundation for Temple University’s planning processes and results. Though certainly not “perfect,” it is this author’s view that Temple’s approach to technology planning has stimulated much more thought and discussion about programmatic planning than existed previously at Temple. Comments in this paper about TLTR activities at Temple mainly focus on University and College annual IT planning processes; however, it should be acknowledged that other TLTR committees have made similar positive contributions. For example, one committee was closely involved in the design of a new high technology classroom building, and other committees have explored prospects for cross-university collaboration on various IT ventures.

As examples of how some “outsiders” (i.e., professionals not participating in Temple University TLTR activities) view TLTR planning, here are quotations from the Middle States Commission on Higher Education Report as a result of Temple University’s review during Spring 2000:

“The TLTR has been a catalyst for infusing academic technology into teaching and learning at Temple. A broad-based and inclusive faculty membership with a commitment to process and communication provide responsiveness and flexibility to re-engineering curriculum with technology enhancements in a collaborative framework. The TLTR operates through a structure of working committees drawn from faculty representing a cross section of all programs. It is fair to say that Temple is noticeably ahead of other universities of similar size and mission.”

“The TLTR created technology-planning guidelines that are used to examine the curricular and pedagogical requirements at the college level and to create the college’s plan for the use of technology to meet these requirements. The TLTR faculty review the college’s plans and from them develop a set of recommendations for funding technology investments and initiatives within the college for the University administration.”

2982
During early discussions about TLTR, many questions were raised as to (a) whether such a venture could be successful, (b) why and how people might be willing to be involved with TLTR in the long term, and (c) what ways TLTR and its respective committees might be a constructive influence for students, faculty, staff, individual colleges, and the University. Some illustrative questions, issues and concerns include the following: What is to be accomplished via "TLTR activities"? Why should TLTR and its committees be existing assemblies, committees and other groups? Why "bother" identifying curricular goals and potential career impact of IT resources, instead of simply "listing" the computers, software and other resources that "we" (in whatever college) really feel we funds or other favorable results? Won't such discussions produce "turf wars" regarding distribution of limited funds and other resources? If college IT plans are required annually to receive funds for IT resources, what kinds of guidelines should be provided for development of college IT plans? Once planning processes (and IT plans) "mature," how might "supplemental plans" be developed annually rather than preparing an almost completely new plan each year? What might happen if "reasonable" rates of funding do not regularly result from regular programmatic planning?

The importance of technology planning is illustrated by the following statement contained in University feedback to annual college IT plans: "The technology planning process is expected to be continuous and active, and can help the University focus its attention on using technology to improve teaching and learning. This process brings accountability to all parties involved, assists in establishing priorities for technology investment, and provides the Provost and Vice President with solid information to make their case for increased technology investment to the Board of Trustees."

College Level: College of Education Technology Planning

Graciela Slesaransky-Poe, Ph.D.
Glenn Snelbecker, Ph.D.
Temple University

The Instructional Technology Committee of the College of Education at Temple University is an advisory committee to the Dean and works in close collaboration with the provost and vice president of Computer and Information Services. This committee, chaired by Dr. Slesaransky-Poe, is faculty-led and includes multiple college and university stakeholders (i.e., faculty members from the four departments; students; staff; administration; and K-12 school personnel, including technology specialists).

The Instructional Technology Committee interacts with other college and university committees. Several committee members also participate in the university-wide Teaching, Learning, Technology Roundtable (TLTR), mostly through the academic planning process, and are members of the TLTR Executive Committee.

The overall goal of the Instructional Technology Committee is to promote and develop improved methods of teaching and learning through the effective use of technology. To achieve this overall goal, the committee creates a very comprehensive annual Technology Plan. The planning process includes: 1) setting priorities based on curricular goals for our students' needs and national and state standards; 2) designing, implementing, and evaluating a multi-modal faculty development process; 3) developing a needs assessment of human, physical, and fiscal resources; and 4) assessing outcomes based on the technology plan.

Several significant outcomes resulted from the solid planning process. They include physical and curricular changes. For instance, all classrooms are connected to the Internet with "smart carts" available to faculty; the College Educational Computer Center is equipped with state of the art hardware and educational software commonly used in K-12; all courses in the new undergraduate teacher education program are required to document how they will integrate effective uses of technology.
These examples resulting from the successful planning and careful implementation of instructional technology contributed to place the College of Education at Temple University at the forefront of the field of technology to improve teaching and learning.

Department Level: Two Approaches to Program Development

On-Line Masters Degree in Education

David Fitt, Ph.D.
Educational Psychology Program
Temple University

One aspect of Temple’s strategic plan is to address the ongoing professional developments educational requirements stipulated for K-12 inservice teachers by legislative mandate. For too many K-12 teachers, the professional responsibilities along with family obligations coupled with geographic distance makes compliance with legislation, such as PA Act 48, onerous if not wholly unfeasible. A second component of the strategic plan is to maintain the University’s commitment to meeting student and pedagogical diversity concerns. These issues were the driving force for developing the Online Master’s In Education 2001 program. Identifying and developing new courses for the program was obtained from face-to-face feedback given by K-12 teachers in surrounding communities who attended information sessions designed to develop locally delivered Master’s programs. Temple’s locally delivered face-to-face Master’s programs vary from site to site because of the expressed professional development needs in each district. However, many of the requests for specific courses from the different districts are quite similar, if not almost exactly the same. The Online Master’s program has targeted ten of these “frequently requested” courses as the basic core for the online program.

Not all participants will want to complete a full Master’s degree. Hence, successful completion of the first three courses in the sequence will earn each participant a Certificate Of Advanced Professional Development In Education. This allows participants the opportunity to meet legislative mandates and to forgo formal matriculation into the University’s Graduate School of Education.

Several of the courses proposed for the Online Master’s program have been taught as web-enhanced courses with inservice teachers where some of the classes have been held online and others held face-to-face. This process has afforded faculty time to experiment with the various aspects of online learning. Not all faculty will use the same online platform to deliver courses but many of the pedagogical approaches are highly similar and reflect the use of best practices for online learning. Feedback from K-12 inservice teachers is extremely diverse. While many K-12 teachers value the online learning process, there is a smaller but significant number of teachers who clearly do not value online learning - despite the active online participation among full classes and smaller group breakout online meetings. We have discovered that one aspect of the digital divide, as it relates to current inservice teachers, is that many of today’s learners have barriers, such as limited learning styles, that will keep them from cyber learning as much as the lack of equipment and a paucity of computer related skills define the digital divide for other segments of society.

Some K-12 teachers are preparing to deliver online teaching to their students for a variety of reasons such as illness, special needs and lack of access. These inservice teachers comprise the strongest body of interested online learners. They should be identified early on and used as models, where appropriate, in a graduate level online course. Somehow these teachers tend to self-select into smaller groups and the cross-fertilizations of their ideas and instructional approaches often stimulate others to become more proficient online learners and users of more experimental pedagogical approaches to teaching.

Instructional Learning and Technology Specialization in Educational Psychology

Susan M. Miller, Ph.D.
Educational Psychology Program
Temple University

The Instructional and Learning Technology (ILT) specialization in the Educational Psychology program is the result of a long-held vision endorsed by educational psychology faculty and championed by individuals throughout the University. This vision gained college and university-wide support in 1999 when an Instructional Technology program was included in the College of Education's Instructional Technology Plan and endorsed by the University's Teaching, Learning, Technology Roundtable. Faculty and professional staff from the College of Education as well as from throughout the university wrote the initial proposal for a Masters degree in Instructional Technology. Of note is that this strategic planning was mirrored by activity at the Pennsylvania's Department of Education where development of new requirements for Instructional Technology Specialist Certification was underway.

The goal of the planning team was to develop a multidisciplinary program that would serve graduate students from a range of professional and academic backgrounds. The multidisciplinary foundation of the program is supported by two kinds of relationships with other academic units. First, courses in other programs, departments, schools, or colleges would serve as cognate areas of study for students enrolled in the ILT specialization. Second, Instructional and Learning Technology courses would serve as a cognate area of study for other programs.

The decision to create a specialization in the Educational Psychology program is consistent with current trends in educational psychology as well as within the field of instructional technology. The mission of the specialization is not just to stress the practical "how" of using learning technologies, but also the "why." This distinction is important in the employment arena, where it is advantageous for an applicant to have a knowledge base in instructional design theories as well as application and technical skills.

Historically, programs in instructional technology have evolved from the confluence of educational psychology and educational media programs. The rationale for the intersection of instructional/learning technology and educational psychology is a logical one. Since its inception as a discipline, the field of educational psychology has been concerned with the "aims," "materials" and "methods" of education (Thorndike, 1901). This attention has taken many forms and the field of educational psychology is widely viewed as a multi-faceted discipline that includes learning, development, cognition and measurement as core areas. In more recent years, this focus has included application of instructional and learning technology. For example, in his review of articles published in the Journal of Educational Psychology, Ball (1984) categorized 14 topic areas. One of these (admittedly a small percent of articles) he identified as relating to "educational technology, media and computers." Similarly, in a review of educational psychology graduate programs, Klausmeier (1988) identified one of 10 content areas as "artificial intelligence and information processing technology" including "computer and other technologies."

In summary, the strength of the new program specialization is that is grounded in this intersection of educational psychology and the technologies of learning and teaching. In addition, it was developed as part of a larger strategic technology plan from an interdisciplinary perspective.

Course Level: Two Approaches to Preparing Preservice Teachers to Infuse Technology in Teaching

The Effective Use of Instructional Technology in the Classroom
Appropriate incorporation of technology into classrooms is essential for any teacher in the 21st Century. The College of Education at Temple University recently implemented a new core curriculum that included a course specifically addressing effective use of instructional technology in the classroom, not merely computing skills. This course was the product of a committee of faculty who worked together, using the standards established by ISTE and the Commonwealth of Pennsylvania, to redesign the original computer-based instruction course from a basic skills course to one that infuses multimedia, web-based instruction, distance education and other emerging concepts in Pre-K12 education. This process continues through bi-weekly meetings to discuss pedagogical issues related to the course, share materials, and to discuss how computer resources are used with other core courses and the subject-specific teaching methods courses. One goal of the continued discussions is to gain insight into how a course on instructional technology can support other pre-service education courses, and vice-versa.

**Project LITT – Literacy Improvement Through Technology**

Claudia Smarkola, M.Ed. (doctoral student)
Educational Psychology Program
Temple University

Project LITT (Literacy Improvement Through Technology) infused technology into classroom academic standards-based instruction in Language Arts portions of our Teacher Preparation Programs from March 1999 to June 2000. In seven cooperating schools (3 elementary and 4 high schools), 160 elementary and 60 secondary preservice teachers (for approximately 7,280 K-12 students) were trained to deliver technology-based classroom instruction. Preservice teachers paired with in-service teachers developed and implemented standards-based instruction heavily steeped with technology resources, and collaborated in two Summer Institutes demonstrating and teaching technology-supported standards-based instruction received classroom instruction influenced by Project LITT.

Results showed that faculty will adapt to using new technologies in classrooms when appropriate equipment, software, training assistance, and technical help are available. Additionally, technology activities started by Project LITT have been extended within the College of Education. Cultural changes have occurred within the language arts teacher preparation program; faculty, students and staff now recognize and accept a role for technology resources along with other teacher preparation resources in preparing our future teachers.

Project LITT staff developed a hardcopy and web-based manual offering college faculty and classroom teachers information and ideas to consider when integrating technology into the classroom. The Project LITT website is www.temple.edu/LITT-L2L.

LITT was supported by Link-to-Learn, PA Dept. of Education, a Microsoft Software Award, and Temple University.

**Community and School District Collaboration: Project RAINBOW**

Jill Teitelbaum, M.Ed. (doctoral student)
Educational Psychology Program
Temple University

Project RAINBOW (Restructured Academic INclusion BOnded with the World) was designed to integrate computer and Internet resources in K-12 classroom curriculum and instruction. This Project, originally scheduled for five years, is currently in its sixth year. Project RAINBOW goals are to help teachers, librarians, and other educators to: (1) increase student intellectual skill development, especially higher
order thinking, (2) reduce student isolation, and (3) provide other teacher training and curriculum development. Project RAINBOW’s vision is that technology resources are valuable in K-12 schools to the extent that they are integrated with more traditional curriculum and instruction resources to facilitate students’ academic achievement and motivation to gain a good education. Activities are designed within a two-level framework – (a) for classroom use and teacher-student interactions, and (b) for teacher-teacher networking via Internet communication – in support of off-line as well as on-line educational application of Internet resources. Project RAINBOW is a collaborative project by Temple University with the Audenried Cluster of the School District of Philadelphia, started as a “Technology Challenge Project” funded by the U.S. Department of Education.

Guidelines for faculty development in effective use of IT resources were developed using a test bed approach, instructional psychology ideas were tested, revised, and implemented to facilitate K-12 teachers’ use of Internet resources in their work. Barriers to achievement of IT training objectives are identified, (lack of/unequal access to instructional technology resources, individual differences in teachers’ prior experience with instructional technology resources and some negative attitudes towards the use of instructional technology resources), and training modifications implemented to address these barriers are described.

Use of FrontPage 2000 to Develop and Manage a Teacher's Educational Web Site

Dr Armand St-Pierre
Department of Business Administration
Royal Military College, Kingston (ON), Canada
stpierre-a@rmc.ca

In this paper, I will describe briefly the necessary steps to build a simple Web site to support the teaching process and promote learning outcomes. Here are the main steps that I will show throughout this session:

Draw a structure of the Web site on paper

You can use the drawing tool of Word to prepare a mock copy of the Web site you like to develop. This approach helps you to think about the elements (course info, student projects, etc.) before building the Web site using FrontPage.

Creation of a quick Home Web page

I will demonstrate how to create a Home Web page for the educational Web site. The Web page may be different for each teacher according to his/her needs. The Home Web page has to be simple and appealing to encourage the learners to surf the Web site. Make it simple ...use simple vocabulary and simple images if necessary. The menu Insert presents objects that you can add to the Web page.
A quick preview in the Browser

As you create a Web page, I encourage you to view it in the browser (Internet explorer or Netscape Communicator). Then, you can bring changes now before you upload to it to the Internet.

Linking the Home Web Page to the other Web pages

Now that your home Page is created, create quickly simple Web pages (2nd level of your Web site) and links them to the Home page. Later on, you can edit them to improve their contents:

<table>
<thead>
<tr>
<th>2th level</th>
</tr>
</thead>
<tbody>
<tr>
<td>Getting Started</td>
</tr>
<tr>
<td>Course Information</td>
</tr>
<tr>
<td>Web Exploration &amp; Useful Links</td>
</tr>
</tbody>
</table>

Improving the appearance of the Web Page

The menu Format presents commands that can help you to improve the appearance of the Web page. You can add a theme, a background, or a style to a page. Some of the features will be demonstrated during this session.

Use frames to facilitate the navigation of the Web site

Why use frames? Frames are useful to organize the display of pages in a Web site into regions in a Web browser's window. FrontPage makes the creation of web pages including frames easy. You can create frame or resize the current ones by clicking and dragging. You can control displaying a page in a frame by creating a hyperlink to the page and specifying the frame as a target of the hyperlink:

Images and Image Maps

FrontPage presents a set of tools to create, edit, and manipulate images. Image Composer, part of FrontPage, can be installed to create images and change their appearance. You can import images or use images from the Microsoft Clip Gallery. A nice way to facilitate the navigation of the Web site is to create hyperlinks from image maps.
Quick creation of a Web site

FrontPage presents a functionality to build quickly a Web site with specific features such as discussion lists, registration form, and calendars. Let us experiment with this functionality (New command from File Menu).

Integration of Web pages created by Word and Excel

Word or Excel can convert a basic document to a Web page (command Save as a HTML page in File Menu) that you can save in the Web site directory on your hard disk. Then, you can import or open this file in FrontPage to improve its contents and features.

Organization of the Web site

As you add more Web pages to the Web site, you may have to organize the Web site that includes several Web pages. The buttons Folders, Navigation, and Hyperlinks, displayed in the FrontPage Views bar, provide different ways to look at Web pages in different directories and reorganize them. I will demonstrate some of the features.

Publication of the Web site

You are ready to show your Web site to your learners on the Web. How do you accomplish this task? You may post the contents of the Web site on an Intranet (inside the organization) or the Internet as shown in this figure (Publish FrontPage Web command under the File menu):

Maintenance of a Web site

After you posted the Web site on the Internet, you have to maintain the Web site on your local disk such as the contents. For example, you may have to change the student project for the course, modify the course outline, add a new homework, etc. FrontPage presents some tools to help you verifying broken hyperlinks (hyperlinks button), check the spelling of all selected pages, add new tasks to be done or complete the ones already started (Tasks button), or include sophisticated features such as animated images, sound clips, and others using (JavaScript or VBScript).

An Educational's Web site sample

The following images present an example of the components of a Web site to promote teaching outcomes.

Conclusion

The field of instructional technology is evolving, especially due to the change in Web technology. We are living in a communication age and open learning systems will dominate traditional classrooms. The Web teaching tools and services now available such as Bulletin Boards, chat rooms, Web pages, e-mail, etc., are present in this society and will be more effective than the old methods for many aspects of teaching. Web-based teaching prototypes with sound instructional technology will be multiplying every day, thus the learner will study anywhere at any time. Distance and time will no longer be constraints to the learning process.

In summary, the goal of this session was to demonstrate the creation of an educational Web site prototype using a tool such as FrontPage.
Collaborative University-Public School Partnerships: Development of an Online Network for School of Education Faculty and Public Schools

Abstract: This paper details the development of a collaborative network that supports a university-school partnership. The intention of this proposed network is to help School of Education faculty develop and maintain collaborative relationships with their public school counterparts. We describe the various stages of development of this network, as well as an analysis of features available in existing online teacher networks. We expected that the testing of this network will yield several issues related to developing effective university-school partnerships.

Proposed Collaborative Network

Increasingly, higher education institutions are expected to develop partnerships with public schools, particularly Schools of Education and Arts and Sciences faculty. Partnerships of Excellence is an example of this type of partnership and is an initiative of East Carolina University's School of Education (SOE). The expectation is to develop a reflective practitioner relationship (Schon, 1984) between SOE faculty and practicing teacher professionals within the East Carolina region. The impact of this initiative is two-fold: (a) enhance teaching and learning in public schools; and (b) augment existing research and theories about teacher education. While these goals are admirable, the issue is how to develop increased and effective collaboration amongst SOE faculty and their partnership school counterparts. How can the SOE initiate, implement and provide online support to maintain existing and form potential collaborative relationships? Though there have been several successful individual collaborative projects amongst SOE faculty and public schools, our question is how can the SOE collaborate with all of its schools in the entire region?

We looked at the existing literature on collaborative teacher networks. Fortunately, there have been considerable collaboration amongst public school teachers. Teachers collaborate with their colleagues in several national and regional computer networks devoted to promote collaborative public school sites (e.g., LearnNC, EdGate). However, we could not duplicate these
networks and expect SOE faculty to effectively work with public school teachers. There are distinct differences between higher education faculty and public school faculty. SOE faculty have different motivations and incentives than public school teachers. For example, SOE faculty not only teach pre-service teachers, but they conduct research that could impact future classrooms and thus, actively pursue external grant monies. We propose that exact duplication of existing teacher networks would not achieve effective collaboration between higher education and public school faculty.

Description of Initial Project

This proposal describes a project that created a collaborative online network that linked School of Education faculty at East Carolina University with their Partnership schools, named East Carolina Clinical Schools Network. There are approximately 800 schools in this network. Initially, we had questions on how to develop such a network. Some of these questions included:

- How will faculty assess the importance of collaborating with public school teachers?
- How can we design a network that will maximize the collaboration between SOE faculty and their public school counterparts?

Namely, the intention of this project was to achieve two goals:

- Build and initiate collaborative relationships between Partnership members with School of Education faculty, and also,
- Build and initiate collaborative relationships amongst SOE faculty members.

Some of the features of this proposed network included:

- "Knowledge bases": These resources inform School of Education faculty and their school partners about current educational trends.
- **Mentoring advice**: This support system offers professional development opportunities for its clients. SOE faculty and school partners participate in peer mentoring activities. For instance, a fifth-grade teacher can offer his/her insights to an Instructional Technology faculty member about the social development of ten- and eleven-year olds.
- **Online review section**: Faculty members or school partners can edit and collaborate on publications and/or grant proposals.
- **Online bulletin board**: Faculty members and school partners can "advertise" about their teaching and research interests. The School of Education thus communicates information about important events or recent information (e.g., clinical teaching intern placements) sponsored by SOE and various partner schools.

Development Process

With these goals and proposed features, we sought to evaluate the effectiveness of our proposed network. We adopted the rapid prototyping approach (e.g., Tripp & Bichelmeyer, 1990) and evaluated the network in three iterative phases. Successive feedback from each iterative influenced the next phase of our project. Below is a description of these three iterations.
Iterative phase #1

First, there was a needs assessment of three major stakeholder groups related to this project. The three stakeholder groups included: School of Education administration, School of Education faculty, and public school teachers. With this information, a prototype was developed. School of Education faculty and teachers evaluated the strengths and weaknesses of the first prototype. The features of this prototype included:

- Partnership Faculty alliance
- Directory
- Current events
- Workshops
- Discussion roundtable
- Research
- Advice
- Information resources

Overall, each participant approved of each of these sections. There was some confusion about the similarities between these sections. For instance, participants were unclear about the differences between the Partnership-Faculty alliance section and the Research. In our next iteration, we sought to eliminate this overlap and consolidate these sections.

Iterative phase #2

Six public school teachers and two School of Education faculty members participated in usability sessions. These individuals evaluated each section illustrated in the current prototype (see Figure 1). There were three goals of these sessions, namely: 1) effectiveness of prototype’s interface; 2) effectiveness of specific features found in prototype; and 3) overall satisfaction of proposed collaborative network between School of Education faculty and public school teachers. These usability sessions yielded the following information:

- Overwhelmingly, participants expressed satisfaction with proposed features found in the prototype.

- Next, the prototype should provide a pathway to specifically find particular items within the collaborative network. Participants did not want to search for specific items. They wanted to readily access features in which they were interested.

- The collaborative network should not be a typical web site, but present some enticement to potential users to visit web site. Next, the prototype should use a newspaper/magazine metaphor.

- When visualizing how they would use network, participants expressed primarily information-related activities.

Iterative phase #3

Prior to the development of the revised prototype, an assessment of current teacher online networks was made. This evaluation yielded additional features that were “borrowed” from existing teacher online networks and incorporated in our current prototype. The intention of this iterative phase was to evaluate the effectiveness of the newspaper/magazine interface. It also examined how School of Education faculty and public school teachers anticipated how they
would use this proposed network. With the results of these usability sessions, the development of a “final” offline beta prototype took place. The initial screen of this prototype is found in Figure 2.

**Final outcomes and impact**

It is expected that the outcome of this project will yield potential answers to several questions related to university-public school partnerships. Some of these questions include:

- Would School of Education faculty collaborate online with public school teachers? If so, for what purposes? How successful would these interactions be?

- How do School of Education faculty perceive the use of a collaborative network? How do public school teachers perceive the use of a collaborative network? Are there any similarities or differences between these two perceptions?

- What kinds of impact does this collaborative network have upon School of Education and public school students?

**Conclusion**

It is assumed that higher education faculty can benefit from forming collaborative relationships with their public school counterparts. Can a networked environment help develop this relationship? Will higher education faculty express the need for such an environment? More importantly, will faculty actually use this proposed networked environment effectively? Our study and presentation will address these questions and related issues.

Smoothing the Transition to the Instructional Technology Age: A Change Model Based on Professional Development and Innovation

Michael Szabo, Ph.D.
Professor of Educational Psychology and Technology
DIRECTOR, TIES Project
University of Alberta
Edmonton, Canada
Mike.Szabo@ualberta.ca
http://www.quasar.ualberta.ca/DRMIKE

"THE SIGNIFICANT PROBLEMS WE FACE CANNOT BE SOLVED AT THE SAME LEVEL OF THINKING WE WERE AT WHEN WE CREATED THEM."

Albert Einstein

Abstract: Transition to the information and communications age will be chaotic and disconcerting for many, including educators. While the bumps are inevitable, there are steps which can be taken to minimize the trauma. Successful transition requires us to rethink the process. More specifically, the past failures of instructional technology to gain widespread use or to provide transformative effects on education can be understood in the light of successful and unsuccessful diffusion of innovation. The TIES was developed to specifically address what we have learned about innovation diffusion over the years. This paper will report on the philosophy, foundation, structure and operation of TIES in a university setting. Extensions to technical schools and public schools will be made.

The Problem of Change

Humanity has passed through several major eras, based on technological advances, which have changed society dramatically. Sometimes the change was for the better, sometimes for the worse. Examples include changing from 1) hunter to agrarian, 2) quill pen to printing, 3) agrarian to industrial, 4) manual to electrical, and 5) bits to digits (the digital revolution). The latter is also called the information technology communications (ICT) revolution and we are currently engaged and embroiled in its infancy.

After each of these major social revolutions became fully diffused into society, periods of relative calm, peace and stability ensued, interrupted by the occasional war. During each of these periods of transition to the new order of things, however, there was major chaos, upheaval, and uncertainty. For example, the transition to the age of electricity witnessed the major dislocation of slaves in the United States as the spread of rural electrification made them too expensive to maintain. The industrial revolution witnessed one of the greatest mass migrations in history as people left rural areas to form burgeoning urban areas which led to the growth of social support systems.

We are currently embroiled in the next major revolution, stimulated by the microcomputer and attendant digitization. This has been referred to as the Information Communications Technology (ICT) revolution. This revolution is resulting in significant changes in the way people and organizations communicate and function. It is radically changing, in both qualitative and quantitative ways, how we carry out our day to day activities.
A subset of this revolution involves the application of ICT to the process of teaching and learning. Known as the Instructional Technology revolution (IT), it is beginning to be evidenced in the way instructors and education and training institutions carry out their day to day activities. However, there are also disturbing signs of implicit and explicit chaos from a variety of sources and viewpoints. If history is any indicator, education will experience significant chaos during the transition process. This chaos may be long lasting and will certainly be highly disruptive. Are we to batten down the hatches and try to survive the bumps and bruises, or is there some way we can minimize the disruptions and smooth out some of the larger bumps along the way? The thesis of this paper is to describe a strategy which may be helpful toward meeting this goal.

Overview

The purpose of this paper is to describe a change system that was developed specifically to increase educators’ use of instructional technology (IT) in the process of bringing about major and systemic change in education. The basic assumption is the major reason that IT has failed to reform education is not in the technology, but in the tendency of individuals and institutions to resist change. While many would agree with this statement, very few systems have been put into practice to deal head on with the issue of change. The strategy of the change system is professional development and the system is called the Training, Infrastructure and Empowerment System (TIES). The roots for TIES stretch back to the middle 1970s but the current implementation was developed over beginning in 1996 and implemented in a large educational institution with funding from the Government and University of Alberta.

This paper will examine some of the things learned about instructional technology (IT) and educational reform during the past 4 decades and compare the ideal, potential state of affairs with reality. The TIES, which is based on characteristics of innovation will be described, with emphasis on the main components of vision building and empowerment through professional development of leadership teams.

What have we learned from four decades experience with digital IT?

IT has been extensively researched over the years (Szabo, 1998a) and it is clear that instruction which makes substantial use of IT, when compared with conventional forms of instruction, results in

- equal or higher achievement,
- equal or better attitude toward learning and the subject,
- significantly reduced learning time, of the order of 10 to 50 percent savings,
- significantly greater access to education through distance or alternative delivery,
- significantly reduced delivery costs (Harapnuik, et al ,1998),
- easily scalable, and
- revolutionary changes which have increased the capacity and ease of use of IT.

While it is difficult to pinpoint the exact role of IT, these findings are impressive and lead us to believe that IT holds great potential to improve and reform the way we conceive of and deliver education. However, examination of the practice in the field reveals a very different picture.

The reality is that while there have been sweeping changes in hardware, software, courseware, tele-ware and skinware (people) during the past four decades;

- very few educators make use of IT; most use is confined to low level,
- education has been left unchanged or unreformed (the self-contained classroom dominates),
- vast sums of money have been spent with little to show for the expenditures, and
- many remain uneducated or under-educated, in poverty, unable to share the riches of an expanding global economy where the vast majority resources and money are controlled by a small number of individuals

Why has IT failed to live up to its potential?

First, individuals and institutions have a natural and rational reaction to anything as different and innovative as IT; they resist it in order to preserve the systems they worked so long and hard to build and are so comfortable with. Secondly conventional approaches to professional development are either unaware of this important aspect of human behaviour or unable to deal with it, resulting in less than optimal results. For example, most professional development efforts are built on the theme “Build it and they will come.” History shows this to be a myth. Finally, there have been many over zealous proponents
of IT who made grandiose predictions about the revolutionary nature of IT. As these predictions fell, one by one, disappointment and disenchantment with the field grew.

In spite of this, professional development efforts grew and flourished. By and large they are characterised as having:

- good and honourable intentions and goals
- high quantity and quality of training
- recognition of the challenge of learning to use IT
- the lack of urgency to provide increased access
- expended significant amounts of money

The poor results are more surprising in light of these positive elements.

What is the solution?

The solution is to create a complete system of professional development around IT which successfully addresses several major topics. First, it acknowledges and works with key elements (hindrances to) change and reform in education. Second, it provides training in the use of how, why and when to use IT to improve education or reach out to new opportunities. Another important element is the use of IT to provide a model which can be emulated and enhanced by instructors. Finally, the system must be delivered in accordance with recognised principles of adult learning and development. But just what are these topics and what do they look like? While all have been addressed in TIES, this paper will focus on the elements of reform and developing willingness to change.

Three guiding principles came out of the study leading up to TIES. First, we must assume that IT is a major and significant innovation in the way instruction is delivered. This leads to the second point that to understand IT means we need to understand the characteristics of successful and unsuccessful innovation. To this end, a study of innovation in society, politics, technology, religion and administration was undertaken. The overwhelming conclusion is that while we verbally accept innovation as an abstract concept, we have a poor understanding of its characteristics. These characteristics are described in the following section. The third principle is to synthesise our knowledge about innovation and develop a comprehensive system for reform around that knowledge.

Lessons learned from Innovation

- Most innovations fail—there is considerable risk involved. Thus, while innovation is warmly embraced, at least verbally, the recipe for disaster may be in the making.
- Successful innovations evolve into something different and more useful than originally envisioned—people need a vision for the future and the ability to tailor the innovation for their own environment and ownership. When there is no clear path, one must have a vision to rely, and be able to adapt in moving toward the vision.
- Widespread adoption is a sign of successful innovation—this presents enormous logistical problems of training, distribution, etc. Every educator, regardless of grade level or subject taught, is a potential user of IT. To train and support all educators, using conventional approaches to training and support is logistically an impossibility. IT itself must play a role if the job is to get done.
- There are three stages to successful adoption of innovation—success or failure needs to be judged based on the current stage.
- Creating an innovation requires a different type of person and organisation than does leading an innovation to successful adoption. The former calls for a person with missionary-like zeal who will face all obstacles head-on to achieve his or her dream. Often this is a person who works alone and because of the fervour has been called the ‘keeper of the dream’. The latter needs to inspire change through leadership (Kotter, 1996) rather than micromanagement or decree, because the former inspires the creativity needed to innovate while the latter stifles it. The leader must also be capable of garnering a team to bring about change.
- Successful adoption of an innovation takes significantly longer than we would like, significantly longer than the tenure of politicians and administrators. It took 250 years from the discovery that citrus fruits prevent scurvy to the requirement that ocean vessels carry citrus fruits; it took 200 years for the industrial revolution to flower; and it took 20 years for
the computer mouse to migrate from the laboratory to everyone's computer. We often do not
have the patience to let innovation flower and either abandon, ignore, or put it out of its
misery.

Other sources of change and reform were consulted in the area of education (Fullan, 1991),
society (Rogers, 1995), business (Senge, 1991; Kotter 1996) and IT (Szabo, 1996).

**Training, Infrastructure and Empowerment System (TIES)**

The characteristics of change and innovation have been crafted into a system to promote change
and reform of education through professional development within the area of IT. The premise of TIES is
rather straightforward. It states that reform of education through IT must be guided by a powerful vision
of what an educational institution will look like in the future and that vision must be implemented by
those who are driving the teaching program of the institution. Furthermore, the vision will be unique to
each institution and the implementation will vary within the institution according to the needs and goals
of the different units.

An analogy is useful here. Suppose there is an individual, who has neither the time nor expertise
of a painter, who wishes to have a particular painting commissioned. The commissioner specifies the fee
and describes the vision of the picture as having a large sailboat, sailing into the sunset on a light breeze,
and there can't be any pink colours in the painting. The artist is then free to interpret this vision using the
skills and resources he or she has developed over the years, within the constraints specified by the
commissioner. This example is analogous the operation of TIES.

**Development of Vision**

In first part of TIES, chief academic officers create, nurture and commit to a vision of what the
institution will look like in some specified period of time, say 10 years. This is accomplished in a retreat
and workshop setting, away from the pressures of the institution. The retreat is ideally conducted over 3
to 4 days and achieves four goals. The first goal is to expose the administrators to the world of IT in
general and more specifically to individual exemplary applications at the local, national and international
level. In part the purpose is to establish a sense of urgency to stimulate action (Kotter, 1996).

The second component of the workshop is designed to produce a vision of the future of the
institution with emphasis on IT as a new form of instructional delivery. The vision is stimulated by the
following exercise. Imagine it is 10 years into the future and the vision you developed at the workshop
came wildly successful. If you were to walk through the institution, city, province, country and abroad,
what evidence would you see of its success? This exercise helps develop a vision which is concrete,
visualizable and realistic. Some time is then taken to refine and polish the vision.

The third component of the workshop is the identification of barriers to that vision. One
common barrier is finding a way to convincingly communicate the vision to the rest of the institution.
Another is to find a way to demonstrate verbal and tangible commitment to the vision. Faculty quickly
recognise that a verbal commitment without tangibles is no commitment at all.

A third barrier comes in the form of providing the infrastructure necessary to meet the vision.
Infrastructure needs to be analysed carefully, as there are two kinds: hard and soft infrastructure.

The list of hard infrastructure varies with what particular brand or flavour of ET is being used,
but usually includes the following.

- **Hardware**—computers, VCRs, projectors, videoconference/audioconference facilities, digital
capture and editing facilities.
- **Software**—application programs for video, audio, computer assisted and managed
instruction, web browsers, e-mail.
- **Telecommunications**—high speed access to the internet and WWW via modems

Soft infrastructure refers to more than people. It includes a strongly positive environment with
respective attitude from all concerned. It includes experts to conduct the training and support for
instructors. It is guided by the vision of the future. It is enhanced by a positive, supportive, and risk-
aversive environment at the department, faculty, and senior administrative levels. This environment must
be demonstrated in overt commitment. An administrator who offers some resources, however modest, to
help instructors use ET is demonstrating commitment, while one who applauds the idea and suggests the
instructor apply for a grant to do the work is exhibiting virtually no commitment, regardless of the words.
A final barrier is the development and support of a culture which promotes reform through IT after sufficient learning has taken place, not before.

In the fourth and final stage of vision-building, the participants begin to prioritise the barriers and identify how they may be overcome. Throughout the whole process, the emphasis is placed upon brainstorming rather than criticising the work to date.

**Develop the Leadership Task Forces to Carry out the Vision**

Once the vision has been completed and communicated, the artist takes over and carries it out. Unlike the painting analogy, however, the administration cannot hire completely new personnel to do the job. They must engage in extensive professional development with the extant staff.

**TLTF terms of reference:** TIES uses teams who will function in a leadership capacity. These TIES Leadership Task Forces (TLTFs) are trained to implement the vision in their unit. Specifically, they are asked to accomplish four tasks (and provided with the training and infrastructure to do so). First, they model the use of IT in their own classes, thereby demonstrating that IT is not so complex that the typical instructor cannot use it. Second, they identify the training needs within their own unit and arrange to meet those needs. Third, the TLTF identify the on-going support needed and arrange to provide that and support. These are to be just-in-time, effective and credible for colleagues. Finally, armed with experience and a good feeling for the size of the task, the TLTFs develop a multi-year, rolling plan to move their unit from the current culture to the new IT culture.

**TLTF selection criteria:** The selection of TLTF members is critical to the success of the system. While a team effort is necessary in order to distribute the work load and involve diverse opinions, most education is not done by teams but by individuals in self-contained classrooms. It is hard to break this mold. The impact of TLTFs must be leveraged, that is they must function at a point of power, where decisions are made or broken. In a university, that is often the department head, while in public schools the head of the school often holds the power to make or break innovations.

**Figure 1. Organizational structure of the TIES**

TLTF members are selected and invited to participate by the departmental administration using criteria supplied by the Central Leadership Team. TLTFs must include key opinion leaders in the
department, as well as at least one departmental administrator. Along with the department administrator comes a commitment to support the Task Force for at least one year following their initial training. A curriculum and technology specialist is also an important person to have on the TLTF. The number of TLTF members should be 10-20 percent of the department, with a minimum of three.

**TLTF training approach:** Training TLTF members must be done (1) to insure the members are qualified and (2) as part of professional development leading to empowerment. As is common in education, the skills and knowledge possessed by the TLTF members varies greatly. In addition, they must be trained using adult learning principles (andragogy).

The training of TLTFs from several department takes place during a one week intensive workshop and one of the goals is to build cohesive departmental teams. Individuals complete an exercise to assist them to identify their skills and knowledge strength and weaknesses and to select which modules to complete. To facilitate a mixture of team based and individual independent study both during and following the workshop, the instructional materials have been assembled in modular format suitable for small group or individual, self-paced learning and delivered via the Internet.

**TLTF training content:** TLTFs need to be well versed in (1) how to use IT, (2) how to integrate it with the curriculum and evaluation structure, (3) how to provide leadership in their environment, and (4) miscellaneous topics, such as copyright protection. There several dozen modules which cover these topics in a self-paced learning format and delivered through the Internet (Szabo, 1998b).

**TLTF support:** A key element in the success of a complex venture such as this is the availability of support during the year following training. A Central Leadership Team, which developed and operated TIES, provides support as needed by the TLTFs. The support provided models the support the TLTFs are asked to provide during their work and should be effective, current and believable. The CLT advises departments, facilitates workshop training, and facilitates communication within and between different TLTFs and administration.

**Progress to date**

TIES was pilot tested in a major research university in Canada in 1998. A visioning retreat was conducted with the participation of chief academic officers of the institution. Five departments or faculties committed to training and support of TLTFs. The CLTs provided support to the TLTFs during the subsequent year. The findings and conclusions from this work have been documented by Szabo, Anderson & Fuchs (1998).

Abstract: This paper will focus on a multidisciplined, integrated, and thematic curriculum unit developed and taught by teachers from two Nebraska school districts involved in a U.S. Department of Education Challenge grant. The teachers from these schools designed the units using an online form and database developed by the grant project's staff. The project teachers received staff development training on several aspects of effective teaching/learning, such as multi-intelligences, brain research, multi-disciplinary strategies, efficient assessment, and the importance of connecting learning to community and real world situations. This paper explains the process of curriculum development, online availability of the units, training for teachers, local school support, lessons learned, and the impact of this type of activity on student learning, teacher growth and attitudes, school climate, and community connection to student learning and the school. In addition, the benefits to undergraduate and graduate education in a college of education will be discussed.

Introduction

"The Connections Project; Strengthening Learning Through Technology-Based Integrated Curriculum and Professional Development" has been successful in helping teachers to use technology effectively and to integrate it into their class curriculum. This project is a United States Department of Education Technology Innovation Challenge Grant, of which the lead sites are four Nebraska school districts and two adjudicated youth centers. In addition 16 school districts are partner sites participating in teacher training and in several interdisciplinary curricular projects that include effective teaching/learning techniques such as multi-intelligences, brain research, multi-disciplinary strategies, efficient assessment, and connection to community and real world situations. The project is designed to improve student learning through effective teaching that includes technology-integrated curricula reflecting state curriculum standards/frameworks and national standards. In addition, special focus is given to high-risk students, as well as developing partnerships among educators, business, agriculture, industry, and parents. The grant evaluation team is from the University of Nebraska at Omaha College of Education Office of Internet Studies. The process of change used in this grant is important to teacher education, as all learn from the successes of P-12 schools and teachers. The university professors on the
evaluation team use the ideas and examples in their own lesson plans for both undergraduate and graduate teacher education classes.

Designing curriculum that engages students, has connections to their community, and has real-life activities has been found to be a successful way to revitalize the learning environment of students. An example of this type of effort is the World Hunger curriculum unit at two Nebraska high schools participating in the Connections Project Challenge Grant.

School Settings

One of the Connections Project's lead schools is Morrill High School, a small rural high school in the northwestern part of Nebraska. Mitchell High School is a Connection's Project partner school to Morrill and is within 30 miles. These two schools work together in many ways. Each month, teachers from both schools meet. Activities include introduction of teachers, discussion of units that they have written, and challenges to write new units. In addition to major units, they also were challenged to work with one other teacher to develop a "mini-unit." The World Hunger unit, the first unit completed and undertaken by teachers from these two schools, was one that would be unique to teachers across the state.

Example of an Integrated Curriculum Unit

Unit Design

This interdisciplinary curriculum unit, designed by teachers from the two partner schools, was titled World Hunger is Local TOO. The goals of the unit were as follows: a) make students aware of world hunger and how it affects their own communities, b) inform students as to what they can do to help alleviate world hunger, c) promote teachers working together to encourage learning, and d) design a unit that could be presented at a conference. The uniqueness of this project was that not only were connections made between curriculum areas but also between two schools and two communities. Curriculum ideas for each discipline were outlined. These included:

1. Geography/Social Studies--research countries and world hunger
2. Home Economics/Foods--compare calorie intake of the countries researched by the geography/social studies class
3. Business/Computers--make charts using the facts found by the home economics and geography classes, make posters to advertise food drive
4. English--write analogies from the information collected
5. Journalism--write an article for both school newspapers and the local town paper, design an advertisement about the food drive
6. Reading--character analysis and story plans on books about hunger.
7. Art--design an advertisement about the food drive, decorate food collection boxes

The unit would be introduced by a PowerPoint presentation, designed by the Connections Project Site Coordinator. This presentation would be shown at both schools, challenging both students and teachers alike to participate in the project.

The timeframe for the unit was between Thanksgiving and Christmas. Classwork began right after Thanksgiving vacation and the actual collection of food was limited to the last five days before Christmas vacation. Some parts of the unit were completed in both schools and some were done in only one school, according to how best each part of the unit fit the situation at the respective schools. It was found that in order to encourage more communication between the schools, it was necessary to have some parts completed at one site and then sent to the other site for follow-up work.

Additions to the project during the implementation included: a) the writing of a script for a skit incorporating the challenge theme, with presentation at each school by the opposite school's students; b) hosting a guest speaker on the subject of world hunger; c) student volunteer work at the local soup kitchens; and d) more teachers being encouraged to become involved.

Introduction
An introduction to world hunger, via a PowerPoint presentation, was presented to the social studies, home economics/foods, reading, business/computer, and English classes as well as to the Student Councils of both schools. Students were asked to bring cans of food for the charity and teachers were asked to use the world hunger theme in their courses. Also each school challenged the other to see which school could collect more cans of food. Numerous facts about world hunger were presented along with ideas of why hunger exists. The presentation encouraged all students to become involved in the project. The "9 Steps to Third World Living" was included in the slide show. This captivating part of the presentation really helped students relate to people in need. Students were also given many examples of Internet resources containing the information needed to complete their specific class assignments. The PowerPoint presentation ended with a challenge to students: "What can you do to help stop world hunger?"

Gathering Facts

The social studies (Morrill) and geography (Mitchell) classes had group discussions on identifying indicating factors relating to their specific curriculum area that might cause world hunger. They gathered data on hunger in several countries on each continent, focusing on such facts as population, life expectancy, literacy rate, arable land, and per capita income. The geography students defined what developed, third world, G-7 and other terms meant while categorizing nations. After categorizing nations, they sent the list of countries to the other classes. Students also looked for facts about hunger in their own county and state. Students searched for data in class textbooks, almanacs, encyclopedias, atlases, and on the Internet. Students started their Internet search with the site [http://www.thehungrersite.com/](http://www.thehungrersite.com/) which has a map of world hunger in which the countries dim when someone dies of starvation. Other Internet sites used in the social studies and geography classes were [http://www.overpopulation.com/index.html](http://www.overpopulation.com/index.html) and [http://www.worldhunger.org](http://www.worldhunger.org).

Students in the home economics/foods class (Morrill) discussed indicating factors that would help determine the cause of world hunger. They learned about nutrition and the food pyramid and studied the food web from their textbook chapter on nutrition. After learning about nutrition, they created a menu for different areas around the world. Next the foods class searched for data on nutrition, malnutrition, and calorie intake for the list of countries that was sent from the geography class (Mitchell). Students searched for information in textbooks and on the Internet using the site [http://www.overpopulation.com/child_malnutrition.html](http://www.overpopulation.com/child_malnutrition.html). Each student chose an area of the world and made a list of foods eaten and the number of calories in the diet for that group of people. After all research was finished students designed a Menu for the Hungry. Students in home economics/foods class also determined the information to be on the tags for world food intake for later use in assemblies. The tags represented world hunger figures: 70% are hungry; 20% are adequately fed; and 10% are well fed. The final project for the home economics/foods class was to prepare the food for the soup kitchen.

Graphs/Menus/Tags/Flyers/Posters

The information found by the classes doing the research was sent to the business class (Mitchell) where students formulated the data, using the software Microsoft Publisher. They created posters with charts and graphs and made flyers advertising and promoting the project. The business class also made the tags for the assemblies from information sent by the home economics/foods class.

The menus from home economics/foods class was given to the computer class (Morrill) where the students made printed menus similar to those found in restaurants. In the computer class (Mitchell) students were grouped in pairs and given research data relating to a country. They used the data to create a worksheet and graph. They then used the worksheets and graphs to make a poster about how their topic related to world hunger.

3005
Paragraphs/Character Analysis/Story Plans

After hearing a poem by Sandra Alesiani, the students in the junior high reading class (Morrill) described to a partner what it might be like to be a victim of hunger. Following the descriptions, students were given a list of books about hunger and the homeless. Each student read one book, completed the character analysis and story plans worksheets, and then wrote a paragraph summary of their book to share with the class.

Analogy

The senior English class (Morrill) received a folder containing all the above materials. Students read and analyzed the materials on world hunger, both in graph and written form. Students then created an analogy and were given a choice of presenting it in either written, narrative, or artistic format. Students then determined what elements were necessary to write a script to challenge the student body at Mitchell High School to participate in the food collection project. They were asked to use things such as humor, facts, cordial challenge, and loaded words. Students used the scripts for skits presented at assemblies, half-time at basketball games, and the final presentation to the food pantry.

Presentations and Advertising

Pep rallies were held in both Mitchell and Morrill. Two to six Student Council members from each school went to the other school's site and challenged each other's school to beat theirs in a food drive. They used the skits prepared by the English class students.

Students in journalism/yearbook business and art classes were asked to design an advertisement for the local paper to promote the food drive. The advertisement was to meet the following guidelines:
1. Have a headline or illustration (or both) that seizes the reader's attention.
2. Have a block of copy that does some or all of the following: a) recognizes the problem/desire of the client, b) recommends a solution to the problem, c) promises benefits, d) personalizes those benefits for the reader; has a call for action; and includes a logo and information on how to purchase or participate.

The journalism class (Morrill) also reported on one phase of the Hunger Project for the school newspaper.

The Yearbook class (Mitchell) took pictures of the project to be used for a display at the final assembly, a page for the yearbook, and a class presentation. They put together a PowerPoint presentation of 5 slides, an avid cinema presentation of 2 minutes, and an 18x24 poster. The business class (Mitchell) made posters (as previously explained) to advertise the food drive in the schools and local businesses. The art class (Morrill) decorated boxes to collect cans for the food drive.

At the Mitchell versus Morrill basketball game students passed out the tags (which indicated the level of hunger) to spectators as they came into the game. The project was explained by students in a skit using the script prepared in the English class with help from Student Council members. World hunger was demonstrated by a representative sample of the spectators: 70% received a pizza crust, 20% received crust with sauce, and 10% received a pizza with all the toppings. Then students encouraged spectators to donate food to help alleviate hunger.

Outcomes of the Project

The Scottsbluff Star Herald published an editorial, saying: "A fun way to give, Morrill and Mitchell students devise a friendly contest to help others at Christmas time." Also, several teachers involved with the unit were excited about its impact. Nancy Sakurada, teacher at Morrill said, "Being able to use computer technology allowed us to see a bigger picture of our world...especially the developing countries where poverty and adversity is the norm. We were able to see that the majority of our world does not live as we do in the United States. I feel that this project and the way we applied the
curriculum changed our way of thinking about standards of living around the world." Teacher Ellen Ramig from Mitchell added, "During the World Hunger is Local TOO project, my students entered the data into spreadsheets and charts. This project was very beneficial to my students. They also were able to participate in a project that required them to take raw data and make conclusions using a variety of learning styles."

After completing World Hunger is Local TOO, the group decided to do more of these types of integrated units. The next unit dealt with an important local industry, sugar beets. The new project is titled How Sweet? Sugar Beet Sweet!

Summary

The efforts of these two schools, in developing a unit that infused technology, centered around a theme, and included two different school districts is an excellent example of a vibrant, exciting curriculum activity. Not only did students become more engaged and excited about learning, but also teachers and the community both benefited from participation in the project. Because of this unit, the teachers at the two schools have continued to develop new curricular units and activities. The community gained heightened awareness about world hunger. These types of activities are important to teacher educators, as they provide examples to research and to share with future teachers.
"Adopt-a-School" – a Program of Hope in a South African Community

Liezel Wilkinson & Guillaume Nel
Department of Information Technology,
Technikon Free State
Bloemfontein
SOUTH AFRICA
liezel@tofs.ac.za
guinl@tofs.ac.za

Abstract: With the aim to play an active role in the community and in support of the National Education Department's Tirisano Project 2000-2004, the Technikon Free State (TFS) in Bloemfontein launched its Adopt-a-School program in September 2000. The program, in which the Lereko Senior Secondary School will be assisted in various ways, is a collaborative action between the TFS and a disadvantaged secondary school in the Free State province. In the first phase of the program, the emphasis is on the professional and personal growth of Lereko's teachers, with computer literacy as one of the main objectives. The TFS equipped a computer laboratory with Internet facilities at the school and started with the training of teachers. The discussion of the progress of the project presents a preview of what can be achieved when the more advantaged reach out to the less advantaged in this country with its unhappy past.

Introduction

The Technikon Free State (TFS) in Bloemfontein, South Africa, launched its Adopt-a-School program early in September 2000. The program, in which the school will be assisted in various ways, is a collaborative action between the TFS and a disadvantaged secondary school in the Free State province (Lereko Senior Secondary School), with the possible support of a business partner. The aim is to play an active role in the community in support of the National Education Department's Tirisano Project 2000-2004. The program is aimed not only at empowering teachers to teach effectively, but also at exposing teachers as well as learners to real technological education in addition to fostering an entrepreneurial climate in the development of school education in disadvantaged communities.

The Partners

Technikons – as they are known only in South Africa – offer higher career-oriented education – and should be distinguished from technical colleges that offer more basic career training. The TFS offers programs in four faculties: engineering, applied sciences, human sciences and management. The programs include degrees, diplomas and certificates in various information technology fields as well as technical teacher education and paramedic sciences. In 1999 the student population totaled 7105, with roughly 60% of the students from formerly disadvantaged communities. The TFS has reached a relatively high level of academic excellence and is one of the institutions that has advanced to the point where the possibility of converting it to the status of a technological university is being investigated.

Lereko Secondary School is situated in the Mangaung township in Bloemfontein, the capital of the Free State province. The school enrolment is roughly 1500 learners, with 45 teachers and a number of administrative staff members. The community is extremely poor and, although the double-storey school building is relatively new, the signs of vandalism and neglect are very obvious. Previous interviews with teachers revealed serious problems such as a shortage of school textbooks; almost no teaching aids (except one overhead projector in a working condition and a television set); only one laboratory for the whole school; a lack of science apparatus; no duplication facilities; and, of course, no computers - even for administrative purposes. Teaching methods are
restricted to the chalk-and-talk and textbook methods. In summary, the Lereko of the past reflected a lack of commitment from teachers and learners and, undoubtedly, a lack of a culture of teaching and learning.

Tirisano is a corporate plan of the National Department of Education (DoE) that was announced in 1999 (Department of Education 2000). The vision of Tirisano is of a South Africa in which all inhabitants have access to lifelong education and training opportunities, which will, in turn, contribute towards improving the quality of life and building a peaceful, prosperous and democratic society. Organizational values such as Team Work ("Co-operating with one another and our partners in education in an open and supportive way to achieve shared goals") and Learning ("Creating a learning organization in which staff members seek and share knowledge and information, and are committed to personal growth") are highly rated.

The TFS Adopt-a-School program clearly falls within the priority range of Tirisano. In the first phase of the program, the emphasis is on the professional and personal growth of Lereko's teachers, with computer literacy as one of the main objectives.

Implementation and Progress

The TFS equipped a computer laboratory with 30 computers and Internet facilities at the school. The training of teachers started in late September. The Department of Information Technology at the TFS handles the IT component of the program. It will carefully monitor the progress of the teachers over the next twelve months and will adapt its training to the teachers' needs. In the first phase attention was paid to keyboard and other basic skills, as about one-third of the teachers have not used a computer before. After doing basic word-processing, they proceeded with Excel, as knowledge of spreadsheets proved to be a handy tool for teachers handling very large classes. From the beginning of 2001, staff members will be trained in using computers for administrative purposes that will greatly enhance the effectiveness of this relatively large school. The provincial administrative program, FREESAD, will be used for this purpose.

As several of these teachers are enrolled at institutions of higher education for postgraduate degrees and diplomas, the utilization of information communication technologies in supporting them in their studies will be investigated. It is hoped that on-line facilities will improve the communication with the provincial department of education and also serve as a tool to keep teachers informed about implementation strategies in Curriculum 2005, the new outcomes-based education model adopted for the country. A logical outflow will be the implementation of IT in classroom teaching and the establishment of computer laboratories as well as literacy programs for learners.

Teachers are considered as full partners in the Project. They are free to air their views and make suggestions to improve the program. They also complete questionnaires on a regular basis. Those who had not worked on a computer before, reported problems with their keyboard skills and with using the mouse and doing the "clicking". They also found the saving and retrieving of information difficult in the beginning. But they are all very enthusiastic. When asked how they were going to use their newly-found skills at Lereko, most said they intended to type their examination papers and undertake the processing of marks. Several expressed the wish to teach computer skills to their learners. They also asked for more advanced skills, such as doing the school's administrative work, preparing timetables and work schedules, typing mathematics papers and drawing geometrical figures.

Conclusion

The TFS has now officially taken Lereko under its wing. Although implementation problems can be expected, the program offers a valuable opportunity to educators at the TFS to serve their local community and, at the same time, gain valuable insight into the problems of implementing information technology programs in a school in a developing community.

Collaborative Technology Exploration: Bridges Between University and K-12 Education

Carol Wolfe, Saginaw Valley State Univ., USA; Jeffery Ashley, Saginaw Valley State Univ., USA; Elliott Nancy, Ubly Public Schools, USA; Ericka Taylor, Saginaw Public Schools, USA; Janice Wolff, Saginaw Valley State Univ., USA

Saginaw Valley State University teacher education and content faculty are engaged in a research and development initiative through the United States Department of Education Title II Grant (Teacher Quality Enhancement). One strand, identified for study and implementation by the Title II Grant, is technology. Content Development Teams (CDT’s), comprised of participants from the following areas; university content faculty, two per team; university teacher education faculty, one per team; and K-12 master teachers, two per team, are expected to use technology in some manner as a pedagogical tool. Content and teacher education professors and master teachers are engaged in learning about and implementing various technological methods. Syllabi are being redesigned to be placed on a web site created especially for each course. Course web sites will include an interactive component, search engines and other online resources important to the course. CDT members will also be trained to use Blackboard technology and will integrate it into redesigned courses. Our group is curious about the effectiveness of technology as a pedagogical tool in university content and teacher education classrooms and elementary and secondary classrooms. In this process, we intend to re-examine our ideas about student participation, instructor roles, and expectations with technology use.

Our project perspective, therefore, is one of collaborative examination and learning about technology as a pedagogical tool in each of our disciplines. Our aim is to work together, examining various technology options and software, Blackboard, GroupWise, PowerPoint, and Daedalous, in in-service development. We are collaboratively and individually investigating the effectiveness of infusing our various practices with technology. Our data consists of recorded formal conversations from weekly meetings and in-service development meetings. Meetings and collaborative work on multiple strands, delineated by the Title II Grant, take place during fall semester 2000, and winter semester 2001. E-mail communications about Grant technology implementation between our CDT members will also comprise data. Student evaluations of technology initiatives, piloted in winter semester courses, will add a student perspective to our thinking. Individual manuals developed through this process including our collaborative work will add substantively to the data as well.

Preparation of classroom teachers requires teacher educators to construct curriculum that uses technology as a pedagogical tool to teach content and methods (NCATE, 1996; Holmes Group, 1988; Michigan Curriculum Framework, 1997). Collaborative examination of technology incorporation into existing curricula by university content and teacher education faculty and k-12 master teachers will facilitate: rethinking student participation, instructor roles, and expectations in the teaching learning process. Additionally, participants will evaluate the effectiveness and pitfalls of technology as a pedagogical tool while piloting a redesigned course. Lessons experienced and analyzed will benefit other teacher education and content faculty members and master k-12 practitioners.

NCATE Standards, 1996.
Telecommunications, according to Webster's Collegiate Dictionary, is "the science and technology of transmitting information, as words, sounds, or images, over great distances, in the form of electromagnetic signals, as by telegraph, telephone, radio, or television." The field has expanded, with the varying technologies that have emerged, and with the types of uses to which those technologies are being put. Education has seen a rapid growth in the use of telecommunications at all levels, for both administrative and instructional uses. Teacher education is in a unique position using the technology to teach current and future teachers, and preparing them to effectively use it in their classrooms. So what technologies are now being used, and what do they contribute to the fields of teaching and learning? Which technologies are promoting appropriate and effective integration of information technologies into teacher education? Who is using these, what are they doing, and what are the results? How do we find the answers to these and other questions that will undoubtedly arise as we both follow examples and develop new approaches?

This year's papers in this, the Graduate and Inservice Telecommunications section, reveal an emphasis on the online world - on courses, activities, resources, and a variety of other issues. The 30+ papers reflect the activities (often collaborative) of 65+ individuals who share their knowledge, experiences, successes, and lessons learned. They provide us with thought-provoking ideas that address the questions above, and suggest paths and ideas that we might take and adapt for implementation in our own programs. Numerous themes overlap, occurring in multiple papers, with the papers themselves often containing a number of these different themes in any given paper. The following arrangement provides a stroll through the garden of Telecommunications in Graduate and Inservice Teacher Education.

Many students are now arriving in teacher education programs with increasingly sophisticated computer skills. There has been much discussion about the need to move from teaching basic technology skills to teaching how to integrated technologies into the classroom. Participation in online classes may require students to do more than learn about the technology - they learn with it, as they are immersed in it. Van der Kuyl, Kirkwood, Grant, and Parton describe a training course for teachers, in which information and communication technology (ICT) skills are learned and practiced in meaningful contexts as and when required in a metacognitively rich learning environment. Teachers are involved in identifying and planning for their own needs. The course is offered in a variety of formats - totally online, in a traditional class (with some required online activities), or as a combination of both. A key to success is the combination of teaching and learning and the active involvement with the technology, rather than just the delivery method alone.

The use of multiple delivery methods is also described by Davis, Li, and Nilakanta, who employ a hybrid delivery method (with both face-to face and online sessions) and a constructivist approach as students examine and develop case studies about distance learning. The authors suggest two dilemmas that exist for instructors: a balance between breadth and depth as it relates to content, and the need for structure as well as the freedom from it. It is interesting to note that these concerns are not strictly related to distance learning - they are issues related to teaching and learning, and not specific to the technology.

Several other papers also describe programs or projects that are grounded in constructivism. Sujo de Montes and Blocher describe a program based on constructivist principles. They discuss the importance of interactions throughout their online Educational Technology Master's degree program, and explain how they incorporate virtual reality, using the program Active Worlds, to promote this interaction. Michelle Adelman describes a program where high school teachers taking Foundations of Educational Technology Theory applied constructivist theory to project-based curriculum, while learning to create web pages, and then combined these two elements as they used them to conduct online research in their content areas and
and Young, who describe postgraduate computer education at least the same as in a regular course. 

Richards and Bhattacharya discuss issues related to converting reluctant Internet users into 'keen' users of the same. They suggest that their conversion model of learning with technology is based on constructivism, but goes beyond in two ways. It emphasizes the important role of the teacher, and the authors suggest that this might make some teachers less fearful of learning the technology, when they realize that they will not be replaced by the technology.

Obermeyer and Gibson describe the Virtual Professional Development School Consortium's shift from a NetCourse model to a NetSeminar model. They discuss problems with and lessons learned from the former, and the advantages of the latter (including the creation of constructivist, problem-solving, and collaborative learning environments), and their belief that there is an even more responsive system that will surface in the future.

Assessment is a major issue throughout education, and the area of distance learning is no different. Roblyer and Ekhaml discuss the importance of interaction in distance courses, the use of rubrics, the importance of interactive qualities in distance learning, and specific interactive qualities in distance learning courses. They go on to explain how they developed their rubric, and include a copy of their Rubric for Assessing Interactive Qualities of Distance Learning Courses.

Research studies are being conducted in an attempt to determine what is and is not effective in the distance learning environment. Molinari reports on a qualitative study of two online groups of nursing students, and describes findings in task, relationship process, and online communication categories. Student responses may provide online instructors with food for thought as they design and modify their courses.

Another area of assessment relates to student reaction to (or evaluation of) courses. Harmes and Barron conducted a study, over six semesters, of students' reactions to tools and techniques used in a distance learning class. Only one of the 79 respondents would not like to take another course via the web, and 99% reported a positive feeling about web courses. Only 13% felt isolated or alone, while 87% felt the level of group participation was at least the same as in a regular course.

Student reactions are also discussed by Joyce, Nodder and Young, who describe postgraduate computer education courses that met face-to-face four weekends, spaced throughout the semester, supplemented by online activities between meetings. For two semesters, from one course, discussion board postings were collected and analyzed, and at the end of each class, students were asked to rate the usefulness of the different course components. During the first semester, when there were more postings, students indicated that they valued classroom interaction more, whereas during the second semester, with fewer postings, students rated the Internet activities above other resources.

Harrison Hao Yang also reports on student responses, with a concentration on the course content. Meeting in a computer-enhanced classroom, students participated in project-based learning, as they studied "Multimedia and Internet for Education." The four major design principles on which the course was built are described, and findings from student final written reports are presented. Students' reflections revealed major positive effects related to the usefulness of extended learning, effectiveness of production, and proficiency of technology integration, and students indicated that they would take what they learned, share it, and continue to use and learn.

Project-based learning is also the subject of Tyndall's paper describing the Camp Internet Distance Learning Consortium. Camp Internet is a project-based teacher technology training and content delivery program that combines live teacher training with immediate online classroom applications. After a 4-day intensive training session, participants have monthly continuing education sessions, and on-line education and support continues to provide assistance with 4th -12th grade classes. The Camp Internet project trains the teachers, and also provides online classroom materials for the entire year.

With the rapid growth in the offering of online courses, it is essential that online resources be available for use by online (and other) students. Many of the previously described papers include information about resources that result from the described courses and programs. Several papers, though, deal primarily with the production or provision of online resources in various content areas.

Peter Serdiukov discusses the structure and organization of ESL websites, with an emphasis on the DEEEE (Distance Education ESL Endorsement Program) website. The website is designed for "teachers who need continuous, updated, effective pedagogical resources for their productive classroom activities and professional growth." Heaton and Stenhagen express concern about problems that keep teachers from fully utilizing the World Wide Web resources for their content areas. Using ARC (the Algebra Resource Center) as an example, they explore three primary functions of content portals on the web. Portals should include filtering, providing content, and building community. Each of these will facilitate the finding and retrieval of web resources, but the final one also has the
potential of reducing the isolation of the classroom, as teachers join together in communities, working and studying together. Materials are also prepared and disseminated as part of a project shared by Klemm. A College of Veterinary Medicine, a Center for Rural Public Health, and a College of Education are collaborating to develop science curriculum and training for rural middle-school teachers in the field of environmental health information. Klemm describes some of the existing and future modules, explains the related teacher training that is available, and provides information for accessing the web sites.

Marcelo, Mingorance, and Estebaranz continue the professional development theme. They discuss the importance of professional development in teacher education, and the concept of networks as professional development. These concepts are illustrated by a description of the Andalucian Network of Trainers program. Key components are the use of asynchronous communication and group web pages. Zhang and Sextro also discuss an approach to professional development. They describe the HOST (Holden Online Staff Training) Model, the goal of which is to move teachers forward in technology implementation in the classroom. One key component is a web site with web-based video-training clips available for all.

Another example of professional development for teachers in conjunction with the creation of online resources is described by Cathy and Terrence Cavanaugh, who explain how university faculty worked with Florida Professional Development Schools teachers to develop an online workshop to address identified needs. The online format was convenient for teachers, and helped teachers become more comfortable and confident, as they worked with the technologies at their own pace. Key to the success was the involvement of university faculty, but faculty involvement with technology is not the case at all institutions. Joel Levine addresses this issue of faculty and technology. He discusses various models that have been developed in the areas of acceptance, adoption, and use of new innovations. He then suggests support strategies that may assist faculty as they move through the various stages in the adoption of distance education technologies.

As online classes, programs, and/or activities are planned, it is essential to

The importance of community is also discussed by other authors in this section. Bennett and Ekhaml state that the development of supportive learning communities is essential in distance education classes. They suggest specific elements that contribute to the development of such communities, advocating the use of case studies and problem-based learning. Laferrière, Breuleux, and Montané discuss their research that takes place within emerging practices, where they are asking “What happens when classrooms get networked?” and “What knowledge is to be transferred in order to prepare 21st century citizens?” In the process, communities of practice shift to communities of inquiry, leading to a community of interpretation and the development of 12 design principles for creating activities for networked classrooms.

In order to build community in an online class (or among any online group), it is essential that frequent effective communication occurs. Abramson and eight doctoral students (Bibeau, Birrell, Cohen, Lundy, Norton, Scalese, Star, and Toral) describe the students’ experiences in the process of preparation, posting, and mentoring online, and provide individual reflections that share best practices. Instructors may identify with many of the observations and other comments presented, and may find some innovative ideas to adopt. A recurring theme throughout this paper is that of collaboration, and communication is a key to that. Vizcaino, Favella, and Prieto also discuss these topics jointly. As they address the issue of group collaboration, they examine one approach to overcome the problem of “inefficient conversations,” which they feel interferes with the collaborative atmosphere. They suggest the presence of a virtual student moderator to overcome student complaints about off-task discussions, and to foster learning. It is interesting to compare the two different – the real and the virtual.

Types of communication have also been addressed in papers about mentoring and virtual teams. Which type of communication is most effective? Pauliene describes how different virtual teams preferred different types of communication. One group facilitator considered the telephone essential at the group formation stage, while others considered only a combination of Internet-based synchronous and asynchronous modes. ICQ instant chat was determined to be quite effective for some groups. Shafer, reflecting on experiences mentoring beginning teacher researchers, concluded that using both synchronous and asynchronous interactions might be more effective than using just e-mail. She also suggests that limiting communication to one medium may be too limiting, and suggests further study in the area. Communication of various modes is referred to by Carlson and Repman, as they discuss some guidelines, techniques, and cautions related to offering virtual internships. The reminder to check professional accreditation and licensure requirements carefully in especially important as people are looking for creative ways to supervise student teaching.

A recurrent theme throughout this section has been the need for teachers to have training and access, so they will know what to do and how to do it, and they will also have the resources that are needed for successful implementation. Iverson and Baxter acknowledge that learning the perfect software program will not help, if the teacher has no access to that technology in the classroom. They have created a Virtual Learning Community (VLC), a set of
free, low-cost, or readily available tools to support teachers and students in traditional classrooms, and they provide related faculty development. URLs of web sites with examples and the tools are also provided in the paper.

Implied throughout has been the concept of appropriate integration of the technology into meaningful instructional settings. Many of the papers have discussed specific projects that illustrate this concept. Gersch uses another approach, as she describes ways to use the Internet in the classroom. Her discussion is filed with URLs providing access to ideas she shares, and she then concludes with a list of suggested design criteria for Internet projects. This paper might provide guidance for instructors wishing to introduce Internet applications into their teacher education classes.

So what are some guidelines that might be considered by people wishing to begin developing online courses. Throughout the papers, there have been comments about what has worked and what people would do differently. We will conclude with a paper that provides a framework for developing online courses, and then two papers that provide lessons learned, so that other people will know what to avoid and to do differently. Leggett, Dirksen, and Anderson present a systematic approach to developing online courses. They present a framework of questions in seven domains to guide instructors who are developing such courses. After teaching an online directed readings course in science education, Kevin Barry has described both the pleasure and the pitfalls he experienced, and then he provides helpful lessons learned, so assist others in the design of their classes. Mims and McKenzie present lessons learned of a traveling type, as they discuss factors to be considered when teaching online course in different countries. Based personal experiences, problems encountered and tips for success are shared.

This stroll through these papers reveals that, in teacher education, telecommunications is far more than "the science and technology of transmitting information ... over great distances ...." as was quoted at the start. It also includes the planning, design, implementation, and evaluation of teaching (and/or training) courses and programs and of resources all designed to improve the education of our students at all levels. Teaching, after all, is teaching, and the delivery mechanism is just a tool to help us achieve our goals. Telecommunications provides a way for us to reach people who are not able to attend classes (due to time, distance, or other factors), and the papers in this section will help provide guidance as we plan for success.

Sue Espinoza is an Associate Professor in the Educational Technology program in the Department of Secondary and Higher Education at Texas A&M University-Commerce.
Abstract: Too much of what is considered conversation is little more than taking turns speaking. When this process is translated to a print medium, such as an electronic forum or bulletin board, it quickly becomes evident that keeping on track is very difficult. The current literature extols the virtues of collaborative learning and the Internet that makes possible collaborative learning across the miles. However, learning is much more than discussion and a good discussion is rare indeed. As part of a graduate course in online
learning environments, distant students took turns mentoring and participating in online conversations that adhered to specific guidelines.

This institutional session will be of great interest to everyone involved in online learning. Graduate students, most of whom are actively employed in distance learning initiatives will share lessons learned and skills mastered in the art of online communication in a learning environment. Each presenter will begin by describing the process of preparation, posting, mentoring and end by reflecting with an emphasis on sharing best practices.

**Introduction**

Too much of what is considered conversation is little more than taking turns speaking. When this process is translated to a print medium, such as an electronic forum or bulletin board, it quickly becomes evident that keeping on track is very difficult. The current literature extols the virtues of collaborative learning and the Internet that makes possible collaborative learning across the miles. However, learning is much more than discussion and a good discussion is rare indeed.

**The Assignment**

In the process of refining a methodology for post-baccalaureate distance learning, it soon became obvious that before one could facilitate a cognitively rich online course, one would need to practice the skills of online communication. Forty students met on campus for a week in July 2000 and then returned to all parts of the globe. A customized Allaire forum system readily available on the World Wide Web (WWW), with password access for students, was the tool used for skills development. The assignment required each student, or students in groups of two or three, to mentor a discussion related in some way to online learning.

These online mini-conference threads or conversations were required to be sufficiently motivational to attract at least three participants. They were to be announced in advance for recruitment and could run anywhere from one week to three weekends and the two interim weeks. The assignment recommended that the mentors not assign homework so that focus could remain on discourse and not subject mastery. Instructions were distributed and discussed in class for methods of conducting an on-line conference thread. At the end of the conversation, the mentor(s) had to post a conference summary and copy it to a class thread called Conference Summaries.

Three weeks following the end of the conversation, each student was required to submit a reflections paper written in the first person. The paper was to include where expectations were met, where the mentor disappointed himself, where others disappointed the mentor, and lessons learned about online conversation.

**The Outcomes**
This first iteration of the assignment has been gratifyingly successful. The makeup of our doctoral classes is very unpredictable since our major entrance requirement is a B+ average in an accredited masters program. As educators, we have learned that a strong top of the class pulls everyone else up. In this case, the top of the class was terrific. Among the students were online community college and four-year college instructors, people in charge of instructional technology for colleges, school districts and even state departments of education, and K-12 technology trainers. Members of the class jumped into the assignment with an enthusiasm always hoped for and seldom seen.

Members of this panel have self-selected to discuss the processes of moderating and participating in online discussions. Although all the participants are doctoral students, the conversations were, for the most part, not cognitively demanding. The best practices learned will apply to a wide range of adult, Internet-based, distance learning environments. Below are reflective remarks about the process prepared by each of the panelists.

Synchronous and Asynchronous Learning Environments
Shelley Bibeau

Three doctoral students who had just met at a week-long summer institute got together in a rather hurried way and decided to share an online conference forum. Crystal Daughtery, Cynthia Townsend, and I, Shelley Bibeau began our collaboration with a very brief discussion of a topic. After institute it seemed a simple thing to plan; after all, we had e-mail and were somewhat computer savvy. So we returned to our home states secure in the knowledge that this assignment would be straight forward, or would it be? For some time I had considered online delivery modes. I was wondering what new experiences teachers were having, specifically with the Internet. It was becoming obvious that synchronous delivery, although useful, was difficult due to schedules, time zones, and the vagaries of imperfect technology. Asynchronous methods seemed to be growing both in use and availability, but development often required time and a learning curve. Soon our group made a first e-mail contact. I jotted down some questions around the topic and asked for comments and other suggestions. When my cohorts responded that the topic was fine I honestly felt disappointed. I thought this was an opportunity to share ideas; instead I felt like the dominant student in a face-to-face classroom who had cowed the other classmates. I resolved to avoid that in the future; after all, this was an opportunity to learn about learning environments while in one, and we did have a good topic, or did we? We decided a one third stint with each of us as co-moderators would be more workable for our busy schedules. We planned to stay in close communication during the forum time period. While we succeeded at that, communication was not always the result. E-mail can be misinterpreted by the reader; more so when you are doing an assignment. I found that my e-mails were sometimes misinterpreted and I misinterpreted others as well. These encounters could be both frustrating and humorous.

The Forum Conference
Our topic was synchronous and asynchronous learning environments. We set out to answer four questions. They were:
1. Briefly describe your experiences with synchronous and asynchronous learning environments.

2. What tools are you aware of/have used before? Briefly comment on their usefulness

3. What underlying pedagogies/andragogies can be found in synchronous/asynchronous learning environments?

4. Do you think there is or should be a difference between synchronous/asynchronous learning environments as used in fully online courses or as supplemental to a traditional classroom? Describe how.

After the call for conference went out and a good-sized group signed up, Cynthia started off the discussion. Her strong communication skills got the participants responding well to question one. She was able to get the group to find common ground by relaying their personal and professional experiences and she sparked lively communication by offering some relevant URLs for the group's reflection on questions two and three. Excerpted articles generated more discussion of how pedagogy should drive the choices of instructional technology, and the baton was passed on to the next co-moderator.

Crystal followed up with an appeal to efforts that would provide a body of research for educators concerning effective techniques and pedagogies for synchronous and asynchronous online activities. Crystal offered some best practices literature and definitions. These helped continue to answer questions three and four. Crystal's leg of the forum occurred at a time when students were struggling with assignment deadlines. She felt her technique was ineffective and would not be consoled otherwise. In retrospect a phone call may have been more helpful than an e-mail - the latter mode does not seem to have the impact as do a few kind words.

I conducted the last third of the forum. The participants now had an opportunity to try some hands-on use of synchronous technologies by visiting a Web-based learning environment, TappedIn, which afforded a free place to "chat." When educators experience various technologies first hand I believe their sophistication increases and will be better armed to work online effectively. In these sessions we continued with our conference questions and examined synchronous learning modes as we compared them to our experience at the moment. Due to the anonymous nature of the sessions people also expressed frustration and anxiety over assignments. Thus, it was difficult for the inexperienced to keep up with several conversation threads, but at the end of each session a log was sent to each participant for their examination and reflection. In general the participants seemed to understand the forum topic and what was expected of them, and they did an excellent job.

After the Forum Conference - Personal Reflection, Personal Foibles

When the forum was over it was time to wrap things up, thank the participants, write a summary and do a few post mortems. Our summary posting was hampered by a few miscommunications, but when it was finally done we breathed a sigh of relief over what was a challenging process. In retrospect I think the forum went a bit too long - nine days would have been enough. I also feel the topic was too broad. If I had to do it again I
would have tried to focus the topic specifically on one mode (e.g. synchronous online real-time conversation) rather than be spread so thin.

A couple of my reflections revolve around some of my own personal foibles. I need to have more patience. When activities are performed electronically there is always a wait time and this is hard for me. Another foible is that I still think about comments made in forum that I disagree with, especially some of the "hot button" issues of pedagogy driving technology vs. technology driving pedagogy. I need to find the courage to speak up more, yet, at the same time not be reluctant to argue with people on issues about which I sense there is an emotional investment. To be honest I'm still not quite sure how to do it but the desire is there. Balancing patience with participation is one of my goals.

Working with two co-mentors was both challenging and enjoyable. Frankly I don't know how I would have gotten it all done without our collaboration and mutual support. I was very satisfied with the job my forum group did. We shared personal experiences, some review of the literature, and a hands-on experiential portion that worked well. In retrospect it may have been better to change the order of those three parts but I'm not quite sure in what way.

There were a few disappointments. We could have had better communication during the forum. With our busy lives this was difficult, however. As I stated before I disappointed myself with my impatience. I have a hectic schedule and in order to get things done in a reasonable amount of time I like to start early. I truly believed that this intimidated my co-mentors. That was not my intention, and to their credit they were much too gracious to tell me. My overall satisfaction with my co-mentors was high, however. They taught me some new ways of interacting with people online. Here are some of the major lessons learned about online discussion groups:

- Early preparation is a good idea - the conference took more time and attention than any of us had anticipated.
- Read and participate in the other forums - they are wealth of free how-tos!
- Communication between co-mentors may require phone calls.
- Keep the topic focus narrow.
- Choose an appropriate time for a forum.
- When people post to the forum give them feedback as soon as possible.

The Best Thing – Variety

If I had to select what I thought was most effective about our forum conference it would be its variety. Looking back I like the three-way approach to the topic -- reflection on previous experience, literature review, and hands-on experience. It permits a variety of interaction styles. Some participants were very active in the chat environment, yet they did not post. Since I did not ask them why they didn't post I can only assume they felt more comfortable in a casual more anonymous setting where their input was neither public nor permanent. My co-mentors, whose personal styles brought different people into the conversation was another exhibition of variety. Each of us had a slightly different array of contributors, posting at a different pace (some more than others). The variety was
effective. The mix made for an effective forum conference. As for conference forums in the future we still need to address the issues of students/participants dominating topics, others holding back, participation, and sharing knowledge and ideas.

Virtual Field Trips
Susan Birrell

Overview of the Process

We are the experts when it comes to our own learning! Participating by being a moderator in this first online forum experience was an invaluable learning experience and opportunity. During the end of September I was part of a triad that moderated a discussion about virtual field trips. The three of us decided to become a team in July because we all worked in K-12 education in the capacity of technology and learning. Very few other students in the class were from this environment. All of us were interested in exploring online learning for students in kindergarten - high school. Many of us had participated in some kind of collaborative project, i.e. Classroom Connect or Scholastic Network, or another curriculum project in the past. However, all three moderators were new to Nova and in particular moderating. We corresponded online about our respective interests, timelines and responsibilities. We came to consensus easily about the rules, dates, and topics for the weekly topic discussion. It was interesting to note that all three of us, upon reflection, had different definitions for "effective virtual field trips" and because of that became learners and open us to new and innovative definitions. I learned a great deal from this experience. First of all by enrolling participants from a wide variety of backgrounds and occupations in this forum we acquired a wide diversity of perspectives. The definition and categorization of a virtual field trip became very dependent on the life experiences, ages, and professions of the participants. I had never really experienced web cams and videoconferencing in the K-12 environment and these new technologies opened my mind to the possibilities. I must admit that when the discussion turned to critiquing the field trips as boring I did take it personally. Tramline's collection of virtual field trips left the voyeur with a flat affect but there was still some thought and effort that the creators of the site employed. I felt a little bit devastated and shy and reluctant to express these emotions in a posting. I also felt a little bit angry that somebody would use such a strong word that evoked negative thoughts such as "boring" in a posting. There was no other way to take this remark without becoming defensive. After the anger and shock and discomfort subsided, I was pleased to see that this label did evoke some wonderful discussion and strong feelings by other participants. The forum became more interesting and more vital. People seemed invested in the topic and wanted to write a response that contained a definitive opinion. It was almost a relief to be able to express some emotion in a posting.

A Personal Perspective

As a first semester doctoral student who has never participated in any forum previously, I notice that many of my postings in my classes do not elicit responses. I am very cautious to make sure that I quote learned authorities and although I have much practical
experience in my field, I often have to squelch my communication because its ideas are solely my own and not a refereed authority. My postings are very impersonal because I am concentrating very much on finding peer reviewed articles to echo some opinions that I vaguely share. However, these posing that must contain references to peer reviewed articles limit my passion and my own voice and commitment to these causes. This structure tends to inhibit my investment in wanting to communicate often and with passion. I am sure there is an art to this and after semester one, my responses will become less stilted and more genuine.

I am grateful for this written reflection paper as it dignifies and makes important my transformative learning experience in moderating a forum. I think I have reframed my experience to be one that can be learned from. I have already begun to post differently to my other class and I am reinterpreting and reframing my ideas and ideals about forums and facilitation. My sense of empowerment and confidence will grow over time with this method of communication. I believe that it will take some practice and some work. Learning about the ways we learn is something that this process of moderating a conference has provided me. By engaging in the process, we become facilitators of the learning experience. Learning how to participate as a team member and work collaboratively is another outcome that as a participant I have garnered.

Your Transition to Online Teaching
Deborah Elizabeth Cohen

My Goals for the Miniconference Thread

The mini-conference thread I led was on transitioning from classroom to online teaching. I hoped participants would explore their feelings about the changes that they had to undergo as a result of teaching in this new way and that they would share best practices. I also hoped this discussion thread might serve as a forum for students to debrief their experiences in moderating these discussion threads. In my invitational statement in which I solicited participation in the forum, I made the participation guidelines pretty broad: “for those who have made the transition from classroom to online teaching (anyone who’s conducted a forum here qualifies) and anyone who would like to learn from them”.

The Process of Preparation, Posting and Mentoring

The process of preparing for the conference was long and organic. The topic had been in gestation for over a year, and I had had the opportunity to do some preliminary research and to engage in some discussion with professors. Due to taking this course, I had participated in many mini-conference threads. The perspective I brought to the topic was that of a former classroom teacher and college instructor and someone who had had the opportunity to watch people transition from vocations to the same vocations incorporating the use of the computer. In my most recent stint as an instructional designer adapting college courses for delivery over the web and Internet, part of my mission had been to help professors transition to their first online teaching. I had never taught online
myself. The Saturday a week before the discussion thread was to start, I started reaching for pen and paper to record notes on ideas that were bubbling forth.

The next day I woke with a start to realize that the forum would be starting in a week. In order to get the attention of those students who do most of their schoolwork on weekends, it would be wise for me to post the invitational statement that day. With the aid of the notes I had put together the previous day, and relying heavily on the invitational statements from previous message threads, I began to compose mine. The invitational statement summarized the content of the thread – the questions we would be addressing - and the “rules” under which we would be operating. I grappled with whether to state my expectation that participants would contribute three times over a two-week period. Was that too demanding? I also wrestled with whether to include a statement asking for participants to treat each others’ postings with empathy. Was that insulting? I decided in favor of including both.

I posted the statement and waited...for two days. It was an uneasy time in which I was beset by many paranoid thoughts about why my fellow classmates weren’t responding. I wrote one recruitment email and pondered writing others, began thinking of alternate topics to do, and finally had the presence of mind to share my dilemma with my professor, Dr. Trudy Abramson. She assured me that the topic was fine and shared that students’ participation was dwindling since it was the end of the semester. Moderators of other mini-threads were having the same experience. She sent an email to everyone in the class, and by the end of the next day I had twelve registrants. (Only seven of the registrants would turn out to be active in the sense of participating regularly.) Every prospective registrant submitted a posting indicating interest. My next challenge was to welcome everyone without being too repetitive. I wanted to convey basically the same message – you’re welcome, glad to have you – but not in identical words. I didn’t get out the thesaurus, but I did spend time and attention wordsmithing my responses.

A day before the thread was to start, I posted the first communiqué, welcoming everyone to the forum and laying out a schedule and an agenda for how the next two weeks would unfold. I began our discussion thread by asking participants to answer the following questions: “How has this transition caused my role to change? How has my relationship with my students changed?” Participants sent in postings, some in response to housekeeping matters, but mostly related to the topic. I checked the forum regularly and responded to each posting in 24 hours or less, trying to zero in on the substance of what the participant had posted. When someone made a point that I thought was suitable for group discussion I highlighted it and asked for responses. I requested clarification when it seemed called for. Often I didn’t receive it. Also – probably to allay my anxieties about feeling isolated – I requested that participants provide me feedback if I did anything as moderator that bothered them. It resulted in one beneficial posting: a request that I provide a heading for the postings of each “round” of the threaded discussion.

This was an example of just one of the ways I benefited from having experienced online instructors participating in my discussion thread. They provided tips that I was able to immediately employ, such as sending out emails to individuals to let them know when an
old thread was being put to rest and another was about to begin. That’s what I did for the
next round. I also posted the next set of questions on the forum: “Are there competencies
upon which I formerly relied that I’ve had to give up? Which new competencies have I
had to develop? Has there been a change in the way I feel about myself as a result of
these changes?” This round generated the liveliest discussion of the threaded discussion,
though probably an equal number of postings as the first round. While I checked the
forum several times daily, I did not answer every posting as participants were doing a lot
of dialoging with each other. I tried to summarize and/or respond to main points.

Time for the next round came around, and I sent out an email saying a new thread was
beginning and the old one was finishing up. I also announced logistics for a synchronous
chat session to which three participants had committed to participate. This was to take
place towards the end of our time together: on the Thursday preceding the Saturday on
which the conference thread was to end. In the discussion thread I posted Round 3
questions: “Have my day-to-day activities changed? Have I felt adequately supported by
my institution in making these changes? What is adequate institutional support?” As an
introduction, I also posted something about the differences between how I would
normally teach a class and how I was moderating this discussion. Results for this third
round were disappointing. Only one participant submitted anything – a link to an
applicable report that she had written. I read her report, which I found very worthwhile,
responded to her in the thread and informed the group that we could discuss her report at
our chat session. There were no other responses.

Four of us showed up for the half-hour chat session. I had emailed two of the participants
the day before to provide a heads up that I would be asking them in the chat session to
clarify some statements that they had made earlier in the discussion thread. The majority
of the chat session revolved around these issues, and it made for an interesting discussion.

Earlier on the day of the chat session (Thursday), the fourth round had begun. I had not
sent out an email publicizing the new thread and announcing last call for the old. In the
discussion thread, I asked participants to share any as-yet-unshared tips for teaching
online. I also asked several questions from a portion of a report I had asked participants
to read in preparation for our discussion, but told people they could answer the questions
even if they had not read the report. The questions had to do with (1) the mechanisms that
are available online to help with teacher attentiveness to students and (2) how concern
that students become educated can be translated to online teaching activities. A single
student submitted three postings summarizing the effectiveness of distance education,
providing information on effective feedback techniques and improving interaction, and
providing best practices for the design phase. I responded to all three postings with one
posting, but no one else did. I ended the mini-conference thread by summarizing the
fourth round, posting a thank you to the participants, and placing a summary of the entire
proceedings in the discussion thread.

Reflections
Was this discussion mini-thread successful? In my estimation, it was mixed. Yes, in that it met its original goals of providing for an exchange of worthwhile information about the practice of online teaching. Yes, in that it provided the opportunity for an inexperienced online moderator to moderate for the first time and to begin to acquire a little bit of skill. Was it enjoyable? I can now identify with the instructors who report a difficult transition to online teaching. I have to disclose that at least some of the time I found leading the mini-thread anxiety producing, and as a socially motivated person, teaching in a classroom is more personally enjoyable to me. What caused the most anxiety, I think, was the sense of loss of personal control: not knowing which of my actions improved the discussion thread and which developments were the results of forces outside of myself. I am left with some certainties regarding best practices. It is helpful to send email notifications when new topics start and old ones end. Personal email in general seems to be a plus. It is important to craft questions so they are clear and focussed. Tracking the discussion carefully and being responsive are priorities. A simultaneous chat session for participants to clarify issues is of benefit. But I am left with many questions. Why were the first two rounds – particularly the second – so successful, and why did people virtually drop out of the last two? Was I somehow responsible? Was it the combined demands of the end of the semester? Should this two-week mini-thread only have been one? Ideally, the next time I moderate a discussion thread I would like to simultaneously employ usability testing to better evaluate the causes of what occurs.

Use of Simulations as Online Instructional Strategy
Jo Lynne Lundy

Asynchronous Online Communication

Communication is the most important activity that we perform as humans; it is the heart of everything that we do. For communication to take place, there must be a sender, a receiver, and a message. If the message is intended as instruction, there must also be an environment in which this educational communication occurs. Asynchronous online communication promotes a type of interaction that is often lacking in the traditional classroom. It allows learners the freedom to explore alternative pathways, develop their own styles of learning, and opportunities to research and reflect on the discussion taking place. This report summarizes my experience of participating in and moderating an online asynchronous discussion thread. Participation in the online class discussions involved reviewing the topics and choosing a topic of educational interest, yet one in which an intellectual contribution could be made. Some of the thread titles proved misleading. Other threads had rigid rules, and participation in these was exhausting and more of an exercise in survival. However, many threads were interesting and relevant, and I benefited from both lurking and participation.

Co-moderating a Discussion

I moderated a thread eight weeks into the term, so I had time to learn from others what was successful and not so successful. The initial plan was to moderate the thread alone, but as I outlined the topic and schedule for the two week thread, a classmate expressed...
interest in the same topic. Over a four-day period, we decided to co-moderate the thread, obtained permission from the instructor to do so, outlined our duties and responsibilities, and posted our opening comments and questions. Planning for the two-week discussion was difficult in such a short time frame, but we were both relieved to not have to face the moderating assignment alone. During the next two weeks, we realized that flexibility, adaptability, good communication, and voicing expectations were the keys to our successful discussion. Keeping our group to a maximum of eight participants allowed us to handle the discussion well; some threads had 12-15 members, and the discussions seemed difficult to manage.

Moderating the thread was more difficult and time consuming than I imagined, but the goals outlined for the discussion were accomplished. I tried to respond to participants within 12-24 hours, and at times was overwhelmed by the pressure to keep the discussion on track, along with acquiring some needed HTML skills. I was challenged by the participants and learned much from the references and links that were posted. Believing that the role of moderator should be one of a facilitator, guide, director, monitor, and peer, I attempted to keep the discussion informal, yet informative.

Reflections on this experience include: feeling more confident about using electronic communication, learning from others what was successful and what invited failure, learning to write in a public forum and for an interactive purpose, learning to analyze and respond to the writing of others, and learning to express an intellectual position on a topic. Learning occurs as a result of both planned and unplanned activities. The asynchronous communication assignment provided a rich learning experience, and should be considered an important instructional strategy for distance education.

Tests??!! We Don't Need Online Tests!! Or Do We?
Mava Norton

Forum Overview

Moderating an online discussion for the first time is a learning process. A classmate and I co-moderated a forum where the goal was to gather input from practicing distance students and distance educators regarding the appropriateness, effectiveness and challenges of online testing. The conference began with participants reading an article to start them thinking about testing and assessments in the online environment. As participants began the discussion they were asked to define the range (level and subject) where they were teaching and/or working. The discussion began with the following questions:

1. In an online course, why type of assessments are appropriate?
2. Does testing even make sense? And if so,
3. Should online courses have tests proctored – either on campus or where the student resides?
4. What assessments do you think most reflect the mastery of course materials?

Other questions addressed during the discussion were:
1. When dealing with online assessments, projects or self-check tests, what are our objectives when developing the assessment?

2. What are the challenges offered with this type (project-based) assessment?

**Participants**

There were nine people discussing the issue - seven participants and the two co-moderators. There were college professors, corporate trainers, and educational technology staff. Several participants posted daily or very often and others posted over the course of two or three days. The times where several people participated with their different viewpoints and opinions being offered created some lively conversation. I feel we had good discussions and received a great list of references and links from the participants. Even though I thought I had my mind made as to what online testing should be like, I have to admit this forum caused me to rethink some of the issues.

**Preparation**

Via email, my co-moderator and I discussed the topic, what questions to start with, whom to post the conference beginning and summary and whom to respond to participants. We decided to split the forum moderating time with him responding to daytime postings and me to nighttime but with both of us participating and responding when we login. Up until the last couple of days of the two-week forum, I was unable to connect to the forum site from work because of firewall issues and he preferred daytime because of family issues. This division worked well for both of us so that we knew someone was checking the forum frequently everyday.

**Expectations**

This is the first forum where I’ve been the moderator (or co-moderator). The topic, testing in the online environment, is of interest but any topic would have worked since it was just the tool for the learning process. I started without too many expectations. I wanted to explore the moderating process and all the aspects that go along with being an effective moderator. And to have constructive forum where all participants receive something. I feel that this was fulfilled through this forum. It was definitely a learning process and I now have a greater appreciation for forum moderators.

**Disappointments**

During the two-week session I was so intent in trying to keep the conversation going that I forgot what a forum should be... communication between participants. My job was to check things like links and other reference contributions and encourage conversation. Not dominate it. I don’t think I was too dominating but I did tend to “push” the conversation without letting it evolve naturally at it’s own pace. Several participants were slow in contributing. As the moderator, this was frustrating; however, looking at it from the other side, I know that I’ve not always been the most faithful contributor in forums for many reasons. I’m sure that they had valid reasons as well. I hope that if these were not class
Lessons Learned

I learned many things from this process. First and foremost, *forum moderating is very time-consuming*. Even if others have not made a contribution, just the process of trying to stay on top of everything requires logging in several times a day. Checking links and references and providing corrected information requires time and effort. I always felt like I had to comment or ask a question to make sure the conversation did not lag. In doing this, sometimes I was too quick and didn’t stop and think. When I moderate a forum again, I will be more careful to read and assimilate the information before responding. Letting some “silence” be around is not bad and can encourage others to contribute. I learned that *I would not like to moderate by myself* unless I was able to do it as my main job function and not in addition to a full-time job, as a full-time student and full-time mom. My classmate and I worked extremely well together in this co-moderating process. Knowing he was there to contribute or keep things going and on track helped keep the pressure from being too overwhelming.

A great lesson learned here and from participating in other forums is that *forums are great places for obtaining current up-to-date information*. Participants provide great links and references. I’m not sure if others have more time or are just better researchers; however, I’ve obtained some excellent references and information to use in research papers. I intend to find conferences to participate in, as I get closer to the dissertation process. I know they will provide valuable information that can be utilized in my research and writing. And maybe I can help someone else in what they need as well. I learned that *having active participants is a moderator’s dream*. I hope I can be a better participant because of this process and seeing the issue from the moderator’s point-of-view. And finally, what I’ve learned is that *moderating and participating in these forums is a great learning tool*. I definitely have more appreciation for the whole process now that I’ve seen it from both sides of the coin (so to speak). Knowing what I do today, I would definitely recommend moderating and participating in forums.

**Communication within Postsecondary OLE’s:**
**Students’ Expectations vs. Professors’ Ability to Deliver**
Ellen Scalese

I co-mentored an asynchronous online forum. Having mentored discussion threads, during the process of instructing in an online masters program, I was secure in my ability to mentor an online forum. I had already had three years of experience, which had helped me to learn the difference between posting answers and questions and communicating. I knew the difficulties inherent in trying to maintain the proper balance of intellectual freedom and keeping the forum to the topic simultaneously. As a first term doctoral student, I was not as confident of my ability to formulate a topic that would elicit peer
participation. I decided that co-mentoring with a more experienced student might be the best method of approach. I met Paula Harvey, a third term student, who was taking the same Institute Courses. We spoke often during various breaks, developed a rapport, and decided to co-mentor a discussion thread.

The Co-Mentored Approach

Before defining our tasks and dividing up duties, Paula and I had to decide on our topic. We listed topics of interest to each of us and then discussed them jointly. Paula wanted to use a topic of particular interest to a variety of students. The topic was student-professor communication as an issue in perceived success or lack of success in an Online Learning Environment. That was a topic I also found interesting. However, as an experienced online professor, I wanted to include not only the students’ expectations, but also the demand on the professors’ time. Many professors in OLE’s, myself included, are faced with larger class sizes and a large number of assignments to be graded, needing to be balanced with students needs for timely feedback. Our topic was formulated and our forum was given a title: Communication within Postsecondary OLE’s; Students’ Expectations vs. Professors’ Ability to Deliver.

By mutual decision, we defined our tasks and divided our responsibilities. Paula would find a referenced background piece that would elicit thought and participation. She would formally state the conference goals and compile thought provoking questions intended to elicit interest and response from: first time distance learners; experienced distance learners; and distance educators. I would be responsible for the daily monitoring of the discussion. Paula would contribute as a participant. I would remain the unbiased mentor until the conclusion. I would respond to participants in a timely fashion. Although not one of her delineated duties, Paula frequently acknowledged participation and provided her personal feedback. I would provide mentor feedback to what was stated and ask additional questions and raise issues to promote response from other participants. I would summarize when needed and attempt to keep the topic on course without squelching intellectual freedom. I would close the forum and provide a summary. Paula and I would communicate by e-mail and telephone throughout our co-mentoring of the thread.

Thread Overview

The goal of this thread was to gather input from practicing postsecondary distance learners and distance educators regarding the degree of communication necessary to retain students, promote collaboration to offset isolation, and to explore communication options, time constraints, and conveyance of professionalism at a distance. Everyone was asked to read a thought-provoking article titled: Response on Demand – Professor Available to Students 24x7. The general topics for discussion included questions to novice distance learners, to experience ones, and to distance educators.

The interaction among the participants resulted in meaningful discussions promoting a further understanding of the amount, formats and timeliness of communication, between professors and their students, perceived by the students to be necessary to their success in OLE’s. It is my perception that it also encouraged the
participants to realize that professors cannot be available 24 hours a day. While we did not arrive upon a definitive “number” for response time or “amount” of necessary words, we did arrive at a group consensus of opinion on several items.

- Communication is perceived as a key success factor for students in an OLE by both the professor and the student;
- The amount of communication is not as important, as a perceived presence of the instructor in whatever online format is being used;
- The exact amount of response time to questions and assignments is not as important as a covenant being determined at the onset and that covenant being adhered to.
- Communication needs to be established immediately in order establish a sense of community and to foster a comfortable relationship between students and the professor.
- Students are not unaware that the professors have many demands on their time, or that there are many more students than professors. They just want to feel that their professor will respond to their needs in an acceptable fashion.

Reflections
I did not anticipate the difficulty we had in recruiting participants to join our forum. When we originally posted our thread, we had one immediate response for participation, then nothing. We waited a few days while continuing to lurk in other forums trying to judge what was garnering their participation. Paula and I both contacted other students and requested their input as to why we were not gathering a forum. We both received the same response several times. People who were interested were already involved in one forum and could not shoulder more responsibility or the timing was poor; there were several assignments due for the various courses at this time. Paula and I decided to repost once again with a new start date and a slightly changed title, as well as begin an e-mail campaign requesting participation. This garnered us the needed participants.

After a rather difficult beginning, the participants who joined the thread promoted lively discussions, meaningful opinions, facts and ideas. They formed a community and responded to each other in a comfortable yet professional manner. The participants not only shared personal opinions and experiences, they shared a wealth of informative references. They appeared to feel comfortable with both agreement and disagreement. They communicated amongst themselves using meaningful and constructive comments. When they became sidelined they were very responsive to my directing them back to the initial focus of the forum. They participated frequently out of interest rather than an assigned number of times. They obviously spent time and thought on their responses.

The partnership that Paula and I formed was most successful. Through the course of our co-mentoring, we discovered that we have differing skills, approaches and experiences that complement each and helped to form a very successful partnership, that benefited the forum as well as ourselves. Paula is an experienced 3rd term DCTE student from a corporate background. She has a wonderfully expressive style of writing and skill with words. She has a way of writing that draws the reader in. She did a wonderful job presenting our initial topic. As a participant, she incorporated humor that promoted
community. Whenever the forum was lagging, she “popped in” to revive things. I, as an experienced distance educator, was already aware of the inordinate amount of time and effort it takes to mentor a thread. I was successful at providing timely acknowledgement of all contributions. I would spend several hours a day reading participants postings and carefully wording responses that were neutral and yet would elicit further response. I am experienced in the fine balance that must be maintained in order to promote freedom of thought in students and stay on task simultaneously. At the midway point, I summarized the consensus we had arrived at to date. I reiterated questions as yet unanswered and requested each participant respond to a few of the untouched issues. I waited until the end of the final week to express my opinion as a distance professor, so as not to distract from the students’ viewpoints.

Having mentored graduate discussion groups in the past, I was already aware of several lessons learned by my partner. I was aware that there would be various qualities of responses among the participants and that careful guidance is necessary to keep a discussion group alive. I learned how much easier it is to mentor with a partner, each having their own roles to play. When I mentor threads alone, they do not usually form such an immediate sense of community and comfort. This is due to my more formalized approach. I will attempt a slightly more relaxed approach in the future. One of the main lessons I learned is that the more ownership or community the students feel in a forum, the more thoughtful and professional their responses become. Pride prevails and they are more willing to invest the “extra time” needed to raise the quality of the forum.

**Are you a Survivor?**

Lisa Star

This discussion thread was created to explore the characteristics required to teach in an online learning environment. We thought this would be an appropriate topic since many of the students in the class have extensive experience with online learning and in contrast others have little to no experience. Using this discussion forum to research the topic and then present results provided a collaborative effort for both learning and evaluating. My partner had no experience in online learning environments and I had considerable experience. We used our relationship as model and it proved a good balance.

**Process of Preparation, Posting and Mentoring**

The timing of our discussion coincided with the sensationalism of the "Survivors" television show, so we agreed to blend that popular theme into our research project. We wanted the participants to search for what characteristics were needed to "survive" teaching online. Our goal was to solicit a dozen participants. We fell short of that, but were glad in the end that we had fewer than expected participants because of the time element of group dynamics and needs.

The participants were divided into two groups and assigned tasks. We wanted to achieve both independent participation and group work. We were also looking to see if certain people would step forward and take a leadership role - no one did. Participants were
expected to do research and submit the characteristics they thought were necessary to
teach in an online learning environment. We requested that their responses be supported
by references that followed the stated format. After each participants submitted a list of
characteristics the two groups each posted them and voted. The top five from each group
were joined to form a list of ten comprehensive references. Then the entire conference
voted on the top five. We did see some overlap in the characteristics and allowed people
to vote for the most articulate responses.

My partner and I met for the first time in class and just seem to connect, so we agreed to
work together with no topic in mind. We spent several weeks exploring online journals
and articles searching for a topic. We even spent a few sessions on the phone. We
established a great working relationship that far exceeded my expectations. Group work
can often become frustrating. We divided responsibilities and took turns monitoring the
threads. It worked out great. This characteristic is a key dynamic of the process, in that
two strangers team mentored the thread creating a wonderful collaborative relationship.
Our institutions were physically located hundreds of miles apart, and I spent the majority
of the two weeks on vacation in California, with a laptop of course.

People signed up and started participating right away. We found they went faster then we
expected at times. I have found this in my own classes, that some students seek out the
next step and if you have it posted they will act on it before you are ready. This did not
prove to be a problem, and groups both completed all tasks.

What did prove interesting was the dynamics of the two groups. My group had a very
diverse set of responses and tended to avoid literary support. Beth's group on the other
hand provided detailed references to most all responses. The participants seemed to
follow the "leader" and mimic the first postings. I believe that I follow this model as well.
I often read the examples posted by others students and respond in accordance to their
style. We only had one person not fully participate or follow our required dates. We
received many outside emails from the group participants and we tried to respond to
group members in email as much as possible. Everyone who joined the conference
completed it. We did post a summary of all the tasks and participants, which included a
check off sheet to show what they had completed. I think that this thread helped clarify
the tasks. Being able to visualize the process often helps in an online environment.

Reflecting on best practices

I must admit that I was surprised by the responses that were finally chosen to represent
the top five characteristics. I found they differed from my perceptions. I also found that
there were large discrepancies in the voting. I was surprised that some of the
characteristics did not make the final vote. I believe that we meet our desired goal of
engaging a group of students to establish a dialogue on this topic. Even if the "list" was
not truly academic, the discussion was lively and informative. I did learn that conferences
take a considerable amount of time. I think that my partner and I underestimated the
amount of commitment this project would take. This may have stemmed from the fact
that we participated and moderated. We were impressed that the discussion went along at a steady pace and the number of hits to the conference exceeded 100.

**Final Five Characteristics Required to Teach Online**

The instructor must be:
- Knowledgeable about subject matter
- Able to communicate effectively
- Warm and Friendly / Human
- A Motivator
- Able to foster a comfortable learning environment

**Collaboration and Interactivity in Online Learning Environments**

Pilar Toral

**Preparation**

The "Seminar in Online Learning Environments" course at Nova Southeastern University required the mentoring of an asynchronous threaded discussion on a topic related to online learning environments (OLEs). During the required week-long visit to Nova for the Summer Institute, another student and I decided that we would to work together on this task, and agreed that we would divide the forum mentoring; she would moderate the first week and I would moderate the second week. Although my co-mentor and I come from different parts of the world and very different cultures (Israel and Puerto Rico), we were both first term students at Nova and biology professors. This common ground helped us establish a comradeship that began that week at Nova.

After returning to our work and families, we continued to communicate through e-mail, trying to decide what issues we would cover in our online discussion. It took us some time to agree on a topic as several of the subjects that we considered had already been discussed in other forums. We continued searching for possible topics and after a great deal of shared brainstorming, we decided on "Collaboration and Interactivity in Online Learning Environments". After researching the literature and discussing the subject, we decided that she would mentor the discussion on interactivity during the first week of the forum and I would mentor the discussion on collaboration during the second week. When time came, we collaborated by writing the forum goals, the introduction, and the conference summary together. Each of us wrote our part of the discussion. We then read and corrected each other's part before posting them in the forum. Our goals for the forum were to discuss the importance of collaboration and interactivity in the success of online learning environments. We also decided on suggesting examples for collaboration and interactivity, reviewing the pertinent literature, and exploring various collaboration and interactivity tools and free software available. These goals, the forum's beginning and end dates, the rules for signing up for participation, and an invitation for peer participation were posted six days before the forum's start date. The discussion was limited to ten participants. We asked them to contribute to the thread at least three times.
during the two weeks. Although references were not required, postings that included references or active URL’s to appropriate Internet sites were welcomed since they would benefit everyone.

The Discussion

Our threaded discussion began on September 17, 2000 and ended on October 1 with five registered participants and one non-registered participant (lurker). My co-mentor began the conference by describing the topics to be discussed and initiated the discussion by asking for the meaning and importance of interactivity in online learning environments. Different definitions for interactivity in online learning environments from the literature, other examples, and shared experiences were discussed. Participants also mentioned the three important types of interaction: learner – content, learner – instructor, and learner – learner interaction. I continued with the discussion in the second week and started with a reference to an article that presented collaborative online activities such as online debate, online peer evaluation, online case study, online guest speaker, and online bulletin board activities. Various free collaboration tools available through the Internet, in addition to two commercial products, were also brought up for group discussion.

The forum had a slow beginning; we received the first contribution after a friendly reminder was posted three days after the forum started. My colleague and I were worried that the small number of participants could make the discussion slow or cause it to have poor interaction. Two other forums were running simultaneously with ours but fortunately, after the slow beginning, we had a good level of participation from our five contributors during the rest of the forum’s existence. Participants could post their replies to any of the previous postings and they would receive our feedback within 24 hours. The mentor who was not moderating at the time, would contribute to the online conversation in order to keep the dialogue active and on the right path. In general, the participants stayed on track, although occasionally they did not respond to the questions or situations that we presented to them. During the discussion we occasionally had to rephrase or change the questions since they were not as well received as we had counted on and did not elicit any responses. Overall, the participants would usually comment on what they already knew or had experienced, sharing their knowledge, opinions, and any references they had on the topic. This is one of the advantages of peer online conversations - sharing one's experiences and expertise with others and at the same time acquiring and evaluating new sources of information. This “knowledge exchange” can contribute to expanding one’s knowledge in a more natural and effortless way.

Reflections

Our threaded discussion achieved the goals we aimed for. Most importantly, I learned the basic skills that are required to have good online conversations and that good communication and collaboration are needed when a forum is co-mentored. I learned that trying to keep an online conversation active and interesting for the participants can consume a lot of time and effort and that it requires good knowledge/research on the topic at hand. The topic of this co-mentored forum is collaboration and interactivity; the
The best example of collaboration in an online learning environment is precisely the co-mentoring of the forum. I truly enjoyed the opportunity of sharing this unique experience with one of my peers. The fact that I was able to work hand-in-hand with a colleague and not alone also helped to relieve some of the pressure and responsibility of mentoring a high-level discussion forum for the first time. I have benefited greatly from reading and participating in online discussions. They have helped me to refine my skills on how to communicate effectively in online environments and to obtain and share information and references on a variety of topics. The discussions also made it easier to maintain direct contact and communication with my peers and professors throughout the term.
Teaching Technology with Technology

Michelle Adelman
New School University
United States
madelman@lucent.com

Abstract: This paper reports on the experience of a two-person team instructing urban high school teachers to use computer technology. The course is presented entirely on-line in an asynchronous environment. It is the first course in a series of four in a Teaching and Learning with Technology certificate program.

Course I, Educational Technology Theory, presents and actively involves student in discussions of cognitive science and learning theories and their practical applications. At the same time, students receive instruction on constructing a web site. As the course progresses, the students build an instructional resource web site that they will be able to use in their classes.

This presentation will describe the process used in the on-line environment, demonstrate student projects, and relate student's plans to implement technology in their own classrooms.

I hear and I forget
I see and I remember
I do and I understand
(Ancient Chinese Proverb)

The pilot program offered by the New School University in the fall of 2000 explored the significance of this proverb and the implications it has for teaching in a 21st century urban classroom. Well situated in the heart of Greenwich Village, New York City, the program was nevertheless delivered asynchronously via the web. Participants were all teaching in New York City alternative high schools or middle schools. Although most of the schools implemented a project-based curriculum with portfolio assessment the teachers were responsible for ensuring that their students would meet new standards on state achievement tests.

The first course in the sequence was Foundations of Educational Technology Theory. Participants examined philosophical and pedagogical underpinnings of the current educational system and began to explore cognitive science principles that facilitate meaningful learning. They reevaluated the work of John Dewey, one of the founders of the New School. They applied constructivist theory to project-based curriculum while focusing on the new state standards.

At the same time they engaged in a parallel activity, learning basic html coding and Macromedia Dreamweaver™, the web-site authoring program. In addition to learning new skills, they engaged in active learning. We believed that they would master the technology and apply it in a meaningful way if they used it in their own learning process.

The New School University provided an opportune environment for this experiment since it has a solid history of offering robust distance learning courses. Dial, a proprietary instructional interface, provided the discussion-based environment. Participants were able to respond to instructors’ questions or assignments, upload responses, and email individuals privately. An orientation period preceded the regular class session so participants would not be overwhelmed by the technology. On-line and telephone support was available 24/7. Our program thus began with a solid technical foundation.
Participants came to the program with a variety of skills. Some were quite proficient with computers. Others were hesitant, to say the least. We wanted to find out how to engage each one on his or her level and help them develop the technical skill set. As you can see in Figure 1, they started by uploading a message introducing themselves.

Figure 1: sample on-line dialogue, student introduction

They then conducted on-line research in their subject matter areas and constructed a Virtual Field Trip lesson as seen in Figure 2.

The asynchronous environment enabled participants to fit the course into already crowded work and family schedules. The discussion based environment facilitated group interaction, resulting in sharing and helping each other, in short, creating a community of learners.

At this point we have only anecdotal observations. More extensive studies will be conducted in the spring. We are especially interested in identifying factors that facilitate conversation and participation.
Pitfalls and Pleasures in a Distance Based Directed Readings in Science Education Course

Abstract

What works when facilitating a distance education directed readings in science education with graduate students that are also teaching full time? The author will share experiences from teaching in the University of Notre Dame’s Alliance for Catholic Education (ACE) masters in education program. This directed readings course includes 25 students that are teaching at Catholic schools in under served areas throughout the south. The course is conducted during the fall and spring semesters using WebCT’s bulletin board system and an electronic mailing list.

Introduction

In the midst of my second time teaching the Alliance for Catholic Education’s (ACE) directed readings in science education course I have had an opportunity to experience a number of successes and failures in a distance education environment. Fortunately the failures have provided lessons that have, based on the anecdotal evidence improved the experience for the students taking the course.

ACE students are in a Master of Education program at the University of Notre Dame. Admission to the program is selective with about 1/3 of the students applying being admitted. There are approximately 75 students in each class cohort and 150 total students in the program. The program is based on the pillars of Academics, Community and Spirituality. Students in the program have there tuition covered and are paid a $1,000 per month stipend. In return they teach for two years in Catholic schools in underserved communities in the southern and western United States.

The program begins with an intensive 8 week summer session during which first year students complete basic education courses and have supervised teaching experiences in local schools. The students then report to their assigned schools where they are full time first year teachers. The commonly have 3, and many up to 5, preps as they begin there first year teaching. In addition to their first year teaching duties these students participate in 2 to 3 three credit, distance based courses that extend across the entire academic year. Second year teachers have completed another intensive 8 week summer session and take an additional 2 to three internet courses during their second year teaching. In addition to traditional assessments of students work they submit a portfolio documenting their teaching experience at the end of the second year of teaching.

The directed readings in science education course consists of a mixture of first and second year students that are teaching at a variety of levels, 4th through 12th grade, and a variety of courses, basic science through AP physics.
Pitfalls

Technical Difficulties

The first time that I taught this course was the first year that the courses were offered in this format. There were many delays in getting equipment setup and some technical difficulties after it was in place. These problems made progress in the course very difficult.

Other Obligations

The students in this class, like those in most distance education environments, have many other pressures that demand their time and unless the class is made a priority it can very easily slip.

Motivation

Students in this class seemed to want direct practical applications for what we were discussing than in my experience with face to face classes. I believe this is a result of their being immersed in real teaching situations and having problems that they need to solve immediately.

Pleasures

Technology

For my second time around teaching this course the technology was, for the most part, in place and functioning. As a result I had a very early assignment that verified everyone’s ability to participate. I found that even in cases where a house computer wasn’t working the students good get access using a computer at their school or public library. As a result of the infrastructure being ready is that we got off to a good start.

Participation as a Priority

Though the students have an equal number of obligations as before they are better able to keep this one in mind as the course progresses. This seems to be from a combination of the early start reserving a place for the course in the routines of the students and a much more structured grading system in which the students cannot turn in late assignments. In the current class over 80% of the assignments have been submitted even thought the structure lets the students opt out of several assignments without a negative impact on their grade.

Motivation
This time around I have taken a completely different approach to my role as a motivator. Before every assignment is due I send a note reminding everyone. Then as the first few submissions arrive I acknowledge them publicly and comment positively on the work that is being done and how important it is to the success of the class. The students seem to respond well to these efforts which, with the measures mentioned above, have resulted in excellent reviews of literature and discussion of those reviews by the students. These are strategies that I have never had a need to use in traditional classroom based settings and were, at first, a bit awkward for me. I have now become accustomed to cheerleading and feel comfortable that by performing that role I am providing a valuable service to the students.
Developing Communities of Learning in Distance Education Courses

Elizabeth Bennett
Media and Instructional Technology Department
State University of West Georgia
ebennett@westga.edu

Leticia Ekhaml
Media and Instructional Technology Department
State University of West Georgia
lekhaml@westga.edu

Abstract: As the popularity of distance education courses increases, so does the pressure to design robust distance courses that support maximum student achievement. One criticism of distance education courses has been that the medium encourages minimal student engagement and passive participation. Incorporating a community of learning approach into the design of distance courses requires students to be actively involved with course content, fellow students, and the teacher. This paper describes strategies that contribute to the development of learning communities in distance education courses.

Introduction

Distance learning courses, whether online or mediated, offer many benefits to instructors and students -- particularly in terms of when and where they can engage in course activities. Many students enroll in distance education courses because of the convenience. However, once enrolled, student participation in these courses varies widely. Some students sign on faithfully and contribute regularly to the online or mediated course activities and discussion. Others "lurk" or participate passively, choosing to limit their interaction to reading posted materials or listening to course proceedings with only an occasional comment. A few students don't participate at all (Kearsley, 2000).

Though it has been recognized that students may derive some benefit from simply listening or reading materials online, students who actively contribute to a group learning experience maximize learning and achievement. Unfortunately, active participation is a goal that may be difficult or impossible to elicit from students in a traditional distance education course. Students may be uncomfortable using the technology, or may not feel the need to engage in conversation with classmates or the instructor since they are geographically removed. However, incorporating a community of learning framework into distance education course design provides strategies to stimulate students to actively engage and participate in collaborative learning.

Communities of learning involve all students as full participants (Vaughn, Bos, and Schrumm, 1997) in a collective effort of understanding (Bielaczyc & Collins, 1999). Learning communities are committed to the concepts that students learn by directing their own learning, working with people, dealing with complex issues, collectively sharing knowledge, and showing respect and appreciation for all (Bielaczyc & Collins, 1999). Applying these principles in distance environments is similar to employing them in face to face classrooms. It means providing students with individual choices to make course work personally meaningful as well as engaging them in collaborative group work to support collective growth. Case studies and simulations offer students the opportunity to deal with authentic, complex issues. Encouraging students to develop and share expertise in individual areas of interest broadens class scope and develops appreciation for individual strengths and differences. Without a supportive learning community, distance education students can easily become isolated, lose interest and motivation, and may eventually drop out. In a nurturing
community of learners, distance students help each other learn, become involved, and contribute their unique experiences and resources.

This paper describes course elements that contribute to the development of learning communities in distance education courses. The major strategies include making sure students and instructors become acquainted with each other early in the course; sharing responsibility for collecting and contributing course-related information and experiences; encouraging and scaffolding mediated interaction; and providing active, authentic learning activities. These techniques have been used successfully in distance education courses to help students become active participants and contributors in both online and closed-circuit video courses.

A number of activities can be employed to help course participants get acquainted. Having an initial face to face meeting provides an opportunity for students to interact directly. Traditional face to face ice breakers such as having students interview and introduce each other can get things started, but posting class member biographies (derived from the face to face interview) and photos is a good follow-up to reinforce connections and awareness. An online practice quiz that highlights interesting information about course members helps participants get to know each other as well as familiarizing students with the quiz utility. In addition, students can be assigned online buddies or assigned to small study groups to begin discussing course issues immediately. The sooner the students become comfortable with each other, and with the communications medium, the stronger the learning community will become.

Students must also accept responsibility for contributing to the class information base. This can be accomplished in a variety of ways. Small groups can research basic terms and concepts, or read different articles and share their findings with the rest of the class via bulletin board postings. The bulletin board also provides a venue for follow-up discussion and clarification of unclear material with students serving as the experts for the information they shared. Individuals and groups can also research and make class presentations on major course issues. Working in groups, even at a distance, reinforces the sense of community as well as expanding the class information base. However, it should be noted that group interaction via distance communication tools can be difficult initially.

Getting students comfortable with mediated public interaction is critical to nurturing the learning community. Most students will be comfortable with private email, but they must also participate in public communications to the entire class. Early activities can be simple listserv and bulletin board conversations where students post personal reflections and experiences about things they are currently doing. As they gain confidence using the communication tools, they can use the chat rooms for structured interchanges and communications. Guest speakers can address the class in chat rooms, and respond to questions from the class. Or, small groups can debate hot topic issues in chat rooms. For chat interactions, communication protocols must be established to take the place of the visual cues that signal when a person is through talking. A common practice is to post the word OVER when a person finishes speaking.

Designing active, authentic learning activities begins with the identification of problems that are relevant and contextualized in real world experiences. Case studies and problem-based learning activities offer students the opportunity to interact via email with real experts about real problems, brainstorm solutions in small groups on the bulletin board, and then share problems and solutions with the whole class using web presentations or videoconferencing. Employing these approaches virtually brings the world into the classroom, and expands the community of learners globally.

Abstract: Online instructors face the dilemma of providing meaningful field experiences for learners. In the Social Life of Information, John Seely Brown and Paul Duguid revisit Jerome Bruner’s distinction between “learning about” and “learning to be.” Brown and Duguid state (p. 128) “In the age of the web, learning about is easier than ever before.” The real challenge for internet-based education is to help students learn how “to be.” Field experiences and internships move students away from focusing solely on information toward an understanding of how knowledge informs practice. This paper explores creative ways to facilitate meaningful experiences in the field of practice for students-at-a-distance.

Internships and more extensive field experiences

Advanced or intensive internships are an important part of many professional education programs, and in many cases certification or accreditation agencies require supervised internships. Internships are a challenge in any setting when students hold down full time jobs and have family responsibilities. Since these characteristics are common with non-traditional students enrolled in on-line courses you will have to consider a variety of flexible approaches, including virtual internships (discussed below). You will also have to find ways to observe students while they complete their internship assignments. This may be accomplished using web cams (synchronous observation) or videotape (asynchronous observation). With either method, be sure to obtain proper permissions from everyone involved. Online students should keep extensive field experience notes, which can become reflective journals. Students should e-mail notes and journal entries to you regularly so you can monitor their activities. Site supervisors should also be in regular contact so that you can provide appropriate guidance and feedback. No matter what method you use, read professional accreditation and licensure requirements carefully. In some fields students may have to complete internships following very specific requirements, including specific qualifications for internship supervisors and direct observation. You should not assume that a licensure agency would consider a virtual internship to be equivalent to a traditional internship.

Virtual internships

A quick search of the web reveals numerous examples of virtual internships. Dr. Thomas Barker from Texas Tech University (http://english.ttu.edu/courses/5378/inet/about.htm) suggests that there are mutually beneficial advantages to this form of internship. For the intern, the experience provides:

- Flexibility - Unlike conventional enrollment patterns, virtual internships may span semesters and summers.
- Experience - Virtual interns develop skills at using the latest communication technology applications and paradigms -- email, file upload/download, desktop videoconferencing, white board, real-time audio and video, and chat in both synchronous and asynchronous modes.
- Convenience - Virtual interns can complete the course requirements from any personal computer, in any location that has the appropriate software.
• Supplemental income - Some virtual internships pay up to 1/2 or more of entry-level salaries. The paid internships are very competitive.
• Research - Virtual interns develop research, writing, and problem solving skills that they will be able to apply in later work experiences.

Virtual student teaching

With more and more emphasis being placed on online instruction, especially for students in advanced teacher education programs, you might want to consider providing a virtual student teaching experience. Unlike the internships and field experiences described above, in virtual student teaching, students practice their instructional skills in an online environment, under the guidance of an experienced distance educator. One example of this model can be seen at http://hale.pepperdine.edu/~bsouza/ed630a.htm. In this graduate education course, students collaboratively plan, direct, and assess and online instructional experience. In this case the students teach instructional units to other students enrolled in the same course, but this model could be extended to other types of virtual learning experiences.

Virtual internship administration

Most virtual internship programs include a formal and business-like application process. Control of the process may be with the educational institution or with the employer, depending on the institutional arrangements. Most require a letter of application, a short resume, and a work proposal or statement of interest. If there seems to be a match between the proposed intern's skills and the nature of the available internship, then there may be a negotiation between the employer, educational institution, and the intern over the specifics of the internship. Specifics about the time commitment (full-time or part-time) and length (starting time and total number of hours or product to be produced) need to be agreed on. The expectations for equipment to be furnished by the employer, employee, and the educational institution must be resolved. Another important detail is whether the intern will receive pay and at what level. Commonly, if the interns are paid, they are paid at about half the rate of an entry-level position. The matter of supervision must also be addressed. Most of the time the employer provides the direct supervision. At the end of the internship, the employer then writes a letter of evaluation to the educational institution. Grades are typically assigned from that letter.

Field experiences and internships are critical parts of any learning experience. Online educators will probably have to work harder and be more creative to establish these relationships until technology and our technology comfort level catches up with our goals and objectives. You might start with a small project, such as having students conduct e-mail interviews with professionals or subject matter experts, and then let this initial communication build into a deeper relationship. Or you may set up a full-fledged virtual internship program based on one of the models described above. No matter what approach you take, you will help your students become part of the community of practice.

Abstract: "Standards of Practice" is a 10-hour, asynchronous web-based workshop designed for a broad range of educators. The workshop provides an overview of curriculum and technology standards, and integration of effective technology into standards-based teaching. Topics include searching, evaluating web sites, and research on the web. The workshop was developed by university education faculty under a professional development schools grant to meet needs of area schools. "Standards of Practice" was offered to teachers in the professional development schools. After completing the workshop, teachers received a certificate that they submitted for district inservice credit toward certification renewals. The workshop is composed of six modules: Introduction to Technology Standards, Sunshine State Standards, Searching the Web, Evaluating Web Resources, Research using the Web, Best Practices in Integrating Technology into Standards-Based Instruction. Each module includes instruction on the topic, links to web materials, self-paced practice activities, and suggestions for finding further information on the topic.

Teachers in a cluster of Florida Professional Development Schools (PDS) recently identified their needs for continuing education. The main themes that emerged were understanding of curriculum and educational technology standards, improving technology skills, and learning best practices for teaching standards with technology. The state university's college of education working with this group of PDS teachers used grant funds to develop a package of professional development experiences addressing the needs of the teachers. The experiences included university graduate courses, hands-on technology skills and integration workshops in an area instructional technology center, and an online workshop. The menu of options enabled teachers to choose topics, schedules and learning styles that best suited them.

The teachers were familiar with courses and workshops, but most were new to online learning. The attractive features of an asynchronous web-based workshop included flexibility in location and time of learning, and self-paced and independent learning. The intimidating aspects of an online workshop involved the lack of face-to-face interaction and immediate instructor support, and the requirement of basic computer skills and web access. The online workshop format was well-suited to teachers who possessed the prerequisite technology skills and access, those who enjoy independent learning, and those who had limited time to travel or meet in a structured classroom. The online workshop also opened the opportunity for teachers who participated in face-to-face workshops to continue and extend their education independently.

University faculty worked with the PDS teachers to develop the online "Standards of Practice" workshop. The workshop was designed for all educators working at K-12 across content areas. The workshop offers an overview of national and state curriculum standards relating to technology, and educational technology standards, and practice with integrating effective technology into standards-based teaching. An evaluation of the technology components within the state standards across the curriculum areas revealed common themes and skills, which led to the workshop topics. Topics include effective searching, how to evaluate web sites, and how to do research on the web. The workshop was delivered using the online course environment WebCT. The workshop is structured as six modules. The module topics are: Introduction to Technology Standards, Information Literacy and State Standards, Searching the Web, Evaluating Web Resources, Research using the Web, Best Practices in Integrating Technology into Standards-Based Instruction.

Before beginning the workshop modules, users are instructed to print the study guide page, as an advance organizer for workshop activities. Each module includes instructional information, online references, self-paced practice activities, and suggestions for further information on the topic. Upon entering a workshop module, the teacher/learner reads an introduction to the topic and its importance. Next, important concepts are described, and
Module Outline:

Module One, Introduction to Technology Standards:
Discussion of the need for educational technology and curriculum standards, review of US Department of Education and International Society for Technology and Education (ISTE) standards for teachers and students, exploration of Milken Foundation Dimensions for Gauging Progress, review of state and American Library Association technology literacy standards, self-assessment instrument where teachers receive a rating on the continuum from Learner to Leader in educational technology, and web sites for further reference on the topic.

Module Two, Sunshine State Standards:
Overview of information literacy, discussion of the state goals for improving education with technology, list by grade and content area of the state curriculum standards relating to technology, a drag-and-drop activity matching information literacy skills and examples of classroom application, and web sites for further reference.

Module Three, Effective Web Searching:
Overview of the value of web searching skills, discussion of the tools for seeking and assessing information on the web and their relationship to the standards, comparison of web searching tools and guidance for choosing appropriate tools, searching strategies and operators, information about critically assessing information located on the web for an education task, a list of web sites for further reference on the topic, and activities in which users compare the results and capabilities of a group of common web search tools.

Module Four, Evaluating Web Sites:
Discussion of the need for web users to critically evaluate web content, questions and criteria to use when evaluating a web page for educational use, a sample web resource evaluation checklist, a list of web sites for further reference on the topic, and a practice web page evaluation activity involving the judgment of sample web pages for specific educational situations.

Module Five, Researching on the Web:
Discussion of the value of using the web for educational research, flowchart of an online research process for students, skills for managing information located online, procedure for citing electronic references, Fair Use guidelines for using electronic information in an education context, a list of web sites for further reference on the topic, a multiple choice activity in selecting the correct citation format for online references.

Module Six, Best Practices in Classroom Computing:
Discussion of classroom structures recommended for effective use of computers for learning, an information literacy approach, teaching and management strategies for classroom technology, findings related to the physical setting for classroom technology, a list of lesson plans and further resources related to the topic, a likert-scale activity for rating the effectiveness of classroom technology scenarios.

"Standards of Practice" was offered free of charge to any teacher in the university's professional development schools, and teachers earned a stipend during the grant period upon completion of the workshop. After completing the workshop, teachers received an automatically generated certificate stating that they satisfactorily competed requirements of the workshop. Teachers submitted the personalized certificates for school district credit toward renewing their teaching certificates.

The workshop met the needs of the target audience by providing them with experience and knowledge within the curriculum standards, skills using the technology as a teacher and learner, and information about best practices for integrating technology into curriculum. The online format was very convenient for teachers who had limitations in attending face-to-face training. This format also allowed the teachers to become more comfortable with the technologies as they worked at their own pace.

"Standards of Practice" was offered free of charge to any teacher in the university's professional development schools, and teachers earned a stipend during the grant period upon completion of the workshop. Abstract: This study explores the dilemmas faced while teaching a course on distance learning based on constructivist learning principles using case studies. The course is open to undergraduate as well as graduate students. It is a hybrid course. The class meets once a week for two hours and the remaining time interacts online using WebCT, an online course management software. The course design draws on constructivist learning theories of Vygotsky and Lave and Wenger's theory of authentic learning. The students are introduced to concepts of distance learning by studying real-life cases and also developing and analyzing their own cases of distance learning. Such an approach presents dilemmas at every stage of its development, for example, the need to strike a balance between breadth and depth of content to be covered. The authors continue to struggle with similar issues causing them to constantly review and revise their design leading to a fuller, richer learning experience.

Introduction

This is a pilot study exploring the dilemmas faced while teaching a course on distance learning using case studies and based on constructivist learning principles.

The year 2000 is a time of rapid transition and convergence with both communications technologies and distance learning. Indeed, such rapid evolution of education is also challenging traditional distance learning institutions, such as the renowned UK Open University. Such rapid changes have intensified the dilemmas faced by teachers. The topics and content of the course to be taught are changing by the month and multiple views must become visible. Indeed, students need to be assisted to handle this ambiguity and rapid change as they learn the principles and a wide range of practice within a 16-week semester.

What is a small course team of one faculty member and two graduate students without start-up funding for instructional designers and technologists to make of this dilemma?

As a response, Dr. Davis developed an approach that is case-based and constructivist in nature with support from graduate assistants, Qian Li, and Rema Nilakanta. The flexibility and "open architecture" of a constructivist approach adapts well to the fast-changing content and technologies. The dilemmas emanating from such an approach are continuously confronted through an action research approach to course development and implementation over time. Action Research has been used in technology and teacher education for some
Course design

The course, Curriculum and Instruction (CI) 407/507: Principles and Practices of Distance Education (DE), is open to undergraduate as well as graduate students. It informs students of current and old practices, principles, and technologies involved in DE. The recommended texts are provided in the reference section of this paper including the required text, Kearsley (2000). The course design draws on constructivist learning theories of Vygotsky as well as Lave and Wenger’s theory of authentic learning. In some ways a constructivist approach to teaching implies that the students are involved in creating their own leaning. The teacher’s approach is to challenge students to search for relevant information and to integrate it within their existing and developing skills and knowledge.

Case-based instruction lends itself to a constructivist approach. Case method has been used for some time in professional schools, such as law, business, and medicine. Cases can be used to uncover underlying principles and concepts similar to a well-defined problem in problem-based learning (PBL) where “the given state, goal state, and the allowable operators are specifically clear to the problem-solver” (Mayer & Wittrock, 1996, p. 48). This kind of use implies an established body of knowledge where the student is expected to acquire the knowledge deductively, as in the fields of law and medicine. Cases can also be used to discover or develop new principles when faced with an unfamiliar situation as seen in the field of business education. This is similar to an ill-defined problem in PBL where “the given state, goal state, and the allowable operators are not specifically clear to the problem-solver” (Mayer & Wittrock, 1996, p. 48).

We are attempting, in this course, to combine the two uses of case-based instruction. The students will be introduced to concepts of distance education by studying cases of DE and also develop rich case studies that they can repeatedly return to as they uncover salient principles and practices of DE. They thus engage with the principles, theories, and models of distance education within the context of cases and project-based learning.

The classes are conducted in a hybrid environment. Students meet face-to-face once a week for two hours as well as online with the help of WebCT, an online course management software. The course contains a rich collection of cases from which students draw the distance education design and delivery principles and practice. These cases are drawn from different situations of distance learning, including higher education, K-12 schools, as well as professional development training. In addition, students are expected to develop and study one case of DE of their own choice as well as analyze the course itself, CI407/507. The approach is unique in that while studying and analyzing different cases of flexible learning students are also actively creating their own case of distance learning because much of their interaction is conducted online. Students thus investigate and evaluate the use of WebCT within their own learning.

The cases used in CI407/507 are different from traditional cases in that these cases are presented using multimedia technology. Traditional cases are mainly text-based, but our cases are presented with many hypertext links, images, and audio files; thus presenting a fuller, richer picture to the student. Bronack et al. (1999) provide another but different example of a case-based learning environment.

Dilemmas of a constructivist approach

The above course design propels the student into active learning, which involves learning through exploration. However, implementing this kind of approach is a challenge. It brings up early dilemmas at every stage of its development. Below are some observations based on data collection.

One of the dilemmas we faced during the early stages of course design and which still continues, is the need to strike a balance between breadth and depth as it relates to content. On the one side, we want to introduce students to a variety of applications of distance education and to let them have a taste of different course management software (e.g. WebCT, ClassNet, Blackboard.com, etc). On the other hand, we believe students should be encouraged to acquire deep understanding of distance learning, which implies a focus on fewer applications of distance education and online courseware. In other words, a superficial browse of a wide range of technologies is unlikely to lead to high quality transferable knowledge.
A second ongoing major dilemma we are facing is the need for structure as well as the freedom from it. How much structure do the students need in order to facilitate their learning, but at the same time have the freedom to explore on their own? In other words, how high and deep should the scaffolding reach? These dilemmas appear to become more acute when dealing with undergraduate students.

**Future plans**

The next stage is to revise this and other courses led by Dr. Davis and the mode of delivery so that they can be studied through distance learning by students in more than one university (ISU and London University Institute of Education). CI 507 will be offered for the first time in Summer 2001 with students on both sides of the Atlantic — in Ames, Iowa and London, UK. Progress will involve expansion of the teaching and action research team as well as evolution of the course design and content. It is also likely to involve more innovative on-line environments and communities of professional development. However, we must not jump ahead too fast. The immediate first step is to complete our first round of development and research on case-based learning at Iowa State University. We also suspect that our development and research is likely to study dilemmas that others face within and beyond the context of the teaching and learning at a distance.

**Acknowledgments**

We would like to express our appreciation to our colleagues and students within CI407/507 as well as the collaborators within ISU, CTLT, ITC and ECE. Oracle’s support for access to their web environment, Think.com is gratefully acknowledged as well as the collaboration with the MirandaNet community created by Christina Preston. In addition, we acknowledge the capture and editing of video by visiting professor, Yevgeny Borsov, Ivanovo State Textile Academy, Russia; and the lively contribution to the course and research group by Dr. Sally Beisser of Drake University.

USING THE INTERNET IN THE CLASSROOM
Sheila Offman Gersh, Ed.D.
City College of New York, School of Education, Center for School Development

This article will focus on how to use the Internet as a tool to enhance classroom teaching. The "Internet Style of Learning" is helping teachers and students change the approaches to teaching and learning. Teachers can easily take one of their traditional lessons and turn it into a web-based lesson using resources from the Internet, or take a topic being taught and create a collaborative inquiry-based project than can be shared with a class in another location, nationally or globally. Once you know where and how to use the Internet to find resources for such lessons and projects, the process is not difficult.

The Internet also allows you to meet hundreds of teachers from around the globe. Why not learn how you, too, can meet them! By going to http://www.epals.com, you can search for educator around the globe and create an opportunity for sharing, collaboration, etc. There are so many ways that teachers around the globe are using the Internet to bring the world into the classroom. Examples of many projects and collaboratives can be found at sites under "Projects" at the web site at http://www.schoollink.org/twin.

Most traditional lesson plans can easily be enhanced by adding Internet activities. These activities can include research exercises, communication with other students or experts, virtual field trips, publishing, collaboration, interactive activities, or Internet searches. It is always good to have students use the search engines that are designed for students (http://www.yahooligans.com) or http://www.ajkids.com (Ask Jeeves for Kids). Teachers can learn a lot from each other when they join listservs. You can find out about listservs by going to http://www.liszt.com. Many teachers have already created lessons that include Internet components, so we should take the time to view such lessons at sites such as http://www.thegateway.org/, http://ali.apple.com/ali/, http://www.sdcoe.k12.ca.us/score/cv912.html, http://edweb.sdsu.edu/webquest/matrix.html.

Some teachers find it better to start with new lessons when creating web-based Internet activities for instruction. They use their traditional lessons as outlines for their new activities. It can take a long time to create the new weblesson. Time has to be spent searching for the right sites for the lesson. Once the sites have been chosen, the next procedure is to develop some meaningful activities for students to complete when they visit the site. If the students are going to communicate with other students/experts, make sure they understand time zones and realize that they won't get responses immediately. Once students are proficient in using the Internet, they can do scavenger hunts on the Internet to find information. Of course, it's a good idea to try out the lesson before teaching with the Internet. Be aware that there might be technology problems so always have a backup lesson. WebQuests are always a good way to get started with Internetized lessons http://edweb.sdsu.edu/webquest/webquest.html. For information about WebQuests you can read SOME THOUGHTS ABOUT WEBQUESTS at http://edweb.sdsu.edu/courses/edtec596/about_webquests.html. An excellent tool for teachers to use to create their web-based activities is found at the Filamentality web site.
http://www.kn.pacbell.com/wired/fil/. After reviewing the site, you can easily create Samplers, WebQuests, and Hotlists. To create the assessment rubrics, you can use a tool at http://landmark-project.com/classweb/rubrics/.

Once web-based lessons become the norm for teaching, Internet projects should be the next step. Such projects should include students collaborating with other classes to exchange data, share writing activities, and create discussions on topics of interest. In addition, mailing lists often post requests for participation in hundreds of Internet projects. There are many commercial projects available for those who prefer to "buy in" to a packaged project. Project ideas can be found at http://www.iearn.org, http://www.thinkquest.org, http://www.gsn.org, http://www.eduplace.com/projects/index.html, and http://www.globalearn.org.

**What is a project**
Projects are collaborative, interactive learning activities that allow students and teachers to interact with each other to carry out a research activity that supports the existing curriculum in new and exciting ways. Students use the Internet's research, communications, and publishing tools to get involved in data exchanges, team writing projects, world explorations, and even global shopping. The classroom walls become invisible as students connect to global partners and experts via the Internet. Through such projects, students around the world work together, sharing the experiences, research, and learning resulting from their work.

Ideas for projects come from students and teachers, and projects vary as widely as the people participating in them. Some projects consist of writing assignments, which are then posted to conferences and eventually gathered into a publication, a Web page, or other multimedia presentation. Others consist of art projects, in which students from different schools exchange works of art. Still others provide ways for students to get directly involved in helping to solve problems in other countries.

Projects are usually organized according to the age/grade levels of the participants and by curricular subject matter. Participation is open to either students of all ages, primary/elementary students, or intermediate/secondary students. Subject areas include environmental or natural sciences; social studies, politics, and economics; arts and literature; language-based; and other/interdisciplinary.

Projects have been classified in a variety of ways. I*EARN (http://www.iearn.org), The Global SchoolHouse (http://www.gsn.org) Judi Harris (http://www.esu3.k12.ne.us/institute/harris/Harris-Activity-Structures.html), and Bernie Dodge (http://edweb.sdsu.edu/webquest/webquest.html) have made outstanding contributions to the use of Internet projects. For example, I*EARN has categorized projects as structured, unstructured, and Learning Circles. Judi Harris has done extensive research in the area of Internet projects. As a result, she has classified projects into the following categories: Online Correspondence and Exchanges, Information Gathering, Problem Solving, and Competitions.
What follows are some suggestions and helpful hints in getting started with Internet projects.

**Suggested Design Criteria for Internet Projects**

While teachers try to accomplish a variety of activities during their classroom instruction, it is possible to achieve many of the following goals when implementing Internet projects into the regular classroom curriculum.

Internet projects should:

- focus on getting students to use their minds well; raise real questions and allow students to do authentic work rather than exercises from a workbook;
- develop instruction around the questions, ideas, and concerns of students;
- recognize and use learners' purposes for learning; view learning as meaning-making and constructive rather than passive reception and regurgitation of transmitted information;
- develop active approaches to learning and encourage students to express their ideas and opinions;
- give students ownership of their learning;
- view teachers and students as co investigators both should seek knowledge and solutions to problems; foster collaborative/cooperative learning and devise activities that help build a sense of community;
- view students as producers of knowledge and publishers of their work;
- provide moments when everyone takes time to reflect on what they have learned;
- contribute to understanding of other nations and cultures;
- strengthen students' literacy and academic skills; and
- provide ample opportunity to strengthen students' technology and Internet skills.

The Internet can make teaching and learning exciting while encouraging students to become lifelong learners, contributing members of society, and valuable members of the world of work. The research, communications, and publishing skills learned by students through Internet activities are essential for now and the future. I have been using the Internet for 12 years. I often ask teachers who aren't using the Internet, "How are you accessing information"? "How are you communicating"? "How are you teaching"?
Assessing Distance Learning Tools and Techniques: A Case Study

J. Christine Harmes
Ann E. Barron
University of South Florida
United States
charmes@tempest.coedu.usfedu

Abstract: Distance learning offers students many advantages over traditional courses. This study examined student reactions (through the use of a student survey) to an entirely web-based course. The course was a graduate-level class titled Telecommunications in Education. Of the 79 responses, all but one responded that they would like to take another course via the web. Ninety-nine percent of the students reported a positive feeling about the ease of use of the web course. Additional items solicited feedback with regard to specific features of the online course.

Introduction

Many studies have compared the effectiveness of learning in a traditional on-campus course with the same course delivered via distance. Of these, several have found that distance learning courses (regardless of instructional medium) are equally, and in some cases more, effective than their face-to-face counterparts (Clarke, 1999). To be effective, these distant courses must include timely feedback from the instructor and opportunities for interaction among the students. In addition, the delivery method must be appropriate for the tasks (Moore & Thompson, 1990; Verduin & Clark, 1991).

Most of the research on distance education has focused on its effectiveness, i.e., comparing student course grades or performance on exams between traditional course delivery and distance-based instruction. Little mention has been given in the literature to students' attitudes and reactions after experiencing distance education. This study was designed to explore student reactions to a course delivered entirely on the World Wide Web. The goal was to gather information that could be used to improve the design and delivery of distance education courses. In particular, the study was designed to investigate students' reactions to tools and techniques used in web-based delivery. Answers were also sought related to student perceptions of community, time commitment, and amount of learning in the web-based environment.

Method

To address these issues, a survey was designed. This instrument contains ten items, each with an individual response scale generally having four or five options. Following these ten items are two open-ended questions designed to solicita more qualitative data about students' overall experience with the distance learning course and advice that they would offer other students who might be considering a distance course. The survey was given to all students in a graduate-level course (EME6936: Telecommunications in Education). This course is delivered completely via the web (using WebCT software). Data were collected over a series of six semesters. There were a total of 79 students in the six-semester period. Individual class sizes ranged from 8 to 15. All surveys were anonymous and voluntary.

Results

An interesting result to note is an overall satisfaction with the distance learning experience from this course. Of the 79 total students, only one responded that they would not like to take another course via the web. Ninety-nine percent reported a positive feeling about the ease of use of the online course.

Of the features employed in this web-based course, students reported that the bulletin board was the easiest to use (37%), followed by e-mail (29%), chat (21%), and the quiz (14%) functions. The chat feature was by far the hardest to use (37%) with the bulletin board (25%) and quiz (14%) following.

Students' perceptions of "community" when taking a distance learning course have
been a major area of concern in discussions of distance learning. Of the students in this course, 87% reported feeling a level of group participation at least the same as a regular course, if not more. Only 13% reported feeling isolated and alone (one student commented that this was a positive attribute).

The most frustrating portions of the distance learning course were reported to be problems with software (e.g. using AOL's browser), trouble communicating with other students, and long download times (30% each). Trouble communicating with the course instructor was reported to be the least frustrating aspect (1%).

When asked about their perceptions of the amount of time required for the course compared to traditional courses, fifty percent of the students reported spending about the same amount of time and work on the distance course as they would have in a traditional on-campus course. Thirty-six percent reported spending more time and work on the distance course.

With regard to the amount of learning they acquired in the distance learning course compared to traditional courses, the majority of students (64%) felt that they had learned more in the distance course than other college courses. Almost all of the students (96%) felt they had learned the same amount or more in the distance-based course.

Data from the first open-ended question, "What is your overall impression of online learning?" were first categorized as positive, neutral, or negative. There were two negative responses, seven neutral responses, and seventy positive responses. The negative responses mentioned dissatisfaction due to the increased amount of time required to complete course activities and frustration with connecting to the USF server. Neutral responses were general comments about distance learning, such as "I'm not an education major", or "Benefits from the course depend on the student." The most common positive response was "I loved it!" Other positive comments included the benefits of time and distance removal, as well as increased personal attention from the instructor.

Responses to the second question, "What advice would you give future students in online courses" clearly centered on the need to keep up with the coursework and not fall behind. Students also wrote about the benefits of having a "buddy" in the course, i.e., someone to encourage you and help eliminate any feeling of isolation. The third most prevalent response suggested the need to be familiar with using the web, and to have the most powerful computer with the fastest connection to the Internet that you can afford.

Summary

As more and more college courses are being offered via the web, it is important to assess students' perceptions and obtain feedback on effective practices and techniques. The lack of variability in this data (with the majority of students providing positive responses) is very encouraging. Further analysis might involve investigation of response patterns over time, as more students became familiar with the web environment. In addition, researchers may investigate patterns in student interactions as they relate to course satisfaction.

Mission Possible: Project-Based Learning Preparing Graduate Students for Technology

Harrison Hao Yang, Ed.D.
Department of Curriculum and Instruction
State University of New York at Oswego
United States
hvang2@oswego.edu

Abstract: This paper addresses how the project-based learning was designed and then implemented in a graduate applied technology course at State University of New York at Oswego. The focus of the course was to engage students to produce projects that were authentic, meaningful, and intended for future teaching and professional use. This paper outlines the course content, provides an overview of the processes involved in developing the project-based learning activities, and reports the responses of students in the course on effectiveness of learning process and perception of technology integration on completed projects. Discussion for using project-based learning and examples of students' projects (educational web review, WebQuest, and web-based portfolio) are included.

Introduction

Project-based learning is frequently used by educators. Why the interest in project-based learning? Research shows that project-based learning can capture the complexities of real life situations. Not only does it provide an effective way for students understanding the connection of knowledge to the contexts of its application, but it also provides students with opportunities for self-reflection and a sense of agency. Essentially, project-based learning is based on tasks, groups, and sharing. It provides a practical method of combining many of the elements of authentic activities and collaborative learning (Wheatley, 1991; Grabe & Grabe, 1998).

Although technology provides many opportunities for classroom projects, we often find that students who completed the projects with technology learned relatively little from the hands-on activities of simply “doing” without “understanding”. In such cases, students are busy taking actions without appropriate reflection and deep learning. Barron and the Cognition and Technology Group at Vanderbilt (1998) have identified four major design principles that appeared to be very important for project-based learning: a). defining learning-appropriate goals that lead to deep understanding; b). providing scaffolds such as beginning with problem-based learning activities before completing projects; c). including multiple opportunities for formative self-assessment; d). developing social structures that promote participation and a sense of agency (p. 306). This paper describes the adaptation of these 4 principles into a graduate applied technology course at State University of New York at Oswego in which students were required to complete authentic, meaningful projects.

The Study

The Course “Educational Topic: Multimedia and Internet for Education” was offered in summer 2000. The class was restricted only to graduate students and was limited in size (17 students, 9 males and 8 females). Students and instructor met 3 hours twice a week for 6 weeks at computer-enhanced classroom.

Learning-Appropriate Goals

Technology especially multimedia and Internet has been changing and growing very rapidly. In order to avoid “doing without understanding” and to foster focused inquiry, three interrelated and graduated “learning-appropriate” goals were developed for the class: 1). Search and evaluate Internet educational
resources; 2). Structure Internet inquiry activities via multimedia tool; 3). Design and develop educational web. These goals helped students reflect on the technology integration, and helped them direct their learning. Furthermore, students were willing to learn how to achieve these goals since they could make easy connection between what they were learning and what they were going to apply in the real world. Specifically, students were required to complete three projects to reach these three learning goals:

1. The educational web sites evaluation report (the first goal)
2. The inquire-oriented multimedia WebQuest project (the second goal)
3. The web-based educational portfolio or educational project (the third goal)

These projects were enhanced each other in contexts and skills and balanced the difficulty of implementation.

Scaffolds Before Initiating Projects

Most students entered the course either with little exposure to multimedia and Internet applications or with limited skills and understandings needed to integrate technology into their teaching and learning. Previous research indicated that it is crucial to create a foundation of necessary concepts and skills for hands-on program (Yang, Shindler, and Keen, 2000). To initiate each of three projects, instructor started with a simulated problem in the form of linear or open-ended project. This scaffolding served two ends: the first end was to share the related concepts/knowledge and particular technological skill that students needed to prepare their undertaking actual projects; the second end was to help student reflect and discuss the possibilities for extending the ideas and technologies into real world projects. For example, after students applied search strategies and educational web evaluation standards to complete their educational web review report project, instructor challenged students by asking how to implement the relevant Internet resources into curriculum and lesson plans, and how to engage learners in “active” involvement with those Internet resources. To seek the answers, Instructor initiated and developed a multimedia slide show “What developing multimedia presentation, the Web Quest -- an inquiry-oriented activity in which some or all of the information that learners interact with comes from resources on the Internet was introduced, six attributes of the Web Quest (introduction, task, process, resources, evaluation, conclusion) were discussed, and multimedia application components were demonstrated. Following the open-ended scaffolding, students were teamed into groups. They began their WebQuest projects on the more flexible levels of skills, understanding, and complexity. The instructor mainly staged in the role of resource providing “just-in-time” suggestions/guidance on the aspects of contexts and technical parts.

Opportunities for Formative Self-Assessment and Revision

Formative self-assessment is one of the most effective ways that promote the quality of the project-based learning. Through formative self-assessment, students get opportunities to see how they are doing and to revise their learning processes as necessary (Barron et al., 1998). The instructor facilitated formative assessment by taking two approaches. Internally, students were working on each common project – web review, WebQuest, and web based educational portfolio or educational project at the same period of time in the same computer classroom. With this common ground, students were encouraged to make communication in the process of completing projects. They were actively sharing the ideas and solution strategies that might be insightful to revise their projects. Externally, the instructor supported the assessment and revision process by providing content related resources links on the class web site (http://www.oswego.edu/~hyang2/edu). These resources allowed students to compare their projects with projects generated by others around the country who have been working on similar ideas.

Developing Social Structures That Promote Participation and a Sense of Agency

There are many ways to establish active, reflective learning. Allocating time for students to present their ideas, methods, and products is one of the most powerful ways. This is essential not only at the conclusion of a project, but also as the project grows. Presenting projects is an authentic activity that provides an enormous motivation for students (Wheatley, 1991; Grabe & Grabe, 1998). According to Barron and the Cognition and Technology Group at Vanderbilt (1998), “presentations, coupled with authentic outcomes and fairly explicit criteria for what counts as a good plan, can provide a strong
incentive to prepare and revise" (p. 286). For this study, when each project was done, the instructor required students to present their products in front of the class. Class interactions and classmates' reviews were generated during and after the presentations. In addition, after the class presentations, students' projects have been published in the class web site for students' future reference and other classes' access (http://www.oswego.edu/~hyang2/edu/studentproject.htm).

Findings

Findings from final written reports reflected positive student reactions in project-based learning. Following are three major positive effects:

- The usefulness of extended learning. Students addressed that interrelated learning-appropriated goals, authentic projects, and interactive learning atmosphere made them emerging as active, engaged learners. One student wrote: "I think the process of web resource research and review to the ultimate creation of the web made sense. We layered on our skills with each new project using the newly learned skill by applying it to the next level... The decision to work in a team helped me achieve my goal of learning, while my partner and I brainstormed to accomplish tasks. Being able to work together took the anxiety out of the way, so learning could be primary. Additionally, after projects were presented the class was able to discuss and with that we learned more."

- The effectiveness of production. Most students indicated that working on their own real and related projects made their understanding deeper than simply "doing and missing". One student addressed: "I was pleasantly surprised and amazed on how knowledgeable my colleagues are within their own content area. I was very impressed on the quality of work that was given to you by your students just in six weeks. To have this information at one's fingertips would be invaluable. Not only is this information good within the content area, but also it would be great to have to share it with other teachers outside my content area. I would like to share this kind of information with teachers who do not use these techniques, and show them that it can be done very easily with a little time and dedication. These new techniques could revitalize some teachers' careers and make the classroom enjoyable again."

- The proficiency of technology integration. Written reports from students showed that by experiencing project-based learning, students knew how to locate, evaluate, and use information and technology effectively. One student reported: "I know that we may only touch the part of multimedia presentation, WebQuest usage and website design. But I'm comfortable enough to continue to explore the possibilities of becoming more proficient with these technologies. I loved what I learned; my challenge is how to incorporate them into my content area. I think integrating technology into the classroom is very important and now I have some good ways to build a curriculum upon and become a more successful teacher."

Creating a Web-Based Curriculum Tool:
Helping K-12 Teachers Harness the Potential of the World Wide Web

Lisa A. Heaton, heaton@marshall.edu
Marshall University Graduate College, USA,

Kurt Stemhagen, krs2r@virginia.edu
Curry School of Education, University of Virginia, USA,

Abstract: The World Wide Web offers a great deal of potential for enriching the teaching and learning experience in the K-12 classroom. In many cases, however, teachers lack the time and skills to locate resources on their own. What can be done to help teachers and students take better advantage of the Web? Using the Algebra Resource Center (ARC) as an example, this paper will describe three areas of focus that can improve the effectiveness of sites designed as content area portals for classroom teachers-filtering, organizing, and correlating content to state standards; providing "real world" context for exploring content; and working to build a community of new and returning users.

Introduction

Resources available through the World Wide Web offer great potential for enriching the teaching and learning experience. A question we might want to ask, however, is—why has this potential not turned into reality? A recent Business Week Online article (Symonds, 2000) indicates that “Schools have rushed to buy computers and plug into the Net, but most students still don’t use the Web much and most teachers don’t either.” The article indicates that about 16% of teachers use the Internet as a resource for developing lessons and around 30% require students to use the Internet for research. Articles by Hoff (1999), Roschelle and Pea (1999), and Trotter (1999) all indicate that teachers need help locating resources, developing technology integration ideas, and improving their skills with technology in general.

What can be done to help teachers and students take better advantage of existing web-based content? Offering the Algebra Resource Center (ARC) as example, we will explore three functions that portals developed for K-12 teachers can serve. While the ARC website focuses on resources for Algebra I teachers and students, the concepts discussed here—filtering, providing context, and building community—are relevant to any content area.

Making the Web More Accessible

Filtering. One of the primary services provided by ARC is locating relevant resources and organizing the results in an accessible format. With the rapid growth of the Internet (over a million new web pages per day by some estimates) searching for relevant information and sifting through the results is an increasingly difficult task. The literature, and our own experience, indicates that teachers do not have time, and often lack the technology skills (Hoff, 1999; Roschelle & Pea, 1999; Symonds, 2000; Trotter, 1999), required to wade through the nearly infinite quantity of information available on the Web for any given subject.

Mindful of the limited time that teachers have to spend sorting through resources, ARC staff members work to locate and organize resources into user-friendly, cross-referenced categories (including a state standards index, topical index, interactive sites, homework help sites for students, and professional resources for teachers). Within each category website links are accompanied by brief descriptions that provide teachers with the information needed to determine whether a certain link or part of the site will be useful to them. Users of ARC have responded well to this approach. Related to the use of website descriptions, a user commented, “Otherwise you are on the computer all the time looking at what it’s about, but if somebody has done that for you it’s going to save time.” Another user spoke thought into it than other people have...like in the activities section you say that ‘this could be tied in here.’ It eliminates a lot that isn’t useful to teachers.”

Providing Context. With the Web, teachers and students have access to more information than ever. While there are a variety of education specific sites that provide activities and lesson ideas, what makes the Web increasingly beneficial is the potential for bringing “real life” applications of content into the classroom. A major challenge for teachers, regardless of content area, is helping students recognize the relevance of what they are
learning. While the standards movement has helped clarify what should be taught, it has at times led to the teaching of isolated components at the expense of application—breaking the curriculum down into small parts or skills to be mastered.

One of ARC's primary objectives is to provide resources and instructional ideas that will allow students and teachers to explore algebra concepts in the context of “real world” situations. The massive amount of data available online, for example, is a primary candidate for exploring everyday needs for using algebraic concepts like graphing, working with matrices, or solving equations. Students can access up-to-date sports statistics and see the equation for calculating a quarterback rating in football. An online source for Hollywood box office data can be the starting point for exploring the usefulness of matrices, and the results of this exercise can be represented graphically. Users also indicate that this approach is helpful “to get the student out of the daily book routine,” and have found the inclusion of sites like the one for “Major League Baseball” as “a good place for finding statistics.” The possibilities are virtually endless.

Building Community. In the process of developing, revising, and updating ARC we have spent a considerable amount of time sharing the website with teachers throughout the state. Early in the development process a teacher asked, “How are you going to let everyone know that it’s there? How are you going to get all the algebra teachers in Virginia to find out about this?” ARC staff quickly recognized that simply putting the site online would not be enough to attract new users and keep them coming back.

Since going online in early February 1999, building community has become a much greater focus for ARC staff. Teachers need to know that the site is out there and many need some degree of assistance getting started. During the past eight months we have been spreading the word about ARC through informational brochures, school district newsletters, focus group discussions, and regional conference presentations.

Feedback has been positive, and the site is growing. A summer workshop attendee wrote, “I enjoyed the workshop we attended because it made me sit down with someone who could help me get through some of my computer difficulties. I have visited this site before but never for more than 5 min. Today, I finally realized what a wealth of resources are not only available but categorized for our use. What a time saver.”

Our interest in building community goes beyond our efforts to build an audience. We also want to get teachers actively involved. There is no better source of instructional ideas for a given content area than the teachers of that subject. This simple but powerful notion is at the core of our hope that ARC will be able to serve as a valuable communication tool for sharing and interaction of and between the state’s Algebra I teachers. While we are encouraged by the site’s use by teachers in search of useful curriculum augmentation, we have hopes that the site will become more of an electronic meeting place where teachers will come to interact with their colleagues. Our online discussion forum is the starting point toward our vision of ARC as a true community of practice for the state’s Algebra I teachers.

Conclusion

It is our belief that ARC has helped make the World Wide Web more convenient and useful for Algebra I teachers. While we are excited about the site's contributions to Algebra I pedagogy, it is the generalizability of ARC's three-pronged focus that we hope might influence website design/construction in other content areas. Our efforts support the notion that web-based curriculum tools employing the three functions highlighted in this presentation—filtering and organizing content-specific resources, providing "real world" context for exploring content, and building a community of users—can be valuable assets for classroom teachers.

Virtual Learning Center: Online Tools Support In-class Teaching

Barbara K. Iverson, New Media Journalism
Janell Baxter, Interactive Multimedia
Columbia College Chicago
E-mail: Barbara K. Iverson biverson@popmail.colum.edu
Janell Baxter: key@mc.net

Abstract: This interactive session presents "old teaching techniques in new packages." It presents an approach to transforming teaching activities, which is economical and does not require too much extra time on the teacher's part. Exceptions in the world of modern faculty development in technology use and application. It demonstrates how teachers can create a Virtual Learning Community of online tools and resources to provide an electronic infrastructure to support their in-class teaching. This Virtual Learning Community can be used by elementary, secondary and post-secondary teachers, as well as teacher educators to transform traditional teaching practices into more effective "asynchronous" online activities, that frees up valuable class time for higher order cognitive activities and for social learning experiences. The tools we demonstrate are low-cost, free, or widely available already in schools, so our Virtual Learning Communities approach can be implemented in almost any teaching setting by any teacher who uses email and the Internet on their own. This is a practical, no-frills approach to modernizing your teaching.

Support that makes sense without expending lots of dollars

We have used and taught faculty how to use a variety of software and hardware and telecommunications tools over the years. In the early days of personal computing, networking, Internet, and telecommunications, just having faculty who had seen or used individual software or hardware tools was an important goal of faculty development. What we have observed, is just as the level of computer experience and the baseline competencies of incoming students rises over time, with increased access to these tools in school and at home, and more effective integration of these tools into teaching especially in the elementary and high schools, so the average competency of teachers as computer users is increasing.

We have also observed that teaching faculty how to use complex software, such as Director, or Dreamweaver, takes more than just the hours of a workshop. Faculty who attend software workshops, but then do have the time and opportunity to continue to use and practice and learn the software, are unable to put their workshop knowledge to use in practical ways that assist them in their teaching. This can be frustrating for the faculty and counterproductive for schools and institutions that are seeking to provide opportunities for faculty development.

However, if our faculty development efforts step back from the cutting edge of technology, and revisit our roots in pedagogical practices and what we know about "what works" in teaching, we can provide effective faculty development that will allow the integration of technology into typical classrooms quickly and effectively.

Thus in our work in faculty development and technology, we now combine simple, widely used tools, like email, and Internet browsing or, in new ways that make what teachers have always done (assign homework, give students individualized feedback, make interesting assignments) more effective. We call our idea of how to use and apply the tools creating a Virtual Learning Community (VLC.) The VLC is a set of tools that create an online infrastructure that supports a teacher and the students in a traditional classroom. It can be adapted to classes with no in-class access to computers and to those that meet in computer labs. It has been our aim to look for tools that are low-cost, free, or readily available for other purposes to make the parts of the VLC. This way, we provide faculty with the means to transform several time-honored pedagogical practices into new forms that
make use of what computers and digital technology do best, and thus free up important in-class, "face time" with students so that teachers can engage in higher order cognitive activities with their students.

Why this Works

Time on task is the strongest predictor of student achievement. If teachers can monitor homework and out of class time more effectively with online technologies than was possible previously, they can gain more "face time" with students to pursue higher order learning. Student motivation, another predictor of achievement, increases with the perception that the teacher is interested in work completed between classes, and is maintaining contact with them out of class. The faster we can provide feedback to students about their learning, the more effective that feedback is. The techniques we demonstrate in this interactive session are easy to learn, can be done with inexpensive software tools, and allow teachers to create an online infrastructure to transform the way they teach by transforming the way time is spent on class activities in and out of class. The tools simply update time-honored teacher practices for the 21st century. It is the ubiquity and ease of use of the Internet and its tools that will bring educational ideas about how computers can assist learning into the mainstream in ways that previous incarnations of CAI were unable to do.

Integrating several telecommunication features into what we call a Virtual Learning Center, teachers can monitor lower order cognitive learning during out of class time, and thus free up more "face time" in the classroom to pursue higher order activities. Scoring and grading can be done immediately, and students can see how they did without waiting until the teacher wades through all the work to be graded. Assessment of higher order learning, which is more complex and requires the teacher, gets more time, because time-consuming lower-order assessment can be done via the online infrastructure. We unify the use of email lists, online forms (mail-in types and automatic feedback types), and simple teacher-created web assignments (from annotated HTML bookmarks)

What You See is What you Learn

In our interactive session we will demonstrate several of our techniques. We sill show how to use email to keep students involved in class between class sessions, how to create online assignments that make students' use of the Internet an effective learning experience (not just a surf session) and how to create online forms to collect reflective student responses. Additionally, participants can view demos of tools they can easily use (in terms of their own skills, and in terms of being able to afford these tools) to see how to create online self-evaluations that provide students with corrective feedback and how to create quizzes and tests that are scored and graded automatically, as well as variations of these techniques.

Most of the tools we use are free, low-cost or at least readily available to educators (e.g. Netscape Composer, MS Office, www.discovery.com teacher tools) and we focus on how to use technology to speed up things like scoring tests, so more time can be spent on learning activities. None of the techniques or tools that we present are original to us. That is the beauty of our Virtual Learning Communities. These are not new ideas that need to be tested. These are applications from technology to solve problems and speedup bottlenecks that have existed and impeded common teaching activities in ways that have been viewed as endemic.

Educational critics often say that a doctor from 100 years ago would not recognize a modern operating room, but a teacher of 100 years ago would feel right at home in the modern classroom. The introduction of networking and computer technologies began the transformation of the classroom in the same way that the operating room has been transformed. In order to continue that transformation, we need to enable teachers to perform simple, basic, teaching activities in new ways, enhanced by technology. This interactive workshop will demonstrate how to do this, and set many attendees on the right track to transform their own classroom or school for our new century.

We can help you if you are...
The audience for this interactive session can consist of teachers and administrators who routinely use email and the Internet outside of their direct teaching activities. This session is not designed for teachers with no Internet experience, or those who have created extensive websites or developed online classes. Teacher Educators should find this an interesting and exciting session, provided they have the prerequisite skills.

The learning objectives of the interactive session are that participants will be able to create email lists for their classes and compare and contrast the use of this kind of email with listserv and one-on-one email. Participants will be able to describe the community building aspects of this tool. Participants will be able to create, reorganize, and use bookmarks (favorites) to create interactive, active assignments for their students. Participants will understand how the vision of Vannevar Bush underlies this tool, and its importance in modern academe. Participants will be able to create an online form in several ways (using hosted tools or a word processor or an HTML authoring program to create the form.) Participants will understand the difference between "post" forms that have their contents returned as email, and forms processed via CGI and other applications that return data that has been graded or evaluated to the form creator.

The software used in this interactive session is Netscape and Netscape Composer, teacher tools from several online sites, such as: (http://school.discovery.com/quizcenter/info/userguide.html), Microsoft Office, and Dreamweaver. Prior to the interactive session, we will provide an example of a Virtual Learning Community, to support the Interactive Session and as a resource for the participants. You can view supportive materials about the theories underlying our work, and Virtual Learning Communities at http://acweb.colum.edu/users/biverson/fipse

USING AN ELECTRONIC DISCUSSION BOARD TO SUPPLEMENT CLASSROOM SESSIONS WITH POST GRADUATE TEACHER EDUCATION STUDENTS

DONALD JOYCE, CAROLYN NODDER AND ALISON YOUNG
UNITEC INSTITUTE OF TECHNOLOGY
AUCKLAND
NEW ZEALAND
DJOYCE@UNITEC.AC.NZ
CNODDER@UNITEC.AC.NZ
AYOUNG@UNITEC.AC.NZ
ABSTRACT
When the postgraduate computer education programme at UNITEC Institute of Technology was developed it was considered essential that it be accessible to students in full time employment. Consequently all classes are held at weekends and Blackboard Course Info is used to facilitate student-student and student-teacher interactions between classes. This paper outlines the structure of the programme, profiles the students, explains the approach taken by the lecturers, and reviews the learning experiences of staff and students in three classes.

Keywords
Postgraduate computer education programme, electronic learning support, student evaluations.

1. THE PROGRAMME
The postgraduate computer education programme at UNITEC Institute of Technology was approved by the New Zealand Qualifications Authority in December 1999 and classes began in February 2000. Students may complete a Postgraduate Diploma, consisting of two compulsory courses and six optional courses, in one year of full time study (or the equivalent part time). The Master's degree requires four compulsory courses, and either three optional courses and a thesis or seven optional courses and a dissertation; it may be completed in two years of full time study (or the equivalent part time). At present the optional courses focus on networks, instructional technology, interactive multimedia, and the Internet.

2. DELIVERY METHODS
To accommodate the needs of students in full-time employment, classes are held at weekends. Each course meets on four weekends, about a month apart, for four hours on Saturday and four hours on Sunday. The lecturers use a range of approaches, including lecturer presentations, student presentations, group work, electronic discussions and individual communications (by email, telephone or face-to-face). The students complete three assignments per course, some as individuals and some in groups. There are no final examinations.

3. THE COURSES
The first course under review is called The Impact Of Information Technology On Society (referred to as 801 below): it explores past, present and future impacts and ethical issues. It was anticipated that few students would have much experience of exploring social issues, which made it very important that they have plenty of opportunity to discuss ideas and situations, both in class and between classes. For that reason, the lecturers reminded the students at all class meetings to use the discussion board to supplement face to face interactions. The course ran twice (once in each semester) with very different student groups.

The second course under review is called Pedagogical Strategies for the Use of Information Technology (referred to as 817 below): it explores how information technology may best be used in teaching and learning. Most of the students in 817 had been in the first semester 801 class. One of the three lecturers is the 801 course
coordinator, another is based in Melbourne and flies over for three of the four weekends.

4. THE STUDENTS
In the first semester 801 class, the 16 students included five computing practitioners, five tertiary teachers, two secondary teachers, two technical support staff, a librarian and a sales representative. Four of them already had postgraduate qualifications, another five had bachelor's degrees, a further five had diplomas at various levels and the remaining two had extensive credits towards bachelor's degrees. All had significant practical computing experience (from six to 20 years) and all but two had English as their first language.

The second semester 801 class consists of 32 students whose first language is not English. Eight students already have postgraduate qualifications, one has an undergraduate diploma and the remaining 23 have bachelor's degrees, mainly in science or engineering. Not many had more than three years practical computing experience.

The 817 class consists of four secondary teachers, three tertiary teachers and a computing practitioner. Three of them already have master's degrees, another three have bachelor's degrees, and the remaining two have diplomas. All but one have English as their first language.

5. THE 801 DISCUSSION BOARD IN SEMESTER 1
Two weeks before the first weekend meeting, the discussion board was initiated and students were invited to give some personal background and explain their interest in the course. Six students responded before the first weekend and seven more followed shortly after. Over the 20 weeks of the course active participation in the discussion board varied greatly (we can only speculate about the activities of "lurkers" - students who followed the discussions, but did not contribute).

Altogether 172 student contributions were made (an average of 11 per student). Some contributions were very brief (for example, asking for a definition, giving a URL or acknowledging a response) and some were quite extensive (for example, arguing a case or recounting an anecdote). The most active contributor (38 postings) was a computing practitioner with 22 years of experience. The next (25 postings) was a librarian. Only one student, a member of UNITEC's IT support staff, did not contribute at all. The biggest occupational group consisted of teachers (5 tertiary and 2 secondary), who might have been expected to be major contributors. In the event their contributions ranged from one posting to 15. A further 14 postings were made by the lecturer.

6. THE 801 DISCUSSION BOARD IN SEMESTER 2
Altogether 128 student contributions were made (an average of four per student). The most active contributors (a computing practitioner from India and a recent graduate from Sri Lanka) made 13 postings each and three students did not contribute at all. A further 26 postings were made by the lecturer. When compared to the first semester course, the student contributions tended to be briefer (which may reflect the language skills of the students) and the lecturer tended to respond twice as often.
7. THE 817 DISCUSSION BOARD
Altogether 101 student contributions were made (an average of 13 per student). The most active contributors (a computing practitioner and a tertiary teacher) made 30 and 29 postings respectively and one student (a secondary teacher) did not contribute at all. A further 29 postings were made by the three lecturers. When compared to the 801 classes, the contributions tended to be longer (which may reflect the language skills of the students and the nature of the subject matter) and the lecturers tended to respond more often (particularly the lecturer who only sees the students at weekends).

8. STUDENT EVALUATIONS
At the end of the first semester 801 course the students were asked to rate the usefulness of the different components of the course. When their responses were combined, scoring 1 for "not at all useful", 2 for "not very useful", 3 for "quite useful" and 4 for "very useful", the following ranking emerged:

3.8 whole class activities
3.5 assignments / internet / newspapers / clippings
3.4 journals
3.2 group work
3.1 books
2.8 discussion board / survey analysis
2.7 survey construction

It seems clear that this group of students valued their classroom interactions and various forms of print and electronic resources more highly than the electronic discussions. Comments about what they liked best included:
"Discussions - expertise of lecturer and participants"
"Group discussions and participatory nature of the course"

At the end of the second semester 801 course, more student evaluations were conducted with the following results:

3.7 internet
3.1 assignments
2.7 newspapers / clippings / journals
2.5 whole class activities
2.3 discussion board
2.2 books
2.0 group work / survey analysis

Whole class activities and group work with this class were not as lively and effective as they were with the semester 1 class (possibly because of language), so it is not surprising that they were rated lower. On the other hand, the semester 2 class rated the internet well above other resources, and it was the only component that they rated higher than the semester 1 class did.

9. CONCLUSIONS
Given that the students were busy people (many of them in full time employment), who only met as a group on eight occasions and were otherwise widely dispersed, the discussion board proved helpful in maintaining student-to-student communication between class meetings. The lecturers also used Blackboard Course Info to make electronic announcements (an average of one a week) to keep students informed (about logistics, resources and deadlines) and give general feedback about assignments. However it is clear from the student ratings and comments that they enjoyed meeting face to face and saw the electronic components of the course only as a useful support and supplement.
PREPARING TEACHERS TO COMPLEMENT MIDDLE-SCHOOL CURRICULA WITH WEB-BASED ENVIRONMENTAL HEALTH RESOURCES

W. R. (Bill) Klemm, Professor of Neuroscience
Texas A&M University, Mail Stop 4458
College Station, TX 77843-4458
E-mail: wklemm@cvm.tamu.edu

ABSTRACT

The College of Veterinary Medicine at Texas A&M University has teamed with the Center for Rural Public Health and the College of Education to develop science curriculum and teacher training for middle-schools in rural and under-served parts of Texas. Our approach is to use the World Wide Web to provide environmental health information at a middle-school level and to train teachers to complement their regular teaching with the information, learning activities, and experiments developed by our scientists. The curriculum receives on-going evaluation and revision. The program also includes in-class visits by scientists to the schools.

Completed to date are Web sites on Cell Biology, Environmental Hazards, and Water Quality. Under development are sites on Organism-level Biology and Hazard Properties, Assessment, and Remediation. Each module provides didactic information and hands-on activities for the students and extensive "teacher pages" that include lesson plan, explanation of learning activities, Internet tools for the teacher, and identification of the state learning objectives that are addressed. The Web site URL is: http://peer.tamu.edu

We will build on this life science core with a seven-year program to create Web modules that can help integrate environmental health science into all middle-school teaching, which in Texas includes economics, English, general science, geography, government, and history, in addition to math and science.

Supported by National Institute of Environmental Health Sciences grants ES 10443 and ES 10735.

RATIONALE FOR THE PROGRAM

Although Texas has received good reviews for its educational reform efforts, reform in Texas is complicated by the fact that it is such a large state with only a few major population centers. The school districts in Texas are spread over great distances and in many cases lack direct access to enriching educational opportunities that are available in large cities. Rural children in Texas encounter serious environmental health situations, but their schools are less likely than metropolitan schools to receive state-of-the-art instruction in environmental health. Enriching rural-school education via the World Wide Web seems to be an obvious and necessary need.

Educators commonly view middle school as a crucial stage in a child's education. In Texas, middle school is a turning point in the lives of rural children when they may either drop out of school or become motivated for a lifetime of
learning. Given the relatively poor performance of U.S. students in science, we believed it was appropriate to focus on science. But not science as it is usually taught, which is often perceived by students to be abstract, arcane, and just plain boring. In particular, we believe that students can become more interested in science if the relevance to their daily life were more evident, as is possible with environmental health issues.

Additionally, there is a great need in Texas for teacher training in science. Only in recent years have new teacher graduates in Texas been required to have an academic major in their teaching area. It is not uncommon to find science teachers in Texas who have no science background.

We also recognized the crucial requirement of cooperation and buy-in from teachers and administrators. Therefore, we arrange for teacher training in the science issues, provide scientist visits (when invited) to schools, have advisory panels of teachers and school administrators across the state, and consult with officials of the Texas Rural Systemic Initiative and the Texas Education Agency.

The Curriculum

Several key features characterize our approach:

- didactic material written by scientists in coordination with curriculum designers
- instruction tied to state-mandated learning standards
- experiments and other "hands-on" activities
- scientist visits to schools
- consultation from a panel of middle-school teachers
- a computer conferencing system that supports collaborative learning and interaction among students and with professors
- comparison of pre- and post-test scores for each given module as a measure of what has been learned
- on-going evaluation of revision of the program and instructional materials

Basic Life Science Curriculum

A three-year federal grant sponsors the development of instructional material for grades 6, 7, and 8. Materials must contribute to State learning standards, known as the Texas Essential Knowledge Standards. Figure 1 shows a concept diagram that is guiding the development of the modules.

Three modules have been completed (Water Quality, Cell Biology, and Environmental Hazards)(see peer.tamu.edu). The water quality module emphasizes a series of experiments on water quality. These are supported by giving commercial water quality test kits to the schools. The cost, over $300 per kit, is borne by the grant and donors. Students perform and evaluate measurements in the following lessons: Lesson 1: mass, fluid volumes, and concentrations. Lesson 2: temperature and its effects on water quality. Lesson 3: dissolved oxygen and its effects on water quality. Lesson 4: pH and its effects on water quality. Lesson 5: nitrates and their effects on water quality.
Protein Machinery" (protein synthesis and function), and "Code and Translate Instructions" (genetics). There is also an introductory lesson on "Levels of Organization" to put things in perspective. We attempt to teach these difficult topics at the middle-school level, and feedback from the teachers so far indicates that we might have succeeded. Each unit begins with a section of "How We Find Out," which explains in simple terms the kinds of observations and experiments scientists make to learn about the cell function under consideration. Then there is a section, "What We Know" that summarizes what we know about membranes, energy production, etc. Finally, there is a unit, "Why Does School children should be interested in knowing these things. Also associated with each unit are activities and experiments, short essays on common toxins that affect the cell function under consideration, and a short biography of a famous scientist, with emphasis on his/her childhood, who made major discoveries in the topic. In addition to pre- and post-quizzes, there are electronic flash-card questions using a new game-like system that we developed (Get Smart: www.foruminc.com/gctsmart).

The Environmental Hazards module has five units. One, a general introduction to environmental science, explains the flow of energy from the sun through the various levels of the food chain and covers carbon cycle, nitrogen cycle and water cycle. There is also a section on the relationship of exposure, toxicity, and risk in environmental hazards. A second unit explains the rules for food safety and identifies sources of food-borne illnesses and contaminants. The third unit common covers indoor air-borne illnesses and contaminants and teaches children about outdoor air-borne illnesses and contaminants. A fourth unit teaches about the skin, and helps children learn to minimize their exposure to pesticides and herbicides and to the sun's ultraviolet rays. There is also a section on parasites. The fifth unit emphasizes good nutrition and identifies health problems that can occur through poor nutrition. Each unit has an activity that is an electronic sleuth game, "Toxic Island," in which students must solve environmental health problems.
Modules now being developed include an extension of the Hazards instruction to include chemical properties of hazards, risk assessment, and remediation, and an organism-level module oriented around the theme of what kinds of things organisms must do to survive and thrive in this world.

**Integration of Life Science into All Middle School Instruction**

A second grant supports a new initiative to incorporate multi-media environmental health instruction into the teaching of English, social studies, math, and general science. We hope to work with TEAMS of teachers in local schools, with the science teacher acting as a focal point to assist the other teachers in the integration process.

This curriculum will be problem based. State tests indicate that critical thinking and problem solving are common areas of weakness. We plan to hire a professional writer to create a 20 min read story line, with child characters, as they go on an imaginary journey in time or to different geographical areas. Each stop along the way constitutes a new adventure in which the children are confronted with an environmental health problem. For example, one adventure now under development is at Luxor, Egypt, where the slaves who are building the pyramids suddenly come down with a sickness characterized by vomiting and diarrhea. The science teacher would help direct students to information on food safety, water quality, and infectious disease. The math teacher might develop exercises based on the geometry of pyramid building. The social studies teacher might deal with the geography of the Nile River basin, the politics of Pharaoh-dominated culture, and the life styles of Egyptian slaves. The English teacher might require additional reading or call for persuasive essays defending a particular view of the problem and its resolution.

These modules will include activities for testing, calculation, reading/writing, role playing, and development of problem-solving skills.

**TEACHER TRAINING**

Teachers receive training in several ways:

- **Summer Short Course.** We host a one-week intensive training session in the Summer. Teachers learn computer and Internet skills, meet the scientists and instructional designers, and learn and critique instructional materials. Teachers actually perform (and de-bug) the hands-on activities and experiments.

- **Internet Conferencing with Scientists.** Biographies of participating scientists are posted on the curriculum web site, and teachers can contact scientists for questions or suggestions. A Web-based, asynchronous conferencing system, FORUM, is being developed that will allow shared editing of Web pages and in-context annotation (see www.foruminc.com for current implementation).

- **Scientist Visits.** Informal exchanges occur during the scientist visits to local schools.

- **Teacher Pages on the Web site.** Each curricular module has a set of Teacher Pages that help explain the material and show how the materials can be used. Worksheets can be downloaded for students to use in reporting their activities and experiments.

- **Web-site Instructional Resources.** The peer.tamu.edu site contains various links to resources on Environmental Health Science Education for teachers and students. These web sites are packed with fact-based information and fun-filled curricula. There is also a link to the TrackStar site.
http://scrtcc.org/track enables teachers to create easy-to-use Web lessons and presentations or to use ready-to-go lessons created by other teachers. The PEER site also links to a collection of environmental health lessons that are created by the teachers who participate in our Summer workshop.

- Curriculum Evaluation Feedback. As feedback is received from the teachers, the feedback will be shared with everyone for general dialog and debate in the FORUM conferencing system.

mmontane@barcelona2004.org

Abstract: University- and school-based teacher educators, pre-service teachers, and educational researchers/learning scientists are seeking to develop thoughtful and effective uses of information and communication technologies (ICT) in networked classrooms across settings in Canada and elsewhere. At the micro level, they design creative, engaging, and productive online activities for collaborative learning and teaching purposes, ones increasingly focusing on knowledge building. At the meso level, they facilitate new adopters’ transition to networked classrooms; once technology is in place and working, the advancement of pedagogy tends to become the object of collaborative inquiry. At the macro level, the vision of interconnected learning communities is guiding the transformative process that is underway. Design principles that were found applicable across sites and levels, and which will guide participation in the Universal Forum of Cultures’ Educational Project (Barcelona, 2004), are presented.

Introduction

In 1994, the idea of computer-supported collaborative reflective practitioners inspired the design of a virtual community of support and communication for preservice teachers registered at a number of Canadian universities, located in Quebec City, Montreal, Toronto, and Vancouver. Ever since, participants have helped one another understand why and how information and communication technologies (ICT) may be used in thoughtful and effective ways. These driving questions are explored by different communities, in specific situations, and sharing research results between iterations. Communities of learners, communities of inquiry, communities of interpretation, and communities of practice all bring their contribution to the understanding of being-a-teacher-in-a-networked-world. Participants are student teachers, teachers, teacher educators, graduate students, and other educators from a number of schools, universities, and associations. This paper focuses on the design principles that were found relevant.

A Design Experiment

Our research takes place within emerging practices; we are not external observers of existing practices but, rather, we are co-engineers of practices—or “designs”—that constitute arrangements of processes, methods, and tools with which we experiment systematically (see Ann Brown’s concept of “design experiments” in Brown, 1992). As such, we seek to articulate an understanding of practices around learning, inquiry, and interpretation.

Situated learning (Lave and Wenger, 1991) is central to the concept of interconnected learning communities. Lave’s concept of “settings for action” (1988, p. 98), and its counterpart, “arenas of activity” helped structure the framework of inquiry: a setting is a process that occurs as the individual establishes a relation with a given arena—arenas for activity are public and durable, existing prior to individuals and, to a large extent, out of their control. The perspective adopted on the continuities and discontinuities in the dynamic
relations being established at each site and between sites built on Lave's notion of continuity of activity as an "active production of the reproduction of settings, activities, and selves (1988, p.187), and on that of legitimate peripheral participation (Lave & Wenger, 1991).

The online learning environments, such as Virtual-U, eGroups, WebCT, and Knowledge Forum, bring continuity within and between sites when the same tool is used. But philosophical approaches and teaching skills as well as cultural differences (school culture, university culture, Francophone/Anglophone cultures) are also at play. The posting of artefacts in online public places and invited virtual visitations allow communities using different tools to share interrogations, resources, and research results (e.g., incoming student teachers doing virtual visits of more advanced student cohorts' discussion forums (VGroups); inservice teachers from different schools reflecting on their practices (eGroups); collaborative knowledge building is demonstrated to interested participants from other sites (Knowledge Forum). That is to say that designs of use and social designs (e.g., graduating teachers staying connected after their undergraduate studies, graduate seminars involving participants from different sites) are found important for new continuities to emerge, and create density as far as classroom, school, and wider-system renewal are concerned. What happens when classrooms get networked? How do pre-service teachers, in-service teachers, school-based and university-based teachers interact within and between sites? The relations among people, activity(ies), including resources and tools, and situation(s), as seen through themes and patterns of connection, constitute a primary focus of theoretical interest (Laferrière, Bracewell, Breuleux, and Willinsky, 1997).

Another question being studied also using a design experiment approach (Brown, 1992) is the following one: What knowledge is to be transferred in order to prepare 21st century citizens? This question entails the technical, practical, and theoretical dimensions of learning to teach collaboratively, and learning to learn, in networked classrooms, schools, and wider systems.

**Inquiry and interpretation practices**

In the enduring contexts of their respective "communities of practice"—and in a movement to create extensions across the traditional boundaries of these practices—educators and learning scientists in the TeleLearning Professional Development School (TL-PDS) are able to design jointly a number of inquiry projects with a fundamental focus on the question: "How can we achieve the full range of sustainable learning and teaching experiences that are relevant to our knowledge society?". Around this inquiry goal, our communities of practice shift to communities of inquiry which include principally practicing educators, teacher educators, and learning scientists (educational researchers) engaged in discussions to cultivate a common discourse and a common knowledge base on **learning**—as a socially situated and governed constructive process—and on how "technology"—as a system that includes culture and knowledge—can help us achieve superior forms of learning. In the context of this community of inquiry, many activities can occur, one of them being to engage in deliberate interpretations: developing and documenting socio-technical processes to identify, capture, organize, and interpret moments from the networked K-12 classroom, where advanced pedagogies, collaborative knowledge building, and technology integration are combined into emerging practices and constitute the focal point of inquiry for the participants. For instance, a range of "recording" tools and shared interpretation spaces can empower teachers to engage in digital "story-telling" within an interpretive community to capture critical events from the circumstances of practice. Technically, this involves fairly common technologies: portable notebook computers, digital video camera, video-editing software, high-speed Internet access; shared web-site, collaborative knowledge building tools. Although these technologies are not "rocket science", for our design experiment it is important to validate their ecology, to articulate their practical alignment in an authentic practice.

The teachers in that setting engage in reflective acts where recording and gathering artefacts is critical to their inquiry goals, organizing them for sustained interpretation with others (resulting in multiple diverging or converging interpretations). Practitioners as well as researchers thus are signaling to each other their emerging practices and the questions they have about them in order to engage in a process of interpretation. It is essential to understand that this interpretive project is grounded in existing networked communities of practitioners and researchers, in relation of trust, sharing common inquiry goals (such as the educators and researchers in our TL-PDS). This community of interpretation is a community whose actions are essentially about sharing
experiences, making sense from the "text"1 of experiences, and where research knowledge is brought to bear. This activity is at the intersection of, on the one hand, narrative-based reflective practice and, on the other hand, "case-studies" or case-based learning. The "story telling" is supported by digital media, the interpretation is using varied online synchronous and asynchronous tools for collaborative knowledge building. Examples of inquiries go from questions of classroom management solutions to support project-based learning in a laptop classroom, to questions about fostering specific understandings in middle-school science with the use of visualization tools, to what constitutes evidence of knowledge building. Thus, we are engineering different socio-technical designs and exploring them, in practice, in order to shape a successful "reflective practice" that takes advantage of current affordances in digital media, shared representations, and collaborative knowledge building.

A Collaborative R & D Process

Higher-thinking and social skills are associated with advanced uses of learning technologies in the classroom (Bracewell, Laferrière, Breuleux, Benoit, & Abdous, 1998). However, the networked classroom means different things to different people. For some it may mean one networked computer and a LCD projector in front of the classroom for the teacher to enhance his or her lectures. For others it may be a classroom whose members have high access to the network (intranet and/or Internet) in and/or out of its walls.

As teacher educators know, workplace contexts affect pre-service and beginning teachers' representations of their role as teachers. For instance, although on campus they may be exploring alternatives to the transmission model of teaching, a traditional school setting is likely to have a decisive influence on their behavior as student-teachers, or as beginning teachers.

The following twelve (12) design principles have progressively been found relevant for designing activities that advance the practice of teaching, and the practice of learning, in networked classrooms:

- **Ease of access.** Networked computers and online resources and tools need to be accessible without loosing too much time once basic technical skills are mastered.

- **Co-constitutionality.** The development of a socio-technical infrastructure relies first on electronic connectivity on the one hand, and on people who value collaborative learning and knowledge on the other.

- **Participatory design.** The development of networking capacity involves university-school administrators (partnerships), university- and school-based teacher educators, in-service/pre-service teachers, and K-12 learners.

- **Local grounding.** Site-based professional learning communities provide grounding. Three were established (TACT, McGill TL-PDS Net, CITE), and connected to the Knowledge Society Network (KSN). Their locus of collaborative inquiry is the networked classroom.

- **Active collaborative learning.** The networked classroom fosters active collaborative learning, rather than individual learning where students/pupils work on computers learning rote knowledge and specific skills.

- **Multi-modal social interactions.** At a local level, learners meet face-to-face, on campus or at the professional development school. Learners also meet online, pursuing locally grounded activities or geographically extended activities. See http://www.telelearning-pds.org

- **The classroom as-a-community of learners.** K-12 learners as well as pre-service and in-service teachers are learning in networked classrooms designed to become centers of inquiry

---

1 the notion of "text" is here expanded to include complex digital representations and artefacts used to convey rich stories, narratives and explanations.
where people, things, and ideas are valued, and where teaching for understanding is a common goal.

- **Diversity.** Learning communities are different in their local champions, circumstances, settings, tools, artefacts, cultures, and languages (English, French and, soon, Catalan/Spanish).

- **Progressive distributed expertise.** Virtual collaborative spaces provide opportunities to share resources and expertise to solve complex and ill-structured problems.

- **Collaborative reflective teaching.** The design task is that of providing a collaborative learning environment within which problem-setting and problem-solving are carried out in relation to real classroom events.

- **Collaborative knowledge building.** This refers to the design of a rich learning context within which meaning can be negotiated and ways of understanding can emerge and evolve. Student teachers engage in designing and inventing tasks such as the organization of the networked classroom, the development of learning projects, the scaffolding of online group or classroom conversations, and the creation of case studies.

- **Interrelatedness.** Knowledge objects, events, actors, artefacts, and authors interconnect in ways that add continuity and integration to student teachers' experience as they learn to teach in networked classrooms. They add as well to the experience of practitioners' working in networked classrooms.

The design experiment is now entering a phase where issues of leadership are crucial. We are examining leadership practices that support the participation of teachers in on-line learning communities, how leaders can develop their own learning communities, and how teachers can become leaders in their school or school board related to the use of ICTs to support advanced pedagogies such as collaborative knowledge-building.

The Universal Forum of Cultures, to be held in Barcelona in 2004, provides a rare opportunity for educators to raise their sight, express their humanistic values, and exercise leadership around a productive, constructive set of activities with the aim of realizing the vision and of learning from that realization. Working and thinking together, all participating countries' educators, governments, business leaders and community groups are capable - with the present knowledge, resources and technology - of creating a community, a family of educators, with a common concern for building their education system's capacity in using information and communication technologies (ICT) properly in and out of the school classroom.

**From Networked Classrooms to Interconnected Learning Communities**

Electronic linkages and associated production instruments (e.g., email, web-page construction, online discussions, online data bases), constitute a powerful vector for learners to exercise the full range of democratic rights, to build and share their understandings with others so that the resulting knowledge is deeper and more robust, to make visible to themselves and to others the wealth of their cultures in ways that allow dialogues and exchanges. Thus, the leadership strategy adopted in coordinating the theme on technology of the Education Project [http://www.barcelona2004.org/corporativa/proyecte-educatiu/index-es.htm](http://www.barcelona2004.org/corporativa/proyecte-educatiu/index-es.htm), builds mostly on this dialogic perspective on new media and information technologies in learning communities, where access inside the community to resources from outside is at the same time allowing the possibility of production from within to the outside and, therefore, stimulates the engagement in responses, dialogues, exchanges, explanations, and the construction of new objects.

Abstract:
Online course delivery is a popular topic in educational circles today. However, little guidance is available in an introductory manner that facilitates the actual development of such courses. In this article, we will provide a systematic approach to developing online courses that will enable beginners to plan and implement an online learning experience. The framework we present involves answering a set of questions that relate to the following domains: learning, teaching, technology, design, support, management, and quality.

Introduction
Online course delivery is a popular topic in educational circles today. However, little guidance is available in an introductory manner that facilitates the actual development of such courses. In this article, we will provide a systematic approach to developing an online course that will enable beginners to plan and implement an online learning experience.

Online course delivery has become a priority at our institution, The Metropolitan State College of Denver. When the college first started putting courses online, many were developed without much thought to design and how to address student learning in the online environment. Over the past five years, however, we've learned many things about online learning and how to provide effective instruction in an online environment.

We believe the key is knowing what to consider when deciding to convert or develop a course for online delivery. A framework we use involves answering a set of questions. These questions relate to the following seven domains: learning, teaching, technology, design, support, management, and quality.

Learning
What kind of course is it? What do your students do? What do you want them to learn? What kind of investment are you looking at in terms of course materials? What performance-based expectations do you have of your students? What are you expecting your students to be able to do at the end of the course? What are the materials and activities you need to have in place to achieve these outcomes? How can these skills be taught in an online environment?

An important consideration in the development of online curriculum is determining the appropriateness of a course for this method of delivery. Consider, does the context of the course deal with a well-defined domain of knowledge, an ill-defined domain of knowledge, or a combination? Each has its own uniqueness and constraints, which will need to be addressed specifically for the online environment.

Teaching
In looking at the content you will be providing in your class, what types of materials do you want to use? Are they text-based such as textbooks or handouts? Are they visual-based such as pictures, photos, slides, graphics, or animations? Are they audio-based such as cassette tapes and sound or music files? Are they multimedia-based such as PowerPoint presentations, films, videos, or software? What materials do you expect the students to have access to?

You also need to consider the types of skills and content mastery that you are trying to achieve. How can you provide for students, in an online learning environment, the experiences they need to meet the desired objectives?
Can you create in an online learning environment a scenario where students can achieve at least equal to, or more than, what can be achieved in a traditional classroom?

**Technology**

Based on the teaching and learning that you want to occur, does the technology at your disposal and accessible to your students, have the capability to fulfill your expectations? In today’s cyberspace reality, there are still subtle differences in computer systems, browsers, plug-ins, and reader software. Let alone, the obvious factors of Internet connection speeds and web server stability and delivery. What are the current limitations? Is your web server supported directly by the institution, a third-party, or is it out-sourced to a vendor? What are the capabilities of the system? What resources do you have at your disposal to develop the course? What is your skill level in using these resources? Does your institution provide training?

Given these considerations, what activities, materials, and resources can you provide your students so that they can meet your instructional goals and intended outcomes? In determining this, think outside of the box. How can you teach traditional skills in a non-traditional manner? For example, lecture in the classroom can be transformed to an audio- or video-streamed lecture online. Class discussion can be accomplished through chat rooms, forums, or white boards in an online environment. Cooperative learning projects and presentations that might typically occur in a classroom situation can be uploaded and made available to students in a common workspace area on the web server.

**Design**

Are you aware of the design elements that are critical in online instruction? Do you know how to implement the principles of visual design for maximum effectiveness? Are you aware of signs or symbols that may not be recognized, understood, or misunderstood? Are your links clearly labeled and do they serve an easily identified purpose? Is the course and its elements sequenced logically and in such a manner that scaffolds learning? Are the screens laid out in a manner where it is easy for the students to see their options and make decisions about how to navigate the course?

From a usability perspective, does the site function and operate effectively for students? Is the course designed to use bandwidth efficiently? Does the site take into account accessibility issues? What kinds of adaptations might be necessary for students with special needs?

Finally, does the course promote interactivity? While interactivity in an online course may be thought of as only occurring between instructor and student, you may want to think about how you can integrate and support interactivity between students. Including opportunities for collaboration on group discussions or projects promotes a sense of community that mitigates feelings of isolation. We have found in our experience, it is important that students feel that they are part of an extended community.

**Support**

In what manner is online instruction valued and supported by your institution? This includes both faculty support for development and implementation, and student support for orientation and access. Is the delivery system under your institution’s control or a vendor’s control? Do you have access to your course materials and email off campus? What procedures are in place for updating course materials? Can you directly update your course materials or do you have to forward changes to be uploaded by another party? Are you expected to provide technology support for your students or is there another resource available on campus or through a vendor? Does the course provide links to online resources? Are links provided where particular software or plug-ins must be downloaded? Where appropriate, are examples of previous student work made available as models? We have found that by providing a frequently asked questions page we can defer many of the common and repeated questions that come via email.

**Management**

Can you handle communications with students that you never see? Are you able to communicate clearly, difficult concepts, procedures, and thoughts in a format other than face-to-face? Are you willing to give the time necessary to receive and respond to emails and voice mails? Are you capable of providing your students with timely feedback concerning their performance? Are your time management skills such that you will be able to proceduralize your classes in a 24/7 learning environment? (We’re not kidding.) Are you able to monitor individual student activity within the course, by tracking course logins, time online, and individual web page access? Does the course have a
mechanism in which a learner can be fairly and accurately measured? What evaluation methods are possible, given the constraints of your delivery system? Have you considered performance-based evaluation measures rather than criteria-based assessments?

Quality
Does the course provide clear expectations of what the student is required to do? Does the course reflect best practices concerning design, accuracy, consistency, and usability? Are you prepared to update courses materials on a regular basis? Are you available to respond to student concerns and questions in a timely and congenial manner? Is feedback on student work provided in a timely and informative manner? Are the same standards and level of academic quality applied to the online course as to a traditional classroom? Is an appropriate online instructor evaluation form made available to students for providing feedback to the instructor and administrators?

Within a framework for analyzing course content, factors such as course structure, types of student/faculty/content interactions, learning outcomes, and support systems are essential. It is important that an online course be designed and developed in such a manner that ineffectiveness is minimized and learning is maximized.

Conclusion
In summary, asking key questions, in the domains of learning, teaching, technology, design, support, management, and quality, are crucial in determining your survival in not only developing, but teaching online courses. You must be prepared to honestly evaluate the opportunities and limitations in your unique situation. Developing online courses is not for the lazy, faint-hearted, or weak in spirit. We have found that by networking with other colleagues, collaborating, sharing, and building off of each others' skills and input, we have been able to survive so far (we think).
Support for Models of Acceptance, Adoption, and Use of Distance Education Technologies

Joel Levine, Ed.D.
School of Education
Barry University
Miami, FL 33161
United States
jlevine@mail.barry.edu

Abstract: The information age has led to increased use of technologies for teaching and learning. Companies, corporations, and organizations are offering courses, seminars and workshops via distance technologies. Universities and colleges need to make significant changes if they want to compete for an increasing number of students who prefer learning via distance technologies. A critical success factor becomes the acceptance, adoption, and use of distance technologies by faculty members at universities and colleges. Planning and implementing change in these institutions must consider the important stages or levels faculty must move through in order to successfully accept, adopt, and use technologies, especially distance technologies. Levels and/or stages are identified from various models, and specific support strategies are recommended to complement these developmental stages leading to acceptance, adoption, and use.

Introduction

The information age is having an impact on education and training throughout the world. We see many corporations, companies, and organizations offering courses, seminars, and workshops via distance technologies. Many use online software-based tools while others are using videotapes, CDROMs, and various teleconferencing technologies. Most corporations, companies, and organizations are offering these courses, seminars, and workshops for their own employees, in order to provide cost effective training and education. However, others exist for sole purpose of providing specialized training or education to individuals, companies, and organizations primarily for profit. Many individuals are enrolling in these courses, workshops, and seminars if they can: 1) afford them financially (or have reimbursement from employers); 2) effectively learn in a particular electronic environment; 3) find the learning valuable for their personal or professional uses. Increasingly more individuals are obtaining training or education in this manner primarily because of convenience of time and/or location. Hence, institutions of higher education really need to ask themselves some serious questions, if they want to be involved in the competition for these students. Most of the questions involve changes in philosophy (vision and mission), operations, and financial commitments.

Many issues that higher education institutions will confront, include image, resources, facilitation, support and quality, which all impact teaching/learning effectiveness. These issues, and others, could be addressed by undertaking a thorough, meaningful, strategic planning and implementation process that will bring about change. The needed changes are not always easy for administrators or faculty in higher education to accomplish. In fact, even when higher education institutions make the philosophical, operational, and financial commitments, often faculty are reluctant or resistant to become involved in using distance education technologies. Hence, we need to understand the decisions and choices faculty make, and how to incorporate the best strategies to ensure successful professional development. These strategies will enable faculty to become successful developers and implementers of distance courses.

Models of Acceptance, Adoption and Use

Faculty members regularly make choices as to the appropriate teaching strategies, materials, and instructional tools to use for their courses. Their choices about what they are currently using or doing, and what they may choose to change, are usually very personal. Personal choices often are based on things like personality type, teaching style, and preferred
methods of instruction. A faculty member that is very independent, for example, may not be willing to adapt to the
dependence on technology and support staff that is often needed for most effective online courses. Hall and Hord
(1987) also indicate that the change process is an extremely personal experience, and how it is perceived by the
individual, will strongly influence the outcome. Hence, if faculty do not see significant benefits for using technology
for their courses, then they will not attempt to, make a change. The culture of an organization also influences the
choices faculty make. If administrators and faculty members are very supportive and encouraging, other faculty will be
more inclined to make the personal commitments to embrace and use technology in their courses. Support,
encouragement, and guidance comes in many forms, but when it is combined with appropriate, ongoing professional
development, it often leads to faculty acceptance, adoption, and successful use technology in their courses.

There has been significant research in the areas of Acceptance, Adoption, and Use of new innovations. Most of this
traditional research can be applied to most innovations, including technology. In fact, there has actually been some
specific research involving acceptance, adoption, and use of technology. Six out of the models investigated, are
presented in this paper. It should be noted that some of these are based more on applied theory than on empirical
research. The six models include:

- Stages of Concern (Hall & Hord, 1987)
- Stages of Change (Fossum, 1989)
- Steps in the Innovation-Decision Process (Rogers, 1995)
- Teacher’s Stages of Instructional Evolution Using Technology (Dwyer et al., 1989)
- Stages of Learning/Adoption of the Internet and WWW (Sherry et al., 2000)
- Stages for Learning to Use Technology (Russell, 1996)

These models certainly have their differences, but their similarities allow us to make some interesting observations.
Specific stages are listed below each of the six models:

**Models not incorporating technology**

**Table 2**
Analyzing the similarities of these stages will help us to understand the personal and professional changes that a faculty member will probably encounter as they use technology, particularly distance technologies. The developmental progress of any one faculty member may follow one of these models or a combination of several models. It is important to understand the progression, and to realize how the various stages or levels can and should be effectively supported in order to increase the number of faculty that will successfully embrace and use various technologies for instruction.

Looking at the models listed above we observe that there is a developmental process for obtaining knowledge, skills, and experiences about an innovation, technology in this case. First, the faculty member should become aware of the uses and benefits of the technology through demonstrations, discussions, observations (i.e. actual distance courses) and even some hands-on sampling. These continued activities should lead to buy-in and acceptance as deemed important or valuable for them, personally and professionally. The second step should involve in-depth learning about how to use and integrate the technology, and what specific teaching strategies can best complement specific technologies. This step should consist of varied professional development activities, including workshops for small groups, mentoring by colleagues, assistance from technology facilitators (support staff) and/or students, and A/V resources.

The third step should consist of continued practice and assistance with using various technologies, in order to gain confidence, realize success and benefits, and subsequently adopt the innovation. This stage should encourage faculty to start integrating some technologies into their traditional courses. The fourth step should reflect significant involvement and implementation through more significant integration of technologies into their traditional courses and/or developing and teaching courses predominantly using distance technologies. The fifth step should involve more regular use of various technologies, that will lead to further empowerment through creativity, experimentation, and application, which enhances the process or outcomes of other instructional activities. The last step should reflect continued growth and empowerment, along with participation in leadership activities which include beneficial mentoring and collaboration. It is important to note that faculty will have the opportunity to experience growth as they move through all of these steps, if appropriate support is provided.

Recommended Strategies to Support Developmental Stages

Support for innovations has been defined in many different ways (Havelock & Zotolow, 1995). Regarding the innovation being discussed, technology, it may involve access and/or amount and/or quality of the hardware, software, staff, other equipment, connectivity services, design/development services, technical assistance, training, mentorship, support groups, community involvement, cultural acceptance, and incentives, as examples. Recognizing the need and purpose for these support components is important. However, it is more important to see how and when these components will be needed and used. An entire infrastructure should be built which identifies policies, procedures, working relationships, and provides continual support for using technologies, specifically distance technologies, effectively and efficiently. This framework for success can be accomplished through effective planning, development, implementation, and evaluation.

When developing short-term and long-term plans, an institution should utilize appropriate individuals who can act as leaders and/or facilitators (support staff) with specific roles and responsibilities. They would insure that the following general needs would be handled effectively and efficiently: 1) Developing supportive organizational arrangements; 2) Training; 3) Consultation and reinforcement; 4) Monitoring; 5) External communications; 6) Dissemination (Hord et al., 1987). There are many strategies that could be listed under each of the categories above. Having reviewing diverse research and some practitioner experiences at some universities, the following support strategies are presented, which can lead to effectively supporting faculty as they move through various stages. These strategies pertain to many types of technologies, including distance technologies.

Institutional Leaders should:
- Develop a shared (with faculty) vision, mission, and expectations about the role of technology.
- Take opportunities (one-on-one, small group, large group gatherings) to discuss with faculty the benefits (and challenges) of using technologies in their traditional courses or fully distance courses, and to encourage them to do so.
- Take opportunities (small group and large group gatherings) to ask facilitators and/or faculty to model or demonstrate effective uses of technology used in their current courses.
- Provide faculty the time (for practice and mastery) and resources (including staff) to develop and implement distance components or entire distance delivered courses.
- Provide faculty technical assistance (staff, and/or students) and convenient access to technologies.
- Provide faculty the incentives and compensation to develop distance components or entire distance delivered courses.
- Recognize, encourage and reward accomplishments of faculty using technology.
- Establish policies and procedures in conjunction with faculty and facilitators.
- Form an ongoing Faculty/Administration Committee for planning, implementation and evaluation. This includes an action plan of Distance Education activities.
- Require facilitators and/or faculty to conduct initial and ongoing needs assessments in order to identify necessary resources, and other forms of support.
- Require facilitators and/or faculty to schedule and conduct technology training for faculty. This should be developmental, beginning with the basics of using specific technologies, and advancing to the use of teaching strategies that complement various distance technologies.
- Require facilitators and/or experienced faculty to provide mentoring for faculty.
- Require facilitators to provide faculty assistance for the design, development, and implementation of courses or course components, utilizing distance technologies.
- Require facilitators to follow-up with faculty regarding their status - progress and challenges.
- Encourage mentoring/coaching and collaborative work among faculty.
- Require facilitators and/or faculty to evaluate and update courses.
- Provide faculty and/or facilitators opportunities to discover and recommend new technologies.
- Become an active participant (with faculty) in all professional development activities.

Faculty should:
- Be flexible and willing to accept new roles and responsibilities which include: facilitator, assessor, resource broker, mediator of learning, designer, and coach (Loucks-Horsley, 1996).
- Recognize technological challenges while developing positive attitudes about using technology for teaching and learning.
- Model/demonstrate the use of technology for other faculty.
- Provide workshops for small groups of faculty members.
- Mentor and coach other faculty.
- Share successes using technology, including student projects and accomplishments.
- Participate in support groups of faculty using technology.
- Reflect on instructional activities and make improvements.
- Communicate technological needs to administrators.

Conclusion

Faculty should consider using distance technologies for two reasons: to improve the teaching and learning that takes place in their current courses; and to accommodate the personal and professional schedules of current or prospective students. The provision for appropriate faculty development, which recognizes stages or levels of guided growth, is the key to ensuring faculty acceptance, adoption, and use of distance technologies. However, it is important to recognize that professional development occurs on an ongoing basis, and that it is considered to be part of the Implementation Process. In fact, the change process that institutions and faculty must confront usually involve the stages of Initiation, Implementation, Continuation, and Outcomes (Fullan, & Stiegelbauer 1991). It is also important to keep in mind two statements from Hall and Hord (1987)
- Change is a process, not an event, and it takes time to institute change.
- Individuals must be the focus, if change is to be facilitated, and institutions will not change until their members change.

Abstract: This paper informs on the creation and development of the Andalusian Network of Trainers in Spain. The Network serves like support structure to professionals of the formation that develop their activity in Andalusia. The Network helps the trainers in its own profesional development. It favors the innovation on themes thought and developed by the own trainers. The participants are professional of the vocational education field in working contexts little ruled and dispersed geographically.

Introduction

The traditional practices of teachers professional development are at the moment in crisis. Clark (1999) referred recently to that the professional development just as it is conceived at the present time it suffers of a series of problems: Lack of appropriation on the part of the teachers of the training programs designed from outside of the professional community; training Programs based in a deficit model according to which the formation goes to "to fix" operation deficiencies, and not to promote a professional development; short term, limited thought and without vision of professional trajectory; a de-contextualized training and without answer options to the real demands; a training in that the teachers adopt a passive paper, and lastly a training more centered in the individual demands of the teachers than in the learnings that the students should carry out.

Research on teacher learning has found some results that they it plows of interest to keep them in mind to plan the teacher professional development. Next we synthesize some results that they have served as base for the creation of the Andalusian Network of Trainers.
The knowledge and the beliefs are built

We have verified so much for the developed investigations as for the practical experience that the teachers, the same as other people guide their behavior starting from the knowledge and beliefs that possess. And this knowledge and beliefs begins to build a lot before the student teacher decides to be devoted professionally to the teaching. These knowledge and beliefs that the student teachers bring get when they begin their initial teacher training they affect from a direct way to the interpretation and valuation that the teachers make of the experiences of the Teacher Education Program. By the light of this statement, Putnam and Borko they end up affirming that "for pre-service teacher education, this means attending seriously to the knowledge, beliefs, and expectations that prospective teachers bring to their teacher education programs, acquired through their own experiences in schools" (p. 1236).

The knowledge is built in social interaction

One has come understanding that the training and the teacher's learning can take place, I eat up to now we have commented, in a relatively autonomous and personal way. But little by little it has gone winning land the theories that understand learning like a process that it not happens in an isolated way but inside a social space. This way, to learn how to teach should not only understand each other as an isolated phenomenon, but basically like an experience that happens in interaction with a context or atmosphere with the one that the person interacts. It is the thesis of the sociocultural focus of the learning that establishes that the individual's cognitive activity cannot be studied without keeping in mind the relational, social and cultural contexts in that it is carried out (Wertsch, 1991). This idea has been assumed by Yinger (1991) who intends to use the concept "working knowledge", to make see that the knowledge takes place in different situations. This author speaks that "we are beginning to see that the focuses and the conceptions change from the individual thing to the cooperative and community, of being centered in the information to make it in the action, from mechanics to organic, from the measuring to the narrative, from the abstraction to the concretion, from the operations to the conversations" (Yinger, 1991, p.5).

It is of great interest and projection this focus, since it shows that the unit of analysis of the process of learning how to teach is the processes of social interaction, getting the attention to the conversational analysis, so the conversation is considered the natural context in which the cognitive abilities of the fellows become stocks and they are built around the social interaction (Schubauer-Leoni and Grossen, 1993). This way, the social groups believe what one has come in calling "discursive communities" that share forms of thinking and of communicating. Communities that establish nets and that they are good to share, to exchange, to be located in the world, to receive support, etc. (Lieberman and Grohnick, 1998).

The knowledge has a situated character

Completing the previous idea, one has come advancing in understanding that the knowledge in general and the pedagogic one in particular cannot be understood to the margin of the context in which arises and to the one that is applied. McLellan (1996) affirms that the pattern of situated knowledge is based on the principle that the knowledge is located, and it is influenced fundamentally by the activity, the context and the culture in which is used (1996). It doesn't fit, therefore, to differ in a radical way the knowledge that is acquired and the context in which that knowledge is used: the knowledge on the teaching cannot memorize in independent way of the situations in those that this is used (Marx, 1998).

The knowledge is distributed

A last characteristic of the knowledge that characterizes learning how to teach, is that it doesn't reside in a single person, but rather it is distributed, among individuals, groups and symbolic and physical atmospheres (Putnam and Borko, 1997). The idea is assumed that for the development of complex tasks, and to learn how to teach evidently is it, no person possesses the entirety of knowledge and abilities in an individual way. To admit this principle takes us to understand that it is the team work what drives to a better use of the knowledge, what takes to improve the capacity of resolution of problems. The idea of the distributed knowledge has been impelled by the impact of the New Technologies, mainly Internet. The possibility that
the teachers can consent geographically to knowledge and personal contacts with distant teachers, the possibility of ownership to "virtual communities" it is enlarging the possibilities of what understands each other to learn how to teach.

**Networks as Professional Development**

Professional Development of Trainers has traditionally allowed scope for learning between peers. Increasingly, claims have been for a training that is participatory, democratic, horizontal, and professional for teachers. In Spain, permanent seminars or work groups of teachers have been established that consider training to be a process in which the "what", the "how", and "when" of training are decided by those involved (Estebaranz, Mingorance and Marcelo, 1999).

The term network is defined as a mesh of persons connected by links around which things flow. These can be objects, work, feelings, evaluation, knowledge, prescriptions, influence and power, interconnecting most of the participants. Networks use a variety of formulas to link different people having different purposes. Various definitions of what is a network have been made. Miles (1977) defined it as "a set of nodes or points connected by lines or links. There is often the implication that various things (such as messages, objects, energy, etc.) travel along the lines, which thus serve as a channel... In social networks, the nodes are persons, groups, or organizations. The things that travel between the nodes are socially relevant... objects, labour, affect, evaluation, knowledge, prescription/opinion, influence and power. So, a network is a connected set of social actors exchanging socially relevant materials" (Ref. in Clark, 1988:34). Lieberman and Grolnick consider that "networks are a way of engaging school-based educators in directing their learning; allowing them to sidestep the limitations of their institutional roles, hierarchies, and geographic localization; and encouraging them to work together with many different kind of people. Participants have opportunities to grow and develop in a professional community that focuses on their own development, providing ways of learning more in keeping with their lived professional lives" (1996:8-9).

Networks are configuring a way different from relationship among the professionals. As Hargreaves affirms "in this postmodern world, many forms of knowledge are emerging as a worthwhile and legitimate in ways that challenge the epistemological superiority of the academic establishment. Strong school cultures and vibrant professional development networks create conditions where teachers can share their own practical knowledge from elsewhere" (Hargreaves, 1996,p. 119).

The bloom of the nets among professors has a lot to do with the aversion of the teachers toward the traditional activities of professional development. The popularity of the nets suggests that the teachers and trainers move away from the conventional activities of training - or they only attend them when they are required - not due to a lack of interest in the professional development but because the format of the training doesn't respond to their necessities (Lieberman and McLaughlin, 1996). But the Networks will only represent an alternative space to the traditional professional development if they promote the learning and the reflection about the daily experience. Day recently said it with the biggest clarity "by definition, networks are also a recognition that learning only from experience will limit development, and that teachers are likely to commit themselves to learning in which they have a stake and which holds personal significance for them" (Day, 1999, p. 177).

Networks have the following features. They are voluntary initiatives, democratic in origin and working, strongly committed to innovation, change and improvement. They share aims and purpose. They are formed by trainers having common characteristics (the material and type of student taught, and the type of school in which they teach). They combine cognitive, social, and emotional learning. They incorporate everyone in active participation at different levels of involvement, with a trust in principles where one can learn from others. They are open, without restriction of participation. They entail full liberty of decision on work content, working method, time, place and frequency of meetings. They create a community that discusses and learns. Leadership is shared among the various members of the network. Through differentiated consultation, the network can seek support from a wide variety of professionals.
The Andalusian Network of Trainers

In this paper we present an example of a Network that we have been developing in Andalusia (Spain) since 1997. The professionals taking part in the Andalucian Network of Trainers (RAPF) are trainers in "Vocational Training". Vocational training refers to the training that Andalucian Government offers to people that are unemployed. It pursues a formation for the employment. It is a public and free training mostly paid by funds of the European Union. The Andalusian Network of Trainers is characterized by the following features:

- Symmetry in relationships: the relationship between members of the RAPF is based on equality. They are professionals having the same status, without differences of position or power. Such condition of equality among colleagues who share and analyse the same problems determines their interaction.
- Collaboration: the aim of the RAPF is not prescriptive. Work is based on a cycle of collaborative problem-solving and agreement. Activity is not assigned from above – the members of the RAPF, via a work procedure based on different collaborative strategies, pact with management the aims, procedure, and strategies they consider appropriate and possible in accord with their situation and interests.
- The practical, committed nature and orientation of the process: the various groups of the RAPF deal with practical business and problems.
- Recognition of the knowledge held by the training professionals: the groups of the RAPF are based more on the experience and practical knowledge of their members than on scientific-technical knowledge gained in traditional training sessions.
- Immediate support in time and space: the RAPF provides closeness of service to the various constituent groups.

The trainers who take part in the RAPF have attained a certain professional level, and can
- Diagnose contextual problems: of organization, management, planning and design of training support material, etc.,
- Recognize their own deficiencies by observation and analysis of the existing social and professional context,
- Identify and find solutions to the deficiencies and problems detected, at both contextual and individual levels,
- and are
  - Professionals with a certain training and prior experience in the field of continuous occupational training, and/or that of adults,
  - Professionals with continuing prospects, and thus with a certain level of professional stability,
  - Professionals with a defined field of activity and with certain resources, such as those of learning to learn, or Internet access.

Currently, projects are set up in response to particular problems of RAPF members, rather than as solutions on offer to other groups. Furthermore, they are
- applicable to the reality of Vocational Training,
- transferable to other professional contexts,
- of high training content for the participants.

The bedrock of the RAPF is group work as an effective formula for self-training, based on the interchange of information and experiences among colleagues of the same and/or different groups, on the reading of the bibliography related with the topics of the various projects, and on the use of new resources, such as Internet, in the search for references of interest.

Each project consists of a different topic, but they have common features:
- The creation of a web page (http://prometeo.cica.es/RAPF) for each work group: the project managers offer the groups an ftp account for uploading all the information available as work progresses. This aspect is vital, in that it is an attempt to make the groups conscious of the importance of disseminating their advances during the project, and not only at its end.
- Support, and technical and methodological consultation, for each project from RAPF managers.
Consultation and support on the use and learning of different software for the development of group work (support in the editing of web pages, instruction in ftp applications, instruction in and management of e-mail, etc.).

Consultation on processes of innovation.

External evaluation.

The asynchronous communication in the RAPF is, perhaps, the most remarkable thing in the project's history. The two resources currently available in the RAPF (the distribution list and the web page) are very highly valued by the members. Firstly, the distribution list of the RAPF (rapf@is.cica.es) was used to create work groups with common interests. During the month before the RAPF officially began, a considerable amount of mail was received applying to form work groups. The list was also used in the resolution of doubts, requests for information, and the interchange of opinions about the various topics dealt with in the project. Secondly, the group web pages are a powerful resource used by the established work groups, many being of high quality (in content and design). The web page managers are available for consultation and teaching (when required) when groups are interested in incorporating this feature into their work.

The topics dealt with by the twelve work groups are

- INTERPROF: an up-to-date electronic library of complementary information for instructors.
- Current situation of employment advice modules in Occupational Professional Training: analysis and proposals for the future.
- Strategies for the introduction of new technologies (hardware and software) in training.
- Diversification of employment advice modules.
- New employment patterns and the detection of training needs.
- Design and validation of a model to predict the effectiveness of occupational training for subjects without work experience.
- Tele-training and working from home. Analyzing the implications of employability.
- Tele-training: resources and media.
- Certification of training companies.
- Ideas and information to get me onto the employment market.
• Creation of an integrated module for the training of entrepreneurs.

Abstract This article discusses the experiences of university faculty in teaching on-line courses that involve both USA and another country’s (primarily third world) participation over a five-month period. Based on those experiences, and the fact that the type and manner of assistance given by the home university can be crucial to a successful program, suggestions and tips are given for faculty and technology support systems who may be contemplating teaching globally.

Global Learning

Global institutions, virtual classrooms, the race for international connectivity are all efforts to assist in maintaining a global environment where students of every age, learn about and from people of diverse backgrounds. Being exposed to people of different languages, religions and cultures create an understanding critical to maintaining and expanding our own appreciation of diversity. America’s leadership in this area depends on how well we use technologies to bring a unique bonding between countries. A bonding that will bring new ideas and cultural richness to our universities and to our communities. Gaining popularity in many countries is the use of Web-based or On Line Learning. It is, for many universities, the way of the future; and with so many programs available, teaching across the continents appears to be a simple solution for bringing a sharing of cultural richness to life.

Although many university/college personnel have traveled extensively, there are additional conditions to check when courses are simultaneously delivered in The United States from foreign countries – particularly Third World Nations. Some possible barriers and concerns besides time zones include accessibility to Internet hookup. This is more of a hassle when the instructor is planning on living outside a university or business setting. Apartments, while having phone service, may not have the proper plugs, or the phones may be permanently attached without the ability to remove or plug in essential parts.
Depending upon the length of stay, we would suggest that the following questions be answered by a responsible person before leaving:

- Can I set up my computer in my flat/dorm room or house, and how secure are the lines?
- What programs and versions of those programs I am using are being used in the visiting country?
- What assistance is there for technical problems?
- What national companies do business in the country and where are they located?
- What ISP is used – to what extent and where is contact for information on this provider?

Once the instructor feels secure about Internet hookup, there are often many bits and pieces to check. For example, in 1996, the primary author taught in the former Soviet Union for six months. She was not, at that time, teaching online, however, it was necessary to check email and to keep up with events at her home institution. The Herzen University in St. Petersburg had limited access to the Internet, and the one computer for possible use was located in the Dean’s personal office. There was a choice of two providers so that part was easy and fortunately the company was not far from the flat. The cost was rather high that year, but with inflation of the Russian Ruble, it is more today. Many United States’ professors work on-line and have continuous access to the Internet from our offices; however, continuing this practice in another country is not cost effective and rates become even higher. Before leaving for Russia, a magazine article discussing items needed to use existing phones plugs proved most valuable for the future. Two plugs were ordered before leaving the USA and attaching them was relatively simple, she did; however, have to purchase a new phone to use the plug.

More recently, the author had the opportunity to work in Mumbai, India for five months. This time, she was charged with teaching two regular classes at her home university from India – entirely through a web-based program. She thought she was fully prepared. A new laptop with CD and lots of memory, a university that had a small computer lab, and the knowledge that she could hook up to an ISP from her hotel room at the international YWCA gave her the confidence to proceed.

First Crisis

The first crisis was not from Indian students, but rather from students in the States who were anxious about the professor they had never seen. Before leaving she burned a CD with six guest speakers and left packets of resource materials. Students bought the CD with their textbooks. She also made sure that a former graduate student was willing to work on-line at home to put out fires. Second crisis: how does one grade papers sent in the web-based course when on-line time may be limited or spotty yet is necessary to read entries? The solution, after a couple of agonizing weeks, was to have the students send their papers for grading on regular email. That way papers could be copied into a word processing program, corrected off-line and uploaded into regular email.

The concept of working with other institutions and using global Internet access is a valuable one to be nurtured for future courses and relationships. We are just beginning to see that the possibilities are limitless, but we haven’t thought out the barriers and ways to deal with them. Several mistakes were found in our thinking and manner of delivery of courses. While the mistakes appear minimal,
they are, never the less, solvable mistakes; and we cannot take for granted that they will not appear the next time we visit a foreign country.

The mistakes

- Third world countries do not always have the latest versions or compatible software.
- Computer labs are not always accessible.
- People work at slower paces in some countries, and getting things done when you want them done may be next to impossible.
- The new cyber cafes may work, but lines form after 9:00 A.M. and continue into the evening. Others stand and stare at you until you decide that reading five out of 15 messages will do for the day. Patience is a virtue.
- Moving to a guesthouse is also not the answer. Reason: other guest may want to use the phone and there is only one line.

Suggestions and Tips

The following check list of needed equipment and suggestions in order to experience web-based learning with a minimum hassle may be useful.

- Laptop with enough hard drive and memory. A CD drive is added benefit.
- Cell phone with Internet capabilities (May be necessary for laptop hookup without disturbing existing lines).
- Telephone plugs indigenous to a particular country
- Back up for programs on Zip Disks
- Zip Disks and/or regular formatted disks brought from your own country (due to possibility of viruses).
- Portable Zip Drive

These are the immediate barriers, concerns and solutions for on-line teaching from foreign countries. There may be more extensive concerns in the future, or when one is going to countries other than those mentioned. The idea of using CUSEEME or like technologies may be possible, however, not all countries have satellite or phone capabilities. This is especially true in the remote rural areas.

In addition, the use of multi-media is not usually common in most areas due to cost of supplies, equipment such as overhead projectors or LCD Panels. It is highly recommended that you carry your own, if possible. One person traveling alone makes this difficult. The faculty member brought finished transparencies; plenty of formatted disks, a laptop, and portable zip drive. Although light in weight restrictions, these items became a burden as carry-on luggage. Since we weren't sure about security x-ray and whether or not the disks would be damaged, we wrapped them in foil and placed them in an easy access folder for hand checking. Sending pictures and files home was the easy part. A graduate assistant downloaded to a zip disk so there was a secure feeling on the return home. All in all, the experience can be positive with just a little forethought, planning and assistance from your home university or business.
Online Group Processing: A Qualitative Study

Deana L. Molinari RN, MSN, Nursing Clinical Instructor, Brigham Young University, USA,
Deana_Molinari@byu.edu

Abstract: A qualitative analysis of two online groups, which occurred as part of course requirements lasting fifteen weeks, developed functional communication categories, concepts, and constructs. Examination of two student nurse groups indicated differences in student ability to use cyberspace for group decision-making. Students adapted familiar communication strategies and invented new ones to complete an action research project. The characteristics identified in this descriptive study indicate some major differences between face-to-face and online decision making groups.

A three phase research study of online asynchronous group processing conducted at Brigham Young University College of Nursing seeks to identify the elements of online communication that affect instructional design. Little fundamental research describes the development of online group norms. It may be that the asynchronous, e-mail based, problem-solving groups process decisions so differently from face-to-face groups that new definitions and process descriptions are needed. How do the unknown timing, transitions, and functions affect problem solving? A better understanding of the group process will promote adequate facilitator use, and accurate evaluations of individual and group participation (Cartwright, 2000; Diekelmann, Schulte, 2000).

Methodology

Strauss and Corbin’s (Strauss, & Corbin, 1998) methods of qualitative research guided the methodology as recommended by Fisher and Hawes (1970) for the development of small group decision-making theory. The descriptive study consists of the construct, concept, and theme analysis of two sophomore student nursing groups using listserv based (automated electronic mail by subscription) discussion groups. The data sources used were demographic surveys of all participants, interviews with five participants about their experience, and electronic mail documents. Analysis of data sources concentrated
on the functions, roles, relationships, transitions and timing of functions. The two groups judged by three facilitators as producing the most and least effective outcome products (research papers) were selected for initial analysis. The author chose these groups based on the assumption that most identifiable concepts would be found within the scope of the two outlying groups. Analysis of all groups thereafter verified the assumptions.

Sample

Forty-eight students, divided into six equal groups, completed a required “family project”. Pairs of students visited chronically ill patients weekly. The fifteen-week project required students to communicate electronically three times a week to define the role of a “family coach” for families. Students studied the issue individually and wrote a group paper online as the product of their participatory action research. Students received letters requesting their consent and describing the research.

Analysis

Data used in phase one consisted of e-mail documents, a demographic survey, and transcribed interviews. An overview of the documents developed constructs and concepts of what was said and done in each group. All documents were then analyzed for common elements and collapsed into categories. The researcher and assistants checked coding and tallying of documents. The functions, roles, relationships, and transitions were linked to the time of occurrence. Participants completed the survey of computer use, group experience, and family nursing during the first week of the project. Interviews of five participants during and after the project sought to verify observations. Electronic mail documents were coded by sentence for function constructs.

Findings

Differences in performance were expected between the two groups studied as the facilitators had judged the groups as producing the least and most effective outcome papers. The first differences noted were the number and size of communications sent. Group one produced the least effective paper and sent 215 messages containing 420 kilobytes of information. Group two produced the most effective paper and sent 446 messages containing 1265 kilobytes of data. The facilitators sent 13 messages to group one and 35 messages to group two.
Students were females between the ages of 19 and 24 years in their first nursing class. None of them had been in a hospital setting and were not familiar with teamwork in an academic setting. Students stated they had used electronic mail between 5 and 20 times in their lives. Students reported the family project as their first experience with online learning and automated e-mail.

A five point Likert like scale measured (1=none/poor to 5=severe/excellent) perceived abilities and anxieties. Students rated their abilities to use e-mail as good and their anxiety to working on the computer for the assignment as mild. Students rated their electronic discussion group abilities as poor. Participants judged their group work anxiety levels between mild and moderate. Students were more nervous about working with families in the home setting with the average score of 2.8.

Categories and Definitions

Concept definitions and category groupings described the functional purpose of communication. Students faced three main challenges during the online decision making process: completing the task, developing and maintaining relationships, and communicating via a new technology.

The task-oriented category was the most frequently used category, while the online communication category identified the most differences between face-to-face and online group processing.

**Task Oriented Category:** Unlike some face-to-face studies of the past (Tuckman, 1977) where relationship maintenance was the most frequently used function, online participants spent most of their communication time on the task. Critical thinking and methods of working on the task were analyzed.

The questioning concept consisted of task and process questions and the requesting information in a statement format. For instance, “Tell me what you think” requests information in a declaration. The creative concept described the development of new thoughts and knowledge. Students most frequently used personal opinion rather than literature, teachers, and local agencies as the authoritative voice. Students tried to eliminate the number of steps in reaching consensus by making declarations that sounded like conclusions and then asking the group for validation. This eliminated a number of steps in reaching consensus. Students ignored debate strategies in favor of idea development.

**Relationship Process Category:** Relationship process coding identified two concept functions: development/maintenance and leadership. The softening statement construct was defined as an attempt to
avoid conflict by offering remark after a strong "stinging" statement that might elicit a negative response; "...but that is just my opinion, feel free to disagree..." The most frequently used concept was validation of individuals and the group. Validation was defined as encouragement, empathy, and individual attention.

**Online Communication Category:** The online communication category focused on the student's use of e-mail and message construction. The study looked at how students used the subject line and reply functions, which are characteristics of the e-mail medium. Participants adapted greetings and conclusions to overcome the lack of visual cues. Students applied two other constructs to ease communication. 1) Organization elements structured the message of clarity and indicated changes in the discussion. 2) The place statement provided orientation to time, place and circumstance. Place statements indicated the situational conditions of the speaker (sender) and provided a shared understanding of where the participant began or ended a thought. The construct usually consisted of one sentence in the first or last three sentences of the message, but could constitute a small paragraph.

**Use of Concepts over time:** Working relationships styles seemed to form immediately with little variance until the outcome deadline approached. Stress appeared at transition points. Individuals transitioned from introductions to content production and then to solution production at different times. When upset individuals received messages that resolved their issues, the distress resolved. These findings support the work of Connie Gersick (1988, 1990) and others working on group norms (Hackman, 1990)

**Discussion**

Differences found between how online and face-to-face groups function could affect instructional designing. Students invented new methods of problem-solving, conflict avoidance, and idea sharing.

**Task/Solution:** Questioning became a strategy to avoid conflict, show openness to new ideas, request help, and explore issues. Students combined statements with requests for validation and social support. "That is my idea. What do you think?" This strategy seemed to serve for body language that conveys a willingness to listen to new ideas.

Telecommunications may deliver fast messages but cannot guarantee when the reader will read the message and reply to it. The abbreviated discussion strategy required individuals to process their ideas before placing them online. Participants presented ideas with thesis and supporting statements. Others replied with supporting opinions and amendments to the idea. No dissenting arguments were noted. When
three or more supporting messages were received the group adopted the idea. The democratic abbreviated discussion style avoided conflict and promoted thorough processing of ideas before presentation. Non-supported ideas were ignored rather than debated. Students spent time and content on the majority-supported viewpoint supported. This discussion strategy required readers to read between the lines. Students side stepped the idea fine-tuning and details normally present in face-to-face communications.

Relationship Process: Students used validation more frequently than the other process constructs. Validation encouraged, comforted, praised individuals and promoted group identity. The most successful group included validation in 90% of their messages.

Online Communication Category: The online communication category produced the most differences between online and face-to-face groups. The written nature of the conversation required each contribution to begin with a name or social statement and to restart a discussion with each message instead of the flowing from one idea to the next as in face-to-face groups. Greetings served the same function as raising one's hand. Students knew each message carried a heading in the subject line but most often communicated a change in speaker within the first sentences of the message. The message opening indicated turn taking with informal group greetings like, “Hi, guys”, and “Hey

Time passage from sending to receiving broke into the conversations. Readers worked hard to remember the conversation thread and formulate replies. Some participants worked to overcome feelings of disjointedness by avoiding greetings and use of the subject line. The use of a greeting and a conclusion emphasize time and distance. The absence of greetings and conclusions also occurred when the participant appeared hurried or felt strongly about the content.

The subject line was used more often than not. The subject line served several purposes but rarely acted as a “thread” (commonly used subject index). The following functions appeared in the subject line: Announcement-“deadline”, group organization-“now”, place statement-“today is a good day”, validation-“great work”, priority notice -“important”, direction-“read this”, greeting-“hi”, and apology- “oops”.

The place statement attempted to create a shared environment, act like body language, warm the environment and ground the group in a common understanding. A major difference between the findings of this study and group processing literature was the frequency of conflict. The two groups avoided conflict
completely. The difference may be due to the sample of nursing students and not the technology as Tuckman found nursing students avoided conflict in face-to-face groups (1977).

Some students expressed problems with using technology for group work. Difficulties mentioned were: reaching a timely consensus, lack of non-verbal cues, delays in response time, remembering what each group member said and remembering the feelings that accompanied the messages. The lack of people in the same room contributed to a "light" feeling or lack of importance to the task solution process. Other students struggled with the weight of emotions as time passed. Immediate clarification and elaboration defuses many misunderstandings in face-to-face groups. New strategies must serve similar purposes in the online environment.

Innovative Teacher Education Using the Web-based Integrated Science Environment (WISE)

James M. Monaghan

Abstract: We present the design, testing, and implementation of a professional development model that uses three essential components: a successful Web-based curriculum environment (the Web-based Integrated Science Environment: WISE); a virtual community of teachers and scientists who discuss pedagogy, collaborate on curriculum design, and offer continuing support for in-service members; and virtual mentoring between new community members and veterans. The Web-based Integrated Science Environment (WISE) builds on the successes of a decade's research on the Computer as Learning Partner project. In this professional development project, we sought to combine solid pedagogy that was the result of extensive funding by the National Science Foundation, with large-scale professional development in a large teacher training institution.

Introduction

The Internet can offer new avenues to effective instruction, where students perform inquiry-based or design activities in current science topics. The challenges of incorporating these new technologies and pedagogical approaches are frequently beyond the scope of current professional development programs. It has been argued that without sufficient professional development support, the Internet will fail to fulfill the promise of supporting improved teaching (Wiesenmayer & Meadows, 1997).

The Web-based Integrated Science Environment (WISE) is a scaffolded Internet-based platform for middle and high school science activities (Slotta & Linn, 2000). These activities are designed according to the Scaffolded Knowledge Integration (Linn & Songer, 1991; Linn, 1992) theoretical framework which emerged from a decade's research in the Computer as Learning Partner (CLP) Project (Linn & Songer, 1991). In a WISE activity, students work collaboratively to utilize Web evidence during self directed, scaffolded, scientific inquiry. In one activity, students consider differing approaches to stopping the spread of malaria. In another, students compare two theories concerning the appearance of deformed frogs in American waterways.

Students navigate through activity steps in the left-hand frame of a web browser, and utilize Web Evidence in the right-hand frame. In a WISE activity, students work collaboratively to explore Web "evidence" relating to critique, comparison, or design tasks. Figure 1 shows the WISE software interface in the Deformed Frogs activity. WISE provides science teachers with a versatile technology for bringing pedagogically sound Internet-based activities into their curricula, promoting the development of integrated understanding and lifelong learning skills.

Even when presented with a tool like WISE, however, teachers require significant levels of support to adopt new pedagogical concepts and methods. For example, teachers need to understand that technology is not an end in itself, and that the Internet must be used carefully to promote constructivist learning. Also, despite great advances in the understanding of students' preconceptions and despite great advances in pedagogy that addresses how to teach to assist students' conceptual change (see Linn, 1992, Clement, 1993, Slotta and Chi, 1997, Peterson & Treagust, 1995), the majority of middle school and high school science teachers still employ more traditional approaches to teaching science. (Poole and Page, 1995) Thus, teacher professional development emerged as an
essential component of the WISE Project. In order to support teachers with powerful new technology, we must help them gain new understandings about effective curriculum activities. Our WISE technology must scaffold students and teachers alike.

Figure 1: The WISE Deformed Frogs activity. Students navigate through activity steps in the left-hand frame, and survey Web "evidence" in the right-hand frame.

The challenges described above provided us with the incentive and opportunity to develop and test effective approaches to professional development that can respond to teachers' needs and constraints while still fostering the development of new ideas and approaches. We designed and field-tested an on-line community to help teachers learn about the WISE pedagogy and technology, for use in their own classrooms. This community was designed to be a self-sustaining professional development resource for its members. We will review the design of this community, and then describe a professional development curriculum that builds on its structure to help in-service and pre-service teachers develop powerful new understanding about science pedagogy.

**Design & Testing**

We designed a professional development model that uses three essential components: a successful Web-based curriculum environment (WISE); a virtual community of teachers and scientists who discuss pedagogy, collaborate on curriculum design, and offer continuing support for in-service members; and virtual mentoring between new community members and veterans.

**WISE Pedagogy and Curriculum**

Our first objective was to help teachers learn the pedagogical principles of Scaffolded Knowledge Integration (SKI) (Linn, 1992), and understand the WISE software and curriculum. In the WISE pedagogy, students engage in the scaffolded knowledge integration format in which

- thinking is made visible,
- social supports for learning are integrated,
- accessible goals and models are provided, and
- autonomous learning is promoted.

After our teachers became comfortable with the technology and pedagogical principles, we scaffolded them in tailoring and implementing an existing WISE activity for use in their classroom. Our goal was to develop teacher training activities based on the same SKI pedagogical principles that inspire our design of the WISE student software and curriculum.
On-line Community of Practice

We designed an on-line community where teachers are engaged in an active discussion of issues concerning constructivist pedagogy, best practices, use of WISE and other technologies in their science classrooms, and development of effective curriculum activities (see figure 2). In our design, teachers can dialog with each other and with mentor teachers, scientists and educational researchers to help gain understanding of the WISE pedagogy, software, and curriculum. The on-line community also provides teachers with technology supports for adopting their own WISE activities, and supports teachers after they have completed the program.

Figure 2: The on-line community electronic discussion tool, where teachers respond to one another’s comments. Other tools support collaborative design.

Virtual Mentoring

Given that new teachers are greatly influenced by mentor teachers during their student-teaching and early teaching experience, a great challenge is to establish ties between new teachers and exemplary teachers. Furthermore, the amount of time that pre-service teachers are able to spend with their mentors is often very limited and comes to a definite ending. Our objective was to connect pre-service and in-service teachers with mentor teachers through a dynamic continuing virtual mentoring program as part of the on-line teacher community. Interactions would be facilitated by the on-line community, and aimed at communicating sound pedagogical approaches as well as technical expertise with WISE.

Working in Partnership to Develop the Program

Extensive development and support of the WISE environment and on-line community technology was done at the University of California, Berkeley. The environment was field tested with in-service and pre-service teachers as part of life-long learning initiatives and as part of coursework that led to the state clear teaching credential at a large university college of teacher education, California State University, San Bernardino. Our goal was to allow a significant research project (WISE) to be implemented with large numbers of pre-service and in-service teachers through an established teacher education and credentialing program. This type of partnership has the capacity to improve both the research of such environments and the implementation of critical research projects in the field with working teachers.
A Multi-dimensional Approach

Teachers who were working on their preliminary teaching credential interacted with the WISE technology and pedagogy as part of their curriculum in a secondary science methods class. Several teachers who were working on their clear teaching credential (which must be completed by teachers before they have taught with a preliminary credential for 6 years) or who were working toward a masters degree in education were exposed to the WISE technology and pedagogy as part of a Technology for Science Educators class. Select science teachers who were working on a Masters degree in Education worked within the on-line community and developed WISE activities as part of their master's degree requirements.

In the first year, all 20 teachers in the Secondary Science Methods course at California State University, San Bernardino (CSUSB), interacted with the NetCourse and were required to implement WISE in their classrooms or observe implementation in another teacher's classroom. Teachers in this class interacted with the WISE NetCourse, and joined the on-line community. They were also introduced to the WISE project by a guest lecture by the director of the WISE project from Berkeley.

During this first year, in the winter quarter, teachers interacted with WISE for approximately 8 hours, spread over the course of a 10 week quarter. Based on post survey data, there is evidence that the NetCourse showed efficacy for training and facilitating use of the WISE curriculum. Most teachers were unable to actually implement WISE in their classrooms, due to lack of access to an Internet ready computer lab classroom. Despite this, there were notable successes by individual teachers who were able to implement the innovative WISE pedagogy in their classrooms.

During the spring quarter of the first year, seven students, enrolled in a special elective course, Technology for Science Educators, engaged in the NetCourse and studied WISE. All but one of the students engaged in the WISE NetCourse. All students could access the on-line community. All students could access on-line mentors. Based on discussions that occurred in the class and based on participant email, participants were split over the efficacy of using on-line in class discussion tools when face to face discussions could be conducted instead. Many participants were hampered by lack of access to sufficient technology to implement WISE in their school setting.

We applied lessons learned in the first year to the second year's Secondary Science Methods class. Specifically, we made participation in the WISE project optional, we reduced the size of the NetCourse, and we again brought in the director of the project who spoke about WISE during one of the class sessions. In the second year, the professor teaching the Secondary Science Methods course required all students to do a professional "risk project". Students were required to implement lessons that reflected a change in how they would ordinarily teach. In the course, the professor emphasized the utility of inquiry methods for teaching science.

We encouraged the use of WISE as part of the professional risk project, a project in which students had to implement a lesson plan (or series of lesson plans) in their classroom in a new way—a way that represented significant learning on their part—a way that meant that they were taking a risk in conducting the lessons. Our intent was to bring these teachers past their comfort zone to enable significant learning concerning teaching in an inquiry manner.

Of the 20 students in the class, seven chose to engage in a modified WISE NetCourse based on interest and access to necessary resources. Several students elected to utilize WISE in their classroom in order to satisfy the requirements of the "risk project." These students were highly motivated to find out about WISE via the modified NetCourse. In this environment, all students could access on-line community. Mentoring was done on an as-needed basis via email. Several students implemented WISE in their classrooms during the academic quarter.

Assessing Our Impact

We assessed the impact of our Professional Development Program through pre- and post assessments of teacher beliefs about pedagogy, the Internet, and specific science discipline knowledge, as well as by interviews of several participants. We assessed the impact of our virtual mentoring through interviews, as well
as analysis of recorded log files of community activity.

Based on exit survey data from the last 2 years of the project, it was clear that a number of students were very enthusiastic about the potential for using WISE in their classrooms. Students commented on the utility of learning about the WISE approach to teaching and learning through the on-line community. For instance, one student stated in his exit survey, "Thank you for enlightening me on this powerful and dynamic learning medium. I look forward to continuing the use of WISE in my classroom and watching this project grow and mature." A number of students have continued their participation in the WISE community, authoring innovative new curriculum units for use by other teachers. In one case, a student from the second year of the project is working with individuals in Thailand on a unit that concerns the rain forest. In another, a student from the Technology for Science Educators class co-developed, with another CSUSB student, WISE personnel and scientists, the WISE unit on how to control malaria. Two particularly notable examples of successes reveal teachers, who interacted with the WISE project through teacher education courses, each becoming teacher of the year for their school sites.

Discussion

Important ingredients for successful use of WISE in classrooms

From our ongoing analysis, we are identifying criteria that appear to be critical to successful use of the WISE materials in classrooms:

- A positive introduction (e.g., course-related, via web, via professional development, personal contacts)
- Computer and network availability with necessary technical support
- Support for pedagogy implementation (In our project, the WISE staff provided extensive support to new teachers).

Teacher involvement is critical to success of the effort

A number of the teachers either have created or are creating new WISE units in collaboration with researchers. Additionally, a number of teachers from CSUSB courses have become WISE leaders, spreading their understanding of the WISE pedagogy and Internet materials to colleagues. These mentors spearheaded in-service workshops and conference presentations. It represents a scaffolding for a vibrant, sustainable, teacher professional development community, in which science teachers are brought together to discuss and implement significant advances in the implementation of inquiry based, technology rich science pedagogy.

Future directions

Current lack access to Internet equipped laboratories has impeded implementation of WISE in many students' classrooms. Most indicated a desire to maintain contact with WISE in the future; a number of students intend to implement WISE activities in their classroom in the near future when they have access to the internet in a computer lab. This is particularly encouraging as schools race to connect to the Internet, often without a strategy for effective use of the Internet in classrooms (for a discussion of these concerns, see Barowy & Laserna, 1997; Wiesenmayer & Meadows, 1997). Given the successes experienced through this collaboration, and consistent with the current guidelines of the California Commission on Teacher Credentialing (CTC) and the National Council for Accreditation of Teacher Education (NCATE), which advocate the integration of technology into methods courses, the WISE Professional Development program has become an integral component of California State University, San Bernardino's Secondary Science Methods class. We are continuing to provide feedback to University of California, Berkeley's WISE team, to continue to enhance research and development efforts to improve science education.

Netseminars: A Strategy for Team-Based Action Research

Gary Obermeyer, Learning Options,
David Gibson, Vermont Institute for Math, Science, & Technology

Abstract: Professional Development School (PDS) partnerships offer a powerful leverage point for the improvement of student learning in the K-12 sector and a unique opportunity to experiment with new forms of online learning for the adults who work in and with schools. In this paper we present lessons learned in the design and delivery of online courses to teacher educators, classroom teachers, support personnel, and student teachers associated with the Virtual Professional Development School Consortium. We describe the NetSeminar model that is evolving through this work, and consider strategies and implications for replication.

The Context

Professional Development School partnerships are sustained local collaborations between a teacher education program and one or more schools, seeking to improve student learning results by using action research to continuously improve both teacher preparation and professional development. A growing number of national organizations support the idea that PDS partnerships be used as a primary vehicle for expanding the quality and capacity of preservice and inservice programs to effectively prepare and continuously support the next generation of America's teachers.

Professional Development School partnerships are fertile ground for online work. By definition, a PDS brings together higher education, the k12 sector, and their respective communities. Collaborative action research provides an effective context for bridging very different cultures and focusing on the shared interest of improved student learning. Among the sites that are truly striving to develop PDSness, there is a built-in readiness for experimentation. However, there are significant barriers to collaboration; among them time and distance – an obvious opportunity to employ computer mediated communication.

This was a central premise for the Virtual PDS Consortium, a US Department of Education funded Technology Innovation Challenge Grant involving 30 Professional Development Schools in nine states. Begun in 1998, and coordinated by the National Institute for Community Innovation (NICI), the five-year project was conceived to help K-12 school-based teams learn together while working together to create a technology-enriched learning environment in a professional development school.

The goals of the Virtual PDS Consortium's online efforts are to facilitate communication with and among the sites and to deliver formal learning opportunities in support of PDS development and technology integration. The Challenge Grant included funding for the development of four online courses to be delivered in sequence: 1) Using Data, 2) Technology Applications, 3) Technology Planning, and 4) Professional Development Planning. The strategy underpinning this sequence was to put the initial emphasis on the examination of local K-16 data related to student learning, and to use these findings as a
basis for selecting technology applications with the greatest potential to affect desired improvements. Similarly, each subsequent course is intended to build on the previous offering, leading to a high-quality professional development program for each PDS.

The online environment for the Virtual PDS Consortium is Vista Compass, a Web-based application built on the metaphor of a campus. Compass runs on a Lotus Domino platform that integrates registration, transcript and billing information, self-service applications, as well as tools to control the security, organization and customization of services. Of primary interest to NICI and the VPDSC was the flexibility to configure private space, group space, and course space in virtually limitless permutations and combinations, as well as the potential to plug in additional applications, i.e. chats, audio, streaming video.

The first online offering was called the “Using Data Netcourse.” Some 200 participants signed up for the course. A Lead Instructor was responsible for designing the assignments and marking up the documents for presentation in the course space, pacing the course via mailing list, troubleshooting local problems through local Data Contacts, and addressing individual participant needs by way of phone and email. Eight Data Mentors served as assistant instructors; each assigned to clusters of sites. Experts in professional development were assigned as critical friends to each of the 30 PDS sites. The goal was to provide a small expert-to-participant ratio. In short, a substantial amount of resource was invested to produce and facilitate the netcourse.

The Using Data NetCourse was structured in a series of “sessions” following the outline of a textbook that had been selected by an advisory group. Participants were expected to reflect on the textbook readings, compare with local practice (in consultation with colleagues, if possible), report to the large group, and engage in class discussion. It operated on a schedule independent of participant’s learning or productivity. In week three, for example, participants were expected to be reading Chapter 2 and commenting on Data in the Change Process. Unfortunately, we encountered a series of technical and logistical crises, so that by the third week we had lost over half of the participants. The 12-week course was extended for an extra month to accommodate the survivors.

Lessons Learned

Direct feedback from the participants and data provided by the external evaluator (through surveys and site visits) were used to draw lessons from the first course:

- Missing Participants – individuals who were not able to access the site and had no technical support to work through access issues, were lost before the course even started.
- Missing Textbooks - sites/individuals who either did not order the textbook in a timely fashion or fell victim to cumbersome requisition procedures, were operating in the dark.
- Overwhelmed Participants – those with little or no experience with web browsers, group space, or course environments felt overwhelmed by the campus and its many features. Threaded discussion was also problematic for many.
- Campus Configuration Confusion – we learned, after the fact, that participants had been registered varied permissions and services – for many the instructions did not match the tools.
- Missing Mentors & Experts – some of the mentors and many of the staff developers were also challenged by the virtual campus.
- Inundated Instructor – the sheer number of participants and the volume of technical assistance needs left little time for the instructor to attend to those who were navigating the campus well for the first three weeks of the course.
- Expectation Variation – many participants came to the course expecting to learn about data use in their respective classrooms, rather than data use targeted to school improvement. Others were frustrated by the constructivist orientation.
- Disappointing Discussion – it was difficult to get participants to comment on each other’s reports and reflections. Most of the interaction was between instructors and participants.

In spite of the impediments, there were many bright spots. One site in particular served as our shining example. Interestingly, it was not the most technically advanced site; rather the star PDS was in a high-need school with very limited technology. Most of the ten participants who signed up for the course had very limited computer experience and had never worked online. To assure success in the course they agreed to work as a team. They held weekly meetings to discuss the readings and improve their skills navigating the campus. They used their online group space to plan agendas, discuss the readings, and prepare assignments. They took turns presenting their findings, conclusions, and questions to the in the course space. Their final project was a collaboratively developed data plan keyed to the school improvement plan that they co-presented to the entire school.

The Data Contact was instrumental in this success. She participated in the course, served as team leader and tech support person, and communicated regularly with the course instructor to offer feedback and clarify course expectations, and to get help with technical issues.

The success of this one team was mirrored in findings from participant surveys conducted by the outside evaluator. The strongest indicators of engagement in the course were related to local support, the degree to which they participated as a team, and the linkages to school-wide goals.

Based on these findings, we made a number of changes in the second online offering. Most importantly, we changed the name to the “Technology Applications NetSeminar.” We offered a pre-course orientation with a special effort to attract participants with little or no virtual campus experience. The seminar began with a self-assessment and a round of introductions. There was no textbook; rather, sites were asked to acquire copies of ISTE standards to be used as a reference. All required readings were provided online. The online activities were designed for groups – with the initial set of assignments for school-based teams, and moving to virtual inquiry groups formed during the netseminar around the specific, individual interests of the participants.
The Technology Applications NetSeminar was led by a Facilitator and two Instructors. The Instructors were responsible for course content and resources, enabling the Facilitator to concentrate on the flow of week-by-week activities. The pace of the course, instead of being driven by coverage of material, was driven by a set of team-based products, which could be addressed when appropriate. At each stage of the seminar, only those documents and tools needed for the assigned work were visible to the participants.

The Technology Applications NetSeminar presented new challenges, mostly related to the fact that we attempted to run the seminar through the summer months. It had the effect of negating the expectation that participants from each site would work as a team. Except that the same site that had been the shining star in the first course made the extra effort to get together over the summer. Once again, informal feedback and participant surveys reinforced the importance of local support, team participation, and the linkages to school-wide goals.

To assure that all sites were prepared to engage in future courses, the third course (technology planning) was put on hold and resources were diverted to assist all PDS sites had fully-developed local action plans and technology plans.

The NetSeminar Model

Even as we proceed with the first sequence of courses, we are incorporating the learnings and retooling the courses. We have updated the Using Data NetSeminar. Figure 1 (below) represents the latest version:

![Diagram of NetSeminar Model](image)

Figure 1.
Data Audit - Data Teams (a minimum of 5 members) from participating schools are provided Group Spaces to serve as home base for their work. A series of questions will be presented to assist teams in the collection of 'legacy data' related to their school improvement priorities. The data audit activities also serve as an orientation to Group Space and the Campus (*approx time frame = 3 weeks*).

Data Theory - participants download and read selected materials from the website. Instructors will lead participants to an understanding of frames for data use and strategies for measuring equity. Outcome of this work will be reflective essays comparing ideal to local practice (*approx time frame = 4 weeks*). Note: the graphic shows the large group conversation continuing in the background through phases 3 & 4, i.e. skill group and data planning are the main focus; however, there will be some reporting and comparing of experience in the large group.

Skill Groups - Participants self-select into skill groups: Curriculum & Assessment, Action Research, Organizational Developers, Cybrarians, and Techies (the reason for requiring that each Data Team will have at least 5 members). Each Skill Group will focus a set of skills/strategies that will become part of a comprehensive plan for engaging colleagues in data-driven school improvement (*approx time frame = 4 weeks*).

Data Planning - Data Teams will apply what they have learned through the audits, readings, discussions, and skill groups to develop tentative data plans. Note some teams will be developing plans from scratch - others will be developing upgrades to existing plans (*approx time frame = 4 weeks*).

Presentations & Commitments - Data Teams will "present" their data plans for review by their virtual colleagues. Data Teams will consider the feedback and develop action plans for securing local support (*approx time frame = 3 weeks*).

Strategies and Implications for Replication

The Virtual PDS represents a rich laboratory for the development of online learning. The personal and institutional commitments made to the project with the extra incentive of the outside funding produces a community willing to experiment and to tolerate errors and omissions. As long as we can sustain the partnership, we have a grace period to continue the experiment.

While we focus on the experiment, we are also mindful of a growing market, among all K-12 schools, for online delivery of learning opportunities for preservice and inservice teachers and the other adults who work in and with schools. The recruitment and retention of a quality workforce in the face of shortages is on the radar screen of ever greater numbers of policy makers across the political spectrum. Meanwhile, the accountability movement continues to gather steam - placing schools and school leaders under greater pressure to more effectively serve ever more diverse student populations and to achieve higher standards. Schools & districts are becoming more selective about professional development and demanding services that can be delivered on-site in the context of school improvement priorities.
As K-12 schools get ever closer to the goal of universal Internet access schools and teachers and other school personnel are less bound by time and distance – they will seek out online resources that best meet their professional development and school improvement needs. Increasingly, it is a buyer's market.

For both practical and pedagogical reasons, the response from higher education cannot be limited to mere translation of existing courses to make them available to schools. Stand-alone netcourses are not responsive to schools, nor can they exploit the richly integrative possibilities of Web technology. An effective response requires tools, strategies, and skills that create constructivist, problem-solving, and collaborative learning environments.

The Virtual PDS Consortium experience suggests that the "netseminar" is a responsive and effective model for meeting the emerging demand for online learning in the K-16 market. Whereas a traditional "course" is structured around a pre-determined set of concepts, knowledge, and skills delivered by an expert to the learner; the seminar format begins with the knowledge, skills, and needs that the participants bring to the group setting. In the seminar, peer-to-peer interaction is essential and central to the learning experience, while the existing knowledge base provides a framework and reference points for the conversation.

Ultimately, we believe that the netseminar is a temporary and transitional strategy that will give way to even more responsive systems. We envision a future in which each individual has access to tools and resources for a truly personalized learning plan, and the capacity to link and interact with peers, mentors, work groups, as well as vast databases and libraries. Our commitment to work with PDS partnerships is built on a belief that the most effective strategy for transforming education is to begin with the learning needs of the adults in the system.

Our experience with netseminar development is currently limited to the 30 Virtual PDS Consortium partnerships. At times progress feels painfully slow as vision and potential outstrip practice. We assume that there are many other examples of online experiments among the 500 plus PDS partnerships that presently exist. We see a great need to develop to create forums to support continuous inquiry across initiatives as a means to accelerate the constructing of new knowledge and to facilitate school transformation. We welcome invitations to partner in such efforts.
Facilitators' Perspectives on Using Electronic Communication Channels to Build and Manage Relationships with Virtual Team Members

David J. Pauleen
School of Communications and Information Management
Victoria University of Wellington, New Zealand
david.pauleen@vuw.ac.nz

Abstract
The use of virtual teams in all areas of education is growing. They can form critical parts of distance education programs, collaborative research projects and joint-management schemes. Research shows that the development of personal relationships between team members is an important factor in effective working relationships in virtual teams. This paper reports part of a grounded action research study of seven virtual team facilitators in New Zealand. It will specifically look at how virtual team facilitators use electronic communication channels to build relationships with their virtual team members. The findings suggest that some electronic channels are more effective than others in building relationships and conclude that facilitators need to strategically use the channels available to them to effectively build relationships.

Introduction
This paper seeks to contribute to the general field of virtual teams by looking at how virtual team facilitators use electronic communication channels to build and manage relationships with their team members. Virtual teams can be defined as temporary, culturally diverse, geographically dispersed, electronically linked workgroups. Virtual teams may communicate and work synchronously or asynchronously through such technologies as electronic mail, bulletin boards, audio/video/data conferencing, automated workflow, online chat, electronic voting and collaborative writing (Coleman 1997). Virtual teams are playing an increasingly important role in organizational life and can offer organizations, including educational institutions, the flexibility to remain competitive. The benefits of virtual teams, particularly relevant in the areas of research and teaching, include reductions in costs and risks and expanded access to expertise and knowledge (Lewis 1998).

O’Hara-Devereaux & Johanson (1994) define facilitation as "the art of helping people navigate the processes that lead to agreed-upon objectives in a way that encourages universal participation and productivity", and place process facilitation skills as some of the most crucial for managing and leading global teams. Virtual team facilitators are often the center of a virtual team. They must be able to manage the whole spectrum of communication strategies via new technologies, as well as human and social processes.

Most of the extant research on virtual teams has been anecdotal and descriptive with little in the way of systematic, empirical research (Furst et al. 1999). This is particularly true when virtual team facilitators are the main focus of study. Although the importance of facilitators in virtual teams is noted in the literature (Kimball 1997; O’Hara-Devereaux & Johanson 1994), and suggestions for facilitating virtual teams are enumerated, no systematic research where the facilitator of virtual teams is the primary focus of study has been located. Nunamaker et al. (1999 p27) state that, "little research has yet been undertaken to understand and improve the process of distributed facilitation." This paper seeks to address some of these gaps.

Communication Channels in Virtual Teams

Technological infrastructure can strongly impact virtual team effectiveness in ways that a facilitator may or may not be able to effectively manage. For the smaller organizations, financial limitations are often a significant factor in the communication resources virtual teams have at their disposal. In global virtual teams, there may be significant problems with access to technology due to underdeveloped national infrastructure or the
high cost of broadband internet connections. Software and hardware compatibility among team members is another issue that can affect the choice of communication channels.

However, while electronic communication channels support the networked organization by providing tools to solve collaboration oriented problems, Coleman (1997) warns that focusing only on technical issues can lead to expensive failures, while focusing on the people and al issues dramatically increases the possibility of success. al policies or the lack of them can impact the effectiveness of virtual teams. Many companies have no formal company or HR policies on virtual teams. Virtual teams are often formed on an as-needed, ad-hoc basis. Another issue that can be a factor is team member competence in using various technologies. This may be an al training issue, but in some cases it may be a member-selection issue (Jarvenpaa et al. 1998) as some people may have a psychological dislike for certain communication channels (Warkentin et al. 1997). Another one of these important “people” issues, is relationship building.

Stronger relational links have been associated with higher task performance (Warkentin & Beranek 1999) and the effectiveness of information exchange (Warkentin et al. 1997). According to Lau et al. (2000), effective communication is the key to successful virtual teams, and one of the keys to effective communication is how well team members are able to build and maintain their personal relationships. Kimball (2000) states, ”the purpose of building and maintaining relationships in teams is to ensure that individuals develop at least enough harmony to be able to get their group work done”. Building relationships with virtual team members is clearly of fundamental importance to a virtual team facilitator. According to Walther & Burgoon (1992), strong relational links are associated with enhanced creativity and motivation, increased morale, better decisions and fewer process losses. Research shows it is easier to complete relationship-building activities in a face-to-face context than in a strictly virtual one (Warkentin et al. 1997). This may in part be explained by media richness theory, which explains that the lack of contextual cues and timeliness of feedback inherent in computer-mediated communication can negatively affect the building of relationship links (Daft et al. 1987).

Research has found that computer-mediated teams do share relational information and are likely to develop relational links over time (Warkentin et al. 1997). However, since many virtual teams are project or deadline driven, there may not be the opportunity to allow relationships to develop over time. The idea of “swift trust”, put forth by Jarvenpaa et al. (1998), describes how virtual team members may be able to accomplish tasks without first having developed relationships. This rational perspective centers on the view of “calculus of self interest” (ibid), which weigh the cost and benefits of certain courses of action between team members. If team members feel confident there will be a “payoff” for co-operating with and trusting virtual team members than they will do so. However, such trust appears to be very fragile and temporal.

In the following section, a methodology that generated data relevant to the question of how virtual team facilitators develop relationships with their team members is discussed.

**Study Methodology**

Because virtual teams are a new form of highly dynamic and ambiguous collaborative interaction, a major challenge of this study was the need to generate relevant data and analyse it in an appropriate manner. To achieve this, a research framework involving a training program format was instituted loosely based on methods already developed in action research, with data collection and analysis based on grounded theory methodology (Glaser & Strauss 1967; Strauss & Corbin 1990). This linking of these two research methodologies has been called grounded action research (Baskerville & Fries-Heje 1999).

The intent of this training program was three-fold: to generate interest and incentive for would-be participants, to give participants information and skills to initiate and facilitate their own virtual teams, and to generate data for analysis. After being recruited, participants were interviewed to determine their prior experience with virtual teams and their perceived needs and concerns in implementing and facilitating their own virtual team. The researcher then developed a ten-week training program to meet these needs. A pilot program and two subsequent training programs were held. As the participants took part in the training programs, each participant planned for, or actually initiated and facilitated a virtual team within their own organizational context. Data was collected from 1998 -2000 and came from face to face and telephone interviews, group discussions and e-mail correspondences. Some of the most significant concepts and their relationships to emerge from the data revolve around how facilitators use electronic communication channels to build relationships with their virtual team members, and this is the subject of this paper.
Results

Although the range of participants, their organizational contexts, virtual team lifecycles and virtual team tasks were varied, the data revealed a common concern among the facilitators as they went about the initiation and facilitation of their virtual teams. This concern has to do with building and managing virtual team relationships using electronic communication channels. According to the facilitators, the development of personal relationships between themselves and team members is an important prerequisite in establishing and maintaining virtual working relationships. What follows are descriptions and discussion of how the facilitators used the communication channels available to them to build relationships with their virtual team members.

Although face-to-face communication is clearly not an electronic communication channel, most of the facilitators in this study believe that face to face meetings, preferably at the formation of the virtual team, are the most effective way to build personal relationships. Why they feel this way is instructive, because in many cases they are seeking to emulate the relationship building processes and results of face to face meetings in their electronic communications. According to the participants, face to face meetings give facilitators the opportunity to understand individual team member communication styles and personal and professional motivations, making it easier to then move into virtual working relationships. One facilitator explains it this way,

You can find out what motivates them, what makes them tick. That's what I think forms part of my thoughts on why you need to meet face to face. You may get a much richer sense of what is important to the person. I would find it much easier to say over a beer what is important to me then in a chat room.

Face to face meetings also allow a deeper kind of rapport, or trust to develop. For some of the facilitators, relationship building is a prerequisite to a working relationship, and face-to-face contact is an essential part of relationship building. In these cases facilitators can only use electronic communication channels after they have developed personal relationships. However, the facilitators working exclusively through electronic communication channels had to strategize ways to build relationships through the electronic channels they had available to them.

The facilitators see e-mail as the basis of their virtual teams' deliberations, effectively linking their distributed teams (Kettinger & Grover 1997), but they are unlikely to agree with Finholt's & Sproull's (1990) contention that e-mail can enable a team to create and sustain its identity without a shared physical setting, at least not by itself. The facilitators see e-mail as a channel more suitable for communicating information and coordinating projects than for building relationships. According to the facilitators the advantages of e-mail - being a universal platform, cost effective, generally accessible, easily learned, offering succinct messaging and the ability to send attachments quickly and efficiently - often carry a down side that on several occasions threatened to derail the facilitators' virtual teams.

One facilitator, who did not make any special effort to build a personal relationship with his team members before commencing a work relationship, relied almost totally on e-mail in his communications with team members. Because this facilitator is very comfortable using e-mail, he made the assumption that his team members were as well. This led to some serious miscommunications. In one instance he made an ironic comment in an e-mail that gave great offense to the team member, who was also the client. In another e-mail the team member "buried" a serious concern in an e-mail with a dozen other points. The facilitator overlooked the point, the significance of which became apparent only at the end of the team project. This problem concerns the low context text-based nature of e-mail, which requires the writer to clearly articulate the intended message (Barnes & Greller 1994). If the client had mentioned his concern in a face to face meeting, the facilitator would have picked it up. The facilitator explains,

He did mention his misgivings in the first instance, but he did not put it out there very strongly and I dismissed it. In a face-to-face situation I would have picked up the nonverbal cues how stressed he was about the whole thing. But as a throwaway line in an e-mail on 10 different subjects....

Another important issue in virtual teams is the timely response of team members to internal communications. Kettinger & Grover (1997) noted that a significant feature of e-mail is that both the sender and recipient can control the timing of their portion of the communication. The facilitators in this study have clear expectations that e-mail, as well as other communication messages such as voice mail, will be replied to in a prompt manner. They believe that a lack of timeliness can lead to poor communication, the creation of ill will, and an undermining of relationships. Two facilitators sometimes felt a loss of control when using e-mail. They
felt they were at the "mercy" of the recipient. When e-mail went unanswered for some time, they had to fall back on telephone calls to try and establish a direct link and rebuild relationships if necessary.

The telephone seems to be an old reliable standby for facilitators when it comes to building relationships with virtual team members. It is apparently more comfortable to use this channel when getting to know people. With the use of the phone being second nature, the facilitators feel that they can pick up paralinguistic clues from their team members, which can assist in relationship building (Perey 1997). Phone calls are often used at the formation of a virtual team in order to get to know some one quickly. One facilitator found these initial phone calls useful for "groundbreaking types of conversations". She explains, "with a phone call I can get a feeling for them and they can get a feeling for me."

Picking up the phone may seem the obvious solution in getting to know team members when working virtually, but for some of the facilitators it is problematic. One facilitator, who owns a global consulting company, finds international telephone calls a major expense. He has resisted using them as a means to build relationships with clients and consultants, although he realizes that he needs to do something to strengthen team relationships. He generally uses phone calls to initiate business relationships, but believes the time and expense to use phone calls to build relationships is not practical. This facilitator feels quite awkward calling people he is involved with professionally to "chat about life the universe and everything". He explained these are busy people and when you use electronic channels it is expected that you will "get down to business".

However, this particular facilitator, who relies heavily on e-mail and synchronous text chat programs to communicate with his team, experienced a number of miscommunications with a team member that he attributed to a lack of prior relationship building. He realizes he is going to have to make a serious effort in the future to get to know his team members better before settling into work relationships. Although his organization is in tight financial circumstances he is now willing to invest in some "upfront" phone calls as an "investment" in relationship building.

One of the most interesting findings in this study was the way facilitators used internet-based messaging and chat programs such as ICQ to set up opportunities for informal, spontaneous communication between facilitators and team members. ICQ is free software that allows its users to know when (in this case) virtual team members anywhere in the world are connected to the internet. It then allows one member to contact another directly and to open up a chat box to hold synchronous typed conversations. Two facilitators looked to ICQ to build personal relationships in their teams. By its nature, ICQ can lead to spontaneous, informal conversations between team members that the facilitators believe can help to strengthen relationships. For one facilitator, with no opportunity for face-to-face meetings, the informality and spontaneity engendered by the use of ICQ was an important relationship building channel, which complemented the more task-oriented e-mail channel. He actively encouraged the downloading of ICQ as one of his first actions in the initiation of his virtual team. He explains his motives,

The idea of ICQ was not as a group meeting thing, but to get some conversations going between the people in the group. And if they were using ICQ properly they would know when anybody else in the group was online. In fact the few conversations with people I had who were on line at the time were more time of day conversations, how are you type, not about anything substantial. But the thought was and it may well be fruit in the longer term, was that if everybody was on ICQ and if we kept going with this process than the opportunity was there for people to talk privately. And I felt the ICQ thing could provide the corridor type of relationship where tasks can progress without the use of planned meetings.

This use of ICQ mirrors suggestions made by Kraut et al. (1993) that informal encounters create a common context and perspective that support group work. ICQ may facilitate socialization processes that allow team members and facilitators to participate in activities happening at the "backstage" (Goffman 1990), where they can exchange feelings and emotions thus building and maintaining relationships and minimizing feelings of isolation that can lead to reduced intrinsic involvement in the team (Finholt & Sproull 1990).

Desktop videoconferencing is another channel that holds great promise for the facilitators in this study. They believe that "eyeing" people is an important part of relationship building, particularly when the only alternative is e-mail or synchronous text-based meetings. Videoconferencing has been in use since the early 1960's (Perey 1997), but in the past it was expensive and the quality was not good. However new internet-based desktop videoconferencing technology is bringing the cost down, although the quality and reliability of internet-based transmissions are often poor.

Most of the facilitators are very interested in incorporating Netmeeting, a free software program by Microsoft and one of the most common desktop applications, into their virtual teams and some experimented
with it during the training program sessions. In desktop videoconferencing, they see a low-cost virtual communication channel that could provide a workable alternative to face to face meetings. Netmeeting, for example, allows two people anywhere in the world to see and hear each other. It also allows team members to share and work on documents. One facilitator believed that setting up an internet-based video conferencing communication channel with an overseas branch office would build personal relationships resulting in greater personal trust between geographically separated organizational members thus strengthening the organization as a whole. As he explains,

I don't mean trust in a professional level of trust, but just getting to know the person, building a relationship with Graham in Melbourne. To my mind, that's the key output or objective of a lot of this.

Lau et al. (1999) argue videoconferencing can enhance social relationships by putting a face to the name. Perey (1997) states conscious and unconscious communications supported by two-way video can build and nurture relationships. However, a recent study looking of the effects of desktop videoconferencing on improving trust relations in virtual team working projects (Nandakuhmar 2000) suggest information and communication technologies, such as Netmeeting, appear to be inadequate for building "trust relations", primarily because they do not support 'backstage' access, normally found in face-to-face environments. In any case, the use of internet-based video conferencing communication is still problematic, as access to sufficient and reliable bandwidth is a significant barrier to many potential users.

Conclusion

Successful virtual teams often use different technologies to enhance the breadth and depth of their communication (Lau et al. 1999). Facilitators in this study realize that they would have been unable to operate virtual teams and accomplish their project tasks without electronic communication channels. At the same time they understand that the use of these channels as the main working communication channels in their virtual teams would be problematic, without having first established personal relationships with team members. The development of personal relationships, according to one facilitator, would make the building of a team "culture of cooperation" more likely. In order to build relationships, facilitators need to strategically use the communication channels they have available to them.

This study finds that when face-to-face meetings are not an option, virtual team facilitators can effectively use electronic communication channels, particularly some of the more familiar or higher-context virtual channels such as the telephone or desktop video conferencing to build relationships with team members. ICQ also seems to hold some promise as an "backdoor" channel that may encourage informal communication and relationship building. The key challenge for virtual team facilitators is to make a conscious and concerted effort, which can be termed facilitator strategies, to develop personal relationships with team members through the use of available communication channels (Figure 1).

**Figure 1: Relationship Building in Virtual Teams**

![Figure 1: Relationship Building in Virtual Teams](image)

Facilitator strategies will include the selection and use of appropriate communication channels and appropriate message content. The level of relationship between the facilitator and team members necessary to accomplish the team's task is one of the key determining factors in creating a facilitator's strategy. Other important factors in determining facilitator strategies, some of which are alluded to in this paper, include issues concerning team member selection and training, organizational and HR policies, as well as the team's desired task outcomes and cultural biases toward communication channels particularly in global, multicultural virtual teams.

Abstract: If the internet in education' is framed and conducted strategically with at least a little insight rather than in an ad hoc way, then learners will be more likely to not only forgive you but even thank you for guiding them through the inevitable stage of temporary frustration to the initial steps of self-empowerment. The paper outlines an integrated approach which would not only encourage but actually serve to 'convert' reluctant learners into actual keen users: (a) as a theorization of the presenters' own experiences with teacher education courses; (b) in terms of simple activities involving, say, information literacy and web design linked together to produce an initiatory 'aha' effect of seeing underlying or generic connections between a variety of internet skills, processes and potential educational applications; and (c) with an appreciation of how even 'difficult' students can be most impressive if allowed initiative with their own learning. The paper will further discuss three practical stages in the process of 'internet in education' conversion which also constitute key principles of an integrated theoretical framework.

Introduction: the transition from old to new learning

There are many human transitions and life experiences where reasoning by reflection or through discussion with others is not enough if a person is to effectively respond to new or inevitable challenges and develop changed habits and practices. For many in the electronic age – especially those who grew up accustomed to books and mere machines – the computer with its various additional networking and multimedia functions represents one exemplary instance where people often need help to individually tackle and overcome underlying fears and critical thresholds in order to proceed confidently in life. Fine ideas about the possibilities and potentials of fundamental new media of human communication and knowledge are not sufficient also. Many people need to be converted not just convinced through progressive and purposeful stages of first-hand practical experience also. On the other hand, young 'internet-savvy' kids today are almost instinctively aware of and easily converted to the attractions and possibilities represented by interactive electronic media. However, those brought up to feel very much at home in the digital age with all its multimedia seductions may well have an increasingly greater need to be converted rather to some of the enduring human needs and possibilities of education exemplified by or mediated through spoken and written words. The discussion below is thus ultimately concerned with the convergent problem of getting any student (including older, parental, and especially teacher learners) interested, excited, and personally engaged with both the process of learning and the use of new technologies – that is, concerned with the dialogue between old and new ways in which young and old students alike learn to productively interact with a changing world.

This paper further represents a distilling of the presenters' personal experiences over several years in terms of a similar reflective inquiry into the problem of integrating computers and the internet more effectively in teacher education courses. Taking the path that such courses really need to have some degree of practical grounding to have any significant degree of applied or even critical integrity, both presenters have come to appreciate that the path towards a more integrated and effective approach towards Information and Communication Technologies (ICTs) in formal teacher education especially is: (a) somewhat similar across different cultural contexts; and also, (b) recapitulates the inevitable learning stages navigated by individual learners of new electronic literacies and technologies. Various innovations help to make this less intimidating and frustrating, and more effective – for instance, the provision of needed support and resources, the 'grounding' of learning and assessment in terms of activities and reflections through electronic portfolios, and allowing an overlap between learner's utilitarian reasons and personal motivations (i.e. work and pleasure) for using various programs and functions.
This, however, there has been a strong sense of how students generally have viewed such courses in retrospect as a 'journey' of engagement initial fears and frustrations - where an engagement with initial fears should give way to a sense of renewed confidence as well as to the excitement of new worlds of possibility.

Most salutary have been the examples of how some of the initially frustrated and intimidated students went on to become some of the biggest success stories in these courses. Of course, we were only too well aware that this was largely their own doing, and also that particular students were exceptional in that they were able to transform initial skepticism into effective practice because they were critically reflective but still sufficiently open to new possibilities. But the question both of us asked when starting new jobs and assigned to teach an introductory ICT skills together was this: if we could only identify more effectively some of the key principles of a successful ICT learning process exemplified by those exceptional students, then we might also develop courses which integrate ICTs more effectively. In the process of attempting to do this in terms of connecting the macro and micro levels of an integrated framework then, we came to appreciate more fully that this is above all else a process of 'conversion' in which the stages of developing ICT competency involve a transition across a threshold of 'temporary frustrations'. Prior to learner conversion, teachers face an uphill struggle against the inertia of initial frustration and general boredom or reluctance. Following conversion, learners become intrinsically motivated by the very nature of a new, powerful, and exciting medium. Enthusiastic learners allow teachers to focus more on designs for applied and higher-order learning (i.e. teaching in the timeless sense of the term), rather than just perpetually getting to 'first base' in the learning process.

Why reluctant or intimidated users of computers and the internet need to be 'converted' in a practical way

Anyone attempting to integrate ICTs in their learning or teaching is up against more than just a simple fear of computers - as pervasive and intimidating as that might be. Indeed, those reluctant to enter the digital age have perhaps not been intimidated so much by computers or the internet specifically, but possibly more by how the social and educational implications of computer networking and associated multimedia have tended to be viewed and discussed in polarized terms of either positive potentials or negative dangers - with little room for balanced or well-informed discussion. Like other technological 'breakthroughs' before, various programs and functions of the internet are regularly and uncritically lauded in a way which may ironically reinforce a general sense of passivity, superficial understanding, and an attachment to old ways of practice. Many people set up an endless cycle of unrealistic expectation and subsequent disappointment by projecting onto the latest new technological tool or concept their secret wish for a 'magic bullet' which would allow them to passively master wonderful new skills and functions without having to get their own hands on the keyboard, without progressively developing a basic ICT competency in terms of thinking about relevant or possible applications. The uncritically optimistic embracing of new ICTs in general as a prescription for future education is often pursued with little understanding of what is needed for effective integration, and in a way which may devalue enduring notions and objectives of education held by parents and teachers. Conversely, an uncritical pessimism which is so quick to point out these faults is not only often blind to valid future possibilities but tends to romanticize and gloss over the existing faults of formal education as a context for learning.

Similar contradictions and ambivalence are evident at the 'micro' level of individuals attempting to become technologically literate and to integrate ICTs into their learning or work, and into their everyday generally. In other words, new technologies represent a useful focus for understanding that what people say and do is not always consistent - even when people are sincere and well-intentioned. To put it another way, many people are not fully aware of their own underlying preconceptions and prejudices about ICTs (Richards, in press). This includes optimists as well as pessimists. The naively optimistic learner who dares to undertake an unrealistic or overly-ambitious use of computers or the internet for whatever purpose may experience the kinds of initial frustration and failure which results in them becoming the kind of cynical pessimist who is equally closed off from further progress and a balanced appreciation of possibilities and potential applications. In short, naively optimistic and cynically pessimistic approaches to IT in education specifically and society generally both tend to reinforce a vicious circle. Thus the rhetorical polarization between optimistic and pessimistic perspectives at the macro level of policy, theory, and mere rhetoric often translates into self-fulfilling prophecies of initial failure and disillusioned expectations at the micro level of hands-on practices and specific learning objectives.

As already indicated, mere 'intellectual conversion' is not enough to effectively learn to use computers and the internet. Perhaps one of the main reasons why teachers often lag behind parents, policymakers, and others who increasingly subscribe with enthusiasm to a future digital paradigm of education is possibly that they realize
better than anyone else how much damage can be done if this is not done well and in a truly integrated way. Teachers inevitably have first-hand experience of the pressures and dilemmas of what might be referred to as the 'macro-micro gap' or 'missing link' between forward-thinking policies and well-intentioned theories on one hand, and specific requirements for across the curriculum integration and hands-on learning on the other (i.e. between thinking and doing, and also educational content and the learning process). They are expected to respond to new policy directives for ICT integration in education and somehow translate these into integrated practices of teaching and learning. Although most teachers are quite aware of the increasing and inevitable importance of the internet for the future, many are simply unable to overcome subconscious resistances and rationalizations to become effective ICT learners themselves, let alone provide learning environments for their students to do this. People who are keen users of the internet are more likely to have become so through the self-taught approach (otherwise known as the ‘trial and error’ or even ‘sink or swim’ method), often with the informal assistance of friends, rather than through formal training, structured courses, and designated support.

In other words, there tends to be a great gap between self-learning and formal education when it comes to ICTs. For most people the ‘conversion’ to ICT competency is a relatively ad hoc process driven more by accidental needs or unspoken desires than a visionary plan. However, if ICTs are not integrated into education effectively then teachers are failing to harness or ‘convert’ the power, the excitement, and the applied possibilities of a new medium which can open up new worlds of possibility for learners (Richards, 1999, 2000). A younger generation of students tend to find the world of the internet and interactive multimedia exciting in contrast to the traditional focus on content knowledge in schools. Those teachers who completely ignore or arbitrarily dismiss the world of the internet and interactive multimedia in contrast to the traditional focus on content knowledge in schools will only reinforce young learners’ sense of boredom and even resistance in relation to ‘old’ notions of education. They will also lose any remaining ‘connection’ with their younger students. Young learners will inevitably interpret such reluctance and even antagonism towards digital media as some sort of signal that their teachers are not really interested in them or their learning – reinforcing a cultural gap between formal education and popular everyday contexts of informal learning. In contrast, strategic teachers do not resist or oppose ICTs generally, but attempt to harness student interests in new media and convert this into productive applications and many of the educational values of ‘old’ learning.

The conversion of reluctant or intimidated students (especially teachers) into keen users of Information and Communication Technologies (ICTs)

The term conversion is often used to refer to the process by which an external agent directly effects a fundamental transformation in somebody or something (e.g. in the sense that a priest or politician might convert someone else to a religious or ideological point of view, or that an alchemist or scientist seek to transform a physical substance into another form). It is used here rather in the two related senses of: (a) a general harnessing of student interest in the internet for learning purposes; and (b) a more specific but still indirect framing of the student learning process. In the general sense, this is really more a facilitation of the learners’ conversion from reluctant or intimidate student to keen user of the ICTs as suggested earlier, akin to the notion of a journey that is its own destination. The idea of conversion used here is thus also an adaptation of the anthropologist Victor Turner’s (1967) notion that learning can be transformed by the liminal dimensions of undergoing a symbolic journey to achieve knowledge grounded in practical experience. The discussion below will thus revolve around the idea that the design of a course structure can always be further refined, and that learning environments for integrating ICTs in education can always be made more effective. Such an idea reflects some underlying principles of transformation which are not simply accidental but represent transferable principles. In terms of an earlier distinction between the process of self-learning and formal course provision, it represents a kind of ‘middle path’ between theory and practice which embraces both intellectual and practical conversion.

The three sub-sections below represent three practical stages in the process of ‘internet in education’ conversion, as well as constituting key principles of an integrated theoretical framework. The first section - setting the stage for transformation - discusses the ‘cultural’ as well as technological requirements for designing learning environments: requirements which are relevant to the changing role of teachers in the internet age, and will also appropriately encourage, support, and guide learners to venture out of existing ‘comfort zones’ into the realm of that which is new, unfamiliar, or undergoing change. The second section will discuss the convergent stage of an initial ‘aha’ effect experienced by learners within an integrated framework as they begin to see the connections between internet skills and programs, experience a provisional sense of accomplishment, effective interaction, and appreciate new media possibilities. In the third section, the paper discusses the ongoing
conversion progress in terms of a generic 'internet literacy' geared for across the curriculum applications, and also the progressive and productive links made between personal and academic learning objectives.

**Designing the context of conversion**

An effective learning environment for ICTs in education requires both indirect and direct elements of design and development which together constitute a 'middle path' between a flexible self-learning process and the formal structure which integrates various elements in relation to the specific context at hand. The indirect requirements for this simply relate to the various ways in which students can be encouraged to feel more relaxed, confident, and interested about learning to use ICTs for educational purposes. In other words, a strategic rather than ad hoc approach attempts to take an integrated approach towards the use of ICTs in education in terms of the following different elements: the provision of better support or safety nets for individual learners; customization of courses in terms of greater relevance to immediate needs or personal interests; a focus on transferable generic skills and applied orientation rather than on skills in a vacuum; and a more integrated approach to the connections between content and process, learning and assessment, etc.

The more direct elements of IT integration relate to a basic activity-reflection cycle at both the macro and micro level of student learning. At the micro level, this cycle refers to the use of specific learning activities to ground reflective knowledge in hands-on practice and also familiarize students with various programs and skills in terms of an applied focus. Of course, the specific design of any course which attempts to effectively integrate ICTs would be dependent on its overall context, purpose and structure. As an organizing strategy of learning and assessment at the macro level, the activity-reflection cycle represents an integrated approach to not only using ICTs in education but using them as general tools for more effective learning. Mention was made earlier to how such an approach can go beyond a mere 'skills acquisition' approach to also focus on both indirect and direct requirements of attitude and application in the use of ICTs in education. Lending itself to concepts of project-based learning and electronic portfolios (i.e. as specific learning and assessment tools), an 'activity-reflection' approach allows a teacher or designer of learning to distinguish in practice between mere competency and higher-order stages and levels of learning using ICTs. Representing a strategic approach which contrasts with a merely ad hoc one of 'just-in-time' planning, it provides a more effective context for reconciling general and specific learning objectives on one hand, and the often contradictory educational imperatives of content and process on the other.

Above all else, a strategic approach to using ICTs in education aims to get students to link up their 'thinking' and 'doing', to become more effective reflective practitioners, and to ground their conceptual and content learning in actual contexts of practice and process. In contrast to the traditional classroom, the internet is a relatively 'authentic' learning resource for various 'generic skills' which involve the accessing of information, communication, and interactive learning. It encourages actual as well as hypothetical exercises in cooperative or independent problem-solving – as policymakers and other academic advocates are aware, a natural vehicle for collaborative, independent, and lifelong learning. In contrast to written or print media, its facility for self-expression and publication (e.g. student assignments developed as webpages for a potential audience beyond the teacher, or perhaps as online interactions with other classrooms or learning communities) represents a most powerful and motivating culmination of the learning process. The key to integrating the internet and associated electronic multimedia in education, and using ICTs to transform education generally, thus lies at the intersection between personal motivation and potential utilitarian or work purposes. To see a connection and make this link also requires a conversion or transformation in thinking and perception from traditional modes of education.

**The initial act or stage of conversion**

The realization of creative or critical insight has perhaps most appropriately been referred to as the 'aha' effect (Koestler, 1989). It is thus a useful term to refer to how the transformation of bored or resistant users of the internet and computers generally in education into keen users often involve a change of perception and thinking. For some people, the transition from seeing mere data, skills and machine parts in a reductionist way to appreciating the internet as the media of a new paradigm of human literacy and learning will be gradual process of realization with a particular stage of conversion – for others, especially the most reluctant, intimidated or resistant generally, it can be an instantaneous act of transformation. The act or stage of conversion was linked above to two related 'missing links': firstly, the problem of linking macro and micro levels of educational design by teachers; secondly, the issue of linking student thinking and doing. As a convergent dilemma, conversion may thus be identified here as either an abrupt or gradual resolution to the threshold or predicament of temporary frustration involved when people attempt to learn and use new technologies. In other words, the
The concept of conversion was invoked in order to describe and discuss how the ‘critical point’ of a transition from basic ICT competency into effectively integrated and applicable knowledge is as much an attitudinal and even cognitive transformation as a process of sufficient skill acquisition. This is the key challenge for an ongoing process of conversion. Just as conventional models of computer education have tended to emphasize the acquisition of skills within a vacuum, so too many teachers make the opposite ‘error’ of focusing on the extent to which ICTs might be directly relevant to the teaching and learning of subject-specific content. An inadvertent result of this ‘add-on’ approach is that an opposition is implicitly set up for many students between the exciting medium of the internet with all its popular cultural associations on one hand, and a growing perception of content learning in subjects like history and mathematics especially as boring or even irrelevant in comparison on the other. The concept of a threshold of conversion in the learning and use of ICTs in education represents substantial progress along a ‘middle path’ often represented as a kind of journey by students. The ‘creative integration’ of ICTs in education has been usefully recognized as the culmination of a series of learning stages proceeding from initial skill acquisition to eventual applications (Somekh, 1998). However, like other similar models, Somekh’s stages represent a somewhat linear progression which does not do justice to the challenge of crossing the ‘threshold of temporary frustrations’ as it has been identified here in relation to the learning of ICTs and new technologies.

The ongoing process of conversion

This is a stage where provisional insights begin to be transformed into new habits or changed practices, and initial excitement is converted into the quiet confidence of a grounded reflective practice. In terms of the typical opposition between naïve enthusiasm and cynical resistance to ICTs in education outlined earlier, it represents substantial progress along a ‘middle path’ often represented as a kind of journey by students. The ‘creative integration’ of ICTs in education has been usefully recognized as the culmination of a series of learning stages proceeding from initial skill acquisition to eventual applications (Somekh, 1998). However, like other similar models, Somekh’s stages represent a somewhat linear progression which does not do justice to the challenge of crossing the ‘threshold of temporary frustrations’ as it has been identified here in relation to the learning of ICTs and new technologies.

The key point of this paper is that the process by which exceptional individual learners in particular informally overcome their initial frustrations and get converted to internet literacy might be structured into formal course provision and education generally much more effectively as a strategic design rather than merely ad hoc happening for all learners. Top-down educational policies for general ICTs integration also require the more informal, bottom-up, and ‘cultural’ elements of effective specific or micro integration as indicated above, at the contextual levels of actual resourcing rather than merely hypothetical access, and in terms of actual learning and assessment practices as well as direct connections to subject-specific curricula. Effective course design will become easier when a critical threshold of internet and digital literacy is achieved by teachers and learners alike. In two related presentations at this conference, we have discussed in more specific detail how the initial conversion of an entire class of reluctant or intimidated learners might be achieved in an introductory internet skills course which capitalize on how many of the basic functions of the graphic interface for computers and the internet are similar for different programs, and also involve a range of transferable skills. Such courses provide an exemplary focus for the process by which ICTs might be integrated generally across the curriculum in terms of developing applied thinking in initial familiarization activities – an orientation grounded in transferable skills and knowledge in relation to generic or typical computer and internet programs. To have enduring effect, any initial act or stage of conversion into the future possibilities and requirements of ICTs in education needs to be grounded in actual practice to some degree and also transformed into a habitual yet confident and flexible practice (i.e. an ongoing or regular ‘literacy’). It is one thing to have an insight into new possibilities; another to translate this into regular practice. ‘Conversion’ is thus an ongoing process beyond an initial act or stage.

The ongoing process of conversion

This is a stage where provisional insights begin to be transformed into new habits or changed practices, and initial excitement is converted into the quiet confidence of a grounded reflective practice. In terms of the typical opposition between naïve enthusiasm and cynical resistance to ICTs in education outlined earlier, it represents substantial progress along a ‘middle path’ often represented as a kind of journey by students. The ‘creative integration’ of ICTs in education has been usefully recognized as the culmination of a series of learning stages proceeding from initial skill acquisition to eventual applications (Somekh, 1998). However, like other similar models, Somekh’s stages represent a somewhat linear progression which does not do justice to the challenge of crossing the ‘threshold of temporary frustrations’ as it has been identified here in relation to the learning of ICTs and new technologies.

The concept of conversion was invoked in order to describe and discuss how the ‘critical point’ of a transition from basic ICT competency into effectively integrated and applicable knowledge is as much an attitudinal and even cognitive transformation as a process of sufficient skill acquisition. This is the key challenge for an ongoing process of conversion. Just as conventional models of computer education have tended to emphasize the acquisition of skills within a vacuum, so too many teachers make the opposite ‘error’ of focusing on the extent to which ICTs might be directly relevant to the teaching and learning of subject-specific content. An inadvertent result of this ‘add-on’ approach is that an opposition is implicitly set up for many students between the exciting medium of the internet with all its popular cultural associations on one hand, and a growing perception of content learning in subjects like history and mathematics especially as boring or even irrelevant in comparison on the other. The concept of a threshold of conversion in the learning and use of ICTs in education provides a focus for teachers to conceptually as well as practically overcome a sense of entrapment in a series of related self-defeating binary oppositions in education: for instance, naïvely enthusiastic vs cynically resistant perspectives, content vs process objectives, personal vs utilitarian interests, and generic vs specific skill acquisition. Instead of having to merely theorize the great gap between initial skill acquisition and eventual mastery of this as applied knowledge, teachers should be able to focus on making practical connections and themselves crossing the critical threshold of ‘temporary frustrations’. Put simply, teachers would be well advised to: (a) focus more on generic skills of learning with ICTs than either specific skills or content knowledge per se; and (b) to begin courses with introductory activities which aim to connect with student immediate interests and needs, and later develop the course in a way which can be more directly related to higher-order knowledge applications of ICTs.
Teachers are often resistant because of a perception that ICTs represent a threat to the integrity of their subject as a specialist curricula. Such teachers would find that ICTs encourage the kind of generic learning and literacy skills which have specific application to different subject areas as well as cross-disciplinary approaches to knowledge in the applied sense. At this point it should become easier for educators to appreciate how and understand why ICTs are not really a threat to the educational profession and the traditional roles of the teacher. Rather, used effectively, they may provide the means for allowing some negative roles (e.g. mere information or skill-in-a-vacuum transmitter, discipline provider, and child-minder) to become less burdensome. Conversely they offer potential to encourage teachers to design contexts of learning which encourage collaborative and independent learning, critical and creative thinking, and collective and individual self-knowledge.

Conclusion: Educational implications of a conversion model?

Perhaps the most well-known model of education as a process of conversion is still the Socratic questioning technique as a method to lead students into making transformative connections between knowledge and ignorance, as well as thinking and doing. Socrates' view of the teacher as a kind of 'mid-wife' facilitating the birth of new knowledge in students has particular relevance for the integration of IT in education. In contrast to the traditional 'transmission' models of education (i.e. where the authoritative teacher transmits 'knowledge' to passive and empty-minded students) and associated theories of learning such as behaviorism, many recent and influential theorists have emphasized the constructivist implications of ICTs in education (e.g. Jonassen, Peck, & Wilson, 1999). The ‘conversion’ model of learning with technology advocated here embraces many of the principles of constructivism but goes beyond this approach in two important senses: (a) it recognizes learning with ICTs in terms of crossing or overcoming a threshold of ‘temporary frustrations’ which delineates initial skill acquisition and attitudinal polarization or ambivalence on one hand, and the applied knowledge of grounded reflective practice on the other; (b) it emphasizes the still important role of the teacher as a designer, modeler, and facilitator of effective learning environments and learner conversion.

The conversion model outlined above derived from initial efforts to reconstruct formal ICT course design in terms of key ‘self-learning’ stages discerned in learners who exemplified the transition from reluctant or intimidated learners to confident computer-literate or ‘internet-savvy’ practitioners. These students were able to bridge the gap between thinking and doing (also personal interest and utilitarian purposes) in terms of a conversion effect which was built on the crucial interplay of effective attitude and sufficient skill acquisition. Likewise, the integration of ICTs in formal education requires an interdependent framework of technological and human resources, curriculum and pedagogy, and learning and assessment which addresses the ‘macro-micro gap’ in a strategic rather than a merely ad hoc way – the crucial interplay of top-down imperatives of policy, theory, and rhetoric on one hand, and hands-on practices or specific learning objectives on the other. Thus, the key stages of educational conversion (i.e. relevant context preceding initial and ongoing transformations of the link between thinking and doing) also constitute key principles of an integrated approach to ICTs in education – the design of effective learning environments and processes, the facilitation of an initial ‘aha’ effect where learners begin to see new connections and applied possibilities, and the ongoing conversion progress in terms of an across-the-curriculum ICT ‘literacy’.

A Rubric for Assessing the Interactive Qualities of Distance Learning Courses: Results from Faculty and Student Feedback

M. D. Roblyer, Professor of Media & Instructional Technology
State University of West Georgia, College of Education, U.S.A.
(mroblyer@westga.edu)

(lekhaml@westga.edu)

Abstract: Results of studies of distance learning courses indicate that interactive qualities seem to be a major factor in determining course quality as reflected in student performance, grades, and course satisfaction. That is, the more interactive the course, the more effective it is. However, the field reflects considerable disagreement on what these interactive qualities are and how they should be assessed. This paper offers a rubric to help instructors begin to identify and self-assess these qualities in ways that assist them in improving their distance courses. Included in this paper are: an explanation of rubrics and their uses; a review of literature related to interactive qualities that led to identifying elements for the rubric; a discussion of methods used to gather feedback and revise the interactive qualities rubric draft; and a copy of the revised rubric itself.

Introduction

Distance learning research literature supports the observation that a primary factor shaping course quality and effectiveness is the amount of interaction in the course (Fulford & Zhang 1993; Klesius, Homan, & Thompson 1997; Zhang & Fulford 1994; Smith 1996; Zirkin & Sumler 1995). Zirkin and Sumler found that interaction seemed to have an impact on students' achievement, as well as their satisfaction: "The weight of evidence from the research reviewed was that increased student involvement by immediate interaction resulted in increased learning as reflected by test performance, grades, and student satisfaction" (p. 101).

However, there seems great variation in what faculty and students view as "interactive qualities." In order to clarify the role of this important factor and encourage faculty to make their distance courses more interactive, the authors decided to design a rubric for faculty to use to determine the degree of interactive qualities in their own distance learning courses (Roblyer & Ekhaml 2000). Such a tool, based on information obtained from a review and analysis of a considerable body of literature and research on this topic, was seen as an ideal mechanism for focusing the attention of distance learning instructors on the importance of interactive qualities and the elements that might contribute to them.

What is a Rubric and How Can it Help?

Rubrics are assessment tools that have seen increasing application in technology applications, especially in problem-based, constructivist environments (Jonassen, Peck, & Wilson 1999). Jonassen,
et al. say that a rubric has come to be defined in education as “a tool used for assessing complex performance” (p. 221) in a way that gives input and feedback to help improve the performance. A rubric consists of a set of elements that describe the performance together with a scale (e. g., 1-5 points) based on levels of performance for each element.

Malone, Malm, Loren, Nay, Oliver, Saunders, and Thompson, (1997, October) point out that both students and faculty have additional responsibilities in a distance environment. Faculty must alter both course design and teaching strategies to take advantage of technologies and assure maximum interaction. But they say that students must assume more responsibility for their learning taking the initiative for requesting clarification and feedback to make up for the immediacy offered by face-to-face formats. Malone et al., cite the need for well-researched criteria to help faculty know what they are aiming for when they evaluate the effectiveness of their distance courses. Thus, an interactive qualities rubric may address a need that currently is unmet. If effectively done, a rubric that presented such criteria could help develop distance learning as an effective instructional delivery format.

**How Do We Define “Interactive Qualities” in Distance Learning?**

As a first step toward identifying qualities and activities that would enhance distance learning courses and that could be assessed in a rubric, the authors reviewed definitions of terms used in the research literature related to interaction. We found not only one word but two: “interaction” and “interactivity.” Also, we discovered some consensus and some areas of disagreement in defining and using these terms.

Based on their review of literature, Gilbert and Moore (1998) define interactivity on computer-mediated instruction as a reciprocal exchange between the technology and the learner, a process that he says is referred to as “feedback.” Gilbert and Moore use the terms “interaction” and interactivity interchangeably. However, Wagner (1994, 1997) draws a sharp distinction between the terms. Like Gilbert and Moore, she says that “interaction” is an interplay and exchange in which individuals and groups influence one another. Thus, interaction is when there are “reciprocal events requiring two objects and two actions (p. 20). On the other hand, she says “interactivity” seems to have emerged for establishing connections from point-to-point … in realtime” (p. 20). Thus, interaction focuses on people’s behaviors, while interactivity focuses on characteristics of the technology systems.

This distinction may add precision to our efforts at assessing distance learning courses, but it is evident that both qualities are necessary to achieve the aspects students find so desirable and that appear to be major contributors to course effectiveness. Also, it is clear there is a close relationship between these qualities; one cannot exist without the other. Technologies that allow high INTERACTIVITY seem necessary to allow high person-to-person, person-to-group, and person-to-system INTERACTION.

**Can Distance Learning Offer Enough Interactive Qualities?**

It should be noted that the literature in this area reveals some doubts among students and faculty that distance learning ever can have the degree of interaction possible in a non-distance environment. For example, a study by Smith (1996) found that about 30% of the nearly 400 respondents to a survey about distance learning options would never choose DL because they felt that it could never provide the qualities they desire in a face-to-face course. However, studies such as one by Miller and Webster (1997) have found no significant difference in assessments of interaction between students in a
synchronous (face-to-face) and asynchronous courses. Horn (1994) and Hirumi and Bermudez (1996) are among those who find that, with proper instructional design, distance courses actually can be more interactive than traditional, face-to-face ones, providing more personal and timely feedback to meet students' needs than is possible in large, lecture hall-type face-to-face courses.

Elements of Interactive Qualities in Distance Learning Courses

Variable #1: Social and Rapport-building Activities

Gilbert and Moore (1998) and Wolcott (1996) note that establishing rapport and collaboration among class members and between class members and instructor is an important role the instructor must undertake in a distance course. They find that interaction in distance courses can have either social and instructional aims. Gilbert and Moore (1998) feel that both purposes are valid and, indeed, necessary, noting that social rapport and increased collaboration can lead to greater levels of interaction related to course content which, in turn, can promote instructional goals and increase learning.

Variable #2: Instructional Designs for Learning

Distance learning studies indicate that effective distance courses are ones in which the instructor promotes interaction in ways that encourage reflection and discussion on course topics and concepts. Much of the literature in this area focuses on instructional designs to increase this kind of participation and feedback (Roblyer & EkhalM 1999). The focus of this dimension seems to be on increasing not only the number of interactions but the number of people involved in them. For example, having students present and discuss small group results with the class is perceived as a better design than merely having students do small group work and present to the instructor.

Variable #3: Levels of Interactivity of Technology Resources

Many authors describe that various technologies can be used to encourage and facilitate interaction. Recognizing that certain technological capabilities make it easier to encourage interaction, the rubric presented here uses Wagner's (1994, 1997) definition of interactivity as the innate capability of the technology to promote interaction. Desktop videoconferencing (Edmonds 1996) and web-based resources (Hughes and Hewson 1998) currently enjoy increasing popularity. However, it should be noted that equally important to the innate capabilities of technology resources are the techniques, designs, and methods used to take full advantage of them (Kimeldorf 1995)

Variable #4: Impact of Interactive Qualities as Reflected in Learner Behaviors

The last dimension involved in assessing interactive qualities of courses seems the one most often neglected: the impact on learners. McHenry and Bozik (1997) point out that students respond to effectively (or ineffectively) designed distance courses with observable behaviors. This dimension evidences itself most often in students' increased or decreased willingness to use the various technology resources (e. g., chat features, microphones), to collaborate with other students, to take responsibility for requesting needed information from the instructor, and to initiate and participate in class discussions and other activities. Thus, instructors can tell if their designs are working if, by the end of the course, students show increased willingness to participate and initiate interactions.

Methodology Used to Develop and Revise the Rubric
After the four elements were identified, the rubric was developed by creating a 1-5 scale with descriptions of levels of performance for each element. A checklist for evaluating the usefulness of the rubric was developed based on criteria for effective rubrics in described by Jonassen, Peck, & Wilson (1999, p. 225). This rubric evaluation checklist is shown in Figure 1.

Instructors and students who are currently involved in distance courses at the University of West Georgia were asked to use the checklist to review the rubric and give their feedback on aspects that should be revised to make the rubric more useful. Some 35 instructors and students responded with comments and suggestions, and the rubric was revised based on their feedback.

Figure 1. Checklist for Evaluating Interactive Qualities Rubric Draft

Revised Rubric: Current and Future Uses

The revised rubric is shown in Figure 2. For this rubric to be most useful to distance instructors, they must first have read the descriptions of the elements and be acquainted with the definitions and, ideally, the uses of the technology resources described.

This rubric is viewed as one of many tools that could help improve the quality of distance learning courses in ways that make them more responsive to student needs. Plans are underway to do additional formative evaluations and revisions of this instrument to increase its usefulness as a self-assessment tool for instructors of distance courses.

RUBRIC DIRECTIONS: The rubric shown below has four (4) separate elements that contribute to a course's level of interaction and interactivity. For each of these four elements, circle a description below it that applies best to your course. After reviewing all elements and circling the appropriate
level, add up the points to determine the course's level of interactive qualities (e.g., low, moderate, or high)

<table>
<thead>
<tr>
<th>Low interactive qualities</th>
<th>1 - 7 points</th>
</tr>
</thead>
<tbody>
<tr>
<td>Moderate interactive qualities</td>
<td>8 - 14 points</td>
</tr>
<tr>
<td>High interactive qualities</td>
<td>15-20 points</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Scale (see points below)</th>
<th>Element #1 Social Rapport-building Activities Created by the Instructor</th>
<th>Element #2 Instructional Designs for Learning Created by the Instructor</th>
<th>Element #3 Levels of Interactivity of Technology Resources</th>
<th>Element #4 Impact of Interactive Qualities as Reflected in Learner Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>Few interactive qualities (1 point)</td>
<td>The instructor does not encourage students to get to know one another on a personal basis. No activities require social interaction, or are limited to brief introductions at the beginning of the course.</td>
<td>Instructional activities do not require two-way interaction between instructor and students; they call for one-way delivery of information (e.g., instructor lectures, text delivery).</td>
<td>Fax, web, or other technology resource allows one-way (instructor to student) delivery of information (text and/or graphics).</td>
<td>By the end of the course, all students in the class are interacting with instructor and other students only when required.</td>
</tr>
<tr>
<td>Minimum interactive qualities (2 points each)</td>
<td>In addition to brief introductions, the instructor provides for one other exchange of personal information among students, e.g., written bio of personal background and experiences.</td>
<td>Instructional activities require students to communicate with the instructor on an individual basis only (e.g., asking/responding to instructor questions).</td>
<td>E-mail, listserv, bulletin board or other technology resource allows two-way, asynchronous exchanges of information (text and/or graphics).</td>
<td>By the end of the course, between 20-25% of students in the class are initiating interaction with the instructor and other students on a voluntary basis (i.e., other than when required).</td>
</tr>
<tr>
<td>Moderate interactive qualities (3 points each)</td>
<td>In addition to providing for exchanges of personal information among students, the instructor provides at least one other in-class activity (e.g., group work, role-playing).</td>
<td>In addition to the requiring students to communicate with the instructor, instructional activities require students to work with one another (e.g., in pairs or small groups).</td>
<td>In addition to technologies used for two-way asynchronous exchanges of text information, chatroom or other technology allows synchronous interaction.</td>
<td>By the end of the course, between 25-50% of students in the class are initiating interaction with the instructor and other students on a voluntary basis.</td>
</tr>
</tbody>
</table>
In addition to providing for exchanges of personal information among students, the instructor provides several other in-class activities designed to increase social rapport among students. In addition to requiring students to communicate with the instructor, instructional activities require students to work with one another (e.g., in pairs or small groups) and share results with one another and the rest of the class. In addition to technologies used for two-way, asynchronous exchanges of text information, additional technologies (e.g., teleconferencing) allow one-way visual and two-way voice communications between instructor and students. By the end of the course, between 50-75% of students in the class are initiating interaction with the instructor and other students on a voluntary basis (i.e., other than when required).

<table>
<thead>
<tr>
<th>Above average interactive qualities (4 points each)</th>
<th>In addition to providing for exchanges of personal information among students, the instructor provides several other in-class activities designed to increase social rapport among students.</th>
<th>In addition to requiring students to communicate with the instructor, instructional activities require students to work with one another (e.g., in pairs or small groups) and share results with one another and the rest of the class.</th>
<th>In addition to technologies used for two-way, asynchronous exchanges of text information, additional technologies (e.g., teleconferencing) allow one-way visual and two-way voice communications between instructor and students.</th>
<th>By the end of the course, between 50-75% of students in the class are initiating interaction with the instructor and other students on a voluntary basis (i.e., other than when required).</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>High level of interactive qualities (5 points each)</th>
<th>In addition to providing for exchanges of personal information among students, the instructor provides a variety of in-class and outside-class activities designed to increase social rapport among students.</th>
<th>In addition to requiring students to communicate with the instructor, instructional activities require students to work with one another (e.g., in pairs or small groups) and share results with one another and the rest of the class.</th>
<th>In addition to technologies to allow two-way exchanges of text information, visual technologies such as two-way video or videoconferencing technologies allow synchronous voice &amp; visual communications between instructor and students and among students.</th>
<th>By the end of the course, over 75% of students in the class are initiating interaction with the instructor and other students on a voluntary basis (i.e., other than when required).</th>

Futuristic Strategies for Designing and Implementing World Wide Web Presentations

Ruby Sanders, Lander Univ., USA

This presentation is designed for people who intend to create and implement pages for the World Wide Web. The techniques and methods presented can be applied not only to create an informative, engaging presentation but also to maintain such a presentation. Emphasis will be placed on four key players involved in the design process: presenters, information stewards, designers, and Web site users. Techniques and methods that lead participants step by step from conception of a project through successful design will be presented.
Online Resources for ESL/EFL Teachers and Students: 
An Approach to Organization and Structure

Peter Serdiukov
DEEEP
University of Utah

This paper discusses the structure and organization of ESL websites and online educational resources. The design, implementation and initial evaluation of the online teaching/learning resource system that is provided through the Distance Education ESL Endorsement Program’s (DEEEP) website are presented here.

Introduction

With the rapid and massive transformation of global informational resources into electronic format and their easy accessibility through the Internet, the daily growing number of users begins to feel overwhelmed with the abundance of information on the Web on any imaginable topic. We now face an increasingly complicated and time-consuming problem of searching and selecting specific information, and we need high-quality, relevant pages in response to a particular need for certain information. We are now in a paradoxical situation in the online education: the more information opportunities we obtain through the Internet, the more difficult it becomes to make use of them. This problem urgently calls for two important solutions: first, to rationalize the Internet navigation through developing new search engines, and second, to effectively organize the online resources and websites themselves, particularly those that offer special information and services. The group of authors under a collective name Members of the Clever Project in their article Hypersearching the Web (1999) focus on the first issue.

To a great extent this issue concerns web-based educational and professional development sites. It is evident that the outcomes of Internet teaching/learning resources’ use and online education in general to a great extent depend on the efficiency of their search and selection, on the one hand, and on the relevancy and structure of informational resources that should be available in a “well-organized form” (Romiszovski 1997, 27), on the other. We would like to share our approach to the second issue of organizing and structuring the educational resources using our experience in creating the DEEEP website. DEEEP (Distance Education ESL Endorsement Program) is essentially a professional development program for the teachers of English as a Second Language (ESL) in Utah.

What are the Educational Resources?

The term “educational resources” (ER) itself that, in our understanding, means an organized and structured collection of relevant information, texts, courseware, and other educational materials available in various formats and used for teaching, training and learning. As we deal with the online ER here, it is presumed that they all exist in electronic formats allowing them to be transmitted through the Web, so we also use the term “electronic educational resources” (EER). We feel that in dealing with the current phase of EER development it is premature to talk about a system of online resources, however it might be a goal in developing an individual resource database. Anyway, it is essential that this collection is organized in some rational way to provide an easy and efficient access to all the resources. The structure of the ER has to reflect its purpose: is it for teachers or learners; is it offered through a college or a business website; is it used to provide accredited distance education, some stand-alone web-based courses or other educational services (e.g. texts, exercises and advice for independent learners), or does it serve as a students’ resource facility developed by a school to
provide in this way online support for traditional campus-based, face-to-face education; is it an organized and well-structured system or just a random assortment of various materials for self-education; is it maintained by an organization or an individual enthusiast; and finally, is it comprehensive (inclusive) and self-sufficient or just a liaison listing the links to other sites.

Resources Online

In (Members of the Clever Project 1999, 54) the authors single out two types of Web pages: 'authorities' and 'hubs', the former being the best sources of information on a particular topic, the latter collections of links to those locations. This is a general subcategorization of the websites that reflects the major distinction between them. Our research of online ESL/EFL resources showed that all existing websites that contain EER can be divided into 3 groups depending on the scope of educational services they offer, and their inclusiveness: 1) comprehensive – provide a whole range of educational products and services, from online courses to related links (e.g. ENGLISHTOWN, GlobalEnglish, Peak English, English Online at The New School, etc.); 2) supportive – offer a variety of educational products and services, like materials for teaching/learning, chat, links, etc. (e.g., Dave's ESL Café, NETEACH-L, The Linguistic Funland, EFL House, etc.); however, they do not support any regular established training and follow-up; 3) intermediary or liaison – only point out to the sites that are associated with the topic and give their links to them (e.g. TESL/TEFL/TESOL/ESL/EFL Links, US State Department's Office of English Language Programs, etc.). As we have discovered, very few sites offer online courses, some provide materials for reading, writing, grammar, vocabulary, pronunciation and other skills development, as well as relevant links. A few sites provide a communicative function offering Bulletin/Message Boards, discussion, or chat (e.g. Dave's ESL Café, SUNY Gopher). There are also promotional sites that advertise their products but do not offer any online materials or support (e.g. World English). It takes time for the user to get oriented in this immense and unstable sea of information, for you do not know which site offers what you need, or what information is reliable and what materials are of good quality; sometimes the information and links on the site are not well organized, often some links quoted by the sites are already dead, etc.

It becomes more urgent that the sites need to be updated and evaluated (Kirk, 1996). There are two most ordinarily used criteria for evaluating the site: the number of hits, and the number of references to the site. An expert evaluation approach can also be used: a group of experts may be asked to evaluate the organization, structure, content and format of the websites in each specific area, e.g. ESL/EFL links may be checked once in a while (once a year?) and the results of such an evaluation will be made public thus serving as a guide in the multitude of Web sites. The question is, who will be able to undertake such a venture?

Clear information representation in the website and easy access to the resources facilitate the user's ability to find and process the available information and materials. The degree to which the user/teacher can access and manipulate those resources should be increased through better structuring and organization.

As the majority of websites are designed for the random individual users, its structure is determined by the willingness and capability of the designers to cover as many topics and items as possible. The ensuing effect is the overloading of the home page. The overload, naturally, hinders the effectiveness of the search, evaluation and use of the resources. The specialized sites that provide certain services, e.g. accredited training and learner support, are more narrow and focused.

A typical ESL website includes, as our analysis shows, the following components:

**Schools**: universities and colleges offering ESL programs
**Organizations**: professional or other organizations
**Distance Learning (classes)**: complete courses, separate lessons and various materials for learning
**Resources (teacher's and/or learner's)**: lesson plans, activities, exercises, texts, poems, dialogues, songs, idioms, slang, quizzes, games, tapes, videos
**News**: news, announcements, newsletters, e-magazines, current events and happenings, and conferences
**Communication facility**: bulletin board, (discussion) forum, chat, message exchange, mailing list, teacher/student email
As we can see, these areas tend to cover all the issues that an ESL teacher might be interested in. However, few websites provide EER for the ESL teachers' professional development (PD) and full-scope support for classroom practices.

**Distance Education ESL Endorsement Program (DEEEP)**

The DEEEP program was developed in 1998 as a partnership project among the University of Utah and the six biggest Utah school districts. The purpose of DEEEP is to prepare teachers of all levels (elementary, middle and high) and school administrators to address the needs of the ESL students in their class. These needs stem from the increasing cultural diversity in Utah, which mirrors the processes going on around the USA that are brought about by intensive immigration from various countries. The program offers a choice of two lines: a Master's Degree in either Education or Linguistics and/or an ESL Endorsement. The implementation objectives were to use distance education technology to deliver the program to the sites at local schools, and a collaborative model involving university faculty, school administrators and K-12 teachers in the program design, course development, program management and decision-making.

DEEEP currently offers two PD formats: a three-year program consisting of 8 courses in Education and Linguistics that apply to both a Master's Degrees and Endorsement, and an Endorsement program of two years that consists of five courses: Issues and Research in Multicultural Education, L2 Methodology, Content Based Language Teaching, Minority Languages' Issues in Education, and Materials Development and Practicum. We are presently developing a one-year endorsement program that will include extensive online support. DEEEP is evolving from a traditional "hands-on", one-time training program with tentative technology use into a continuous, Web-based, multifunctional, in-service professional development and support system based on contemporary technologies.

**DEEEP Website Organization and Structure**

In 2000, DEEEP developed and put online its website. It was designed as an online teachers' continuous professional development and support system that would offer two major types of ER for the teachers enrolled in this program:

1. Resources in ESL/bilingual issues (based on the DEEEP curriculum and courses, and also using outside sources) that can be used in a face-to-face workshop-type facilitator-supported group training and for individual learning through the Internet as a professional development resource.
2. Resources for the teachers' classroom activities.

The structure of the website is determined by its goals. We realized that the teachers in the DEEEP program needed the following:

- Information about the Program
- Access to the courses, course materials and instructor
- Support of their teaching practices in the classroom.

The structure and organization of the DEEEP website meets these needs. It contains information about the Program, about the courses offered for the ESL Endorsement and Masters' Programs (Virtual Campus), the Teachers' Resource Online Library (TROL), a News and Events section, and a Help Desk. The Program part also displays the syllabi, course and reading materials. TROL offers materials for teachers to use in the
DEEEP Online Educational Resource System

TROL is an essential part of the DEEEP Website. It is organized so as to provide maximum support for the teacher in search of the needed materials, information and advice.

There are various formats of the online resource organization: menu, table, scroll, map or chart. One of the most efficient, in our view, is the hierarchical organization of the resource website: from the more general topics to the more concrete. In the development of the DEEEP website we applied this principle: The first level was presented on the home page - we had only seven main items in the menu that hyperlinked to the chapter homepages (second level). Each chapter had its own menu that took the user to the third level where, actually, the access to the materials proper started. However, we found out that we needed the fourth level that provided the necessary detailing of the materials. From each page of the subsequent level the user can return to the previous level as well as to the main homepage.

Here is the chat of the DEEEP EER system that is intended primarily for the schoolteachers who need support in solving ESL problems. We named it TROL (Teachers' Resource Online Library). Students can find the resources for themselves there as well.

<table>
<thead>

<td>Self-study materials</td>
</tr>
<tr>
<td>2. Reference materials</td>
<td>Expert support</td>
</tr>
<tr>
<td>3. Communication</td>
<td>Communication</td>
</tr>
</tbody>
</table>

There are 2 major parts in this system: the Teacher's and the Student's. The former is divided into two chapters: Professional Development Resources and Teaching Resources, the latter contains Learning Resources. Each of the three chapters has an index page.
The contents of each chapter have three levels: 1. resources (programs/courses and materials for teaching or self-study), 2. support (reference) level and 3. communications level (BBs, discussions, chat and conferencing).

The Teachers' support level also includes Expert modules that have two implementation forms: an automatic expert system TESS and live expert service. Other Reference modules include encyclopedias, dictionaries, links to other reference sites and materials, etc.

Each individual part is a module of the system. The modules and items within them can be hyperlinked and be used for creating new structures. This assures structural flexibility of EER and their more efficient use.

**Organization of the Resources**

The resources in this website are organized around several principles, the major one being adherence to the core curriculum, then content areas, levels, structure of the resources, and their format.

The ESL ER offered through this website are divided into two parts:

<table>
<thead>
<tr>
<th>ESL Issues</th>
<th>Language</th>
</tr>
</thead>
<tbody>
<tr>
<td>Across the Content Area</td>
<td>Cultural Issues and Strategies</td>
</tr>
<tr>
<td>Content Area</td>
<td>Linguistic Issues and Strategies</td>

Each material is ranged according to six different levels of education: K-3, 4-6, 7-9, 10-12, college, other.

All the EER in TROL are arranged according to the following major formats:

- **Text-based Materials:**
  - Textbooks
  - Other (texts, poems, songs' lyrics, tongue-twisters, idioms, etc.)

- **Audio-based Materials:**
  - Audio courses
  - Other (phonograms of the texts, dialogues, poems, songs, etc.)

- **Video-based Materials:**
  - Video courses
  - Other (video clips, movies, documentary, etc.)
• Computer-based Materials:
  - Computer courses
  - Other (computer games, learning programs, software for teaching/learning, etc.)

• Web-based materials:
  - Distance courses
  - Other (online teaching and learning materials)

The materials in each group may also include activities and tasks (problems, exercises, cases, etc.), and reference materials (encyclopedias, dictionaries, reference books, etc.)

Evaluation

As the DEEEP website and TROL are still in the developmental stage, we have not yet been able to evaluate them. However, based on the feedback from the DEEEP facilitators and students, as well as from the colleagues, we have grounds to believe that this organization and structure of the online ER will be advantageous to the users — schoolteachers who need continuous, updated, effective pedagogical resources for their productive classroom activities and professional growth.

Telementoring Beginning Teacher Researchers

Lynn Shafer
Center for Multilingual/Multicultural Education
George Mason University
United States
lshafer@gmu.edu

Abstract: This study examines the daily processes that occurred as a telementor worked with a group of beginning high school teachers on their classroom inquiry projects. It outlines the basic issues that were confronted during this project: motivation and involvement, what kinds of advice to give, which tools to use, and how to help teachers find answers within themselves. This study contributes to the knowledge base concerning the issues that telementors might face and suggests further areas that might be explored.

Introduction

Qualitative forms of classroom-based inquiry such as teacher research (http://gse.gmu.edu/research/tr/) have been gaining credibility and popularity among educational practitioners. With the development of new technological tools, we now have additional opportunities to begin linking teacher researchers together across distance and time (Shafer, 1999). At this juncture, it is important to look closely and carefully at what actually happens when experienced teacher researchers mentor beginning teacher researchers. How might the work of beginning teacher researchers and the school-based change initiatives they are exploring be supported?

During the 1999-2000 school year, I served as the university-based mentor for the George Mason University Language Minority Teacher Induction Project (LMTIP). Along with two school-based teacher mentors, we supported a group of seven beginning teachers who taught in a high school in the District of Columbia. During the first half of the school year, the teacher mentors focused on building community among the group of new teachers. They gave advice and support on how to navigate the bureaucratic processes and daily routines of their school. During the second half of the year, the focus of the group shifted to classroom inquiry projects.

Induction training that involves classroom-based inquiry projects is important because as Brown, Collins, & Duguid (1989) point out

the activity in which knowledge is developed and deployed, it is now argued, is not separable from or ancillary to learning and cognition. Nor it is neutral. Rather, it is an integral part of what is learned. Situations might be said to co-produce knowledge through learning and activity. Learning and cognition, it now possible to argue, are fundamentally situated (Brown, Collins, & Duguid, 1989, p. 32).

One of the goals of the LMTIP was to find ways to help beginning teachers develop connections among the theory they had learned in their graduate coursework and the practical realities they faced each day as they taught.

Besides supporting the two teacher mentors as they worked with their group, my role (or so I thought) was to my six years of experience conducting teacher research as a classroom teacher as I worked directly with the teachers as they conducted their classroom inquiry projects. However, because of scheduling conflicts, I could not attend every one of the bi-weekly meetings at the school. I needed to find an alternative solution for mentoring the teachers.

The study

While I had read descriptions regarding others' attempts at telementoring such as Spitzer, Wadding, & DiMauro (1994), I still was not sure how the process might unfold for me. I decided to do my own inquiry project on my experiences, using the teacher research process to do a study on my experience.
As part of this study, I looked at my research question from several angles, collected data and reflected on that data, and triangulated it with others' perspectives and a variety of evidence (MacLean & Mohr, 1999). As a result of the first casting of my research question, the layers within it were

First question cycle

I. **What** happens when teachers use email to talk about their teacher research projects?
II. **How do** teachers get motivated to use email to talk about their teacher research projects?
III. **What kinds of** email conversations (or events in their lives) lead teachers to use email to talk about their teacher research projects?

As the project developed, I recast my question to examine it from a different angle:

I. **What happens when** I give advice to teachers on how to do classroom inquiry projects?
II. **How do** teachers use that advice?
III. **What kinds of** advice are more effective?

At the end of these two question cycles, I poured all of the written data (51 emails from the researcher; 38 email replies back; and 18 journal entries) into NVivo, a qualitative software program, and analyzed it for underlying patterns. I used coding analysis and connecting analysis techniques (Maxwell, 1996) to organize my data into chunks of text that contained recurring themes and to look for the connections among those themes. The four topics that emerged during this analysis centered the following themes:

- Motivation and involvement
- Advice
- Tools
- The validation of the production of local knowledge

Findings

**Motivation and involvement**

When I had first suggested to the seven teachers that I wanted to try to use email to help them with their projects, they had responded enthusiastically. I divided the teachers into three groups of two, two and three teachers. I hoped that by using groups, they would be under less individual pressure to respond to every one of my emails if their schedules became too hectic. I chose email because I wanted to use a communication tool that would be part of their daily routines—and since most of them check their email every day or so, it seemed that there would a higher likelihood of them using it.

I began by sending out regular emails to each group every Wednesday and Saturday. Yet after a month, I had grown frustrated and worried over the fact that I was only getting sporadic replies. I became worried that, if this trend continued, their projects might progress so slowly that they would not have explored their questions enough to be able to write about them at the end of the school year.

Several factors may have played a part in the initial low level of involvement. First of all, teaching is quite time-intensive and demanding. One teacher finished one of his emails, commenting, “Right now I am blank again. Talk about being fried. My brain does not want to function anymore.” Another factor may have been that the teachers were getting enough support from the face-to-face (F2F) bi-weekly meetings. Those meetings had both oral and written sharing times. It may have been easier to not participate as much in less-contextually-rich interactions such as email when it is easier to get a higher-context interactions in a F2F meeting. The added task of writing emails to me may have been one more task to add to their already-too-full lists of things To-Do.

Perhaps the beginning teachers had too many options for support? Perhaps it was easier to focus more on participating in the F2F on-site meetings than doing the online activity? In this light, the online support I offered may have been a bit superfluous. One important aspect of online telementoring is to find out what kinds of on-site support might also be occurring.
In the end, what seemed to motivate the teachers to contact me and spend more time on their projects was the final deadline. In June, they would need to submit and share their final project at a conference with the fifty other teachers who were part of the LMTIP. In mid-March, Rob captured this sentiment when he ended his email with the comment, "I feel my clock ticking..."

Yet what did work well with the telementoring approach that I was using? When I looked more closely the teachers’ response rates, I found that, except for one of the seven teachers, I was only getting scattered responses to my emails. Why were any of the teachers writing back to me?

One teacher’s reply showed one of the advantages of using email. For him, it was a private way to ask additional questions. Rafael began one of his emails with the following paragraph:

Date: Mon, 7 Feb 2000 18:40:55 -0800 (PST)

Well, here goes nothing. I am still unsure about what my research question should be or should focus on. To be perfectly honest, I don't know what I am doing at all. I was feeling a little embarrassed to bring this up with the entire group. Currently there are some issues occupying my mind....

In this regard, it seems that the choice of communicating via email seemed much more useful because it was more private than, for example, using an asynchronous discussion board.

Advice

Yet, Rafael’s response rate was intermittent. One other teacher, Naomi, corresponded with me regularly. What was she doing in her emails? Naomi seemed to approach her inquiry project differently than the others. When she began her project, she did not begin by focusing as much on the steps of the research process. Instead she spent more time reflecting on what was happening in her classroom. It seemed that she used her emails as part of an ongoing dialog with Rob, the other teacher who was part of her email triad, and myself. As she talked to us, her emails seemed to be a way that she could give advice to herself.

Date: Wed, 23 Feb 2000 20:00:46 0500

Hi all -

I think I may have found something. There is one student I have in my Intermediate ESL Reading Development class. She is always there (good attendance) and participates, and adds to discussions, and seems to genuinely try hard, but she is very disorganized, and often fails to complete and turn in assignments, although she seems to know the information. I noticed her good intentions but extremely messy backpack and papers. Her papers from her different classes were sort of wrinkled and crammed together in various spiral (without pockets) notebooks. She rarely knew where any specific paper or assignment was. When her name has come up with at least one of her other teachers (and I know the others so I can talk with them), he rather shook his head with half a chuckle and half a moan and said, "Oh yes, ______. I know her.... I would be interested to see if helping her (and some peer tutoring) be more organized would make a difference in her performance and achievement overall. I have helped similar students get organized once and then usually not checked on them again. I wonder if one on one attention and consistent help with organization and study skills can help her (and students like her) in my class and across the board. I could check in with her teachers from last semester, look at her grades and progress reports, and also speak with and check in with her teachers from this semester (and that way measure progress), and perhaps make contact with the family. I have just seen so many people say (about other similar students) that it does or doesn’t make a difference to work with and pay attention to these things.

So, that is what has grabbed me - it grabbed me before I even considered it for a research project. What do you think.
Later,
Naomi
When I compared her final project to the Teacher Research Continuum Ratings Scale (Shafer, 2000), it seemed that the reflective writing Naomi had done had helped her to reexamine the assumptions she held about her teaching practices—one of the key aspects of qualitative classroom inquiry.

However, in retrospect, I can see that the advice that I offered on the actual steps of the research process was not clear enough. Before my study had begun, I had assumed that it would be important for me to provide technical advice on how to actually do some of the techniques related to teacher research. I also wanted to give real-life examples of how to conduct an inquiry project. At this point, I wondered if the examples I used from my own parallel project to exemplify the steps were helpful insights or just a distraction to them? So often, a mentor's first impulse is to tell his/her own story rather than focusing on the other's story first and foremost. That seems to be what I had done. At the end of this study, several teachers told me that my initial technical advice about how to cast a question and collect data on it had been helpful and interesting, but that it was too indirect in how it was delivered.

Tools

When I had begun this study, I had assumed that I would be able to help these new teachers just by using email. However, when I gave a survey to the teachers as part of my data collection, Rob commented that “the emails need to feel more like a dialogue.” Bakhtin (1986) suggested that no utterance comes from out of the void, but relates to that which came before it (Bakhtin, 1986). Cobi, one of the teacher mentors, built on this idea when he made the following observation in an email to me. All of these comments helped open my eyes to the importance of these dialogs.

Date: Sun, 20 Feb 2000 09:08:09 EST

You say [in the email you wrote last time] that e-mail is a lot more conducive to thinking. I suppose that conversations are more spontaneous and interactive and less reflective, but people are also talking to themselves in those conversations as much as they are talking to the others in the room -- just as we are when we e-mail. It's always interesting to see people’s wheels turning as they consider new ideas in the conversations.

The advice that Naomi was giving herself did not take place in a void, but was situated within an ongoing conversation. The challenge for was to tap into the dialogs that were taking place at the school and continue them in our email conversations.

Both comments led me to reexamine my use of email as my primary communication tool. It left me too far out of the loop. It occurred to me that I needed to offer the teachers many different kinds of tools and interactions, not to limit myself to one style. At this point in the study, I began to explore the kinds of tools and interactions that might support the development of these dialogues.

In light of what I was learning about the power of giving advice to one’s self in order to reveal one’s assumptions and the importance of situating this advice within a dialog, I began look for other kinds of strategies that might offer these two elements. I attended a presentation by Marino Alvarez of Tennessee State University. He described how he was using concept maps as part of the Explorers of the Universe Project. University-based researchers were holding asynchronous dialogs with high school students in order to help them to organize their own thinking for their high school science research projects (Alvarez, Burks, Sotoohi, King, Hulan, & Graham, 2000).

I wondered whether I might use concept maps in a synchronous interaction, as part of individual, F2F conferences? During the conferences I would use guiding questions that focused on the teachers’ assumptions about their teaching practices. As the teachers talked about their projects, I would record and map out what they said. Afterwards we would both go over the map and try to draw connections between the assumptions and the instructional practices that they were putting into practice—both of which they had just described to me. My taking over the writing aspect of the task, I would free up the teachers to think and speak about their question—and still be able give them record of what they had said when we were done.

As these individual conferences progressed, I noticed how different they were from the asynchronous interactions we had conducted via email. On April 13, I wrote
I realized that when we’re doing these F2F synchronous conferences, we needed to hear the sound of each other’s voices and have super-fast writing tools. I wrote so quickly across each page as they each were talking. There was also a strong emotional component to these conferences. We had the ability to look at each other directly and read facial cues. We had access to 3-D supplies to support the conversation.... The technology just is not there yet. For now, I would need F2F meetings to get this rich type of exchange.

Even a chat room exchange would not have captured the energy or layers of information that exchanged during our meetings. For the time being, online synchronous interactions still do not reach the depth of F2F synchronous interactions and therefore, limit the amount of information and context that is available to the participants. Written dialogue does not offer the free flow of thought or interplay that oral dialogues have. There seemed to be a strong affective quality to our conferences. One teacher, My-Ling, later used what we discussed during her project as the central frame for her final written project (George Mason University Language Minority Teacher Induction Project, 2000).

Advice (revisited)

I looked more closely at the advice that My-Ling had given herself during our conference. It seems that the F2F synchronous meeting was useful to her because, as she was describing her project to me, she was showing changes in the underlying feelings and assumptions that she held about her instructional practices. She demonstrated emotions such as frustration, confusion, surprise, and happiness during our talk together. Looking back, I can see that there was much more of an affective (AHA!) component in our F2F conference than in our email exchanges.

My-Ling described how surprised she felt when realized that she was spending so much time on making her math lessons fit the progressive methodologies that she had learned as part of her teacher preparation program, when, in contrast, her immigrant students kept telling her that they were more comfortable with, what she described as, traditional forms of instruction. She wondered if she had been asking them to make too big of a cultural leap too soon after their arrivals to the United States. As we went over her map, she saw how her underlying beliefs were telling her one thing, while her students were telling her another thing. In the end, she decided give her students more of a balance between traditional and progressive styles of instruction so that the students might use learning styles that fit their cultural backgrounds and gradually acculturate themselves to the more progressive forms of instruction that they might meet later on in the mainstream classroom (Delpit, 1988).

Validating the production of local knowledge

When I began this study, I assumed that the teachers would quickly take to the idea of searching for their own answers to their problems. Throughout my study is seemed that the teachers were having difficulty accessing their own prior knowledge regarding the instructional challenges they faced.

It seems that, from the very start of the project, the beginning teachers saw knowledge and expertise as residing in others or in research books and articles, but not as much in themselves. Granted, they were new to the profession, yet I found it interesting to listen and watch as they used the dialogs that they had with the teacher mentors, each other, and myself to reveal to themselves how they might approach their instructional problems. I recorded one example of this in my journal in mid-April.

During our conference, Hans commented, “I need some articles.” “Why?” I asked him. “What specific things that you’ve seen in your classroom do you want to check out?” “Well, I need to find which strategies I should use...” he replied. Then he proceeded to recount all of the strategies he remembered from his coursework at a local university. “I might use this strategy or I could use that do you need more articles for when you’ve got the stuff in your head? You just need to organize it and then try it out to see if it works.” “That’s the next step?” he asked. “That’s the next step,” I replied. “What do you think you might do tomorrow?”
Conclusion

I learned during this project that, even before direct advice on the steps in the research process can be followed, it is important for teachers to either write or talk reflectively about their questions and to begin identifying their underlying assumptions regarding classroom instructional practices. In the future, I would like to look more closely at how to effectively use online communication to convey the actual steps of casting questions, gathering data, triangulating evidence and other technical aspects of teacher research. Beyond that, it seems that the reflective dialogs we held as they focused on classroom inquiry projects were useful in helping the teachers to make connections between theory and practice—at the same time as they also helped teachers to think more for themselves.

In the future, I would also like to explore how to combine asynchronous and synchronous tools to get the best of both of these types of interactions. As Dede & Kremer (1999) point out, most subject matter has the potential to be understood better with a mixture of media. Perhaps we are limiting ourselves when we use one medium. Perhaps, we might use synchronous interactions to get those synergistic leaps of thought and to increase motivation, while using asynchronous interactions to promote reflection and to fit in with teachers’ busy schedules. Because the telementor cannot always have the luxury of F2F communication, more research needs to be on how to expand our repertoire of communication tools.

Michael Blocher, Ph.D.
Center for Excellence in Education
Northern Arizona University, USA
Michael.Blocher@nau.edu

Abstract: This paper addresses how Northern Arizona University (NAU), an institution that serves mostly rural students in Arizona, created and implemented a totally online Master's of Education in Educational Technology degree that is based on the constructivist theory, promotes and fosters interaction among students, between student and instructor, and between student and content. A discussion of the fourth type of interaction, interaction with the technology interface, is also addressed. Finally, the authors talk about how Active Worlds, a three-dimensional, virtual reality environment that allows interaction, is built into the master's program.

Introduction

The last two decades of human history have seen technological advancements with no parallel in previous years. Telecommunications, especially the Internet, have changed the way people do businesses, have leisure activities, and attend to schools. Global networks link millions of users around the planet, and the rate of adoption is growing dramatically (Harasim, 1993). New distance education degrees that use only the World Wide Web as the interface of delivery are flourishing everywhere. In fact, many institutions fear that they will be extinct if they do not offer web-based distance education courses (Roblyer, 1999). This paper addresses how Northern Arizona University (NAU), an institution that serves mostly rural students in Arizona, created and implemented a Master's of Education in Educational Technology degree that is not only totally web based, but that uses cutting edge technology to promote and foster interaction.

Background Information

The Master's of Education in Educational Technology (MED Tech) aims to prepare technology forerunners in PK-12 schools who will (a) exhibit instructional leadership and model the integration of computers and related technologies throughout the curriculum, (b) implement effective solutions to instructional challenges including the design and development of instructional materials, and (c) identify, select, install, maintain, and manage computing hardware and software. Because the mission of this degree is to prepare classrooms teachers to view technology as an integral part of their teaching, focus groups and numerous discussions were held to (a) identify the philosophical framework that would drive the degree, (b) agree on different strands that would run across courses and which would give unity to the program, (c) develop new curricula, (d) get approvals that ranged from in-house committees to the Arizona Board of Regents, and (e) adopt the appropriate interface for the web courses that would ensure not only the seamless delivery of the program, but that would foster interaction among students, between student and instructor, and between student and content.

Review of Literature

As the Internet becomes commonplace, the "school without walls" has slowly emerged and is claiming its niche among the brick and mortar schools in the American educational system. In this kind of school, learning takes place anytime and anywhere when resources found at home, museums, libraries, and universities are woven
together to connect learners that collaborate in distinctive new ways to form a community of learners (Spindler, 1995) joined not by geographical location but by common interests. As a consequence, the use of the Internet as a learning space has revolutionized distance education in higher education (Abrahamson, 1998). The segment of the population that embraces online distance education is largely composed of people who need to go back to school either to retrain or to keep abreast with changes in their professions, and classroom teachers are no exception. However, teachers need not only the knowledge base to integrate technology, but apprenticeship experiences that will build their confidence in technology use. To achieve that goal, special care was put to address the different types of interaction that research suggests are best practices in distance learning.

Moore (1989) described three desirable types of interaction in a distance learning setting: (a) learner-learner interaction, (b) learner-instructor interaction, and (c) learner-content interaction. The result of all of these types of interaction is the sharing of ideas, concepts and valuable feedback. The implication for educational practice is that collaboration and group interaction should be actively supported to promote learning (Teles, 1993). To support such interaction, each course in the MED Tech program has the following components: a web site for course content, personal email capabilities, course listserv that sends messages to all class members at the same time, bulletin boards, and chat rooms. Although all tools overlap in their target interactions, it can be said that bulletin boards and chat rooms support the student-student interaction, personal email and listserv the student-instructor interaction, and the web site for the courses the student-content interaction.

Yet, there is a fourth type of interaction in distance-learning environments: the technology interface for course delivery. As Norman (1993) discussed, technologies are never neutral. They impede some actions and aid others. Hillman, Willis, & Gunawardena (1994) explained that learners also interact with the technology through the course delivery interface. The MED Tech uses Course Tools in a Box, WebCT, and Blackboard as the technology interface. In WebCT and Blackboard, students use the bulletin board to discuss readings and post assignments, chat rooms to discuss and agree on group work assignments, have synchronous communication with the instructor during virtual office hours, and as a forum for guest speakers for the course. Quoting Norman (1993), we can say “appropriate tools are designed by starting off with human needs, working with those who will be using the tools to fashion them into the most effective instruments for the task. Above all, such tools allow people to be in control: This is an appropriate use of an appropriate technology” (p.252).

Virtual Reality

As part of promoting interaction in the MED Tech courses, yet another avenue for interaction has been added to the program. Active Worlds, from Eduserve, is a three-dimensional world that takes interaction a step closer to reality. In this graphic-rich, game-like world, students can walk, talk, wave, and even dance. To perform all these activities, the students choose an avatar. An avatar is a graphic representation of the person and it can be human-like, insect-like, alien-like, or any other form that the creator of the world wishes to design. With a fair amount of sophistication, the student can even create his/her own avatar and add the features he would idealistically have. There are perceived advantages and disadvantages to this medium, though. Some researchers state that working in three-dimensional worlds makes it easier for students to interact with one another and brings a human touch to the distance learning experience, while others argue that this type of interaction is too much of a distraction for a student (Young, 2000). One thing is certain: these three-dimensional worlds are on the cutting edge of technology and there are no studies that report on the perceptions, consequences, and advantages of using them. All what is learned in these first endeavors will constitute the seed for future research.

Conclusion

Web-based instruction is still a new field and much needs to be researched to understand its intended and unintended consequences. Although many degrees that use the World Wide Web have flourished, not all of them take this endeavor seriously enough to have the same or more rigor and interaction than a face-to-face learning experience. The Master’s of Education in Educational Technology from NAU has been designed to address interaction at all levels. Because technology is not neutral, special attention has been put on using interfaces that are aligned with the program’s goals. Lastly, the use of virtual reality for interaction brings a new dimension to this degree and opens the door for unforeseen possibilities in the arena of distance learning.

Camp Internet Distance Learning Consortium  
Current work with advanced Internet Applications in K-12 classrooms, including GIS, Internet delivered video and interactive quiz units along with new reports on advanced Teacher Technology skills training.

The Education Technology Revolution Challenge

The American education system is in the midst of a challenging revolution as it steps from the 20th century chalk and blackboard environment to the 21st century multi-media electronic networking environment. This transformation has created new teacher professional development needs, and presents new innovative content delivery opportunities. To successfully make this transformation from the blackboard to the electronic classroom, the national education community must now challenge technology to deliver on its promise of redefining American education practices.

What is now most needed are new innovative teacher training programs that do much, much more than merely show a teacher ‘how’ to use a computer this new style of teacher education will help teachers experience the WHY and the empowering WOW that educational technology can deliver. This training is not about hardware or software, it is about real applications for the technology on a daily basis in the classroom. And it is fostered most effectively in new innovative distance learning communities that involve teachers, students, and parents in rewarding demonstrations of real, tangible improvements in learning ... and in teaching.

To win this 21st century education technology revolution, schools must now learn to integrate technology literacy skills right into the very fabric of the classroom teaching and learning environment.

We would like to review the CAMP INTERNET Distance Learning Consortium as an active case study of an empowering Technology Integration Solution

Camp Internet is an innovative project-based teacher technology training and content delivery program that addresses the technology revolution challenge. The Camp program puts Internet-based technology to work to bring motivating reading, science, math, and social studies learning experiences right into the classroom every day, every week, all school year long. The Camp has been successfully training teachers and delivering innovative online content and hands-on projects in California classrooms for since 1994, and has been honored to gain recognition from the Smithsonian Innovation Network, the California Dept of Education Technology Literacy Challenge Grant program, and the USDA Rural Utilities Service Distance Learning and Telemedicine Program.
From a single schoolhouse in a rural community, to large urban districts such as the Los Angeles Unified School District, Camp Internet is demonstrating new ways to integrate technology into the classroom and the community. Currently serving over 4,000 4th to 12th grade students and 15 USDA assigned cities in California (where Camp is made available both in public schools, libraries and afterschool programs).

Camp Internet recognizes the larger, historical significance of this point in the history of American education. This is the juncture when educators deserve to demand that the online technology finally PROVE itself as a learning tool unmatched by traditional print, television, or even earlier computer media. The Camp's consortia of teachers, researchers, and educators are working to develop and deliver a live and online training program, one that establishes a new methodology for promoting teacher skill development and paves the way for the actual integration of the 21st century learning tools right into the very fabric of the classroom.

*Camp Internet's greatest strength is that it combines live teacher training with immediate, tangible online classroom applications. This methodology stimulates the teacher's professional empowerment, fosters higher student academic achievement, and helps build supportive parent involvement.*

The Camp's distinctive training and content delivery methodology serves as a catalyst that empowers teachers to discover new and more rewarding uses for computers in their classrooms by focusing their training goals on highly motivating curriculum enhancement content. At Camp, mastering hardware and software is the not the ultimate goal. Experiencing positive new ways of learning and teaching in a supportive distance learning community is the goal.

We will look at four primary components of the Camp Internet project:

1) Teacher Training  
2) Development and selection of curriculum enhancement materials which work easily in nearly every classroom  
3) Application of video and gis technologies  
4) Creation of a Community of Teachers involved in a shared education and learning process

Let's begin by looking at the Camp Internet Teacher Training program. Designed to empower teachers with new and essential Technology Literacy skills the program works with teachers from throughout California.

Participants attend a 4 day intensive training program. Teachers, Librarians and technology staff work in the lab and in the field.

In the lab Teachers learn to use the video and video chatrooms within Camp by taking part in daily chats with subject specialists who will come online later in the year to work with the teachers classroom in live chat sessions for the whole class. They also learn to use the special online quiz units, the Internet delivered video and audio units which support each study area and they learn to develop web sites for their classroom, web sites which will become part of the upcoming years learning record.

In the lab Teachers begin to review important skills necessary for their students in the coming year on Camp Internet. One of these skills is Dialog. The ability of students to come into a chatroom with a subject specialists (we call them "Trail Guides" but they are University Professors, staff from federal and state agencies, marine scientists and many more, see http://www.rain.org/chats to view the archive), ask meaningful questions and then respond or make use of the answer to their question is important. We have

3148
noted over the past five years a continued need to give students the skills necessary to absorb and remember what they do online in a distance learning classroom. Teaching this skill in classic Dialog provides a framework for the students. They enter the chat sessions prepared and come away from the sessions with field reports that reflect actual learning.

After spending a day in the lab Teachers take part in a fieldtrip where they receive instruction in the use of GPS and GIS tools. Camp Internet provides a special Internet Map Server for classrooms to use to develop local gps/gis projects. They visit local Chumash Indian preserves, a Natural History Museum and NOAA's Channel Islands National Marine Sanctuary. At these sites they meet some of the people who will serve as “trail guides” during the coming year.

Following the days field trip teachers prepare Field Reports. These become the first of their many field reports to be filed with Camp Internet as they progress through the year. Digital cameras, gps units and computer resources are provided to make it possible for each teacher to experience authoring an online report.

Following the four day intensive training participants take part in monthly online continuing education sessions to expand on what was learned during the training session. This guarantees that along with working with Camp Internet in their classroom daily teachers receive special attention every month to support their technology learning. The in-service online training sessions are archived and have become a source of continuing education for teachers working with technology in the classroom.

After training comes the issue of content to be delivered in the classroom. Camp Internet, http://www.rain.org/campinternet, has been in development since 1994. The Camp has received the Smithsonian Institution Technology Innovation award, two AOL Community Education awards and is currently funded through four USDA Rural Utilities Service distance learning grants and a California Department of Education Technology Literacy grant program. Camp Internet also works with many school districts through private subscription. Los Angeles Unified School District draws on Camp Internet for both classroom content and teacher training.

The Camp Internet curriculum enhancement materials are designed around an “Expedition” model. Content is created through multi-agency data exchange, drawing on content from federal, state and regional agencies. The Expedtions cover curriculum ares from literature and art to science and history.

Interactive quiz and field report activities take place daily via the Internet. Classrooms meet with a “Trail Guide” once a week to explore that weeks study units. The Camp Internet content is designed to work within classroom curriculum requirements. Study units are timed and adjusted to work with both 9 and 12 month school year cycles.

Special GIS and database servers provide students with unique tools for creating journals, building gis datasets and establishing multiple classroom learning projects which can take place via the web site with geographically distance classrooms.

Teachers receive special instruction, if desired, in the use of GIS as a classroom “knowledge management” tool. We have see the introduction of GIS to have a significant impact on science learning as well as student involvement through special projects.

Teachers receive ongoing support, throughout the year. Monthly chat sessions are held with groups of teachers. During their intensive training teachers studing similar units of Camp Internet are teamed up with
an alumni (a teacher with a year or more experience working with Camp Internet) as the Team Leader for each team. These groups get together once a month online, meeting with Camp staff and with each other.

We have see from this the beginning of an effective framework for creating “Communities” of educators who are able to work together to expand skills and resources. Camp now has three years of archived sessions that are beginning to provide valuable assessment data. It is our feeling that the Internet provides an essential bridge, linking teachers and other knowledge specialists, together, regardless of location. We have seen this linking lead to teachers teaching each other and helping to empower one another as they take on the complex task of incorporating new technologies into their classrooms.

One of the reasons Camp Internet is funded by USDA RUS as well as Department of Education is because of the significant role ‘community’ and ‘family’ level education plays in the design of the Camp Internet program. We recognize the necessity to create online learning centers and curriculum enhancement tools that can be used to create cross-generational learning, to work effectively with highly at-risk students and families as well as directly in the classroom.

Classrooms are assisted in establishing monthly Parent nights. On these nights special interactive activities take place that allow parents to see and experience some of what their students are experiencing in their classrooms. Tremendous results have been see over the past two years with these parent nights leading to a very positive assessment.

Special units of Camp Internet are designed to work with afterschool and library environments. We have found ways to incorporate life long learning content into the Camp program which permit it to be useful in the larger community setting as well as classroom. We have seen students meet at their public library to go online and complete a Camp Internet assignment.

With the millions of dollars being invested for hardware and connectivity in schools across the country, it is now time to demonstrate real, concrete methodologies that integrate technology as a core classroom tool, and that challenge teachers to use the technology to make significant improvements in how they teach core curriculum subjects. Technology holds tempting promise as a trainer-to-teacher, teacher-to-student, and school-to-community education reform vehicle. The Camp Internet project is demonstrating a training and content delivery methodology that helps teachers succeed in making technology deliver on its promise to transform the American classroom environment.

Camp Internet can be visited at http://www.rain.org/campinternet. Use the guest i.d. of: campdemo and the password: islbcsnw to visit the special parts of Camp Internet.
Designing & evaluating a powerful online environment to support teachers to integrate ICT into the curriculum.

Tony van der Kuyl: University of Edinburgh
Margaret Kirkwood: University of Strathclyde
Rob Grant: Northern College, Aberdeen Campus
Nigel Parton: University of Edinburgh

Abstract:
Traditional ICT courses for teachers cover the basic skills of operating hardware devices or the key features of software applications, and may provide some examples of appropriate classroom use. Such courses rarely have lasting impact. The knowledge and skills gained on the course are soon forgotten as other priorities take precedence in teachers' working lives.

The programme we, the Scottish Teacher Education Consortium, have developed as an approved provider for the New Opportunities Fund (NOF) Training for Teachers Programme in Scotland is designed for lasting impact. It uses the technology it seeks to promote and is capable of delivery online via our website, with accompanying printed and CD-based resources to offer flexibility in the mode of delivery.

It teaches about appropriate classroom uses of ICT through case studies based on the Scottish primary curriculum, and is designed to engage teachers in problem solving & reflective engagement with issues. The course activities support teachers to integrate ICT systematically into their practice. It is needs-driven and differentiated - ICT skills are learned and practised in meaningful contexts, as and when required.

We have developed a metacognitively rich learning environment. Teachers are prompted to identify their learning needs and review their progress regularly, and this process culminates in the development of a personal forward plan. There is strong scaffolding for inexperienced users of ICT, and the potential of the technology to engender collaboration is fully exploited.

The evaluation framework uses teachers' self-assessments and samples teachers' portfolios of evidence accumulated over the course. There are end of unit and end of course evaluations completed by participants online. Focus group discussions and interviews with tutors, participants and others with a locus in the training will supplement this evidence. The first evaluation of the course will soon be completed.

Background

NOF and the NOF training for teachers

The National Grid for Learning (NGfL) is both a structure of educationally valuable content on the Internet, and a programme for developing the means to access this content in schools and elsewhere (DfEE, 1998). Part of the UK Government's commitment to schools is to ensure that serving teachers feel confident and are competent to teach using ICT in the curriculum. The funding to support the training of serving teachers is £230m nationally, with £23m of this going to Scotland. This is available through lottery funding (specifically the New Opportunities Fund (NOF)), the timescale being from Spring 1999 until 2002.

The main aim of the training is to raise the standard of pupils' achievements by increasing the expertise of serving teachers in the use of ICT in subject teaching. Two of its key features are a focus on the knowledge, understanding and skills necessary to make decisions about the effective use of ICT in the classroom, and the integration of training in ICT skills with training in the use of ICT in their subject (for primary teachers, this is in Mathematics, English Language and Environmental Studies). At the end of their training teachers will develop an action plan for their future professional development in the use of ICT.

Schools can choose from a range of approved training providers, and a national quality assurance framework is in place. The training is voluntary and it is suggested that, where possible, it should take place in the classroom so that teachers can try things out as they learn (this will also minimize any disruption to pupils' learning resulting from teachers being released during the school day to attend courses held centrally).

Two criteria must be fulfilled by the school before training can be embarked upon:
- it should have an ICT strategy in place, covering, for example, its policy on protecting pupils from on-line access to undesirable materials;
- it should have adequate level of hardware available for staff to benefit from the training.

Expected outcomes of the training

The expected outcomes of the training are categorized under five headings:
- Working creatively with ICT
- Evaluating & selecting ICT resources
- Monitoring, evaluating and assessing teaching and learning
- Developing ICT capabilities
- Technical skills and applications

This categorization is not intended as a teaching order, and it is suggested that the approach should be integrative across these elements. Forty-six competences are specified, for example, in the category of Working creatively with ICT:

- Have an understanding of the potential, benefits and limitations of ICT to support a range of different teaching and learning strategies:
  - with individual pupils, groups and whole classes;
  - with a range of abilities, age ranges, subjects and levels as appropriate.

The following advice is given to schools on the teaching approach (NOF, 2000):

1 ICT in Context: Classroom Case Studies, produced by the Scottish Interactive Technology Centre (SITC) and the Scottish CCC. Also a set of case studies of ICT use in primary schools developed by the STEC team.
Appropriate ICT skills and knowledge are best developed in relation to a "real task" which motivates the learner. As a consequence of using ICT in a meaningful way the learner will be encouraged to extend their skills and knowledge in relation to more challenging tasks and ideas.

Investment in infrastructure

Separate funding has been made available by the Government for schools to purchase new ICT equipment. Investment in training should follow closely on investment in equipment. By 2002, the ratio of pupils to modern computers should be established at 15:1 in primaries and 5:1 in secondaries.

Current research findings on ICT in Scottish schools

Stark & Simpson et al. (2000, a & b) have conducted a national survey with Scottish teachers and ICT coordinators, designed to elicit their perceptions of ICT in schools, experiences with ICT and ICT skills, and to provide baseline data on the impact of national ICT initiatives. Their general impression was,

... of professionals who recognize the importance and potential of ICT as a tool to enhance many aspects of their professional duties, but who were finding difficulty in securing the equipment conveniently within their workplace, and in finding time to acquire the knowledge, practise the skills and integrate the beneficial outcomes into their already complex routines and crowded timetables.

They found that the uses of ICT associated with electronic communications were not well established in primary schools, for example, only 10% of those sampled were securing opportunities for pupils and teachers to access curriculum materials directly from the WWW, and only 6% were establishing collaborative projects with pupils in other schools using ICT.

The positive benefits cited by the respondents included improved motivation, enhanced learning and teaching, improved communications & access to information, improved efficiency and promotion of independence.

Need for lasting impact

A key consideration is sustainability in relation to both infrastructure and appropriate use being made of ICT in the classroom which keeps pace with the developments in the technology and emerging good practice.

Pedagogical considerations

Infusing ICT into classroom practice

An approach which infuses ICT into classroom practice is clearly called for. In some classroom activities the primary purpose will be to teach the subject content using ICT as a tool, in others the primary purpose will be to teach about ICT using a meaningful curricular context. Many classroom activities will combine the two purposes, attempting to strike a good balance between achieving content-related and ICT-related objectives. We encourage participants to be clear about the purposes of any classroom-based ICT activities, to specify the objectives clearly in advance (both content- and ICT-related), and to monitor the achievement of the specified objectives.

Fostering understanding

It is important to foster teachers' understanding of the potential and limitations of ICT as a tool for learning and teaching; an approach which focuses on skills acquisition alone is inadequate. The course activities create varied contexts for performances of understanding (Perkins & Blythe, 1994, Gardner, 1993) to be demonstrated by participants. Opportunities for shared understandings to emerge are created through collaboration on tasks both within the school setting and between participants in different schools, the sharing of ideas and solutions, and exchange of feedback. These are prompted by the course activities and supported by online tutoring (see Figure 1 below for two examples of activities involving peer interaction).

Task 9:
Preferably with a colleague, make a checklist of up to ten key factors to consider when assessing the suitability of software for classroom use.
Send this list to other participants in your tutorial group.
In the light of any feedback and suggestions from other course participants, revise your list of factors.
Use this fresh list to create a "Software Review Template". Use your template to evaluate an item of software.

Task 10:
Whenever the opportunity next arises, observe a group of pupils closely as they engage in joint planning and carry out an ICT activity. Try to intervene as little as possible.
When the activity is finished, ask the pupils to review the activity.
Were you surprised by anything you observed? How well did your observations tie in with those of the pupils?
Share your findings with others in your tutorial group (outline the context first).

Figure 1: Two examples of tasks involving peer interaction.

Reflective engagement with issues enables teachers to develop deeper understandings and thus to reach insightful decisions about when and when not to use ICT in the classroom and how to use it effectively. The issues range widely, from safe use of the Internet, selection of ICT resources, arranging file access for pupils to equipment and teacher support, to how teachers can best develop their own ICT competency. Case studies in which school managers, teachers and pupils discuss the issues and relate their practices provide a good stimulus for reflection and discussion (see Figure 2 below).
Task 5:
Lydia Catto is the Headteacher of Forthill Primary School in Broughty Ferry. Click on the picture icon below to hear Lydia's advice on developing ICT competence.

What is your approach to developing ICT competence?

![Lydia Catto](image)

Creating a metacognitively rich learning environment

How to promote self-awareness and self-regulation of the learning process was a key consideration. If this is not developed, and teachers are totally reliant on others to call the next steps, how can they then develop and adapt their practices to take account of advances in the technology, and how can they find creative solutions to the problems and challenges they face day-to-day when attempting to integrate the technology effectively into their classrooms?

Nisbet and Shucksmith (1984, 1986) propose combining direct teaching, modelling of solution processes and developing metacognition as an effective way to improve children’s capacity to think and work strategically. The approach can also be applied to teacher's learning about ICT, to improve their capacity to think and work strategically. The key point about direct teaching is that any procedures must not be taught as tricks to cope with specific tasks: teaching must stress the potential for transfer rather than being mechanistic. Modelling involves the teacher (or tutor) sharing with students how his or her own learning, the task and the learning context influence performance. Students should also be allowed to explore their own metacognitive knowledge by discussion and exposure to a variety of contexts or circumstances where it is called into play.

Prompting participants to reflect on their own learning is a key feature of our training. We ask participants to conduct a systematic review at the end of each study unit, by:

- assessing their progress towards specific learning goals;
- planning any further work that is necessary to achieve these goals;
- identifying any problems encountered with the work;
- continuing to review their learning priorities.

Provision of effective scaffolding

Teachers are all at different stages in terms of their use of ICT in the classroom and their understanding of its potential and limitations. For those with the least experience, effective scaffolding must be provided to ensure that they can engage fully with the course activities and gain the necessary experience and insights. This was a key consideration when designing the architecture of our website on which the course materials are mounted. Teachers are learning about the technology through using it within our course, and lack of familiarity should not create an artificial barrier to learning.

One important method of scaffolding within our course is to take participants systematically through the processes of orienting themselves to the task demands and the situation, planning, implementing, assessing & evaluating, leading to application within three different curricular areas and synthesis of the performance of these processes within a 'mini project'. This approach is mirrored in our course structure (see figure 3):

```
Tutorial units
Unit 1 - Orientation
Unit 2 - Planning to use ICT
Unit 3 - Implementing ICT
Unit 4 - Assessing and Evaluating using ICT
Unit 5 - Using ICT in English Language 5-14
Unit 6 - Using ICT in Mathematics 5-14
Unit 7 - Using ICT in Environmental Studies 5-14
Unit 8 - Mini Project
Unit 9 - Personal Forward Plan
```

Figure 3: Course unit titles.

This is a problem solving methodology which has its basis in Polya's (1948) four stage model of problem solving - understand the problem, make a plan, carry out your plan and review your solution.

Another method is through an ongoing process of needs analysis, which begins prior to participants embarking on the first course unit and uses an online questionnaire. Teachers update their learning priorities regularly as each unit is completed.

Promoting ownership of the learning process

The course is needs driven - participants must reach decisions about the appropriate next steps in learning for them, with the tutor providing guidance if this is sought. The following two short extracts from the materials illustrate the approach (figure 4):
Unit 1: Orientation

If you don't feel very confident yet about using the Internet, there is an online workshop to do. First of all, find out which browser program you are using and make sure you can go online. Then click on the picture (or icon) below to do the workshop. To get back to this page when you have finished, close the workshop window.

Unit 8: Mini Project

Putting ideas into practice

Essentially, this unit is intended to support you to put into practice some of the ideas and approaches you have met on this course within the context of an ICT activity chosen by you. The tasks in this unit are intended to provide a structure to guide your thinking and actions.

This ICT activity should be selected to make a positive contribution to learning and teaching within your classroom or school, and to provide a context for developing your ICT competence.

The scope of the activity is not restricted to one involving your pupils directly. It could instead relate to a whole school ICT issue, such as developing the school's website or mapping the school's existing ICT curriculum to the new guidelines on ICT 5-14.

Figure 4: Illustrating the 'needs driven' philosophy of the course.

This approach promotes active learning and should therefore better ensure that teachers feel ownership of their work to integrate ICT into classroom and school practices. If this becomes established, the prospects for lasting impact are much brighter.

Promoting collaborative & situated learning

The role of collaboration to enable participants to develop shared understandings and to support each other's learning has already been discussed. Many of the course activities relate to actual practices and procedures within the participant's school or local authority (for example, examining school policies or creating a framework for progression in pupils' ICT knowledge and skills) and therefore learning is situated in an authentic context.

Key features of the delivery

Establishing partnership arrangements with local authorities & schools

The course delivery operates through a partnership model, for example, the course tutors may be drawn from schools or from a pool of ICT coordinators within a local authority. Responsibility for the quality of provision remains however with us, the approved provider.

Mixed mode & mixed media

The course can be delivered entirely online, in mixed mode (part face-to-face, part distance) or as a traditional taught course. It uses online resources (our website and external websites), and CD-ROM and printed resources which echo the resources mounted on the website, although for certain activities participants require to be online.

Flexibility

Flexibility is a key consideration for any course aimed at practising teachers. Teachers need to be able to work in different settings and sometimes in short bursts of activity, and at a pace which takes account of their other working commitments. The mixed-mode, mixed-media format should help deliver flexibility, for example, some of the work can be done using the printed resources when teachers do not have access to a computer, or using the CD-ROM when there is no Internet connection. A set of Record of Work resources, containing checklists, a diary format, and notes pages listing the tasks, activities & key teaching points, enable teachers to keep track of their progress more easily.

Encompasses NOF teacher competences & specified curricular areas

The forty-six competences referred to in the Background section of this paper were carefully mapped onto our nine course units, grouped and conflated, and restated in more direct language as Purposes and Main Aspects of Content (see figure 5):
Unit 2: Planning to use ICT

**Purposes**

To enable you to...
- identify when ICT can support learning and plan pupil activities which are stimulating and challenging;
- select appropriate ICT resources;
- decide on teaching strategies and classroom management, ensuring safe use of ICT within your classroom;
- develop your pupils' ICT capabilities.

**Main aspects of content**

1. **Supporting learning and planning pupil activities which involve ICT**

   You need to look for opportunities to integrate ICT into your teaching.
   
   You need to design learning activities which are appropriate for all of your pupils including those with SEN.
   
   You need to ensure that any learning activities are stimulating and challenging, and encourage pupils to generate their own ideas.

2. **Figure 5:** Purposes & Main Aspects of Content (from Unit 2 on Planning to use ICT).

**Links to Scottish 5-14 national curricular guidelines**

There are currently national curriculum guidelines covering ICT (draft), and Mathematics, English Language and Environmental Studies, for pupils aged five to fourteen, which provide reference points for any pupil activities within our course.

The draft ICT guidelines identify seven process oriented ICT strands, as follows:

- using the technology
- creating and presenting
- collecting and analysing information
- searching and researching
- communicating and collaborating
- controlling and modelling
- developing informed attitudes.

**Evaluation framework**

The evaluation framework will use teachers' self-assessments, evaluations of the course units, a sample of their portfolios of evidence, and interview discussions with a sample of tutors, participants and others. A national quality assurance framework is in place.

**Teachers' self-assessments**

In their self-assessments teachers will have indicated the extent to which each main aspect of the content within a unit has been overtaken and if they plan to do any further work on it (see figure 6).

<table>
<thead>
<tr>
<th>1a. Look for opportunities to integrate ICT into your teaching plan.</th>
</tr>
</thead>
<tbody>
<tr>
<td>completely overtaken</td>
</tr>
<tr>
<td>partially overtaken</td>
</tr>
<tr>
<td>not yet overtaken</td>
</tr>
<tr>
<td>Comment:</td>
</tr>
<tr>
<td>I plan to do further work on this.</td>
</tr>
<tr>
<td>I do not plan to do further work.</td>
</tr>
</tbody>
</table>

**Notes:**

They will have appraised their progress towards personally determined learning goals and perhaps substituted others.

**Portfolios**

The portfolios should contain resources that teachers have gathered from classroom-based ICT activities (such as examples of pupils' work, teaching plans and worksheets) as well as a written or word-processed record of their responses to the activities and tasks built into the course.

**Figure 6: Teachers' self-assessments.**
Unit & end of course evaluations (online questionnaires) completed by participants

The end of unit evaluations range across many aspects of the learning environment and learning activities, covering the following areas: interest, relevance, level of demand, clarity of instructions and ease of navigation, time spent on studying, quality of online tutor support, collaboration and communication with colleagues, skills learned, use made of the resources on our website, and overall rating. In addition, the end of unit course evaluation asks:

- Overall, how well did the course address your learning needs in relation to ICT use in the classroom?
- How much do you feel your pupils benefited from any classroom-based ICT activities stimulated by the course?
- Finally, if you have any specific recommendations on how the course could be improved, please indicate these below.

This data will be held on a central database, collated and communicated to tutors and the course design team.

Focus group discussions & interviews

Focus group discussions and interviews will allow a more in-depth exploration of issues and problems, and increase the range of perspectives contributing towards the evaluation. The findings from these sources will supplement other findings and will enable the data to be triangulated.

Implications

Need for greater realism in national planning

It has become very apparent from the slow rate of uptake of the training that it is very difficult to reconcile a voluntary programme of training, which may require teachers to study in their own time, with the requirement for them to undertake a very extensive set of competences. There does not seem to be an easy way to resolve this difficulty unless there is a further injection of funding to provide cover costs for schools to release teachers to study during the school day and/or the competences are revised. Furthermore, the extensive nature of the competences is likely to discourage those teachers who are already technophobic, and may result in a 'surface skim' for those who do opt into the training, rather than any serious engagement with the key issues and the development of real competence with using the technology in the classroom. Not all of the defined competences are of central importance to using ICT effectively in the classroom, and this makes it harder for teachers to discern where their real efforts should be directed. As Gardner (1993) would say, less is more!

Need for better coordination of major educational initiatives

While uptake of the NOF training has been slow in the primary sector, it has been virtually at a standstill in the secondary sector. The implementation of a major curricular reform, Higher Still, which affects all S5 and S6 pupils and all secondary teachers, is bound to have had a major impact on teachers' willingness to undertake the NOF training.

While investment in training should follow closely on investment in equipment, this has not in fact occurred in many local authorities. The roll-out of the infrastructure has been too slow, and consequently there is no online access, or only very limited access, for many teachers.

Potential for uneven & fragmented experiences & outcomes

Variability in the format, content and quality of the training offered by different approved providers (some, for example, do not use the technology itself as a delivery medium and some do not address the NOF competences fully), and the uneven situation with regards to technical infrastructure, may result in very uneven outcomes nationally.

The focus on how ICT can contribute effectively to learning & teaching will be sharpened

On a positive note, the NOF framework has shifted the focus towards appropriate use of the technology, properly integrated into the curriculum and supporting teachers in their day-to-day role.

Abstract: Learning in collaboration has numerous advantages. However, sometimes situations that damage collaboration arise. This is the case for instance, when students divert their attention from the learning situation at and for a long period of time. New technology can be used to detect and avoid some of these situations that hamper learning in a group. This work focuses on a specific problem “inefficient conversations”. The paper proposes the use of a virtual agent to control and guide the students’ conversations when learning a procedural subject, namely programming. The virtual agent can play a role similar to that of a human monitor with the additional advantage of being always available.

Why is learning to program so difficult?

Programming is a discipline difficult to teach and to learn. Last year of the 339 students who registered to our University’s introductory programming course only 131 students presented the final exam, and only 90 of them passed. Programming is a complex skill to learn where even languages designed for the novice such as Basic and Pascal contain many traps for the unwary (du Boulay, 1986). This discipline is complex to learn for two main reasons:

- Programming involves a great variety of subtasks and types of specialised knowledge that are necessary to perform effectively (Pennington & Grabowski, 1990).
- Programming is a procedural discipline which must be "learned by doing". Many students are not used to work in this manner.

Programming differs from other neighbour domains such as mathematics or physics in two ways. First, there are no everyday intellectual activities that can form the basis for the spontaneous construction of mental models of programming concepts such as recursion or variables. Secondly, programming requires of a physical machine whose functioning may not be transparent to the learner (Rogalski & Samurçay, 1990).

Learning to program in any language is not an easy task and programming teachers are well aware of the myriad difficulties that beset beginners (du Boulay, 1986; Rogalski & Samurçay, 1990). Additionally, programming is also a complex subject to teach, in programming there are many abstract concepts like recursion or data structures, and it is difficult to find clear examples to illustrate some of these concepts. Pedagogical strategies advice teaching using real-life examples to make it easier for students to remember and understand them. In programming to explain the abstract concepts with examples based on the real life is very difficult.

New technology can be used to help students develop new skills, such as the abilities necessary to become a good programmer. Students can be assisted by providing them with computerised aids that are designed specifically for the novice (Smith & Webb, 1999). Many systems have been developed to teach programming. It is interesting to note that although novice programmers normally prefer work in labs where they can ask their doubts and get advice from other fellow students, none of these systems were designed to support collaborative learning.

We have developed a system aimed at assisting students learning to program in a collaborative environment. However, although collaborative learning offers many advantages (see Johnson, Johnson & Smith, 1991; Dillenbourg et al., 1996; Dillenbourg, 1999) sometimes situations that damage collaboration arise. An example is “inefficient conversations”. We call "inefficient conversations" to those conversations that are not related to the problem at hand and that distract the student's attention. This paper proposes the use of a
virtual student or agent to control this negative situation. The contents of this paper are organised as follows, section two describes current tools designed to teach computer programming, section three presents HabiPro a collaborative system designed to train students in programming, this section also describes an experiment performed with HabiPro. Inefficient conversations were detected in this experiment. Section four proposes adding a simulated student to HabiPro in order to control students’ interaction and to avoid ‘inefficient conversations. In the last section, conclusions and future work are presented.

Current Tools for Learning Programming

Several systems have been developed to assist the teaching and learning of computer programming. Frequently, however, these tools are based on an advanced understanding of the language, and they are not really useful to train novices. The next paragraphs describe the main features of four programs designed to teach programming or help students to debug their programs.

Lisp Tutor (Anderson & Reiser, 1985) was built around a model-tracing paradigm. That is, the tutor has built into it an ideal student model, a production system model of the different ways in which a student should write LISP code, that follows along with the actual student coding a function. Each production corresponds to the student either typing or planning a portion of the function. When the student deviates from the correct solution path, the tutor gives specific feedback and requires the student to try again (from the most recent production firing, not from the beginning of the function). Student errors that have such remediation are referred to as diagnosed bugs.

If the tutor does not recognise a student’s input as correct or as a bug, the tutor displays “I don’t understand that” and asks the student to try again. These errors, student inputs for which no feedback exists, are referred to as undiagnosed bugs. After entering two undiagnosed errors for a particular input, the student is given the answer that the tutor expected (via the ideal student model) and an explanation of why the answer is correct. Students may also obtain a particular answer and an explanation of the answer at any time while coding a function by pressing an explain key. In sum, there are four actions a student may take that are relevant to each coding-production: entering a correct answer, entering a diagnosed error, entering an undiagnosed error, and typing pressing the explain key. The tutor records each student interaction in terms of the productions that can be expected, the student’s input, and the tutor’s response.

PROUST (Johnson, 1985) uses an intention-based approach to identify and explain bugs written by beginning programmers. It is an on-line aid for novice programmers. PROUST has been designed to operate in an ordinary interactive environment. The students edit and compile their programs; whenever a program passes through the compiler without errors, it is automatically passed over to PROUST before it is executed. PROUST then analyses the program for non-syntactic bugs.

For each programming problem that the students are assigned, a problem description is prepared, using a special problem description language. Currently these problem descriptions cannot be developed by the course instructor, but must instead be prepared by someone who is familiar with PROUST’s knowledge base. The problem descriptions are collected into a library. When the student submits a program for analysis, PROUST retrieves the corresponding problem description from the library. Using the problem description as a guide, PROUST determines what exactly the student’s program is intended to do, and how it was intended to do it, identifying bugs in the process. For each bug in the program, PROUST determines where possible what the probable cause is, and uses this information in describing the bug to the student. If the bug was due to a misconception, then PROUST describes the misconception in English.

Proust and Lisp Tutor have two different approaches to automated feedback. The Lisp Tutor ‘watches’ the student as s/he writes the program and intervenes as soon as the student types in some incorrect code. Conversely, Proust takes a complete (syntactically correct) program and suggest correction to it (Bental, 1995).

Ceilidh (Benford et al, 1993) is a framework which provides computer-based support for course administration and the teaching of computer programming. Ceilidh has the ability to assess student’s programs, to provide feedback on their programs and to provide on-line assistance when the student asks for help. In Ceilidh, interactive tutorial help is provided via electronic mail to a human tutor.

Ceilidh environment have been developed to teach languages including C, C++, Pascal and SML (a functional programming language similar to LISP).
Ceilidh presents one exercise to the students. It also presents a file containing a framework for the code. The student edits the framework file to complete the functions. The student can then elect to run the functions s/he has written on tests of the students’ own devising and on pre-set test data. When the student is satisfied with the exercise, s/he can elect to submit the program to Ceilidh for assessment. Ceilidh assigns a mark to the program and informs the student. Each student can see the marks s/he has achieved and if the student is unhappy with the mark can ask for help from a human tutor by sending electronic mail from within Ceilidh.

Ceilidh’s assessment is based largely on the correct compilation and on dynamic testing. Some marks are also awarded for the style of the program (absence of redundant, correct type signature with each function). Marking is only of limited use as feedback. If a program does not compile Ceilidh does not offer any extra help.

SOLVEIT (Deek, 1997) combines the process and the tools to support the functionality of a traditional programming environment with a battery of utilities used in problem solving and program development. It provides an intuitive graphical environment complemented by online help and enforces a structured methodology. SOLVEIT consists of six stages. The first three stages are problem-solving stages and the next three are program development stages. SOLVEIT guides the student through a linear process of problem solving.

When people begin to learn programming, apart from reading a book about the language that they are using, and attending courses, if they have access to the Internet, they might join mailing lists, or news and work groups where they can ask question or advice from other programmers. Thus, the students look for the experience and collaboration of other people. This suggests that in programming learning collaborative techniques are often used because students join together to write programs and to take advice about their doubts in a spontaneous and natural way.

Stacey (1995) explained that a tip to debug programs is to request help from other students or teachers. Many times the bug might be a simple spelling mistake, but the psychological set (the phenomenon of seeing what you expect to see) or psychological distance (the ease with which two items can be differentiated) phenomenon prevent us from finding the mistake. On the other hand, other student or teacher can detect the mistake with a quick look at the program as Gerald Weinberg (1998) observed “the human eye has an almost infinite capacity for not seeing what it does not want to see... Programmers, if left to their own devices, will ignore the most glaring errors- errors that anyone can see in an instant. Unfortunately, only Ceilidh allows students to contact other people, in this case a person with more experience, the teacher. In this way students can request advice to the teacher or show him/her their programs.

The next section describes HabiPro (from the Spanish “Habitos de Programación”), a collaborative and distributive system designed to help novice students develop good programming habits.

A Collaborative System to Learn Programming: HabiPro

HabiPro is a collaborative learning system aimed at helping novice students develop good programming skills. The application was designed to support collaborative learning because of two main reasons: Firstly, when novice students begin to program they usually make several mistakes in their programs. However, it is often difficult for students to find their own mistakes (similarly, when a person writes a paper it is often difficult for him/her to find their own errors). Because of this, in many cases, students prefer to program at laboratories where there are other fellow students working on similar problems. This way they can discuss doubts, interchange ideas or ask for help to find the mistake/s that prevents the program from working correctly. This fact shows that collaboration can be of great help when students begin to create their first programs. Students can learn through the mistakes that their fellow students have made, students are also more motivated to work than when they are programming alone. The second motivation for the system to be collaborative, is of a social nature: Professional programmers usually work in groups, quality control techniques, such as code peer review, for instance, are recognised to be very effective practices. So, it is convenient for students to become accustomed to work in a collaborative environment from the beginning. In this way, they can also learn social skills necessary for their professional development.

Use of HabiPro: HabiPro has three main windows; the chat window, the work window, and the answer window. The chat window enables students to discuss how to solve the problem. The work window displays the problem to be solved. In the answer window students write the possible solutions to the problem. To work with
HabiPro at least two students have to be connected, each student works from a computer and of course, students are able to stay in different geography locations. Each student can write his/her proposal of solution in the answer window, learners have to reach an agreement about the correct solution. HabiPro has a help system that offers two choices, clues and counterexamples.

In order to test HabiPro, an experiment was carried out. Students divided into groups of different sizes were asked to solve the same set of exercises. Each group member used a computer and could communicate with his/her peers via the chat. The chat conversations were stored. Analysing the conversations it was observed that in many cases students talk about topics that were not relate to the exercises, for instance they talked about the football match that they saw the day before. When this type of conversation was brief, it presented no problem, rather, it could even be advantageous in some occasions because it helps to relax the environment and makes students more comfortable with the group. But if these interactions continue for a long time they may be prejudicial to the learning process. As Sipusic et al. (1999) claims more interaction among participants in a collaborative learning group would be beneficial for learning, however one exception is if the discourse is mostly off-topic and detracts from the time and effort devoted to learning.

The students were asked to complete a questionnaire after they finished the exercise. To the question: “Do you think that you have learnt more working in a group than working alone?” a majority of students (80%) answered positively, a minority (5%) answered that they did not know it, and the rest of students (15%) answered negatively. Students had to give an explanation to their answers. Most student who said that they did not learn more working in a group complain about the few motivation that their groupmates had, and in many cases (76%) they commented that their fellow students wasted a lot of time talking about other topics.

It is interesting to note that the problem detected “inefficient conversations” is not produced by technology factors, this situation also arises in collaborative learning without computer. The question is can new technology avoid or decrease the adverse effects of this situation?

### Can a Virtual Agent Avoid Inefficient Conversations?

When a teacher monitors a group's activities, students seldom talk about other topics not related to the task at hand and normally they are more concentrated. The presence of a coach or teacher who controls and directs the group can avoid several problems that arise in a group (see Katz & O'Donnell, 1999).

In order to measure the degree in which a monitor influences group dynamics a second experiment was performed. In this case each group included a teacher acting as a moderator. The moderator's task was to intervene when students began to talk about topics not related to the problem, with comments meant to motivate students to continue solving the exercises, such as: “Come on, let’s finish the exercises and we can talk after that about this”, or giving a clue such as "I think that the solution is 0,2,4". This technique improved the results and students solved more exercises (average of 3.6 exercises more) and used less time than when no moderator was used. The technique of adding a monitor was really useful but it is inconvenient when there are many groups, since it requires one teacher for each group. In order to solve this problem, we decided to implement a virtual student to play the roll of the moderator.

Virtual students or simulated students have already been used in collaborative environment (see Ayala & Yano, 1995; Inaba & Okamoto, 1997). The next paragraphs explain several advantages of using virtual students in collaborative systems.

- A simulated student can play a role that fosters learning. For instance, Webb (1989) found that learning correlated more with the number of times a student answered a question of another student than with the number of times a student asked a question. Suppose one of the students in a pair learning situation is a simulated student. It could ask questions to the human student. Answering the questions should increase student's learning.

- In traditional collaborative work when a teacher has placed students in a group and given them a task, there is little control over the group’s interactions because the teacher can only spend a fraction of his/her time with that group. On the other hand, with a simulated student as part of the group, all kinds of pedagogically beneficial interactions can be staged from within the group itself- thought provoking questions can be asked, taciturn students can be prodded to speak, bad ideas can be questioned, small slips can be caught before they have serious consequences, attention can be directed away from areas that are already mastered and onto areas where students are ripe to learn (VanhLenh, Ohlsson & Nason 1994).
A simulated student has an additional advantage over a real student: a second knowledge: the expert knowledge base. When deciding how to act, it refers both to its "own" knowledge base and to this expert knowledge base. This expertise is necessary for the teacher when he or she guides a small group, so it should be necessary for the simulated student as well. The lack of such expertise in a group composed only of human students dooms it to be less effective than one with a simulated student, in principle at least (Webb, 1989).

A virtual student can also monitor the group and correct misunderstandings or detect miscommunications. Another important advantage is that each group may have a simulated student. This simulated student is available at any time, so students do not need to worry about whether or not someone else is connected or if the partner is busy.

A virtual student acting as a moderator is even better than a teacher, because when students work with a teacher they often feel more pressure and they are not so comfortable as in a student-only working group. The virtual student can have other additional functions, for instance, to propose a new course of action when the group is stuck. In this case, students can discuss the proposal and reflect on it obtaining significant learning. On the other hand, when a teacher proposes a solution, usually, students do not doubt the information and believe it without reflecting on it. For the virtual agent to act efficiently, it needs information about the group with which it interacts. Two resources are mainly used by the virtual agent to obtain information: First, a group model where the learning evolution and some social aspects of the group are represented. And second, the group's conversations from which the topic of discussion can be inferred. The system has a database containing the words that students normally use to solve the problems. When the system finds in a conversation a word that does not belong to this database, it checks if this word belongs to a second database which contains words related to playful conversations. The words are divided in different groups, depending on the group to which the word belongs, the simulated student uses different motivation techniques. If the word is not found in the second database, the virtual agent asks a question in order to assess the progress of the conversation.

Conclusions and Future Work

Collaboration can be very useful in procedural learning, more concretely in programming, but sometimes when people collaborate situations arise that hinder collaboration. For example, when some group members begin to talk about topics that are not related to the problem at hand. This paper proposes to use a virtual student which monitors the group's conversation and acts when "inefficient conversations" are detected.

In order to test the efficiency of the virtual student we are designing an experiment to test whether the agent correctly detects "inefficient conversations", how many times they are corrected, and most importantly, if students learn more by using the new version of HabiPro. This last aspect is the most important one since the goal of CSCL is to improve students' learning, so our main goal is not to design a perfect virtual student but for students to learn more or faster using it.

tsextro@holtonks.net

Abstract: Educators continue to experiment with different technology training of teachers for more effective models, turning to the internet and instructional software tools in order to create an educational environment that supports the knowledge and skill-building approaches to learning. This paper intends to share the successful technology training experience of inservice teachers and educators of preservice teachers using video instruction and Internet as delivery tools. We intend to share our resources for those who are interested in self training and those who are in charge of technology training in their staff development program.

It has been almost two decades since microcomputers were introduced into public schools. Many school districts have spent millions of dollars to purchase hardware, software, and to connect classrooms with the World Wide Web. However, we continue to see misuse and under utilization of educational technology; teachers continue to struggle to master the core technical skills and are struggling in their search for effective and beneficial ways in which to use technology (Clouse & Alexander, 1997).

Educators need to get beyond perceptions that the World Wide Web is merely a communication medium for Email, for not only is it a vast global knowledge base for document distribution, it has significant and proven benefits when used as an instructional tool that reinforces effective and interactive learning. Internet technologies empower the teacher to create a global learning environment, as well as a virtual educational setting that transcends traditional boundaries. Teachers now have a treasure chest of information tools, resources and growing experience in their use with which to reinvigorate the educational process for themselves and their students.

The adoption of compressed digital video makes full interaction possible between the instructions and the learners (Garland, 1999-2000). With occasional human facilitation and reinforcement, this has created a learner-centered environment in which learning can occur at different times and in different places, as well as at different paces according to each individual’s special needs (Locatis & Weisberg, 1997). We believe that specially designed instruction utilizing digital video clips and the Internet as delivery tools give learners increased control over the pace of their own learning. All too often, however, technology training emphasizes discrete skills development, ignoring application or practices that enable users to gain an understanding of the relation between the training and its use in the classroom. Therefore, the learners are discouraged to continue to increase the application their skills and knowledge gained through a particular training session. In fact, many training models fail to make the transition between the training and the classroom implementation. Traditional training has usually taken the form of providing information that may or may not be relevant to the end user.

Our technology-training program utilizing the HOST Model (Holton Online Staff Training Model) was conceived with the intention of making the training highly meaningful and personalized to each individual teacher, with emphasis on the learning process and end products rather than on discrete skills.

Teachers were given multimedia instructions to help them attain a mastery of a specified set of skills directly related to the end products. The instructions were designed in a progressive way that mastery of one set of skills leads naturally to instruction of the next set of skills. The skills were organized according to their complexity moving from easy to intermediate to difficult. This is derived from the objectives for the training, the delineation of content, and the creation of activities for practice. The training model was based on the principle that everyone has the opportunity and ability to achieve a certain level of complexity, and therefore assists the teachers in building their interest in classroom implementation of technology, as well as the confidence in being able to do so. The possibility of instantaneous publishing to a worldwide audience has
had an energizing effect on the teachers, resulting in greatly enhanced motivation to continue learning new
skills, and thereby improving their final products.

The fact that educators do not feel that they have the necessary technological to transform the
educational process is due, in part, to the ineffectiveness of past staff development activities based on
outdated training models. In response to that, Holton USD 336 created a new Web site
http://www.holton.k12.ks.us/training designed to help individual institutions improve their staff development
activities based on what shall be referred to as the HOST model. All video instructions on this site are
freeware and may be downloaded and saved to any computer. With the support of TLCF and Educate
America grant funds, in the fall of 1997, a technology training model called HOST was developed by a team
of educators in Holton district USD 336. In the fall of 1998, Holton USD 336 received a TLCF Professional
Development Grant for nearly $50,000. Through this award, the district developed an innovative staff
development web site that was used for teacher training (for 1998 staff members).

Web-based training video clips are used in the HOST model to explain various concepts and skills.
Because of the multimedia capabilities of these videos, the user is able to use all their learning channels to
master and apply the concepts. Users have no limit to the number of times they may want to repeat the
original task they are facing, which helps them not only to better understand the nature of the task, it provides
ample opportunity to achieve a deeper learning of the necessary skills to complete the task. Throughout the
training, concepts are introduced slowly and they are built linearly on one another, from simple to complex.
All activities have been designed to correspond to the district goals, and participants have received training
matched to their own pace of learning through the training on the web. The training material is available for
teachers to access from school or at home to provide continuous learning opportunities even after the initial
training. The overarching goal of any HOST model training is to move participant teachers a step forward in
technology implementation in their respective classrooms.

Prior to each training of the two workshops, every participant was asked to fill out a profile to self
evaluate their technical skills in the areas of operating systems, word-processing, graphic editing and
presentation tools. When they finished the formal training, they were asked to answer the same questions to
reevaluate their knowledge and skills. Their self-evaluations were then used to measure the learning
outcomes. Ninety-eight teachers participated in the first workshop, sixty-two responded to both pre- and
post-evaluation questions. The pre-evaluation results showed that among those responded, the average was
48.2%, and the post-evaluation average was 72.1%, among which the highest percentage was 35 and the
lowest was 0. The difference between the pre-evaluation and the post-evaluation in the first workshop was
very obvious. In the second workshop, which was held during two consecutive Saturdays in March, 1999,
there were 51 teachers and seven college professors participating. In this case, everyone responded to the
profile questions regarding the basic knowledge and skills of utilizing Internet technology in their teaching,
pre-evaluation averaged 20%, while post-evaluation averaged 82%, which shows a very significant average
improvement.

The workshop finished with teachers sharing their final products with the group. It was obvious that
these teachers showed great interest in creating instructional materials on the Internet and the Internet was a
great place for learning and sharing. (Please checkout the following URL to see some of the projects.)
Overall the workshop was a success. All the participants felt that they had gained a lot of knowledge and
skills through hand-on experience. We hope that this model will contribute to the course of technology
training of teachers.

Technology Systems, 28(1) 59-66.

100-103.
The overview paragraphs have been organized by the last name of the first author. As the reader moves from paper to paper in this section, it is important to remember that a uniformity of nomenclature in preservice teacher education does not exist. There is general agreement about foundation courses (beginning) and methods courses (usually intermediate). However, practicum may be part of a methods course or may be the student teaching experience. Usually, practicum is something that takes place in a school under the supervision of a classroom teacher and a college professor. Field experiences may occur anywhere in the teacher preparation sequence. In some places, preservice teachers are undergraduates; in others, they are post-baccalaureate. Each presenter group will define its own circumstances. Each presentation combines the use of electronic technology and preservice teacher education.

Structuring electronic portfolios using web-based document management
Eric Aplyn and Carl Hoagland of the University of Missouri at St. Louis discuss solutions they are framing to overcome barriers to institutional implementation of electronic portfolios. This will be a discussion of a work-in-progress. The authors are developing experimental portfolios with a web-based knowledge-sharing technology developed by Xerox Corporation called DocuShare. The presentation will conclude with a full group discussion about the broader issues associated with institutional and regional implementation of electronic portfolios.

Links to the classroom: Technology in early field experience for elementary social studies
Linda Bennett, University of Missouri at Columbia, presents a paper describing her research. The questions she answers are: Did prospective teachers use the Internet to reflect on teaching? How did the prospective teachers use online journals and summative writing to reflect on technology and teaching?

Factors that promote and inhibit discourse with preservice teachers on a non-restrictive, public web-based forum
Alec Bodzin, Lehigh University, reports on an investigation of asynchronous communication factors that influence the electronic interactions of preservice science teachers. The students were able to access the SciTeach Forum from home, the university and the school in which they were based. The research question was: How does the medium promote or inhibit online discussion?

Impact of asynchronous discussion on preservice teacher education practicum experiences
Aaron Doering, Marc Johnson, and Sara Dexter, all of the University of Minnesota, address one facet of their PT3 grant, Ed-U-Tech. The players in the online discussions that are the focus of their presentation were college instructors of the methods course, preservice teachers, the middle school cooperating teacher and the middle school pupils. The presentation will detail ways in which the technology has assisted the preservice teachers to conceptualize their future roles as teacher and how the technology enhances the learning process.

Telementoring to improve literacy: Preservice students as online mentors to K-12 students
Melanie Goldman, Boston College, will conduct a roundtable discussion on the use of Internet-based mentoring and the teaching of writing. At one end are the K-12 students who write to the student teachers at the other end. Through online exchange, the preservice teachers interact directly with school-based children and improve their own writing as they provide guidance. The school children gain audience for their work and personal coaches as they learn to write.

Preservice teacher education and the Internet: Expanding perspectives toward a profession
Jennifer Gramling and Jamie Nelson, both of University of Tennessee, will present research gathered during the use of an online course management system (CMS) to supplement classroom instruction in a preservice teacher education class. The course title is Introduction to
Instructional Computing. The CMS used was Blackboard’s CourseInfo.

Regional list servers as a means of peer support for an online learning community

John Green, The Open Polytechnic of New Zealand, describes a process in which regional list servers were introduced to support the online classroom. The objective was to create small, supportive groups on online learners within a large online class. Whereas a chat is real time, a list server is asynchronous and peer support may be built at a less furious pace. The presentation will discuss organization, people, implementation and results.

Going the distance: Developing guidelines for the creation of online courses

Norma Henderson and LaMont Johnson, both of University of Nevada at Reno, will present standard criteria to guide the development of a quality online course. They will discuss a brief study whose results prompted the guidelines.

Umm.. I don’t think its working: Why our class-to-class E-mail exchange didn’t work (and what can be done to fix it)

Lauren McClanahan, Ohio State University and Linda Clady, Westerville City Schools, paired undergraduate teacher education students with middle school students in an E-mail writing project. This presentation traces their experiences.

Student perceptions of the value of online instruction

Barbara McKenzie, Elizabeth Bennett, Nancy Mims and Tom Davidson, all of the State University of West Georgia, will discuss their use of WebCT, a distance delivery system. Their remarks will encompass student reactions, WebCT tools, the impacts on learning and recommendations for change.

Connecting trainee teachers and school mentors with university educators via MultiPoint Desktop Video Conferencing (MDVC): The Singapore experience

Swee-Ngoh Moo, Foong-Lin Angela Wong, Leslie Sharpe, and Lachland Crawford are all from the National Institute of Education, Nanyang Technical University, Singapore. This presentation will describe the technology and the pedagogy using a state of the art video conferencing system. The pedagogic aspect relates to the added value to the curriculum of preservice teachers and will focus largely on the quality of the practicum (student-teaching) experience.

The study of the impact of learners, learning interactions on web-based tutorial program, to satisfaction on the use of web for educational purposes and academic achievement

Jaitip Na-songkhla, Chulalongkorn University, Thailand, will describe the use of a web-based tutorial as a classroom supplement in a freshman-level course, Foundations of Computer for Education. A wide range of participatory activities were provided and participation was encouraged. Feedback questionnaires were administered and analyzed. Results will be shared.

Research and development on practicum training system for preservice teacher education using Internet in Nara University of Education

Wakio Oyanagi, Nara University of Education, Japan, will present research dealing with the development and evaluation of a system to improve teaching practice using the Internet. The questions explored relate to the practicum in teacher training. Specifically, the Internet is used by the preservice teachers for reflection on observation practice, lecture and practicum.

Compressed video technology, innovative teaching and realistic experiences: Recommendations for CVT Usage

Gary Rosenthal, Nicholls State University, Barlow Soper, Louisiana Tech University, Lamar Wilkinson, Louisiana Tech University and James Barr, Nicholls State University. This presentation explores the implementation of compressed video teaching (CVT) at a number of universities in Louisiana. This technology allows remote students to see and hear everything that is occurring in each classroom. The presentation will be largely a “lessons learned” recounting and recommendation to new users of the system.

The Imfundo project: ICT in teacher education in developing countries

Michelle Selinger, Cisco Systems, UK, describes the technology and professional development program in which ICT was used to enhance distance education in underdeveloped countries. She will explain the problems facing teacher training in remote areas such as the sub-Sahara and the ways in which electronic technologies are being used to support teacher preparation programs.

The handheld web: Using mobile wireless technologies to enhance teacher professional development

Paul Shotsberger, University of North Carolina at Wilmington, discusses use of this new digital technology to connect preservice and inservice teacher training. He will describe a project that infused technology into the undergraduate curriculum for preservice mathematics.
teachers, while strengthening the relationships between his university and its partnering public schools.

**Preservice teacher education: Electronic/distance**

Leon Wickham, Massey University, New Zealand, will review the ways in which his university met the challenge for delivering teacher education to those who were unable to attend a traditional program. This alternate teacher education program delivers instruction through the media of the postal system and the World Wide Web.
Issues in structuring long-term electronic portfolios with web-based document management tools

Eric Aplyn
Dr. Carl Hoagland
E. Desmond Lee Technology and Learning Center
College of Education
University of Missouri – St. Louis
United States
caplyn@umsl.edu
hoagland@umsl.edu

At the College of Education of the University of Missouri – St. Louis, we have set out to look for solutions to 3 major barriers we found to institutional implementation of electronic portfolios:

- Fear of being evaluated on visual elements rather than on content,
- No obvious common software platform for portfolio development
- Evaluation and management difficulties with typical storage and software technologies

As a way of overcoming these barriers, we are developing experimental portfolios with a web-based knowledge sharing technology developed by Xerox Corporation. Similar products are available from other software developers with varying costs and varying capabilities. We will provide an overview of our work to date, provide our research on other technologies with similar capabilities, and hope to launch a discussion that explores the broader issues associated with institutional and regional implementation of electronic portfolios using this strategy. One primary concern is the need to address inter-institutional standards, particularly for 2-year to 4-year college transitions and transitions to long-term professional development. Other key issues include student/faculty trust, usability and stability, long-term management, security, and ownership of portfolios.

Technology in Early Field Experience for Elementary Social Studies

Linda Bennett, Ed.D.
Curriculum & Instruction
University of Missouri-Columbia, USA
lb@missouri.edu

Abstract: This paper describes a model for integrating technology into early field experiences. The focus of the paper is on what technologies were used and how prospective teachers utilized technology in early field experience. Two recommendations are for diverse models of integrating technology into field experience are developed and those diverse strategies for integrating technology into social studies are designed.

Introduction

What do prospective elementary teachers need to know about technology and how should they utilize technology in teaching social studies in the elementary schools? To address these questions, the International Society of Technology in Education (ISTE) developed profiles for preparing tomorrow's teachers to use technology (2000). ISTE stated six performance profiles for the professional preparation of prospective teachers. The performances are:
(1) technology operations and concepts
(2) planning and designing learning environments and experiences,
(3) teaching, learning, and the curriculum,
(4) assessment and evaluation,
(5) productivity and professional practice, and
(6) social, ethical, legal, and human issues.

Technology is a powerful tool for prospective teachers to communicate and develop knowledge, skills and attitudes about teaching. Students can use electronic communication tools, Internet resources, and multimedia documents to research information, develop inquiry skills, or discuss diverse viewpoints. Communication tools can link professionals, educators, and prospective teachers interested in social studies. Through technological methods such as these a community of learners can be developed (White, 1996). Projects can be developed for prospective teachers to work collaboratively on computer-mediated technologies in the social studies classroom.

As a new resource for education, technology has influenced the nature of teacher education. This study describes how technology was used in an early field experience taken in conjunction with an elementary social studies methods course.

Research Questions

(1) Did prospective teachers use technology in early field experience?
(2) What technologies did the prospective teachers use to teach social studies?
(3) How did the prospective teachers use technology to teach social studies?

Methodology
Participants

There were twenty-one undergraduate students. All the students were in the first semester of their senior year. Two students were males. The minority participants included one African American student and one Hispanic student.

The students were enrolled in the Social Studies in the Elementary School course and corresponding field experience. The course is a required three-semester hour course for undergraduate elementary teacher education students at a large regional university. The field experience is a required two-semester hour course in which the students are in an elementary classroom from forty to sixty hours during the term.

The location of the field experience was Parkade Elementary School in Columbia, MO. The field experiences were in three fourth grade and four fifth grade eMINTS (enhance Missouri's Instructional Networked Teaching) classrooms. Classrooms are networked, teachers are trained, and each classroom contains a SMART board. The classrooms have between one to four to one to two computers to student ratio. The cooperating teacher, three undergraduate field experience students and approximately twenty elementary students work as a team to apply technology while learning social studies.

The MU Partnership for Preparing Tomorrow's Teachers To Use Technology (PT3) Grant http://www.coe.missouri.edu/~ptnut/ provided support for the technology at the university. The Navigator@Parkade and eMINTS (http://emints.more.net/info/central/classpages.htm) provided the technology support for the elementary school.

Data Collection

During the fall term of 2000, data were collected using online journals, final reflective papers, interviews, observations, e-mail messages, self-evaluations by prospective teachers, and cooperating teacher evaluations about the field experience and the use of technology. The researcher periodically visited the classrooms and discussed the progress of the project. There were group meetings for the classroom teachers and prospective teachers at the beginning and end of the field experience. The researcher corresponded through e-mail with individuals and groups of prospective teachers and classroom teachers throughout the field experience.

Findings

Technology Expectations

The performance expectations for prospective teachers in the project were:

- Use e-mail, a class discussion list, and online forms
- Design and implement a WebQuest in the classroom
- Design a concept web using Inspiration on a social studies theme
- Design units of study and lessons, which infuse technology into the curriculum
- Building a technology resource list for the social studies curriculum
- Teach the unit in a local elementary school

Technologies Used

The technologies used in the elementary classroom were determined by what had been purchased in the grants. The university and the elementary school had access to very compatible hardware and software. The grants supported hardware, Microsoft Office, and Internet connections. Technologies used in the classroom included but were not are limited to the following:

- SMART board (interactive white board)
- Computer stations for small groups for elementary students (1 to 2 ratio)
- Microsoft Office
- Webquest (http://edweb.sdsu.edu/webquest/webquest.html)
- TrackStar (http://scrtce.org/track)
- Inspiration (http://www.inspiration.com/)
Integration of Technology into Social Studies Instruction

The prospective teachers were required to write and implement a social studies unit that integrated technology. The fourth and fifth grade classroom teachers selected the following units for the prospective teachers to teach: The Land and Its People (The United States and Australia), The Oregon Trail, The 2000 Election, Missouri Government, and Colonial America. These are typical units taught in fourth and fifth grade classrooms and the classroom teachers provided a lot of print resources for the prospective teachers to use in planning and implementing the lessons. The new aspect of the lessons would be the use of technology.

The SMART board, PowerPoint, and Web sites were used on a regular basis in the lessons taught by the prospective teachers. For example, the SMART board was used to brainstorm ideas, post information, interact with Web sites, and present projects. The prospective teachers designed WebQuests (http://edweb.sdsu.edu/webquest/webquest.html) for the elementary students to complete a task using selected web sites. TrackStar (http://scrtec.org/track) is a web site that provides a form for teachers to develop a lesson or list of related web sites for students to search.

The lessons included opportunities for elementary students to use technology. Primarily, the Internet was used by the elementary students to complete a task with one or more specific web sites as a resource for information. Typically, PowerPoint was used by the elementary students to develop presentations to demonstrate what they had learned.

The prospective teachers brainstorm the content for the unit used Inspiration. I am unaware of the Inspiration being used in instruction. It is the only software that was used in the university course that is not in the elementary classroom. The prospective teachers could have downloaded the software but did not. The software has been ordered for the elementary classrooms.

Technology for Course work

The university courses were web-assisted and all assignments were on a Courseinfo web site. The prospective teachers used technology to complete the assignments for the university courses. The primary objective for the elementary social studies methods course was to write the social studies unit. The online forms were used to complete a weekly reflective journal on the field experience. Electronic communication tools were used to share ideas among the prospective teacher, university instructor and classroom teacher. The prospective teachers shared concerns and gave ideas on how to use technology to teach social studies lessons in an elementary school.

Summary of Technology Use

The prospective teacher, classroom teacher, and elementary student used technology to plan, implement, and assess the social studies unit the university student was teaching in the elementary classroom. It is difficult to generalize the locus of control in the use of technology. Within each classroom the prospective teacher, classroom teachers and the elementary students determined the use of technology. If any one of the individuals had an interest or need to use technology then they did. In most cases, the opportunities to use the technology were open to anyone.

During the lessons taught by prospective teachers, technology was used in every lesson I observed. Technology was used either by the prospective teacher to introduce the lesson or by the elementary students to complete a task.

Through observations, the researcher made several generalizations about technology in the fourth and fifth grade classrooms. The hardware and the software on the student computer stations functioned without glitches and technical difficulties were not discussed. I observed on one occasion a teacher came from another classroom to help students scan an image into PowerPoint.

Each prospective teacher had some prior technology experience during their professional education course and self selected projects. The SMART boards were a new piece of technology for
everyone in the classroom so some students were nervous about using it. Training sessions to learn the technology were set up at the university as needed. Students prefer for the sessions to be conducted using the elementary school equipment.

**Recommendations**

Based on this study, the following recommendations are made for the integration of technology into early field experience.

- Provide training for the prospective teachers on the use of technology and design social studies lessons during the first few weeks of the semester before going to the elementary classroom.
- Video taping or teleconferencing to show models for integrating technology into social studies curriculum.
- Develop a personal target to learn and effectively use 2 to 3 technology tools in teaching social studies and conduct a follow-up review on the success of the implementation plan.
- Use other aspects of Microsoft Office such as Excel to graph and chart social studies data.
- Provide access to technology at the university to that found in the elementary classroom (SMART board and Inspiration).
- A balanced distribution of old pedagogy (worksheets) and new technology strategies (inquiry).
- Sufficient time to plan for the infusion of technology into the social studies curriculum.

**Closing Comments**

The findings of the study begin to document the rewards and challenges for infusing technology in field experiences. It was the first attempt at having prospective teachers in a rich technology environment for field experiences and having prospective teachers implement a social studies unit with technology. I feel this experience is the beginning of a partnership for using technology in field experiences to enhance social studies in the elementary classrooms. One prospective teacher stated: “I wanted to let you all know that this is the best field experience I have ever had in my teacher preparation.”

**Conclusions**

The shift in the pedagogical infusion of technology is key to the success of early field experiences in teacher education. As instructors, classroom teachers and prospective teachers make use of technology as an integral component of their daily life, we can discover new methods for infusing technology into the elementary social studies classroom. Through the technology links of early field experiences prospective teachers, classroom teachers, and elementary students can grow together, learn from each other, and develop models for infusing technology into elementary school social studies.

Factors That Promote and Inhibit Discourse With Preservice Teachers on a Non-Restrictive, Public Web-Based Forum

Alec M. Bodzin, Department of Education and Human Services, Lehigh University, USA amb4@lehigh.edu

Abstract This study investigated asynchronous communication factors that influence the discourse of preservice science teachers on a non-restrictive, public Web-based forum. Salient elements that promoted discourse among the participants included the level of interest in a topic, the immediate relevancy of a topic to a participant at a particular time, and interpersonal factors among participants. Limitations using asynchronous communication perceived by preservice teachers included receiving feedback too late to be of use and issues pertaining to the absence of visual cues during discourse exchanges. The linear, temporal interface of the Web-based forum appeared to be a factor that limited the depth of the discussion.

Telecommunication networks are transforming higher education. Recent developments in computer telecommunications technology have emerged as a means for providing support to beginning teachers. University teacher educators can continue to provide preservice teacher training with electronic networks when students are at remote student teaching placements. A fundamental advantage of computer networking is the flexibility it offers. Geographical and time constraints are overcome because messages can be sent at any time of the day and from any place. Electronic communication can provide a communication bridge that increases the frequency of interactions among student teachers and university personnel (Thomas, Clift, & Sugimoto, 1996). The fact that the network is available 24 hours a day is a strength only this technology can offer. In addition, combining the network with good on-site support greatly improves the quality of supervision in teacher training (Casey & Vogt, 1994).

As Web-based learning tools proliferate in higher education settings, there is a need for focused research on how such technology augments and redefines academic learning environments (Koschmann, Myers, Feltovitch, & Barrows, 1994). Since the World Wide Web is accessible to preservice teachers at home, at the university, and in their student teaching placements, it is important that research be conducted to evaluate the impact of preservice teachers’ use of Web-based forums, as well as their perceptions of dialoguing with the aid of this new technology tool.

Purpose

The purpose of this study was to investigate asynchronous communication factors that influence the discourse of preservice science teachers on a non-restrictive, public Web-based forum. The following two research questions were investigated:

1. What differences do preservice teachers perceive between Web-based asynchronous communication and face-to-face-communication?
2. How does the asynchronous Web-based medium promote or inhibit online discussion?

Methodology

The participants in this study were composed of 32 prospective secondary school science teachers enrolled in the Professional Semester at North Carolina State University. This consisted of Methods of Teaching Science, Instructional Materials in Science, Seminar in Science Education, and Student Teaching. Twenty-one participants were female and 11 participants were male. The age of the students ranged from 21-26 years with a mean age of 22.3 years and a median age of 22. The students’ initial telecommunication expertise and comfort level ranged from those with little experience and comfort using e-mail and the World Wide Web...
to those who felt very comfortable and used telecommunications on a daily basis. Most students (n=23) reported that they were not confident using a Web-based forum. Only four students had some type of previous experience using a Bulletin Board System (BBS), online chat, Web-based forum, or other electronic conferencing system.

The participants had completed the majority of their academic requirements for a Bachelor of Science degree in Science Education with 10 students concentrating in biological sciences, 10 in physical science, and 12 in middle school science and math. Students were on campus daily for course instruction during the first five weeks of the semester. All high school science preservice teachers (n=20) attended the Instructional Materials in Science course for two hours per day during these five weeks. These students were divided into different Methods of Teaching Science courses based on their science concentration area. These courses were instructed by science education faculty members other than those who taught the Instructional Materials in Science course. The 12 middle school preservice teachers were instructed in separate instructional materials and methods courses than the high school preservice teachers.

Students were on campus daily for course instruction during the first five weeks of the semester. For the following ten weeks, each student was assigned to a public school in a school district near the university for a student teacher internship.

Context

In order to examine the potential benefits of preservice science teachers engaging in an electronic professional community of science teachers on the World Wide Web, a public Web-based forum called the SciTeach Forum (http://www.ncsu.edu/sciteach) was constructed in July 1997. The SciTeach Forum was placed in the context of a large public science education Web site. The SciTeach Forum serves as an online support network for both inservice and preservice science educators.

The SciTeach Forum was designed to be a place where science teachers share ideas, reflections, and conversations on teaching and implementation of technology in the classroom and other instructional pedagogy, while also providing support for each other as members of an electronic professional community. The SciTeach Forum was designed with NetForum software. NetForum is a Web based group communication and collaboration system provided by the University of Wisconsin Biomedical Computing Group. The program is written in Perl and works on any UNIX-based system with Perl 4.0.1.8 or later that supports CGI subdirectories. Forums are organized into discussion topics and messages. A simple, intuitive toolbar allows user access to NetForum features. Forums can be created and managed by "forum owners" with the administrative tools via the World Wide Web. Forum topics and messages can also be edited via the administrative tools. Forum owners can customize many of a forum's features and can add html codes into the headers and footers of each of the forum's web pages.

The NetForum software was selected to create the SciTeach Forum because it was available at no monetary cost since our institution has a site license to use the software. Another reason to use the NetForum software for this project is ease of use. In addition, the software allows the users to initially structure the discussion topics on the forum in any order. The software also enables any user to add a new discussion topic to the forum. Within each topic area, a user can post a new message, reply to a message, or reply to a reply of a message. When users first enter a topic area, they are presented with a list of message and reply titles. Each message and reply title displays the author of the message and the date the message was posted on to the forum. Message threads are displayed in a temporal sequence with the most recent message listed at the top of the screen. Each message and reply title is a hypertext link. The user clicks on a message or reply title to view the posted message. The software also enables the user to read an entire thread of successive replies to the original message.

The SciTeach Forum can be accessed by anyone with a connection to the World Wide Web. A special e-mail account or password is not a requirement to read forum messages or post messages to the forum. Unlike other previous studies involving preservice teachers using telecommunications during their student teaching semester, there was no additional funding to equip the preservice science teachers with laptop computers and telephone modems (Bull, Harris, Lloyd, and Short, 1989; Casey, 1994; Loiselle, Dupuy-Walker, Gingras, and Gagnon, 1996; Merseth, 1991; Schlagal, Trathen, and Blanton, 1996; Thomas et al., 1996; Thompson and Hamilton, 1991; Waugh, 1996; White, 1997; Zimmerman and Greene, 1998). We assumed that at least one computer in the school where a student teacher would be placed during the student teaching internship would have online access to the World Wide Web. Each school did have access to a networked computer. However, eight students were unable to access that computer during their internships.
The SciTeach Forum contains discussion topics relating to teaching science content, incorporating instructional technology into the curriculum, and topics relating to teaching pedagogy in general.

The preservice high school science teachers were introduced to the SciTeach Forum during the first on-campus day of their Instructional Materials in Science course during the Fall 1998 semester. The preservice middle school science and math teachers were introduced to the SciTeach Forum during the fourth on-campus day of their Methods in Science and Math course. Each student was instructed how to use the SciTeach forum in class and required to post a message on the forum to introduce themselves in the “Preservice Science Teachers” discussion topic area. As part of the required course work, each student was required to post two messages to the SciTeach Forum for the entire semester each week. Of these two postings, one posting each week was required to be placed into the “Critical Incidents in the Science Classroom” topic. Critical incidents are defined as an event which confronts teachers and makes them decide on a course of action which involves some kind of explanation of the scientific enterprise (Nott & Wellington, 1995). The following is an example of a critical incident:

You are doing another inquiry lab. As you walk around the room you notice several students off task. You move more closely to observe them and to get them back on task. A student says to you, “This is dumb! You could just simply tell us the answer and how to do the lab. We’d learn the material more quickly and get to new things.” What kinds of things would you say and do at this point?

The majority of the instructor-posted critical incidents placed on the forum adhered to Nott and Wellington’s definition. A few of the critical incidents posted involved non-specific science pedagogy issues that could apply to any preservice teacher. These included issues such as covering all course objectives for the “end of the -teacher/cooperating teacher relationship.

The preservice teachers, four science education faculty members, six science education graduate students, and eight persons unassociated with the university participated in the forum discourse during the semester. The forum was monitored regularly by two university instructors of the Instructional Materials in Science course. At the beginning of the semester, an invitation was circulated to each science education faculty member and selected graduate students to participate in the forum discourse. An e-mail list was established to notify participating faculty members and graduate students of forum messages posted by the preservice teachers pertaining to specific concerns of their internships.

Data Collection

A survey was administered to each subject at the end of their student teaching semester. The survey consisted of open-ended questions, Likert-type attitudinal questions, and multiple choice type questions designed to identify the preservice science teachers' perceptions and attitudes regarding their experience interacting with a Web-based forum during their student teaching internship.

Nine interviews were conducted from a stratified random sample of preservice science teachers. Preservice teachers were stratified based on their methods course. Three subjects were interviewed from each of the 3 different methods courses. The interviews addressed the participant’s experience, attitude, and perceptions with using the Web-based forum during the 5 weeks of on-campus course work and during their student teaching internship. Three interviews were conducted during the second week of the participants' student teaching internship and six interviews were conducted during the week following the end of the participants’ student teaching internships. Interviews were recorded using audio tape and then transcribed by the researcher.

Findings and Discussion

Promoting Discussion

An assortment of factors appeared to promote discourse among the participants. The level of interest in a topic appears to be an essential factor in promoting discussion. The immediate relevancy of a topic to a participant at a particular time is also an influential element to the depth of the dialogue. Furthermore, interpersonal factors among participants were salient elements in promoting discourse. The participants were a group of preservice teachers experiencing similar situations during their student teaching internships. As the participants encountered similar classroom management and discipline problems, they used the forum to share and discuss their related situations.
Discussion of controversial topics also increased the depth of the forum dialogue. As one interview participant stated, "When you get fired up about something and you're really interested and passionate in an idea, I think you are going to talk about it more than if you just feel so-so about it. If you're not real sure how you feel then you are not going to respond as much. But if you know what you're thinking, then you're going to talk a lot more.

On the forum, participants expressed their personal opinions and views in discussions involving ethical issues. Throughout the discourse and in the participants' interviews, several critical incidents in science teaching were referred to as "touchy" or controversial issues. These participants perceived discussing controversial issues as getting them "fired up". Furthermore, they were interested in hearing what their peers thought or how they would react to a given situation. In the discourse, participants explained and defended their moral positions and beliefs. Some participants also said they were more willing to contribute to the discussion of sensitive issues than to other topics.

The forum promoted discussion by allowing one access to others' perspectives. It allowed for different opinions to be analyzed and agreed with or argued against. For students who were isolated in their student teaching placements, the forum promoted discussion just by being there. The forum provided a place where isolated student teachers could share and discuss their teaching experiences.

Inhibiting Discussion

The interface of the Web-based forum appeared to be a factor that limited the depth of discussion on the forum. Replies to posted messages are organized temporally with the newest reply at the bottom of the message thread. This mirrors the organization of a bulletin board system. Users could also read an entire thread of successive replies to an initial message. In this manner, an entire thread resembled a face-to-face conversation. However, the nature of communicating asynchronously in a temporal, linear manner was sometimes perceived as restricting the discourse. An interviewed participant stated: "It's not an immediate dialogue. Its put a question up there or a problem up there and somebody replies back and you read it whenever you get to a computer. It's not a constant dialogue. It's not back and forth, back and forth, back and forth. It's a posting, then a reply. That's it. Because it's not immediate, you can't really challenge it or ask more questions or ask to go into further detail. Not the way it was set up. I guess you could e-mail that person and ask them. But as far as the forum went, it wasn't set up.

The nature of asynchronous communication does not promote an immediate back-and-forth dialogue that is often required by a person to get the specific type of feedback one is looking for. When one engages in face-to-face conversation, the nature of the communication is often a continuous process. The forum interface does promote a reply, but not a "back and forth, back and forth" discussion. A natural flow of conversation is not easily achieved when participants access the forum on a weekly basis. Participants viewed the forum's linear structure as impeding the flexibility of the communication because they could not place their replies directly to specific messages in a thread.

A large number of participants responding to the same critical incident appeared to cause a saturation effect in the discourse. In many of the message threads, after half of the students responded, the responses began to "sound along the same lines". One participant shared her insight to this phenomenon: "I think people will wait to see other people respond to it. And then pull their responses up on the screen and be like okay, this look good. I'll type that down as well. Versus sitting down and really thinking about the incident and being like, well, this is the way that I would handle it, let me see someone else's view, but this is the way I'm going to handle it. Versus comparing and contrasting, they'll just take the easy route out and write just what someone else has or type out what someone else has."

Some participants read the postings of others and then contributed to the dialogue by restating previous ideas by adding "a new twist" to the discourse. In some cases, the participants responded to a critical incident without reading the responses of others. However, this was not the case for all participant postings in the latter stages of the thread. There were students who often posted toward the end of a message thread with a reflective posting that built on the ideas of others. In order to reduce this saturation effect, one might want to consider reducing the number of participants responding to a critical incident, or have a group of students adopt different thinking-related roles in their response to the discourse generated in a critical incident thread. These roles could include a "devil's advocate", speculator, brainstormer, optimist, pessimist, or judge. Even though we structured critical incidents with dialogue prompts to intentionally promote discussion of science-specific pedagogy, it appears that more structure is required in order to facilitate large group discussions on the Web.
Conclusions

The findings in this study illustrate a variety of factors that influenced the discourse of preservice science teachers using an asynchronous, non-restrictive public Web-based forum. The asynchronous nature of the Web-based forum allows preservice teachers to communicate in a reflective online community at their convenience. Many of the message threads that occurred on the forum were topics that were not part of the preservice teachers' in-class instruction. The forum offered new opportunities for participants to discuss and reflect on classroom issues that were directly relevant to their student teaching experiences. Our findings also revealed there are some constraints and limitations with using asynchronous communication with preservice teachers. These include receiving feedback too late to be of use and issues pertaining to the absence of visual cues during discourse exchanges. Moreover, if we expect preservice teachers to use telecommunications tools to engage in reflective communities of practice, then it is important that time is provided in their daily routine to use these tools to reflect on their practice.

The conventional rules of communication change in the online medium. Non-facial communication issues are intrinsic to this situation. Communication exchange is not guaranteed among all participants since participants can choose selectively which postings to read or not to read. Most participants (n=28) stated that they read messages posted on the forum by scanning the content for issues of interest, while disregarding messages or skimming others. One participant stated that he usually skimmed through messages and read only those posted by peers from his methods class. Furthermore, the comfort level with the Web-based medium itself might be a factor to how students communicate with each other. In Web-based communication, there are no personal nuances such as facial expressions or hand gestures, which accompany the dialogue. Since the forum provides a means to communicate asynchronously, it permits the more timid and reflective learners in a group a chance to participate in the discussion more than they might in a face-to-face conversation. The structure of the forum also enables each participant the opportunity to have time to reflect on what has been said, think critically, and then respond.

With many asynchronous conferencing software packages available to more research needs to be conducted to determine the most appropriate design structure to use with a public, non-restrictive asynchronous Web-based forum. Ease of use with respect to the design structure is an important factor to consider. Most asynchronous conferencing software packages use either a linear or hierarchical tree structure. Linear structures add a reply in a temporal manner to the end of a linear chain of messages. A hierarchical tree structure allows a user to attach a response directly to any message. This allows a discussion to potentially branch out infinitely. The linear structure is simpler to navigate and more closely resembles a face-to-face conversation. However, some of our participants felt frustrated with the lack of flexibility in the linear structure and wished the forum provided a hierarchical tree structure. Although we view the linear structure as easier to navigate, some participants still experienced difficulty locating older messages threads on the SciTeach Forum.

Conferencing in delayed-time versus real-time with preservice teachers placed in remote geographical internships remains an issue to be further explored. A disadvantage some participants perceived with using asynchronous communication was that they did not receive immediate feedback to problems they were experiencing in their classrooms. This situation exists because immediate feedback can only be provided if the participants of the Web-based community read and respond to each new forum posting on a daily basis and are provided with easy access to the network. Using synchronous communication with preservice teachers could provide for immediate feedback to problems and concerns they experience in their classrooms. Furthermore, a synchronous environment would enable participants to participate in a dialogue which more resembles a face-to-face interaction. We believe that the logistics of coordinating synchronous communication with our participants would have been extremely difficult given the resources in their school placements and their schedules. Unless provisions could be made to ensure each participant has access to a networked computer and busy schedules could be coordinated, engaging preservice teachers in synchronous communication would not be feasible.

We have just embarked on a journey to understand how preservice teachers use asynchronous communications in a public, non-restrictive Web-based forum. We are learning how the structure of a Web-based medium promotes learning in a social context. As higher education continues to integrate Web-based tools into teaching pedagogy, it is important that we continue to analyze and research the mechanisms that facilitate learning online. Given our results, we plan to continue to use public, non-restrictive Web-based forums with our preservice science teachers. In the forthcoming semester, we will include another cohort of preservice science teachers from a different university to actively participate in the forum. We plan to have groups of students adopt different thinking-related roles in their response to the discourse generated in the
critical incident in science teaching threads. These roles will include a “devil’s advocate,” speculator, brainstomrer, optimist, pessimist, and judge. We will also post four different critical incidents in science teaching each week to the forum instead of one per week to see if this reduces the saturation effect that appeared in the discourse during this study. As a result of this research, we are continuing to understand how preservice science teachers communicate with their peers and instructors from remote locations using the World Wide Web to develop into a community network of practice.

Impact of Asynchronous Discussion on a Preservice Teacher Education Practicum Experience

University of Minnesota
United States
adoering@umn.edu

Abstract: Teacher education programs have long recognized that in order to develop their pedagogical capacity, pre-service teachers must have teaching experiences and interactions with students during their program of preparation. At the University of Minnesota we implemented the use of web-based asynchronous discussion areas to increase the quality and quantity of English education initial licensure program students' interactions with middle school students during a practicum experience. We describe here the necessary coordination and communication among methods and technology course faculty, technical support personnel, and the cooperating middle school teacher in identifying and implementing this technological support to a collaborative project. We also describe the preservice teachers' positive and negative impressions of this mode of communication.

Introduction
Teacher education programs have long recognized that in order to develop their pedagogical capacity, pre-service teachers must have teaching experiences and interactions with students during their program of preparation. This fall the English Education licensure program at the University of Minnesota implemented the use of web-based asynchronous discussion areas to increase the quality and quantity of pre-service teacher and student interactions during a practicum experience.

The use of these discussion areas is part of a larger effort in our College of Education and Human Development to integrate technology into our teaching methods courses. Through our Ed-U-Tech project, a Preparing Tomorrow's Teachers to Use Technology (PT3) grant from the U.S. Department of Education, faculty in fifteen content areas in which we license teachers are learning about educational technology and creating teaching materials to support its integration. The methods instructors and technology course instructor are working together to successfully model the integration of technology. These efforts provide opportunities for pre-service teachers to use technology as an instructional tool and receive feedback on those efforts.

Telementoring through Asynchronous Discussion Boards
As part of the reading and writing methods courses, the English education cohort (34 post-baccalaureate students) had a practicum in a middle school centered on a co-inquiry project that required the college and K12 students to write together in multiple genres. Each pre-service teacher was teamed with four students with whom they discussed the topic of their inquiry, relevant sources of information on it, the revision of their writing products, and generally just got to know one another. But, communication was a challenge because our pre-service teachers couldn't always be at the school during the English class period of their assigned students. We needed a mode of communication that could support our pre-service teachers' interactions with students. We turned to web-based discussion areas for our solution, a method the Ed-U-Tech project had already successfully used as a part of our project’s outreach efforts.

Technical Contexts of K-12 Public Schools and Universities
When deciding the method of communication, the technical contexts of both the K12 public school and the university were taken into account. All of the preservice teachers had email accounts, but because of privacy issues and the school’s Internet use policy, students in the middle school weren't allowed to use email at school. In addition to preparing for the cooperation with the methods and foundation's technology course at the university, even if the
use of an email account was acceptable, the cooperating teacher would have had to work on setting up individual emails for each middle school student adding an additional burden.

Efficient use of time was an important factor when deciding the use of the technology. The middle school students only met with the preservice teachers twice a week. They needed more frequent and in-depth communication in order to complete an entire multimedia project. The asynchronous discussion boards would allow the middle school students and preservice teachers to post and/or answer questions when they had time, whether in class or at home.

Supervision of the exchanges was also considered in the selection of this communication method. This project was new for the methods instructors, cooperating teacher, preservice teachers and middle school students. Therefore, the ability to oversee and reflect on the communication that was taking place was very important. The asynchronous discussion board allowed all people involved in the project to simply go to the web site and view the conversations that were taking place between the preservice teachers and the middle school students.

The Benefits and Drawback of Asynchronous Discussion

We sent an email to all 34 pre-service teachers who participated in this project. Twenty-five of the 34 students responded to the following three questions: a) How did the ability to post and receive messages via the Internet impact the learning and/or teaching process with your middle school students?; b) How did the ability to post and receive messages via the Internet impact the mentoring process with your middle school students?; and c) How did the communication between you and the crosswinds students enhance your final multi-genre project? We grouped similar comments and then categorized them as generally positive or negative

Benefits

The benefits of this activity were: a) the students were able to get to know their cooperating preservice teacher much better before and during the project; b) the students and preservice teachers were able to share the content of their final project with each other on a regular basis; and c) the preservice teachers and the middle school students have become more confident in their use of technology.

After a one-time face-to-face meeting they began to communicate with one another online. The middle school students were able to ask general questions of the preservice teacher with whom they would be working the entire semester. This also gave the preservice teacher the same opportunity to get to know the middle school student better and their interests, which was important as their first task was to determine the theme of their project. A preservice teacher commented that the middle school students were "at more ease asking questions and obviously weren't so nervous" as they had been when they met each other in person. He commented that the students would ask questions about "how old we were and why we were deciding to become a teacher."

The ability to have and maintain a mentor-student relationship was also very valuable. A preservice teacher said, "using the Internet site with my students was a great way to maintain a mentor-student relationship. When students were allowed access time to the web site, I received a number of messages from all of my students. The preservice teacher and K12 students readily shared the content of the multi-genre project throughout the semester. Most beneficial was the ease with which they could share relevant web sites, ask questions, and receive responses at any time throughout the semester. A preservice teacher commented that "it was extremely helpful to be able to send students URL sites on the web that would help them to locate information about the person we had chosen to do our report on for the multi-genre project. Then students could easily access these sites by just clicking on the address. This eliminated a great deal of unnecessary confusion."

The asynchronous discussion web site greatly eased the process writing the bibliography for the final project. All the sites the preservice teachers and middle school students had previously visited were already stored on the asynchronous web site, so they could easily write down the author, title, URL and other information necessary for completing the final project.

All of the preservice teachers questioned about the project experience, including the use of the asynchronous discussion board, felt it helped them to increase their overall technology ability. A few who resisted this mode of communication at the beginning commented that they found how much of an asset it was to use with their students and therefore were motivated to use it. They also commented that the both they and the middle school students "were actually able to see how communication over the Internet could be of value to the classroom."

"Drawback"

Only one drawback resonated throughout the experience: computer access for the middle school students. The preservice teachers wished that the students could have had daily computer lab time to check the discussion
board and reply or post as necessary. The preservice teachers commented that the "majority" of the students did not have access at home and relied completely on the school for access. The preservice teachers identified this as the only real drawback of the entire collaborative, technology-enhanced project. As one preservice teacher commented, "The potential was amazing, the reality disappointing. Students simply didn't have enough time in the computer labs to respond."

Conclusion

This multi-genre writing, multimedia, co-inquiry project produced successful end products. The middle school students gained experience in writing in a variety of genres, communicating through multiple media, and using education technology to do so. Likewise, the pre-service teachers developed their skills in these same areas. More importantly for our pre-service teachers they gained teaching experience and had a chance to interact with students while in the role of the teacher. This mode of telecommunication facilitated increased social and substantive interactions between the middle school students and the pre-service teachers from the beginning to the end of the project. We caution that computer access on both sides of the partnership is key to communication via asynchronous discussion. Once that is overcome, as this paper reports the potential benefits are many. With successful planning and implementation, asynchronous communication can be a successful tool for increasing the quality and quantity of preservice teachers' interactions with K12 students during a practicum experience.
Regional List Servers as a Means of Peer Support for an On-Line Learning Community

John Green
The Open Polytechnic of New Zealand
Wyndrum Avenue
Lower Hutt
New Zealand
Grejoh@topnz.ac.nz

Abstract: This paper describes an on-going experience of using regional list servers to provide peer support to an on-line learning community of 248 students already using an electronic forum to study by distance. A regional list server is a list server providing peer support to students in a specific geographic region. Fifteen list servers were used for the course.

List servers with a large number of students have the problem that if even a small number post messages the list participants have too many messages to digest. Students have commented that they prefer to work in smaller groups. Regional list servers provide students with a more intimate experience and reduced message load. The underlying principles are discussed and an explanation is given of how the interactions on the 15 list servers are stimulated and monitored.

Introduction

The creation of a community spirit is an essential prerequisite for success when using an electronic forum (Hiltz 1998) (Anderson 1998). Without this feeling of camaraderie people feel inhibited from posting for fear of looking foolish, or from responding to postings for fear of being branded a "tall poppy" or know-it-all. Speaking up in small class or posting in a small electronic communication space seems much easier because the participants develop relationships and trust with the others in the class. In previous work with an electronic forum (Green & Eves 2000) students commented that smaller workgroups would allow them to get to know the others with whom they were working. In an effort to provide this more intimate space, several regional list servers based on the regions of New Zealand were created. It was hoped that the relationships and the peer support network that developed would increase the rate of participation in the Delphi forum (Delphi), our virtual classroom. We were also interested to see how students would respond to the increasingly varied means of student-student communication at their disposal. A major benefit envisaged was that the smaller population would reduce the information overload that can occur in list servers with larger populations.

The Open Polytechnic of New Zealand is the largest provider of open and distance education in New Zealand. The majority of teaching is done by distance. The students described in this paper were studying a Computer Concepts paper that is a compulsory part of the National Diploma in Business course and approximately equivalent to first year degree level. Most students are adults in their late 20's to early thirties approximately two-thirds female and mainly Pakeha (non-Maori). The Maori were the first people to settle in New Zealand, those not of Maori descent are termed Pakeha. The majority of students on the course had little experience of using a computer for anything more than word processing. A small number used e-mail regularly. Very few had experience of using Internet forums, list servers or on-line chats.
Method

The postings of students were monitored over a period of 17 weeks. The list server chosen was Listbot (Listbot). Listbot is a free service provided by Microsoft on the Internet. The site allows the creation of list servers for either announcements (one to many) or discussion (many to many). There appears to be no limit on the number of lists that an owner can operate. The on-line creation of a fully working list server takes less than five minutes which includes selecting any information that you wish the list server to gather on registration. Each list server gathers demographic information when the student subscribes as requested by the list owner. Thirteen list servers were set up based on the New Zealand regions. Two list servers based on ethnicity/language were set up with the intention of supporting those students whose second language is English in the believe that they could get additional peer support in their first language. These list servers supported Maori and Chinese students.

Students are not spread evenly across New Zealand but tend to be concentrated in the main population centres two thirds of which are in the North Island. The mountainous South Island, often called the Mainland has less than 1 million people. It was estimated that a group of around 5 students would be able to form a viable and cohesive group. During the first two weeks of the course it was essential to support single students and encourage them to subscribe to one neighbouring list server if students numbers were low in their area. This also increases the cross fertilisation of the groups without destroying the intimate sense of the space.

Marketing the list servers

The regional list servers were marketed in our electronic forum (Delphi) and by mail before the start of the course. In addition whenever communicating with students by phone, fax, e-mail, or during weekly on-line chat sessions on the forum, students were reminded of the importance of using their regional list server. The functions of the various means of communication were described to the students as follows in order to help them understand how to use the various tools:

"The forum is our electronic classroom; it is necessarily formal and tightly controlled. It is your place to ask questions, to get guidance how to get started on a particular activity in the course and the place to find and receive answers. It is your frequently asked questions resource. It is not a place to have personal conversations."

"The on-line chat is your student common room, bar or seminar room, it is informal and uncontrolled. It is the place to meet up and talk about the course, what’s on TV, to gain motivation and direction, and generally get to know your classmates. Brief personal conversations are acceptable but remember it’s one-to-many, so try and follow the threads of the conversations that will be fast and furious!"

"The regional list servers are like inviting people into your home to study with you. It’s quick, simple, informal and direct. The e-mail you will receive will be from an individual, but everyone on the list will receive the same e-mail. It’s the equivalent of a small study group without the hassles of having to travel. People on your list server may be your close or distant neighbours, we encourage you to also use it to arrange social events and form study groups."

Monitoring the List Servers

The list owner is automatically subscribed to each list server. This could potentially result in information overload for the tutor even though the tutor role in a peer support network is more for policing than for interaction. In order to control the flow of e-mail, a series of rules were set up in the tutor’s e-mail client, Outlook 2000, to direct the mail to a series of folders, each named after the respective list server. To ease tutor communication with the list servers a personal distribution list was also created. This provided the students with a small intimate view of their list server, whereas the tutor had an overview of the activities taking place in every list server. The tutor could address the whole class, a regional group, or an individual. It was considered important that the data for this study was gathered automatically to enable the tutor to concentrate on the tasks
of motivating and directing the students in the forum. A weekly e-mail report from each list server informed the tutor who has subscribed or if anyone had unsubscribed. E-mail from the groups was archived both on the tutor’s computer and in the archives of the list servers.

Results

We selected four regional list servers out of the 15 to analyse. The two largest urban list servers based on the Auckland and Wellington regions contained 23 and 31 students respectively. The two rural list servers selected were based on the Bay of Plenty and Waikato regions and contained 7 and 9 students respectively. It should be noted that although well promoted the two list servers set up to allow ethnic students to discuss ideas in their own language were barely used. Both Maori and Chinese students participated fully in the regional list servers and ignored the option of using their own language even with the opportunity of support by a Chinese-speaking staff member.

Some questions

1. Do students have preferred learning partners with whom they communicate on a regular basis?

Students were asked to identify themselves by posting an introduction to the list server in the first few weeks of the course. In larger list servers students had more potential partners than in smaller list servers. However the data below shows that in larger list servers more than 50% of students select just two partners with whom to discuss issues with. In smaller list servers most students make contact all the other students. Students either posted messages to everyone (shown as ‘All’ below) or addressed the message to a specific individual. The number of messages posted to their first and subsequent partners were summed and expressed as a percentage of the total number of subscribed students. The percentages shown would have been higher if expressed as a percentage of the active students. People talk to more people in smaller list servers than in larger list servers.

Figure 1 – A comparison of the rates of posting and the number of partners in large and small list server populations
2. Do larger populations produce more postings per capita than smaller populations?

It might be expected that the number of interactions would be greater in a larger population due to the greater range of opinions and personalities. This does not appear to be the case. The Bay of Plenty and Waikato list servers received 127 and 287 postings respectively from an active student body of just 7 students each. Auckland and Wellington received only 215 and 202 from 20 and 22 active students respectively. Waikato students posted an average of 41 messages each, compared with Auckland's average of just 10.

3. Is there an optimum size for a list server population?

When size of list server population is graphed against the average per capita posting for each list server over the period of study, a peak is seen around 9 participants. It is suggested that this optimum figure could rise if a group functions for a longer period of time and more people come to recognise each other as individuals. Self disclosure, the divulging of personal information, is a key element in raising the level of participation. Those individuals who expressed themselves more fully had more contacts and a greater number of partners than those who merely asked for and exchanged information.
4. Is there a difference in use of the list servers in urban and rural areas?

In the Wellington central business district, which is compact compared to the sprawling Auckland central business district, the list servers were used to arrange face to face study groups which met at weekends and during lunchtimes. This was entirely due to the response of one individual to a tutor suggestion. The posting rates described above was measured before these groups formed and do not account for the differences in posting. No organised groups formed in Auckland though some students did pair up occasionally. The data shows that the regional list servers were used much more in the rural areas, probably due to the distances between students.

5. Is there a relationship between the number of messages a student posts and their success on the course?

Certainly most successful students are students with postings in the high 30's, however several low posters also obtained good results in the assessment and several high posters received lower scores. It is not possible to ignore the fact that everyone received the messages whether they actively participated or not. There is no obvious relationship between posting rate and success on the course.

6. Does increased peer support result in success for all on the list server?

There was no clear difference in the percentage of students on the list servers achieving A+, A or C grades and those who chose not to be on the list servers. A larger sample of students may show that those with an intermediate skill level of B+ or B may improve their achievement by interaction with and observation of higher scoring students.
7. **Does increased peer support result in increased retentions?**

There was no apparent difference between the retention rates of the trimester with added peer support by list server and the previous one without this support. Loss of students is almost always due to personal problems with work or home life rather than any course related issues.

**Conclusion**

The main conclusions of this study are as follows:

1) Students post more messages per capita in list servers with smaller populations.
2) The optimum size of a list server population in terms of the number of postings per student appears to be 9.
3) Students in list servers with small populations had more partners with whom they corresponded regularly than list servers with large populations.
4) Most students had only two regular partners in a list server with around 20 active posters.
5) There were insufficient numbers to determine if there was a relationship between being in the list server and success on the course.
6) Retention rate was not affected by having peer support.
7) Posting rate is an unreliable indicator of future success on the course.
8) Receiving peer support does not appear to influence the percentage of students achieving grades A+, A or C but it is felt that a further study may demonstrate that intermediate students may benefit from interaction with higher scoring students.

Abstract: This paper reports preliminary findings of a study assessing the quality of existing online courses at five Internet sites including three university institutions, and two commercial sites that provide software packages for educational online course development. This study was performed in two graduate-level information technology in education courses. Findings indicated that, overall, students were dissatisfied with the quality of online courses available. In fact, this study indicated that many of the purported online courses were merely traditional course syllabi placed online, or traditional correspondence courses where the study materials are obtained online. Suggested guidelines for the development of an online course include: a comprehensive description of the course, including purpose and objectives; time required to complete the course; tuition costs; grading policy; accreditation/degree fulfillment; prerequisites, including technology skills; minimum system requirements; and testimonials. Also important is inclusion of a brief demonstration of a course module for student evaluation prior to registration.

Introduction

Educational headlines today proclaim both the successes and failures of using technology and the World Wide Web in the form of online courses for distance education. Indeed, there are many advantages and disadvantages to the escalating wave of online courses offered through the World Wide Web. Strong supporters of online instruction cite positive effects such as ease of accessibility to students in rural areas, students with disabilities, and students with busy work schedules. Those who question the use of online instruction cite increases in student attrition rates, tuition costs, and time management requirements. However, these stances are meaningless unless online courses are developed using standard criteria that ensure a quality product (Harris, 2000). Although there are no ideal rules that encompass every situation (Carr-Chellman & Duchastel, 2000), basic guidelines should be developed and implemented (Madden, 1999). These basic guidelines will assist instructors in the development of their own online courses. For the purpose of this paper, distance education via online instruction was defined as the ability to complete course work through the use of a personal computer only. That is, the student would never have to attend classes in a traditional classroom setting for lectures or exams, and would have the capability to interact with the instructor and fellow classmates via the computer. We acknowledge that other valid combinations of distance education exist that include various combinations of traditional classroom activities enhanced or supplemented by Internet resources, but for our purposes we identify those as Web-enhanced instruction as opposed to online instruction. Material for traditional correspondence courses may be placed online, but if they do not include interaction between the instructor and the student, or among students, we also identify them as Web-enhanced instruction. The purpose of this paper is to present suggested guidelines for developing an online course.

The Study
Web sites promoting distance education instruction via online courses were selected for evaluation during the fall semester 2000. Twenty-five graduate students enrolled in information technology in education courses evaluated 125 online courses located at five different Web sites. A six-point Likert scale (Very Strongly Disagree; Strongly Disagree; Disagree; Agree; Strongly Agree; Very Strongly Agree) was used to rate the following ten categories:

1. General appeal (Web page design, ease of use, clear instructions)
2. Quality (overall assessment)
3. Online and offline activities (bulletin board discussion, video presentations, readings)
4. Interactivity (ability to interact with instructor and/or classmates)
5. Asynchronicity (chat room, real-time discussion groups)
6. Accreditation (credit toward degree, licensure, certificate)
7. Advantages over traditional classroom
8. Advantages over traditional correspondence course
9. Potential (degree to which this site would successfully qualify as an online course)
10. Technical problems (navigation, ease of use, time spent, system requirements)

Students were encouraged to evaluate subjects of interest to them. Subjects varied across the spectrum from Introductory Statistics to Japanese. Students also recorded the amount of time they spent attempting to retrieve basic information about each online course evaluated, and noted any technical difficulties.

Results

An analysis of these evaluations showed that of the five Web sites evaluated, three received an overall rating of 3 (Disagree) on the six-point Likert-scale, and the remaining two received an overall rating of 4 (Agree). The students spent an average of 45 minutes per course to evaluate the ten categories listed. They expressed disappointment that many of the purported online courses were simply traditional course syllabi placed online, or traditional correspondence courses where the study materials are obtained online. In fact, for many of the online courses, students were still required to attend class on campus. Another common issue students reported was the inability to preview the course, and for many courses, even a syllabus before registration. They noted that when considering a course on campus, most would investigate the merits of both the course and instructor through peer discussion before committing the time and money. However, there was little opportunity for students to do so for most online courses.

Conclusion

Suggested guidelines for the development of an online course include: a comprehensive description of the course, including purpose and objectives; time required to complete the course; tuition costs; grading policy; accreditation/degree fulfillment; prerequisites, including technology skills; minimum system requirements; and testimonials. Also important is the inclusion of a brief demonstration of a course module for student evaluation prior to registration. This should demonstrate the integration of course materials and instruction with the student’s technology capabilities. Distance education is an important component of our society today. It is hoped that these preliminary findings will further the research associated with the advancement of standardized guidelines in the development of online courses for distance education, and thereby benefit student, instructor, and institution.

Abstract: Last spring, my teacher education students and I decided to partner with a local middle school via the Internet. Since my college students were in the process of learning how to be English teachers, and the middle school students needed help with their writing, the match seemed to be perfect and beneficial to both parties. However, the technology, rather than being an invisible vehicle for communication, got in the way. The middle school teacher and I, try as we might, had many difficulties with not only scheduling, but also utilizing the technology itself. While we still feel that our project was worthwhile, there are many changes that we will make before attempting another e-mail project in the future. This paper addresses those changes.

Introduction

I knew that we were in trouble from day one. For the past few weeks, Linda and I had been discussing connecting our two classes via the Internet. My undergraduate pre-English education students were to act as a “real” audience to critique her eighth-grader's creative writing. In theory, it was a wonderful idea. Much research has indicated that providing an authentic audience for students can help to raise not only their level of motivation for writing tasks, but their technical skill as well (Hawisher, 1992; Citrino & Gentry, 1999). The Internet, and e-mail in particular, provided the perfect medium for transferring large amounts of text in a timely fashion, much faster than relying on old-fashioned “snail mail.” Plus, Linda’s students were eager to use the computer to type and send their stories. At the same time, my undergraduates were eager to get their hands on “real” student writing, the kinds of writing to which they were training to devote their professional careers.

The Initial Project Goals

The students registered in my Introduction to English Education course last spring came to me with varying undergraduate backgrounds, but all hoped to apply to the following year’s Master of Education program in English. All were eager to get their hands on "real" student writing. It was one thing, we agreed, to read about helping students to become better writers, but quite another to actually put our words and thoughts to action. My students were aware that technology in the secondary school classroom is here to stay, and most had little to no experience in how to integrate that technology successfully into the existing curriculum. By engaging in this project, my students would see how Linda, a classroom teacher, would use technology to connect to them, pre-English education majors, for mutual gain. The goals for my students were simple: once their middle school partner sent them a piece of writing, they were to read it carefully and offer praise for what was done well and suggestions for improving what still needed work. They were told to look not only for the obvious, surface-level errors with punctuation and spelling, but also ways to improve the overall tone or feel of the piece. Once comments had been made, an e-mail containing the middle school student’s writing and the college student’s response was sent via attachment to Linda’s account. We decided that there needed to be a bottleneck at some point to
monitor what was being sent back and forth to avoid any inappropriate comments from taking place. Also, to insure anonymity, student initials were used in lieu of full names.

What Worked

In some cases, middle school papers that were sent to my student's personal e-mail accounts via attachments actually arrived intact. When that happened, it was joyous! My students were amazed at the quality of the writing being sent and were eager to bring in their partner's work to share with the whole class. One of my students was stunned at the level of vocabulary her partner was using, incorporating words such as "chasm" and "oblique" into their story. I found that I had to allow some time during each class for my students to share what they had received, and discuss with their peers (and future colleagues) how best to respond. The excitement upon receiving their partner's work was palpable and contagious.

As the project progressed, I also sensed my students paying closer attention to reading assignments that focused on assessing student writing. No longer complacent receivers of information, my students now had a context within which to work and respond to the textbook. Issues such as "teaching grammar in context" and "self-selected topics" became real, as well as how to allow for such creativity when standardized testing requires many teachers to use highly prescriptive styles of writing. Issues that once seemed distant were now very relevant, and my students simply couldn't get enough!

What Didn’t

As happy as some of my students were when they first began to receive e-mails from their partners, others were frustrated. For some, attachments were unable to be opened due to differing platforms. What could be easily opened by some computers appeared as cryptic code to others. For the first exchange, Linda had to physically carry hard copies of her student's work to my classroom. For technical reasons on their part, Linda's students were unable to send all of the papers to their assigned partners via the Internet. Rather than waste any more time, Linda felt it necessary to "get the ball rolling" by bringing the papers to us. Strike one. Our hope was to involve as little paper as possible, fully utilizing the technology with which we were so eager to engage. However, both sides were getting antsy, and hard copies of student work were better than no student work at all.

On the university side, questions arose as to the most efficient way to comment on student work. Since cyberspace precluded physically writing comments in the margins, my students found themselves commenting in narrative form to what they were reading. It was difficult for them to say, "Notice that in paragraph three, second sentence, you use the incorrect form of 'there.'" Comments such as this were tedious. Strike two.

My students and I also determined that scheduling conflicts played a major part in the failure of this project. First, the project was started in April. For my students, a new quarter was underway, but for Linda's middle school students, the year was winding down to a close. I felt that it was much easier for my students and me to stay focused in the absence of end of grade testing, activities, and general lethargy that tends to set in at the end of a long school year. Second, while my students had just returned from their spring vacation, Linda's students were eagerly anticipating theirs. I have no doubt that starting a major project such as this with spring break mere weeks away was difficult for Linda and her students. Strike three. Future projects will address topics such as choice of platform, utilizing comment tabs, and taking into account scheduling issues prior to the project's start date.

Abstract: This paper explored college students’ basic perceptions of WebCT on-line instruction, focusing on why students chose or did not choose to use this format, tools and activities preferred, and if this format should be continued. The findings revealed that students did not use on-line instruction due to lack of computer access. Students who chose to use WebCT did so to access course materials and for e-mail connectivity reasons. Tools and activities preferred were accessing class materials and posting to the bulletin board. The majority of the participants indicated that on-line courses should be continued.

Introduction

Online web based education is escalating at higher education institutions across the nation (Kearsley, 2000; Khan, 1999; Piccano, 2001). Today, students often have the opportunity to pick the way they would like to take courses, with possibilities including traditional face-to-face formats or some form of distance technology. Students also have the option of choosing to attend colleges or universities that offer courses in a format that matches their life style and learning preferences. Learning online, however, is much different than learning in a traditional classroom. Students must be more independent, be self-starters, have basic computing skills, and be disciplined with their time management skills. They need to be taught a new set of study skills if learning is going to be effective and meaningful to them in this type of environment. (Kearsley, 2000; Williams, 2000).

Background Literature

Research examining why students elect not to use distance learning has identified several factors. These have included: the significant decrease in face-to-face interaction between the instructor and students in class; difficulty in participating in an on-line class with having access to a computer and basic computer literacy skills; changes required by the student to participate in the class using a distance format; lack of time to complete the course; lack of technical assistance when needed as computer related problems emerge; and lack of the time to complete Internet searches for the class (Berge, 2000; McKenzie & Davidson, 2000, O’Malley, 1999; Roblyer & Guarino, 1999; Weber & Schoon, 1998).
Research on why students choose distance technologies for instruction is not extensive. However, it is becoming an increasingly important area of interest as new and emerging types of distance technologies are being used with greater frequency in higher education institutions and business and industry. Several factors emerged from studies that have been completed: distance classes were convenient, matched students' schedules better than the more traditional face-to-face classes; saved students time; and provided collaborative opportunities (Barron & Lyskawa, 1998; Berge, 1998; Klesius; Homan and Thompson, 1997; McKenzie & Davidson, 2000; O'Malley, 1999; Roblyer & Guarino, 1999; Rose & Collison, 1997; Stokeband & Althoff, 1977).

Purpose and Rationale

This study had several purposes. The first was to identify whether students would choose to access supplemental course materials provided on WebCT, and the reasons why they did or did not use WebCT. The second purpose was to identify whether students felt their use of WebCT enhanced the course, and if so which tools and activities they found the most useful. The third purpose was to determine if WebCT should be continued with these courses in the future. The information collected will provide formative information for future decision making in planning, implementing, and evaluating WebCT courses.

Methods

Participants

The participants in this study consisted of students in seven classes, both undergraduate and graduate levels, taught by the same instructor during the 1999-2000 academic year. All of the classes used WebCT as a course supplement. The same course tools and activities were used as consistently as possible by the instructor.

Courses

During the 1999-2000 academic year the instructor had a joint appointment with two departments, the Physical Education Department and the Media and Instructional Technology Department. To collect a greater range of information on student perceptions of distance technology and whether students would choose to use this format if available, the instructor conducted a yearlong study. In the fall of 1999, students enrolled in two undergraduate classes in Physical Education Department (Health and Wellness and Introduction to Sports Management) were given a class that was enhanced by WebCT. During the spring of 2000 two undergraduate courses in the Physical Education (Curriculum and Instruction in Physical Education and Supervision) and one graduate class in the Media Department (Videotape Production and Utilization) were also provided an on-line enhanced course along with the traditional face-to-face instruction. Two graduate media classes were added to the study during the summer of 2000 (Administration of School Library Media Programs and Instructional Technology). Students were given on-line instruction through WebCT and encouraged to take advantage of the various tools and activities provided.

Instrument

After reviewing the literature and talking with distance experts, the research team designed a one-page survey to collect preliminary data about student perceptions on the use of WebCT. The questionnaire consisted of both closed and open-ended questions. The closed-ended questions focused on student demographic data including student grade level, prior experience with WebCT, whether WebCT had been used in class, and whether WebCT had enhanced the class. Five open-ended questions were designed to collect information on student views of WebCT. These were: Why did you not choose to use WebCT? Why did you use WebCT? What WebCT tools did you find the most helpful? What WebCT activities did you like the most? Should WebCT be continued as a tool for teaching and learning in this course? Why or why not?
Before the instrument was administered it was pilot tested by a committee of distance experts. They were asked to review the instrument and add or delete anything they felt was necessary. Suggested modifications were made before the questionnaire was distributed.

**Data Collection Procedures**

On the last day of each class the instructor distributed and collected the surveys. Students were asked to respond to the survey and write their names on the back for extra credit. They were informed the data would be kept confidential and used to assist in future on-line course decision making. The vast majority of the students, approximately, 98%, chose to participate in the study.

The closed-ended questions were analyzed using the Advanced Statistical Package for the Social Sciences (SPSS). In addition to frequency distributions, some of the data was analyzed using non-parametric statistics. Chi square tests were run to determine if relationships existed between WebCT use and selected categorical variables such as gender, student's grade level, content area, and prior experience with WebCT.

The research team performed a content analysis on the open-ended questions. Student responses to each of the open-ended questions were typed and collated into a data report. Responses were read multiple times by two members of the review team who have an extensive background in content analysis. Categories were extracted and agreed upon by the two reviewers from the reports for each of the research questions. The reviewers then individually reread the reports and coded the responses into the appropriate category. Several content checks were done to ensure content reliability. The reports were read and statements that did not relate to the question were thrown out. Second, an intraclass correlation was computed to estimate interrater reliability, \( r = .86 \)

**Data Analysis and Results**

Of the 161 students participating in this study, 93.2% (N=150) of the students chose to access and use WebCT course materials. Only eleven students chose not to participate in the on-line web based instruction. Their reasons for not participating fell into two major categories: (1) difficulty locating a computer to get on-line with to access the course (N=4) and (2) technical difficulties when trying to access the class website (N=3). Other reasons cited were personal in nature; some students felt they learned more in class when they took notes while listening to the instructor talk (N=2), and one student did not have the time to learn the basics of navigating on-line web to access an on-line course (N=1).

Little relationship was discovered between student demographic factors and their use of WebCT. The majority of males and females used the online course materials, and no statistically significant gender differences (for \( p=.005 \)) were found for WebCT use (see Table 1).

3194
There was also no statistically significant relationship between student's grade level or prior experience with WebCT and their use of the supplementary WebCT course materials. A few freshmen, sophomores, and juniors chose not to use WebCT materials, but all seniors and graduate students accessed the course materials (see Table 3).

**Table 5: Use of WebCT Materials and Prior WebCT Experience**

Of the 150 students who used WebCT, 94% indicated that using the online materials enhanced the face-to-face instruction. The main reasons students used the online course components were the ease of accessibility WebCT provided to course materials, the convenience it provided for communicating with the instructor and other class members on a regular basis, and it saved them time.

The type of on-line tools preferred by students were: class notes (N=120), bulletin board (N=93), e-mail (N=55), and the class calendar listing weekly course activities (N=26). Students indicated they liked to participate in a variety of activities on WebCT. The five most popular were: posting information on the bulletin board (N=44), accessing course notes (N=24), taking exams on-line (N=13), completing extra credit assignments that were made available on-line (N=9), e-mailing the instructor (N=6), and e-mailing other class members as needed (N=6). Table 5 summarizes the content analysis.

rather than face-to-face meetings on campus.

4. The instructor required students to participate in WebCT as part of class.

5. On-line instruction provided students with course notes so they could spend more time listening to information presented in class.

6. On-line instruction provided an environment that encouraged students to explore and collect new and recent information in their area of study.

7. On-line instruction fostered an environment that urged students to share information with their peers.

Table 5: Reasons Students Chose to Participate in Web Based On-Line Instruction

When asked if on-line courses should be continued, the overwhelming majority said “yes”. One hundred and fifty five of the 161 respondents (98.7%) who completed this survey felt on-line instruction should be ongoing. Reasons students cited for supporting continuation of on-line course components included the ease of obtaining course materials at any time from any place, course organization and its helpfulness to student learning, and enhanced communication between the student and instructor. Table 6 summarizes these findings.

Table 6: Reasons Web Based On-Line Instruction Should be Continued

Conclusions and Future Directions

The overwhelmingly positive response students exhibited to the use of WebCT as a course supplement suggests that online course components are a valuable educational resource -- even when the primary mode of instruction is face-to-face. It is encouraging that almost all students chose to use the online resource, regardless of gender, grade level, area of study, or prior WebCT experience. However, the fact that some students did not use WebCT because they lacked computer access suggests that the digital divide will continue to be a factor for some students, and may limit the number of students who choose to engage in totally online courses. Colleges and universities must take this into consideration and provide computer access for students who may not have the means to acquire computers and Internet access individually. Other students indicated technical problems prevented them from using the WebCT course materials. Providing round the clock help-desk support can help students with personal hardware and software problems, but institutions also have a responsibility to assure that web servers are reliable and accessible at all times.

The online course components rated highly by students, specifically ease of access to materials and increased communication opportunities with the students and instructor, offer the potential to strengthen all instruction regardless of course delivery format. Posting course materials helps students discern course organization, and can help them organize their own study strategies. And, as a number of students noted, being able to download course notes from the Web frees them to listen more closely in class. However, for students who learn through the process of taking notes overreliance on posted notes may actually be a detriment. One possible solution to this quandary is posting an outline of course lecture materials prior to class. Students can download this material, and elaborate on the outline notes as the instructor covers the material. The communication tools, email, bulletin board, and chat, provide great support for student collaboration outside class and strengthen the development of true learning communities.
This study provides an initial look into why students use online course materials and what barriers discourage them from using those resources. However, this study was limited to students in two content fields at one university. Additional research should be done to determine if these findings are generalizable.

Connecting Trainee Teachers and School Mentors with University Educators via Multipoint Desktop Video Conferencing (MDVC) : The Singapore Experience

Moo Swee Ngoh, Angela F. L. Wong, Leslie Sharpe, Lachlan Crawford, Hu Chun, S. Gopinathan
National Institute of Education
Nanyang Technological University
Singapore
snmoo@nie.edu.sg

Abstract: Computer video conferencing as a computer-supported collaborative learning (CSCL) technology brings learners closer to real-world environments and it provides increasing opportunities for learners to share experiences across time and space. This paper describes how multipoint desktop video conferencing (MDVC) is used in pre-service teacher education programs in Singapore to add value to the practicum. It enhance the professional development of trainee teachers and teacher mentors by allowing them to share ideas, experiences and resources in teaching and mentoring in real time with an audience wider than the schools where they teach.

Introduction

The Multipoint Desktop Video Conferencing (MDVC) project at the National Institute of Education (NIE), Singapore, was launched in 1999. It explored the use of this new communications technology as part of initial teacher training at the NIE. It built on the high speed, broadband, island-wide ATM network, known as SingaporeONE which enabled schools and NIE to hold good quality MDVC conferences using ordinary desktop computers with ADSL telephone lines. Hence, the potential of MDVC in connecting people at different locations for discussions in real time was realised.

The project has two main objectives. The first is technical and developmental in nature, involving the practical feasibility of putting into place a reliable MDVC system that fully exploits existing technologies. The second objective is pedagogic in focus and is concerned with establishing how MDVC can add value to the professional preparation of NIE's trainee teachers, especially in the practicum component of the training programme. These objectives were achieved within two parts of the project - the 'Pre-Service Study' and the 'Mentor Study'.

This paper will document the development of this project and its current status, and present findings from studies made of the participants (trainee teachers and teacher mentors). It will discuss how these will help in moving the project forward, as well as the potential of MDVC in enhancing collaboration among trainee teachers, teacher mentors and university supervisors, thus adding value to the practicum experience for all.

The Organisational and Technical Aspects of the MDVC Project

The project uses the White Pine CU-SeeMe Meeting Point server and end-user hardware and software. Schools involved in the project and NIE are linked to the project server over the SingaporeONE broadband network by ADSL telephone lines. It is possible to hold conferences with up to six participants, with adequate frame rates and smooth audio. Typical conferences last an hour or more. To achieve this quality of transmission, it had been necessary to agree on common settings for the CU-SeeMe software and to engage the help of the technical assistants from the schools both in maintaining the school equipment and in providing assistance to conference users.

With regards to the organisational aspects, it became clear from feedback from conference participants that MDVC conferences needed to be structured. Each conference group was allocated a time slot and members were told to join the conference at that same time each week. In addition, a conference programme with a clear agenda relating to different aspects of teaching/teacher mentoring for each session was drawn up.
The Pre-Service Study

In the pre-service study, MDVC was used to link trainee teachers who were undergoing their practicum in different schools with each other and with the NIE supervisors/researchers. Throughout the duration of the practicum, the supervisors/researchers held regular time-tabled discussions with the trainee teachers regarding school attachment issues. In this part of the project, MDVC was used to:
- enable the trainee teachers to hold private discussions on matters relating to their practicum;
- help the trainee teachers to discuss practicum matters with members of the research team/NIE supervisors;
- collect basic quantitative and qualitative data related to the technical and pedagogic aspects of conferencing.

Feedback from Trainee Teachers using the MDVC System

Responses from the trainee teachers were positive. Through these MDVC conferences they were able to discuss their practicum experiences with fellow trainees from different schools during the practicum period. They reported that:
- a) they all experienced a wide range of problems;
- b) the common problems encountered were similar;
- c) it was helpful to talk to other trainees via MDVC;
- d) they felt less isolated;
- e) they were able to implement some of the ideas shared during MDVC;
- f) they would be willing to have MDVC sessions again.

The Mentor Study

The second part of this project, the Mentor Study, used MDVC to link together the School Coordinating Mentors (SCMs) in eight secondary schools. The SCM is a new role for senior teachers in schools. SCMs are required to oversee the management of the practicum in their respective schools. As the tasks and responsibilities presented new challenges to these teacher mentors, they would benefit from networking with each other and with the NIE researcher via MDVC. To date, one batch of SCMs has used the technology for this purpose during a 9-week practicum period. They have been able to:
- share information on school-based mentoring programmes, and discuss the issues and problems;
- discuss and share case studies of teacher mentees, and the frustrations and rewards of mentoring.

Feedback from School Coordinating Mentors (SCM) using the MDVC System

The SCMs reported that:
- a) they felt positive about having the MDVC;
- b) they gained a much clearer understanding of their SCM role;
- c) they valued the networking opportunities provided and found the discussions very helpful;
- d) their confidence was increased, and professional development and effectiveness enhanced;
- e) their trainee teachers and cooperating teachers also benefited from these gains.

Recent Developments

In the current phase of the MDVC project, the researchers are exploring the feasibility of combining MDVC and the streaming of digital video clips made by conference participants of aspects of their classroom teaching. These clips are transferred electronically from the schools to NIE using the File Transfer Protocol (FTP). At NIE, these are edited and placed in a password-protected area of the project WebPage on the project's video server. Trainees then video stream the clips and discuss them as part of their MDVC conferences. The SCMs during their own MDVC conferences will also make use of these video clips as a basis for discussing lesson observation issues.

Discussion and Conclusion

The purpose of our project is to investigate whether and, if so, to what extent MDVC can improve the quality of the practicum. Thus our motivation as educators lies less in the technology itself and more in its pedagogic potential. Findings from the piloting phase have shown that MDVC conference participants were positive about their MDVC experiences. The benefits gained have added value to their practicum experiences and helped improve the quality of teacher preparation for them. Our particular interest is in how the MDVC technology can be further harnessed so that it will make a significant difference in reshaping teacher education, and education in general.
Abstract: Web-based Tutorial program was developed to serve as a supplementary classroom activities for freshman in Foundations of Computer for Education class. The program consisted of two types of learning interactions: human-to-computer interaction and human-to-human interaction. Online materials, lecture notes, recommended reading, and review tests were identified as human-to-computer learning interaction; whereas, human-to-human interaction was set up in form of learning activities for students via web-board, chat forum, and e-mail. The research was aimed at describing the relationship between two types of learning interactions, learners' factors (cognitive, affective and social culture domain) and learners' satisfaction to the use of the web as a learning tool. Artifacts were recorded. At the end of the semester, questionnaires were distributed to students. 130 questionnaires were completed. Among three types of motivation (task value, intrinsic, and extrinsic motivation), task value had a significant correlation with students' satisfaction to the use of web.

Overview

Web is an innovative educational communication channel underlining a concept of learning alone with others. Learners must take their roles as activators constructing their own knowledge as well as contributing to others. In multi-nation virtual atmosphere, however, researches found Asian learners are mostly take their participation less than their counterparts. Presently, educational materials available on web are not pertinent to Thai context and no study has been conducted for how Thai students learn on web environment.

Web-based Tutorial program, then, was developed to serve as supplementary classroom activities for freshman in Foundations of Computer for Education in 1999. Basically, learning activities in the web were arranged via two concepts: Human-to-computer and Human-to-human Interaction. Online materials, lecture notes, recommended reading, and review tests were identified as human-to-computer learning interaction; whereas, human-to-human interaction was set up in form of learning activities for students via web-board, chat forum, and e-mail.

The study

The research was aimed at describing the relationship between learners' factors --cognitive, affective, and classroom culture domain-- and learners' satisfaction to the use of the web as a learning tool in two types of learning interactions (human-to-computer and human-to-human interaction). Students responded to the questionnaire before they were introduced to the web. During the semester, students were strongly encouraged to use the web. Artifacts were collected. At the end of the semester, questionnaires were again distributed to students. 130 questionnaires were completed.

The results showed that there was a significant difference between students' feeling about making use of web for educational and general purposes. Students inclined to the use of web for general purposes. They tended to be satisfied with the human-to-computer interaction type when using the web tool. In classroom, however, students tended to prefer their learning with groups to learning by themselves. Among cognitive domain (prior knowledge about computer skill), three types of motivation (task value, intrinsic, and extrinsic motivation), and classroom
culture (study alone and with group); task value had a significant correlation with students' satisfaction to the use of web. Finally, statistics did not show a significant correlation between academic achievement and other variables.

Learning with web is still a new learning phenomenon for Thai students. Students felt that web was not for learning but for entertaining. Students passively used web for educational purposes. They appreciated the web for its delivering class materials. They tended to be satisfied with the web, when they realized the value of web in accomplishing their learning task (Velayo, 1994). Students participated in activities on web chat and web board for the main reason of completing class assignment rather than for their own wishes.

Furthermore, the study found that students' classroom culture inclined to be group learning, which should be able to be supported by human-to-human interaction via web. However, the study showed students' satisfaction to the web in human-to-computer interaction type instead of human-to-human type. This probably happened because students did not comprehend the application of web learning tool. They did not realize an educational potential of the web. The web was used as a passive media delivering necessary contents for their examination. Learning on the web is more than pre-instruction or content-based learning programs. Web is a value added of computer network capacity. Sharing sources of knowledge and learning interaction among users can be made to happen in online environment. During this early stage of adoption, Thai instructors who wish to integrate web to classrooms not only be careful in learning activities design, they must be aware of preparing their Students to develop set of skills in acquiring information, generating, and synthesizing their knowledge with others.

Conclusion

In order to defuse the web technology as a learning tool, policy makers and instructors should shift the focus from students' technical training about web to educational aspect. The usefulness of the web could occur only when students become active learners: interact with educational contents and collaboratively learn with others via the web. When students realize how to make use of web as a learning tool and optimize its educational benefits by acting as active receptors and contributors; web increases its educational benefits and Thai scholars network will be expanded. The diffusion of such type of communication technology as web for learning will possibly grow in exponential rate (Rogers, 1995).

Abstract: Compressed video teaching with the VTEL TC2000©, teleteaching system, is a promising new technology that offers the opportunity to effectively teach a large number of students at both local and remote sites. With compressed video technology, the televised image and sounds of an on-campus course (lecture, discussion, and audio-visual teaching aids) are sent to compressed video classrooms at other locations, while the images and sounds of remote students simultaneously return to the on-campus classroom. Image and sound quality with this technology are excellent but (as with any new technology) effective pedagogy requires understanding the medium, prediction of pitfalls, and modifications in teaching techniques. The presentation will offer insights into effective compressed video teaching based upon the first-hand experiences of teachers who have presented compressed video, as well as technicians and directors who lay the groundwork for such courses.

Introduction

College administrators, faculty, and students are justifiably excited about the wealth of new teaching technologies that promise a revolution in pedagogy. Our colleagues often report being introduced to these technologies with either a "panacea" or "avoiding doomsday" scenario. In the "panacea" scenario, technology solves all of the ills of collegiate teaching ("it will increase your teaching effectiveness at least 100%"). In the "avoiding doomsday" scenario, faculty members are warned to "use ITT or lose it!" In this world view, ITT (Innovative Teaching Technology) is characterized as eventually populating the world with Disney©-spawned mechano-profs, lecturing remote students on-demand via the internet; and the "it" being lost, is "our jobs" if our University is not in the vanguard of such techno-wizardry.
CVT is one of the most innovative of the new technologies. Our presentation is designed to cut through the hype and explore the implementation and growing pains of Compressed Video Teaching (CVT) at a number of universities in Louisiana. The capabilities of CVT vary, but at a minimum CVT allows two-way simultaneous audio and visual communication between on- and off-campus classrooms. CVT also allows teachers to transmit any audio-visual materials (computer displays, overheads, video-clips, etc.) to remote sites. Thus, Local/Remote students see and hear everything going on in each classroom, for better or worse, much like a large single classroom.

This presentation concentrates on recommendations to teachers, administrators, and support personnel concerning what we have found to be effective and ineffective CVT practices, and strengths and concerns unique to this medium. The paper will begin with a brief method section that describes the equipment in a typical CVT classroom, and what it does. It continues with recommendations based upon CVT teachers and technicians' training and experiences, as well as the relevant literature. Advice will be presented in two subsections, one for faculty and another for administrators and technicians.

Method

Materials

The VTEL TC2000 System. The VTEL permits real-time two-way audio-visual (AV) communication between teachers and students at the local and remote sites, and provides an alternative AV source to send high-quality video (tapes, DVDs, CDs), computer animation, still-frame pictures, and/or sounds to remote locations (VTEL Corp., 1999). The picture and sound quality at both local and remote sites is equal to very good cable television. It should be noted that while an alternative video source is transmitting to remote sites, remote students can hear (but not see) the professors or their classmates at the Local Site, though the local site's view of remote classes is uninterrupted.

VTel sites. The cost for each VTEL site varies depending upon the number of students per classroom and how much extra equipment is purchased beyond minimal requirements. To illustrate, total equipment costs for the least expensive site of which we are aware was $8,000, most sites range in price from approximately $14,000 to $18,000.

The Nicholls State site cost $28,000, was designed for 20 students and included the following major equipment: (a) the VTEL TC2000 Base System video conferencing equipment, with dual monitors, a Pentium based PC with CD ROM, and proprietary software plus one Sony® Pan Tilt Zoom (PTZ) camera, (b) one Cameraman® Presenter Camera System (capable of automatically focusing on the student at an "open" desk microphone, (c) ten Cameraman® Push to Talk desk microphones for the above, (d) two additional Sony® PTZ cameras (capable of panning throughout the room), (e) a Canon® Video Overhead Projector/Graphic Tablet Display, (f) two Boston Acoustic® speakers, (g) a wireless lapel microphone (for the professor), (h) four Sony® (35 in) screen monitors to display the alternative video source and remote class, (i) an additional Pentium II® computer with CD ROM (this allows the professor independent control audiovisuals), (j) VHS and Beta videotape players, (k) an electronic whiteboard (capable of displaying dry erase markings on the remote monitors), (l) a 35mm Ectographic® slide projector, (m) wiring and remodeling. Naturally, these expenses are in addition to usual teaching furnishings, such as: podia, desks, tables, and chairs. In addition, the VTEL TC2000 system requires that the local and remote CVT classrooms be connected to each other by dedicated coaxial cable. The cost of cabling must be factored in as well.

It should be noted that often funding for remote sites may be provided or offset by other agencies or institutions which house the remote site (e.g. school systems, hospitals, civic organizations) which are eager to become part a CVT network. In Louisiana most CVT classrooms can be connected with each other.

A diagram of the local site is presented as Figure A. At Nicholls State, a director in the AV room has "input control", determining whether an image of the teacher, alternative input, etc. is sent to a monitor. At other universities, teachers may control the cameras/inputs.

Courses, Faculty, and the Director. The authors and their colleagues have taught a variety of graduate (Advanced Child and Adolescent Psychology, Introduction to Educational Research) and undergraduate (Introduction to Sociology, Basic Algebra, Basic English) courses via CVT at Nicholls State University and the University of New Orleans. All are senior faculty with a minimum of ten years teaching experience. The training
of the Director, varied from a Ph.D. in Mass Communications to an undergraduate student majoring in Mass Communications.

Discussion

Recommendations to CVT Teachers

The primary lesson that the current authors have learned about CVT instruction can be summarized as follows: "the same things that make a face-to-face lecture clear, informative, and engaging will make a CVT lecture clear, informative, and engaging". Students and Directors agree that if teachers come into the CVT classrooms and read their lectures into cameras, students will react by tuning out and turning off. The following are some things we suggest to avoid this.

Point 1. Vary the pace, activity, content, and focus of class. Remember is "variety is the spice of life." Change the various aspects of presentation to maintain interest. Avoid becoming a dreaded, 50-minute, talking head. Even the most diehard lecturers among us (CV'Teers) learned to vary the speed of presentation, move about the room, intersperse facts and theories with puns, jokes, songs, overheads (e.g. PowerPoint), cartoons, and animations. On the subject of sights and sounds, our mass communications co-author constantly reminded the CV'Teers that CV is an AUDIOVISUAL medium, and that to be effective we had to engage our audiences' eyes, ears, and bodies. Too much of even a good thing (films, discussions, questions or even jokes) may become tedious. The current generation grew up watching MTV and the like; they know what TV is supposed to look like, and make no mistake about it, they perceive CVT as TV! Bore them and they will tune you out! Even those of us learning to use the medium did so from time to time when presentations dragged.

Point 2. Please release me, let me go, cause I'm preparing CVT! It takes a lot of time to prepare for a CVT course, and professors should ask for release time. CV teachers cannot merely use their old lectures with this medium. The necessary changes involve a substantial time investment. CV teachers have to learn the equipment, this takes time. They have to optimize their presentations for CVT, this takes time. They have to create new materials, this takes time. They have to teach much larger classes, this takes time. CV teachers should get release time to prep each course.

Point 3. Have a director if possible; every TV show does. One of the advantages for those who taught at Nicholls was the presence of multiple cameras, so that what was on the screen (both local and remote) varied. The Director changed the camera feed as interest waned, focused and tracked presenters as they marched around the room, showed students who were "nodding off", "excited", or "making faces". We simply could not fall back into the talking heads mode even if we wanted.

All of the faculty who teach CV classes who were fortunate enough to have a Director, swear by them. They relieve the CV'Teers from having a "second ball in the air", teaching plus having to control camera/video feeds. We owe no small measure of our CVT success to the Directors who Nicholls State provided; and while many CVT setups make the presenter direct, this is a mistake and detracts from optimal CV instruction.

Point 4. Engage your audience. Captain Picard said it best; when he looked at the helmsmen and said "engage" (this is a S.T.E.M. geek test). Among the best CVT moments the first author had was when he asked members of the audience to stand and sing with him during a developmental lecture. It worked because it required students to be active and it brought the presenter and class together as a group. Student's stood (altering their posture and perspective) and followed a bouncing ball PowerPoint presentation of the lyrics (varying the focus), sang (varying the activity), and loved it!

We are not suggesting CVT operettas, but professors must ask students things, hand them something (for Remote students you will have to plan ahead), have them move about, participate in class demonstrations, have them occasionally do something aside from listening. Active learning beats passive hands down. Passivity causes brain lock and robs both Local and Remote students of the opportunity to feel a part of the group. Remember, more than ever, you are entertaining, like it or not. That is what everyone is accustomed to watching on the tube.

Point 5. Dramatize. Have you ever listened to a professionally recorded novel on audiotape? If not, think of the last play you saw. Attention is best maintained when the presentation is made dynamic and real. Varying ones tone of voice, rate of speech, and general demeanor may do this. Gesture, move, and act. Not only does this maintain attention; it forces students to follow presenters as they move literally and figuratively.
Point 6. Never forget you are teaching ALL students in class - local and remote. Remote students are at a distinct disadvantage if the CV'Teer forgets to acknowledge students' existence at least every few minutes. It is especially good to learn their names and CV'Teers often should scan Remote Class's faces on the monitors. Remote student's only grip on the presentation is through the sounds and pictures emanating from the TVs. The grip is tenuous at best. Therefore, the CVT professor must remember to look directly at the camera as often as possible, not talk to the board, ask students questions, elicit comments and opinions, and encourage students to discuss with each other at both local and remote sites. Discussions are excellent. But try to avoid the development of a we (local) versus them (remote) mindset. We also suggest that professors deliver at least one presentation during the semester from each remote site. In-class student projects can also facilitate group involvement.

Point 7. Check both local and remote students for "fisheyes." Fisheyes appear on recently deceased halibuts after about two hours on ice. In humans they denote a lack of understanding or interest. Fisheyes staring at you are bad! An excellent way to avoid fisheyes is through organization and clarity. In service of this end, a co-author belatedly outlined his materials and presented them via overheads. But even with an outline certain rules have to be followed. Too many PowerPoint presentations make Jack or Jacqueline a dull teacher. Alternatives to lecturing do not relieve one of the responsibility to being the prime source of information. We know a professor who colleagues refer to as "Cecil B. de teacher" because of overuse of film clips.

Visuals should enhance the points made, not make them. They must remain teaching aides or adjuncts, not be mistaken for actual teaching. Avoid the curse of the "disembodied narrator" who becomes a spirit voice behind too many visual aids. This brings us to the next key to clarity, make sure the audience can read each overhead from every point in the local and remote rooms. Ways to facilitate this include presenting only key themes and ideas, and not trying to present verbatim lectures; clarity is often synonymous with brevity. Use short, telegraphic-style clauses and try to follow the "one slide - one or two points" rule, more points should equal more slides. The teacher is there to elaborate. Next, use a legible font of appropriate size on a clear background. If in doubt use too large a font, not too small. Certain fonts and background colors do not work at all. One must experiment in an actual projection setting before deciding on ones' usual slide design. However, occasionally by altering fonts and/or backgrounds, students may be surprised and interest piqued. Dramatic color or font may be used as isolated instances, but remember to present the same information immediately following in the more legible format. Check VISUAL and AUDIO clarity before beginning, and check them from all points in the local room. Assure that the same is done at all remote sites.

Point 8. If presenting outlines or graphics, always provide hardcopies. The best way to handle any visuals in a presentation is to provide reduced copies (three or four slides to a page) to local and remote students before commencing. We prefer to hand out such materials immediately before class so students do not lose them. Again, this requires planning for the remote sites. If students do not get copies and are not told that they have copies, they will try to compulsively write down every word on each overhead and avoid engaging their brains throughout the class.

Point 9. Plan and prepare, plan and prepare. Teaching Remote students necessitates a high degree of pre-planning, more than the typical class, and not only with respect to distributing handouts, but also the administration of tests and quizzes. Before and/or after class conferences with students can be problematic if the CV link to the remote site is turned on immediately before class and off immediately after class. Planning for this and other contingencies makes for a better class. Alternative methods for teacher to student contact are essential.

Check with a technician or director whether or not the VTEL and peripherals can do what you want. Time after time, when CV'Teers encountered problems, they had stretched the envelope with an untried peripheral or program. For example, one CV'teer stored a complex animation on a Zip\(^\circ\) (100-megabyte high capacity) disk when there was no such drive installed on the computer; another, prepared a series of Macintosh\(^\circ\) slides for a Windows\(^\circ\)-based computer; and yet another tried to install new software onto a hard disk with no space left.

Point 10. Plan for disasters and have backup. What can go wrong, will go wrong, this is sometimes called the Titanic principle. Anticipating problems before they occur is better than trying to solve them afterwards. Imagine a planned PowerPoint\(^\circ\) presentation but the computer or the program failed. It has happened. In one instance, the computer gen-lock which converts screen images to TV signals malfunctioned. Having backup (handouts of the overheads) saved the day. Consider what would happen if you lost audio to remote sites? Have a BIG magic marker and newsprint pad ready to write messages that they can see on the monitors. Know the phone number of the site. Know the closest phone on which you can call them long distance.
While the VTEL's have performed flawlessly since their installation, all has not always been rosy in technoland. CVT teachers have to have a working knowledge of the VTEL TC2000 and its peripheral equipment and programs. This is critical if there is no Director. Backup plans for equipment failure must be decided on in advance. For example, on the first night of one class, the site was disabled when an oversized (jumbo) shrimp truck cut the coaxial cable.

Potential for problems increase with presenter's desire to use more VTEL features and peripherals. To illustrate, one of the authors prepared a PowerPoint presentation on spurious correlation. The two-minute presentation took approximately four hours to prepare, integrating animation with a sound track. While the presentation worked perfectly on the home computer, the Microsoft© computer audio program was out of date and could not process the required audio format. The animation ran great, but totally devoid of sound. The presenter chose to hum the tune and provide the required audio as the silent animation crossed the screen. This could have been avoided if the author had heeded the Titanic principle.

Point 11. Practice, practice, practice. Not only are these the directions to Carnegie Hall, but to effective CVT presentations as well. It is essential to actually try out all aspects of the presentation in advance at the local site. Whenever new hardware or software is utilized, preparations should include a dry run without students. This dry run should take place long before class, while professors still have time to fix any difficulties. Only in this way can the presenter develop competence and skill with this promising new technology.

The above points are by no means an exhaustive list of everything teachers need to know about CVT instruction. But we will follow some of the advice given in our Point 7 "clarity is often synonymous with brevity" and address some recommendations to administrators/technicians planning to introduce CVT to their campuses.

**Recommendations to Administrators and CVT Technicians**

Administrators and CVT Technicians are often concerned with different aspects of CVT technology than teachers. Bearing this in mind we offer the following points for consideration.

**Point 1.** Plan, plan, everywhere a plan, and remember there is life after installation. Implementing even a minimal CVT setup involves YEARS (yes, YEARS) of planning. It has been our experience that universities plan for some of the things but forget others. Some universities are very good at getting equipment, but have no coherent plan how the equipment will be used. Planning is necessary for implementation and hardware issues like: (a) securing the funding; (b) selecting the sites (issues of availability versus potential audiences will have to be addressed), and equipment; (c) purchasing equipment (cost/benefit analysis and compatibility issues come to the fore); (d) construction and installation (where will the equipment fit, soundproofing, accessibility); and (e) debugging.

Planning is also necessary for: (a) which courses will be CV'ed, (graduate--fewer students but more dollars per student or undergraduate--larger potential population, but fewer dollars per student); (b) which professors will be selected (we suggest the best, most innovative and motivated teachers); (c) how teachers will be trained to use the equipment (this becomes especially important without a Director and we definitely advise against sink or swim, on-the-job-training); (d) if CVT doubles professors' workload, will they receive additional pay; (e) advertising that a course is available remotely; (f) who will manage the remote sites (if the door is locked who should the students go to); (g) how will professors physically get materials to remote students? The above is by no means an exhaustive list, but we believe we have made our point.

We would suggest that one person with adequate training oversee the process, rather than a committee. At Nicholls we have been fortunate to have a mass communications professor with a fundamental understanding of the media in charge, he and other involved faculty and staff have made CVT a success. But even with these resources there have been bumps in the road. Another good idea is to contact other universities and agencies already utilizing CVT and ask them for their assistance and suggestions. The Nicholls site was built in cooperation with a VTEL reseller, Contact persons for the reseller are presented as Appendix B.

**Point 2.** It takes money to make money. Any ongoing project involves continuing costs. Often universities implement new technologies for financial rewards. After CV is purchased, administrators may expect money to start rolling in. In fact, almost all technologies (computers included) have a start-up period when the university is actually losing money. People have to become accustomed to the equipment before it is used efficiently; but with proper PLANNING and implementation, this period can be minimized. CVT if effectively managed should be more than self-supporting; it should turn a profit.
Conclusion

Is teaching by compressed video a panacea, or does it signal doomsday? As with most technologies, the answer is neither. Our own doomsday scenario consists of the following: without support, understanding, and nurturing from all sides (administrators, faculty, and students) CVT technology will not succeed. If it fails however, it does not signal doomsday, the students just won't take the courses. A bad CVT course, just like a bad regular course won't make. Any tragedy lies is the wasted potential of the medium.

We are convinced that with planning and vision, CVT will emerge as a beneficial new way to teach. The basic value of CVT is that professors can to teach students material they could not previously. CVT decreases the hassle of being a student. It offers easier access to courses and less travel time. CVT decreases the hassle of being an administrator. It offers the possibility of combining sites to "bring" more students into the classroom, and can ease scheduling. The true value of CVT however, may be that it forces professors to reform some tied old teaching strategies and begin to innovate.

The Imfundo Project: ICT in teacher education in developing countries

Michelle Selinger
Education Specialist, EMEA, Cisco Systems, UK
mselinger@cisco.com

Currently 130 million children across the world do not go to school. In many developing countries those that do attend school often leave functionally illiterate. Many teachers on sub-Saharan Africa are dying of HIV/AIDS, and in the worst cases more teachers are dying than are being trained and recruited. UK Prime Minister, Tony Blair launched the Imfundo project in April 2000 and gave the team six months to find ways to support the international quest for universal primary education by 2015 using educational technology. The decision was taken to focus on teacher education as the most effective way to improve both access to education and the quality of that education. This paper describes the project’s findings to date and describes one of the pilot projects.

Introduction

Well over 100 million children throughout the developing world do not attend school. While some regions including Latin America, the Caribbean and East Asia are on course to achieving universal access to primary education, other parts of the world are slipping behind. The problem is particularly marked in sub-Saharan Africa, where the number of children not in school is increasing. In 1998 this figure was 42 million of whom 56% were girls. The Imfundo project was set up in March 2000 following a meeting in London between Tony Blair, the UK Prime Minister and John Chambers, President of Cisco Systems to consider how information and communication technology can be used to support education, particularly teacher training, in developing countries and be supported through a public-private partnership.

A project team was set up at the beginning of May led by the Prime Minister's private secretary for economic affairs; myself a specialist in the use of ICT in education, seconded to the project by Cisco Systems; a wireless communication expert from Marconi Communications; a business development manager from Virgin Direct, and three other members from the UK Department for International Development (DFID). The remit of the Imfundo Project was to concentrate on basic education, while supporting other forms of education and training only where it had a knock-on benefit for basic education (e.g. teacher training). In order not to increase the digital divide the project considered the way in which support can be provided for the education of marginalised communities and those who and have poor access to education, including those in rural areas and women.

The team chose to focus on teacher training, since HIV/AIDS is decimating the teaching profession across Africa. The number of teachers trained in sub-Saharan Africa will have to increase substantially if:

- primary and secondary gross enrolment rates are to increase from around 50% today to 100% by 2015 (the year designated for the achievement of international targets)
- class sizes are to come down from around 50
- the loss of teachers to HIV/AIDS is to be offset by training new teachers

The international development targets mention the quality of education, but do not give it sufficient emphasis. Two thirds of children who go to school in sub-Saharan Africa leave school illiterate. About half of teachers in developing countries are unqualified in terms of their own country’s formal standards for teachers’ education. Teaching methods are often antiquated with an overemphasis on rote learning, and too
little learner-centred, outcome based. Another source of improvement is in the quality of educational management. Imfundo will address both these issues.

The Project tasks

Imfundo was tasked to identify ways in which ICT could be used effectively to provide large numbers of new well-trained teachers, as well as developing the quality of teaching through extensive part time professional development programmes. This can only be achieved through high volume distance learning materials. There is neither the human or physical capacity to bring teachers out of schools into teacher training institutions, nor to substantially increase the number if initial teacher training places. Distance learning enhanced through ICT may be the only effective solution in terms of costs and scalability. Distance education for professional development offers a way to enhance the skills of teachers, to promote new pedagogies, facilitate the introduction of new curricula, and to support teachers, while leaving the teacher in the classroom to teach lessons.

However both computers and Internet access are relatively expensive in developing countries, compared to alternative uses for that expenditure, such as more teachers and books. This is both because of relatively high communications costs in developing countries, heavy duties on imports of computers and related resources, and more importantly, because the cost of labour, including teachers, is much lower. The improvement in quality of primary and secondary education resulting from their use would need to be significant to justify the cost of their use in classrooms.

Therefore, although the remit was to explore new technologies, the project team took the view that radio is currently the most cost effective ICT for enhancing the quality of education in the classroom. Radio remains the most widespread and accessible ICT in Africa. In some countries it has near universal penetration. The costs of producing educational material for radio are one tenth of the costs of producing material for television, which has much lower coverage and is more expensive to access. This will change as prices of technology and Internet access fall as they have done in developed countries. Therefore the team explored the use of radio in conjunction with newer technologies.

Establishing teacher resource centres

In many African countries, our research indicated that it was possible to establish teacher resource centres in market towns, where there might typically be, but not always, access to power and telecommunications, which could be equipped with computers and Internet access. Teachers from the surrounding areas could then visit the resource centre from time to time (e.g. once per fortnight in term time) to collect materials and interact with other learners and the tutor.

There is not a straight choice between using new and old technologies in distance education for teachers. For example, where teachers were supported through resource centres, it would be possible to use radio for delivery of some of the training materials in schools, such as radio programmes that encourage teachers to engage learners more actively. Teachers would visit the resource centres from time to time to interact with others, watch videos or use interactive programmes delivered over the internet, collect new reading materials, etc. Imfundo are not aware of any teacher education programme that combines new and old technologies in this way, but it appears to have potential.

More work also needs to be undertaken on the opportunities for regional initiatives, to share technology, curriculum and infrastructure, across a number of countries. For example, it is significantly cheaper to adapt curriculum materials that have been produced in a neighbouring country than it is to start from scratch.
Infrastructure

However many of the areas in which we are considering equipping teacher resource centres lack the infrastructure to support the use of ICT. Some have either no or unreliable electricity supplies and poor telecommunications facilities. Telephone call charges and ISP access are prohibitively expensive so any possibility of sustainability at the end of the funding period is seriously reduced. Wireless technology offers a cheaper solution while also arguing for deregulation on satellite communication. In some countries satellite technology can only be used to access resources and no uplink is permitted. Solar power can solve electricity issues, and as prices fall it is becoming a realistic power source. Indeed a private ISP in the Gambia powers 6 servers and over 30 computers on solar power and to date has never lost its connection. Additionally it appears that developing countries pay a high price for access to the Internet. Developing countries who want to connect to the global Internet backbone must pay for the full costs of the international leased line to the country providing the hub. (More than 90 per cent of international IP connectivity passes through North America.) Once a leased line is established, traffic passes in both directions, benefiting the customers of the hub country as well as the developing country, though the costs are borne primarily by the latter. These higher costs are passed on to customers. The net cash flow is from the developing South to the developed North.

Costs of PCs are also high with high tariffs on the import of computer equipment. Therefore the sustainability of any project is difficult to foresee. One solution Imfundo was investigating was the dual use of teacher centres, either as business training centres, or for the delivery of other government services, such as training of health workers or agricultural extension workers, or the provision of women’s services, so that the costs can be shared across a number of public and private services. Such centres can also facilitate e-commerce, by selling locally produced goods (notably agricultural produce, but also artisan goods) and cutting out the middlemen, or by buying products through the Internet for sale locally. Different pricing structures would need to be established for business and educational uses.

Pilot projects

Imfundo is setting up a number of pilot projects set within sector wide approaches to education and therefore in close co-operation with Ministries of Education. The projects will test some of the educational ideas being developed about distance learning as an effective method of supporting both initial and inservice teacher training, and explore how the local and international private sector can help support the sustainability of the infrastructures required. The projects currently being discussed and explored are:

- Teacher training centres for the inservice training of 1000 secondary school teachers who have little more than secondary education themselves. Here distance learning materials will be developed and delivered through the traditional channels of video, audio and text and also through the Internet and facilitating the use of electronic forums;

- Equipping 2 or 3 rural primary schools with Internet connectivity to 3 computers to help in a new distance learning programme for pre-service primary teachers;

- An informal city learning centre to provide education for those children who cannot go to schools because of severe overcrowding caused by urban drift and to train teachers in this sector;

- Linking a teacher training college or regional resource centres to a network which will enable distance learning materials to be sent to the centres and making it easier for teachers to access training on a part time basis. (Often attending training is prohibitive as it means long journeys and time away from families and other responsibilities).
Details of one of the pilot projects

Rwanda was ravaged by civil war in 1994 that led to the loss of huge numbers of teachers. The shortfall was made up by a large number of unqualified teachers who were drafted in and comprising of people who have no more than secondary education themselves, and a few not having even completed that. An emergency short training programme on teaching methodologies was mounted in programmes of up to five days, but this was inadequate to meet their full training needs. This measure was less than sufficient for teachers to gain appropriate skills but all that could be done in a time when the priority was to rehabilitate and refurbish schools so that children could return to school with sufficient teachers to teach them.

Therefore there is a pressing need to develop both content knowledge and professional capability. In addition the number of secondary schools is rapidly increasing. Class size is usually around 40-50 but in some schools it can be nearer 70. 16% of children go to secondary school and this number is intended to rise to 20%. Teachers can not be taken out of school in large numbers for the extensive training programme that is required. In reality this should be at the very least a three year, full-time training programme and certainly equivalent to a pre-service programme in both subject knowledge and pedagogy. Removing teachers from the classroom for this length of time is unworkable and the teacher training institutions would have neither the physical capacity nor the human resources to train such large numbers.

It seems that distance education is the only feasible alternative, with teachers training while still teaching. The benefits would be to keep them in classrooms while undergoing training so school attendance targets could be maintained and it would allow teachers to put new ideas into practice so integrating theory and practice. A number of initiatives have been put into place in order to sensitise and develop the possibilities for the success of the programme. These included visits to head teachers and local education officers and identification of training centres in regional centres throughout the country that have telephone access and an adequate power supply. There are plans to staff these centres with a well-qualified teacher as a tutor and with an administrative assistant.

Head teachers have been made aware of the need to give teachers undergoing the training extra time to study by, for example, allocating them smaller workloads, exempting them from evening and weekend duties, and granting loans to purchase transport (bicycles or motorbikes) to support their travel to training centres. Part-time study for further qualification is becoming an accepted aspect of further education in this country so there is a firm belief that there will be heavy demand for these courses. Another problem the country faces is the capacity to develop distance learning resources. The initial costs of setting up such programmes are high compared to traditional courses, and there is lack of expertise in developing distance learning materials. This problem has been solved through donor funding to bring in distance learning expertise and a number of subject experts from other countries for a fixed time period to develop the materials and to train existing staff at the teacher training institution.

As in many developing countries the costs of books and other resources is high, and maintaining up to date libraries is expensive. Postal deliveries are unreliable or take a long time, so the exchange of assignments and materials would be slow and would also make student progress slow. Tutors based in regional centres would have to be expert in all secondary subject areas if they were required to support all students and any extra support from the central teacher training institution would be restricted to phone calls and post. Telephone lines are limited with very few lines available outside the country's capital.

**ICT as a solution**

A range of new and old technologies could help. Internet connectivity in each of the regional centres would provide teachers in training and the regional tutors with fast access to the central teacher training institution. Here subject specialists could respond in electronic discussion forums to questions posted by tutors or trainees; extra materials could be supplied digitally for printing at the local centre; and some interactive internet based resources could also be accessed by teachers after school and weekends, at times to suit them. Video materials could be sent via a satellite link or on videocassette; and up to date resources could also be accessed through the Internet.
Imfundo is currently in discussion with the Kigali Institute of Education to help them refurbish the identified centres, install a small computer network in each centre, employ technical support and to help integrate ICT into the programme. Imfundo are enlisting the support of the ShoMa foundation in South Africa to set up some Internet based activities to complement and extend the paper and video based materials, and will also make use of the Resource Bank to support the setting up of a computer conferencing system. The ShoMa project is already proving successful in using the Internet to train teachers in South Africa.

**Details of the training**

It is planned to integrate a modified version of the ShoMa materials into the programme, and Imfundo have facilitated personnel from ShoMa to work with the teacher training institution. The training will start at diploma level and develop to degree level as resources become available and teachers become accustomed to improving their skills through distance learning. Modules will develop knowledge in two subjects and in pedagogical skills, and will be based on the new four year full-time initial teacher training course that is currently in its third year of operation at the teacher training institution.

The original plan was to train 1000 students per year over 5 years but after further discussions it has been decided to roll out the programme more slowly opening two centres in January 2001, training between 50 and 100 teachers in each location. The training centres will come on stream in a phased progression and will be open six days a week, and there will be organised weekend and evening sessions as well as opportunities for teachers to drop in and use the facilities. Residential summer schools will be run of approximately two to three weeks duration in four identified locations across the country.

**Sustainability**

Technology is expensive, and even in developed countries the costs of maintaining and updating ICT is of concern. In developing countries, issues of sustainability have to be addressed not only in terms of the maintenance and renewal of equipment, but also in the provision of spare parts, qualified engineers and trained personnel to troubleshoot minor issues and train users. Many development projects have failed once funding has ceased because long term sustainability was not taken into account.

The ResourceBank is one way in which sustainability can be addressed. The international private sector are being asked to give support in terms of reduced costs for or donations of equipment, software etc, or to provide personnel to train local people or to project manage the establishment of the centres. Local private companies have been invited to make use of the spare capacity of teacher training centres to run basic ICT skills and adult literacy courses, and small businesses are to be encouraged to make use of the facilities for their own work at a small charge. In other words these teacher training centres will aim to double up as multi-purpose community centres. The development of the ResourceBank is discussed later.

**The KnowledgeBank**

Additionally Imfundo have established a web based KnowledgeBank (http://www.imfundo.org) to provide analysis in the form of twenty to thirty short papers about the issues facing ICT and education in developing countries. The Imfundo KnowledgeBank will be an accessible, wide-ranging analysis of the opportunities for the use of ICT in education in developing countries, to be drawn on by anyone involved in this work. The KnowledgeBank will be continuously improved and updated in the light of experience and comments, and summarised in a report to which will be published in paper form. This data will enable all stakeholders and experts in each field to review and comment on it, and papers will be amended where necessary to reflect those comments, and updated in the light of the Imfundo pilot project experience.
The ResourceBank

Our contacts with the international private sector suggest a widespread willingness to contribute time, resources and materials to education in developing countries, often on a concessionary basis. Therefore Imfundo has begun the process of establishing a ResourceBank of expertise and commitments from the private sector. Although companies have a range of motives for contributing to education in developing countries, few have the opportunity to make a contribution. Most companies do not have resources or expertise for project identification, or for working with recipient governments to identify how their expertise might contribute to strategic improvements in the education system. For most companies, an unaffordable large-scale effort would be needed to design and negotiate a project, and then to manage it.

The proposed ResourceBank is intended to facilitate private sector contributions and Imfundo will establish a database of pledges from the private sector. These might be pledges of expertise and time, of kit, software, content or of intellectual property. Imfundo will then work with donors and recipient governments to identify projects that support the education reform strategy and are cost effective. As the projects are developed and implemented, Imfundo will then draw down the private sector commitments, by asking the company to provide the resources they have pledged.

An aim of the ResourceBank is to provide a mechanism for partnership between the public and private sectors. For the recipient government and donor agency, it offers security that projects will be designed to deliver education and development goals, and will not be technology led. For the companies who contribute to the ResourceBank, it offers an opportunity to become involved in education in developing countries, without having to take on the task of project identification and negotiations with government.

It is important that donors Western private industry and government activities do not crowd out the activities of the local private sector (e.g. by undercutting the private sector provision of internet cafes or business bureaux). Imfundo and the Western private sector will work with the local private sector to provide support and assist with capacity building. Whilst 'bridging the digital divide' is not a direct concern of Imfundo, it would be foolish to ignore the synergies where they are of obvious connection and benefit. Successful collaborations with the local private sector are one of the best ways of ensuring sustainability.

The future of Imfundo

At the end of six months the Imfundo team have reached the conclusion that educational technology does have a significant role to play in distance education of teachers and in information management in the education system; and that the private sector can make a positive contribution, and would welcome the establishment of an organisation which coordinated and channeled their resources into development-led, sustainable activities.

Over the next five years Imfundo will be developed as a centre of excellence in distance education of teachers, continuing professional development and in the management of information in education. The aim will be to use technology to train teachers, not simply to teach teachers about technology and how to use it in their teaching. Imfundo will be available as a resource centre for the Department for International Development regional offices, for other donors, for the private sector and for developing country partners. It will assist with project identification, design, monitoring and evaluation. Imfundo will specialise in drawing in the resources and expertise of the private sector, and analysing the opportunities for using ICT. This will include the management of a ResourceBank of private sector and civil society partners who are willing to provide expertise and resources on a concessionary basis. It will not fund the implementation of projects directly, though it will meet its own costs, and it will have a small fund for the identification and design of project proposals.
The Handheld Web: Using Mobile Wireless Technologies to Enhance Teacher Professional Development

Paul G. Shotsberger
Department of Mathematics and Statistics, University of North Carolina at Wilmington, Wilmington, NC USA, e-mail: shotbergerp@uncwil.edu

Abstract: The project described in this paper represents an effort to more thoroughly infuse technology into the undergraduate curriculum for prospective mathematics teachers, while strengthening the relationships that already exist between the University of North Carolina at Wilmington and its partnership public schools. A key component of the project involves the use of Jornada 720 Handheld PC devices and supporting equipment/access, including a mobile telephone. This technology adds a new dimension to just-in-time training and support by allowing preservice and inservice mathematics teachers to be literally anywhere and receive information, collaboration and support using Web resources. The initiative represents a unique field application of mobile technology that has the potential to benefit not only universities and their students, but regional schools, teachers and their students as well.

Background

After approximately ten years of innovation and development, the World Wide Web seems to have thoroughly pervaded U.S. society. Most Americans use the Internet daily to stay in touch with family and friends; colleges and universities have included instituting Web-based courses among their mission goals; top business priorities involve establishing and enhancing customer services on the Web; and television and other media are replete with Web addresses and Web enhancements for their programming and advertisements. It is difficult to imagine how the Web could become more integral to our daily lives. Yet, it appears that the next revolution is right around the corner, and this technological transformation has the potential to fundamentally change the way Web-based instruction and training is done.

Mobile wireless technologies are not particularly new. We have had cell phones with us throughout the 1990s, and whereas they might at first have seemed only a luxury or a novelty, in this decade they are viewed as more of an accessory and a necessity. An important change in mobile communications took place in the late 1990s with the introduction of digital (as opposed to analog) transmission technologies. Though a quiet innovation at first, with only a few companies such as Nokia taking advantage of the new capabilities, it is becoming apparent that two-way digital services may be the "next big thing" in wireless communications (AT&T 2000). This is because digital wireless can transmit not only voice but also data, and it is wireless data that many believe will be the dominant form of Internet communication within the next five to ten years (Lewis 2000).

A critical issue for teacher education today centers on the relationship, or lack thereof, between preservice and inservice teacher education. There often is little attempt to make the connection between preservice and inservice training, even though there exist many common needs. Partnership efforts such as Professional Development Schools (PDS) are one means of addressing this shortcoming. Additionally, advances in technology offer new opportunities for collaboration among preservice and inservice teachers. Specifically, novice and experienced teachers can both benefit from using the information and communication resources of the World Wide Web. An abundance of useful information related to curriculum and pedagogy is easily accessible for classroom planning and implementation. In addition, numerous opportunities exist for interacting online with other educators who have common concerns about important education-related issues. This kind of interaction benefits preservice teachers by supporting the development of concepts and skills,
while inservice teachers profit from multiple perspectives and continued opportunities for professional growth. The Web provides a flexible means of training that can be adapted to demanding work or student schedules for both of these groups of educators.

The author teaches undergraduate secondary mathematics methods courses at the University of North Carolina at Wilmington (UNCW), which employ the Web extensively as a tool for research, investigation and collaboration. In addition, over the past five years the author has directed a program of Web-based professional development for inservice teachers (Shotsberger 1999). Being "wired" has given both preservice and inservice teachers access to a world of information and interaction that was unheard of ten years ago, eliminating some, but not all, of the physical isolation barriers common to the profession.

Whereas the term “just-in-time” is used to describe this kind of computer supported learning, the truth is that even as physical walls are being removed between teachers, time constraints remain a huge barrier to collaboration. The causes of this roadblock range from limited availability of network connections at the schools to the problem of scheduling collaborative meetings within the constraints of a full teaching schedule (even at the same school).

We are now beginning to see programs targeting the constraints of time and place in teacher education. The present initiative was inspired in part by the LIVE Project, a three-year effort spearheaded by the Media Education Centre of the Department of Teacher Education at the University of Helsinki, Finland (Nummi, Ristola, Ronka & Sariola 1999). From the beginning, the LIVE Project has incorporated mobile wireless technologies to create open and flexible learning environments for preservice and inservice teachers and their students. Project researchers have found that teachers regularly choose to employ a range of communications technologies, sometimes simultaneously, including telephone, e-mail, fax and conferencing. Thus, a key aspect of establishing highly interactive, mobile learning environments is offering flexibility in terms of how to communicate, as well as intentionally honing participant skills in obtaining, managing and communicating information and ideas. Results of the LIVE Project have led its researchers to wonder aloud: “Is the future of teacher education in digital nomadism?” (p. 1092).

The Project

The present project represents an effort to more thoroughly infuse technology into the undergraduate curriculum for prospective mathematics teachers, while strengthening the relationships that already exist between the University of North Carolina at Wilmington (UNCW) and its partnership public schools. A key component of the project involves the use of Jornada 720 Handheld PC devices (Fig. 1) and supporting equipment/access, including a mobile telephone. This technology adds a new dimension to just-in-time training and support by allowing preservice and inservice mathematics teachers to be literally anywhere and receive information, collaboration and support using Web resources. The initiative represents a unique field application of mobile technology, in the spirit of the LIVE Project, which has the potential to benefit not only universities and their students, but regional schools, teachers and their students as well.
The Handheld PCs were purchased through an on-campus grant program during fall semester 2000. The devices are being loaned out to secondary mathematics interns from January through May, 2001. Training will be conducted in January regarding the functions and capabilities of the technology for research, communication and reflection. Partnership teachers who express an interest in having another student intern assigned to them the following year will be allowed to keep the devices past May, 2001. In addition to the collection of evidence of use such as chat transcripts and messages posted on a discussion board, preservice and inservice teachers will be requested to keep an ongoing log during the spring semester of when, how, and for what length of time the Handheld PCs were utilized. Additionally, a survey will be given to each participant at the end of the semester to assess their overall impressions of the impact the technology had on their professional lives. Feedback from the logs and surveys will be used with the following year’s secondary mathematics interns to better adapt the technology to their needs. The SITE 2001 presentation will include initial results from the project.

**Anticipated Outcomes**

The Jornada 720 Handheld PC includes a full keyboard, Microsoft Office productivity software, a Web browser capable of handling HTML 3.2 and Javascript, handwriting-recognition software and the capability for recording short voice messages. These features expand a teacher’s options for research, collaboration, record keeping and documentation, both in and out of class. It has long been lamented by the education community that teachers generally do not produce written or even oral records of the strategies they employ in the classroom. Handheld devices could give teachers a highly portable way of documenting the results of implementation, which could then be shared with colleagues face-to-face, in a chat, on a discussion board, or as a Web page.

For student interns and their partnership teachers in older school buildings where classroom wired network connections and telephone lines do not exist, or in the situations where these teachers “float” from class to class and do not have permanent room assignments, the capability of communicating via wireless devices provides an excellent way for them to stay in touch with colleagues and parents. Teachers no longer need to wait for access to a limited number of telephones or computers with an Internet connection. The realities of wireless data coverage in southeastern North Carolina are that an Internet-ready mobile phone is required in order to establish a reasonably fast wireless connection (56K) for the Handheld PC. This arrangement, while somewhat cumbersome, provides a very flexible platform to teachers, allowing them to research Web resources or contact parents or absent students at any time of the day. This combination of technologies also enhance Web-based professional development by giving teachers immediate (as opposed to delayed) access to other interns and partnership teachers by communicating asynchronously (message board), synchronously (chat), and by voice. A particular concern during spring semester 2001 is that one of the interns will be the only mathematics placement at a high school that is approximately 60 miles from all other placement schools. In that situation, mobile wireless technology will be a lifeline for ensuring that the single placement does not become isolated and discouraged in the absence of peer interaction.

In southeastern North Carolina, the majority of high schools are on a block schedule system consisting of four 90-minute periods. With fewer and longer periods, teachers have greater opportunity to collaborate with colleagues who have the same planning period. Unfortunately for teachers at smaller or rural schools, there may be only one or two teachers from the same discipline available for collaboration at any given time. Participants from different schools who possess wireless devices could notify colleagues of their availability to chat synchronously online, and if the chat is text-based, the transcript could become part of an archive asynchronously accessible by all partnership participants. With the added capability of surfing the Web while conducting a chat, these teachers would be able to jointly plan lessons that incorporate Web resources and that profit from the experiences and insights of a larger pool of practicing teachers. This would be especially
beneficial for preservice teachers, who often only have their partnership teachers with whom they can collaborate on a consistent basis.

Ultimately what is desired is a comprehensive understanding of how teachers employ this kind of technology on a daily basis and of the potential for the technology to transform classroom practice. Teachers generally do not lack for ideas of how to use technology such as the Web in their planning and teaching — they are constantly exposed to new practices through attendance at workshops and conferences. Rather, they suffer from an inability to implement new approaches due to a restrictive environment that is too often technology-weak. Nonetheless, the question of how extensively teachers will employ wireless technology placed in their hands is an open one. It is likely that some uses for this technology cannot be anticipated prior to implementation. Will the Handheld PC be used in place of the desktop computer, or simply as a supplement? Which features of the Handheld PC will prove most useful? Will the mobile phone be used simply for routine calls, or will teachers take advantage of paging and messaging features for contacting colleagues? A primary feature of the project, then, will be negotiations between the participants and the technology, which will likely produce a number of unanticipated but desirable results along with the intended outcomes.

Abstract: Teacher Education in New Zealand traditionally has been taught internally and on campus by the Colleges of Education.

This paper and presentation will review how Massey University College of Education went about meeting the challenge of delivering preservice teacher education to those who, for a number of reasons, could not attend an on campus programme. Programme delivery will be outlined demonstrating the linkages between traditional extramural delivery and the use of WebCT for web based delivery. The results of surveys and studies of the students involved in the programme in the first four years of course delivery will be presented within the discussion.

Over the past ten years there has been a growing demand from the New Zealand Ministry of Education, the schools and the client base of teacher education to have preservice teacher education programmes delivered extramurally. Massey University has met this challenge. The advent of the Internet and the merger of Palmerston North College of Education and Massey University has enabled extramural delivery of the Bachelor of Education (Teaching) Primary degree. Massey University bought its expertise in extramural delivery of degree programmes and the College of Education its expertise in teacher education.

Introduction

Traditionally the delivery of teacher education world wide has been embedded in the notion that Universities and Colleges of Education are the repositories of knowledge and teaching and that the client should attend such an institution to participate in teacher education programmes. "For over a thousand years universities operated under the assumption that information would be stored centrally and scholars would come to the central store of knowledge and collaborate to produce more information that would be stored at this site." (Ferry, Kiggans, Hoben and Lockyer 2000) p 496

In the 50s and 60s the advent of extramural studies delivered through the postal system began, in some parts of the world, to shake that tradition. During these two decades a number of universities around the world pioneered the delivery of extramural studies to clients who were geographically distant from the institution delivering the programme. Many, like Massey University in New Zealand, retained "apron strings", in that clients were expected to return annually to the "repository of all knowledge and information", to attend on campus study days or weeks during the delivery of the course or paper.

The 80s and particularly the 90s have seen these notions of the client attending the repository of information shaken from its foundation. The tide of development in electronic delivery, telecommunications, email, and the World Wide Web have combined with business approaches and market models to force the providers to deliver programmes to the client at an access point suited to the needs of the client. Innovative providers have found that this delivery can be facilitated anywhere in the world through the World Wide Web. Ferry et al (2000) "thus, instead of people coming to the information, people can now have the information come to them" p 496.

In 1996 the College of Education at Massey University recognised the growing demand for teacher education to be delivered extramurally (the University coined the term externally) within New Zealand. The challenge had been thrown down by the New Zealand Ministry of Education, schools, and those of the public who, for a number of reasons, wanted to become teachers but could not access the traditional on campus programme. There had been a history of recruitment enquiries to the College of Education from many prospective clients wanting external studies leading to teaching qualifications. Reasons behind these requests ranged from geographic isolation through changed circumstances and finance to family circumstances.

The College acknowledged the need and a working party was set up to investigate the feasibility of launching an external Bachelor of Education (Teaching) Degree programme. Much investigation and debate centred around such issues as:

1. Were there enough prospective students out there who would be suitable (a) academically and (b) within the criteria of the New Zealand Teacher Registration Board to be registered as teachers in New Zealand?
2. Given government restrictions placed on funding for extramural study of university papers could such a Preservice Teacher Education Programme be financially viable?
Evidence from overseas (Daniel, 1996) indicated that entry level costs into the type of course proposed were continuing to be reduced annually making it feasible for all institutions to enter the online education world.

3. Would already busy staff at the College be prepared to accept the responsibility of adapting and re-writing papers to meet the needs of external and World Wide Web delivery?

4. Was there a scaffold within the World Wide Web which would support such delivery and was there evidence to support the assertion that the World Wide Web was a viable medium for course delivery and debate? The working party found the answers to all these questions to be yes.

“When information comes to people via the World Wide Web, there are potential benefits. Such benefits include: direct access to a broad range of information; access to learning environments outside normal lecture and tutorial times; greater opportunities for experiencing a variety of instructional strategies including small group discussion and collaborative projects; and exposure to a forum for expressing and sharing ideas.” (Lockyer, Patterson and Harper 1999).

The Bachelor of Teaching (Primary); now the Bachelor of Education (Teaching) Primary Degree; External Delivery Option (EDO) was offered for the first time in 1997.

The degree mirrored the on campus programme with some restrictions placed on the optional Studies in Subjects for Teachers papers. Papers are studied internally and externally concurrently and Teaching Practice in schools is also concurrent.

In the first year, 1997, the programme was delivered by email using Eudora and, although this worked well, the coordinators had continued to search for a web delivery option that would allow greater real time collaboration amongst the students and the staff delivering the programme. WebCT was the supporting environment that was found to stand up to the scrutiny that the coordinators placed on finding an interactive environment which could handle reasonably large volumes of traffic. The College has used WebCT 1 for delivery since 1998 but will move to WebCT 3 in 2001. “Networking technologies, both hard and soft, that make possible online instruction are evolving at a continuing rapid rate that keeps shifting the grounds of possibilities for increasing learner information interaction.” (Carr-Chellman and Duchastel 2000)

1997 and 1998 saw fifty well qualified students selected into the programme. The restriction of fifty was placed on the programme to maintain quality of service during the initial development of electronic delivery. In 1999, 2000 and into the foreseeable future the intake will be restricted to 70 clients. The College maintains that given the level of service expected by the clients and the continued excellence of delivery the College wishes to maintain, 70 is the maximum number of clients the programme can sustain in any one year group. To go beyond this number would risk compromising the quality of delivery of the programme.

The Online Structure (see figure 1)

The first four years of the programme saw it structured around four sites supported by WebCT Version 1.0. All sites provide for whole group interaction, EDO chat group discussion; these are sub groups within the year group of 5-8 students and are private to the group; and private email facilities.

1. The Main Site: all students and staff have access to this site for general discussion, which in most cases is initiated by the programme coordinators. Students are discouraged from initiating discussion in this site or in the year group sites. However, there are times when students do initiate site discussion. Discussions generated around this site are usually of an administrative or programme structure nature. Socially the site is used to announce news of the birth of new babies, social gatherings, lecturer visits to particular locations where students may want to meet with them etc. On this site the weekly College newsletter, Stupot is posted.

The EDO group are the most regular contributors to this publication.

2. The three Year Group Sites: There are three separate sites, one for each year group and allow the students within the year group to interact over matters pertaining to that group. Within each year group site students are sub divided in chat groups and paper forums; one forum for each paper.

Chat groups are groups of 5-8 students formed to facilitate close small group discussion about topics generated within papers. The chat groups are private to that group of students. Staff do not have access to chat groups.

Paper forums are set up for all students enrolled in particular papers and the staff member who coordinates that paper. Staff generate weekly focussed discussions within each paper forum on the paper theme for that week. These discussions, which also include discussion of assignment topics, take place in EDO discussion groups. They have the same personnel make up as the chat groups. EDO discussion groups are a simulation of the internal groups that form on campus by chance and out of in class interaction. Staff are encouraged to take an active part in discussion that emanates in the paper forum. Students who take an active part in these forum report as do staff that they gain a great deal of personal satisfaction and academic growth from the stimulation that ensues from this form of discussion.

Thus there are a number of forum both public and private which encourage dialogue between student and student and student and staff bearing out (Tinker 1997). “The principal way of encouraging student dialogue in the pursuit of learning is the availability of online forums, where the entire learning community can participate in an intellectual exchange profitable to all.”

The Online Environment
WebCT is the electronic software programme used to enable the students and staff to work in an interactive online learning environment. Clients are delivered through the postal service a set of paper based study guides, one for each paper, at the beginning of each semester. Activities for online interaction are built into the study guides and are initiated by lecturers during their online work with students. The students are encouraged to develop these interactions amongst themselves on a weekly basis for each paper in EDO chat groups (fig 2). Taking turns, one student from each group reports their interactions back to the paper coordinator/staff member.

Students report that the asynchronous environment allows time for reflection before comment and that this is a feature of their communication with others. Online discussions certainly have different time frames to face-to-face discussions. A typical time frame for online discussion has been found to be 7-10 days although discussion may proceed for weeks. 1-2 days would be a fast response within this environment. This does happen particularly when students have pressing, urgent interactions to make.

One of the original aims of the programme was to provide an interactive learning environment for the students and to a considerable extent this has been achieved, despite the fact that, to date, it has not been compulsory for students to participate in online work.

The ‘learning community’ notion is not always welcomed for several reasons. Some of the more traditional students see study as individual. They do not want to share and do not expect others to share. These students communicate only rarely during the semester. Staff and fellow students find themselves asking if this response is appropriate behaviour for one who is about to join the teaching profession. We think not and this has prompted the coordinators to initiate a signed agreement for the 2001 group. Interaction will be compulsory and will be reviewed with the group at the end of semester two 2001. A portion of paper assessment will be based around these interactions.

Students report continued annoyance when members of chat groups choose not to take part but also report that, for them, online collaboration is the first dispensable component of the programme when they come under constraints of time, especially at the end of the semester.

In 2000 this manifested at the end of semester two when students had four assignments to complete immediately after a two week full time school placement and examinations beginning one week later.

Technical Support

Staff are supported in the WebCT environment at three levels. The programme coordinators give a small degree of collaborative support when and where they can. A full time technical administrator administers the overall sites. This person enters all staff and students into appropriate groups, assigns passwords, and gives individual technical support to staff. Finally staff have access to the central helpdesk of the University Computing Services Department. Students are supported at a number of levels. The full time technical administrator is available to them at all times when the university is in session. The staff and in particular the programme coordinators give academic technical support as and when needed and the student body are brilliant at giving collaborative support to one another within and across year groups. The main site is a source of collaborative technical support between staff and students and students and students. Technical problems are the main reasons for students initiating communication on the main site.

Problems Faced

There have been relatively few problems with the programme delivered through the web. The nature of some interactions/non-interaction between students has already been discussed as a source of some frustration.

An ongoing problem which it is hoped will be overcome with the move to WebCT 3 has been the fragility of the environment at some times, particularly when traffic volumes are heavy. This is not necessarily the fault of WebCT but is embedded within the support network and servers of the university. As the use of WebCT has increased so has the fragile nature of the environment. The University has upgraded the server in 2000 and this has bought greater stability.

Students are selected with the full knowledge of the hardware and software requirements demanded by the delivery of this programme in the WebCT environment. However it is one thing to communicate the need to such frameworks but another to be sure that students obtain specified computers. When students do not upgrade they report problems with speed of access and continuing access to the course forums. At these times staff note that the interactions from such students decreases.

In some instances the isolated geographic location of some students is a problem. Telecommunication lines in some remote locations are fragile and can cause major problems when they go down for long periods of time. Students and staff have learned not to compose in WebCT. They risk the loss of pieces of work. Coordinators recommend to all staff and students who are working in WebCT that they compose in a word processing programme then cut and paste or attach the document in the communication being composed in WebCT.

Finding the time staff training is a continuing issue which causes later problems for coordinators when students become frustrated over communication problems with staff. In 2001 the coordinators are instigating a peer support system for staff where a staff member established in WebCT will pair off with a new staff member and give technical support to that new staff member.

Teaching Practice, which is the placement of students in schools on some days, placement days, and for up to six continuous weeks was identified early as a potential difficulty. Students are placed with a practising teacher who has been recommended as a suitable role model during these times. Many of these placements are remote making it difficult for the College to monitor the student and the associate teacher. Every effort is made to have a staff member visit students every
time they are in school placement. Isolation, travel restrictions and time restraints do not always allow this. The World Wide Web has not been used to support this function. A feasibility study for this will be carried out in 2001.

The Future

As the EDO programme has evolved, change has been inevitable. The most dynamic change has come in the basic structure of the course in terms of its demographics. In its purest form, which is how the course was set up and was the vision for the course, year groups were to remain intact. It was believed that the selected group had such academic potential that they would no fail. The reality has been different. For a variety of reasons students do fail or pull out of papers and as a consequence the dynamics of each year group has changed. In 2000 the dynamics of all groups is such that each has students across year groups. Reasons include: family dynamics, time constraints, paper fails and the group of students who join the programme having been given cross credit for previous study or having completed up to four papers within the programme part time before entering the programme. A further dynamic has come from the group of internal students who transfer into the EDO programme and the group of students who transfer into the programme from other college and university programmes. Figure 3 illustrates the dynamics of those studying across year groups in the year 2000.

In 2001
1. all students who transfer into the programme from an internal programme or another College of Education or University will be interviewed to establish that they are ready for online external teaching and that they match the dynamics of the group.
2. A greater emphasis will be put on paper forum. It is envisaged that students who find themselves working in two year groups will identify with the paper forum rather than the EDO year group forum.
3. The annual survey of students had always indicated that students strongly disagree with all material being online. Carr-Chellmann and Duchastel, 2000 speak of the study guide as the student’s main reference to the content, structure, and activities associated with the online course. In 2001 one paper will be delivered totally online and carefully monitored as to how the students cope with the dynamics of this form of delivery. It has been the study guide that has always been physically posted out to the students yet Carr-Chellmann and Duchastel assert that online study guides work for them. They point out that, “online study guides must provide a level of detail that is sufficient to enable the learner to proceed without substantial further personal interaction or clarification from the instructor.
4. WebCT Version3 will be used as the medium for programme delivery from 2001 onwards.

Conclusion

This paper limits its discussion to the current operation of the EDO programme of Massey University College of Education. The programme has met its main objective; the creation of a supportive, interactive, online environment for distance students that enables those students to gain a preservice teacher education qualification recognised by the New Zealand Teacher Registration Board. This qualification is the Bachelor of Education (Teaching) degree.

Proof of the success of the programme lies in the graduation of the first 36 students in May 2000. A further 41 students will graduate in 2001.

Reeves and Reeves (1997) stated “despite all the interest, little research evidence exists to support claims for the effectiveness of web-based instruction.” (p 59)

The success of this programme provides further evidence of the potential of WebCT as an online environment for the delivery of off campus learning. In the year 2002 a second Teacher Education Undergraduate Degree, the Bachelor of Education (Teaching) Early Years – birth to eight years will be offered based on the model developed for the primary programme.

The concluding comment is left to one of the 2001 graduating group, “I have surprised myself and my family in reaching a lifelong dream; that of becoming a teacher and I have done it without ever going on campus. I will see you all at graduation.”

Acknowledgement: My thanks to Bill Anderson and Mary Simpson, Senior Lecturers at Massey University College of Education. Bill and Mary were responsible for the development of the EDO programme and carried it through to the year 1999.

Telecommunications systems and services are the foundation of the 'Information Revolution'. From a user services perspective it is clear that issues of systems and services are related to people as well as to technology. In this section we will focus more on access and training than on technical and software developments, as might be expected for this conference which focuses on technology and teacher education. We realize the importance of developing an infrastructure that addresses the complex issues of access and support. In our context we have experience of user services for more developed parts of the world, especially USA and Europe. Polly Mumma was coordinator of academic technology at the University of North Alabama for three years and recently she has been closely involved with user support for ClassNet online learning environment and its latest iteration, which is called Ecademy (http://webacademy.cc.iastate.edu and Mumma & Boysen, in preparation). Niki Davis has been involved in design of online services for teacher professional development with technology for over a decade, including the recent creation of an ICT Educational Research Forum (http://telematics3.ex.ac.uk/erf and Davis, 2000).

This section addresses a wide variety of topics, thoughts and interests. There is a notable range of papers from countries across the world, including several from developing countries where access issues take on a new dimension of challenge for systems and services. The primary theme this year is access, and how to best provide more equitable access to individuals. A second theme is content, which is approached from ways in which content can be made accessible and transferred across media for both teachers and learners. This is a usability approach, rather than one of instructional design. Training of systems and service personnel, including the training of trainers, is added by a further group of papers that mainly come from authors more directly associated with service centers and corporations.

One of the most interesting articles in this section comes to us from Annette Wilkinson and Liezel Wilkinson, from South Africa. They take a look at the issue of access in their country. Their concern not only lies in how to provide individual learners with access to the necessary technology, but providing instructors with access to learners. This is an issue that is equally important but is more frequently overlooked. Through the Curriculum 2005 project, they investigate how to best move away from traditional classroom models. The authors refer to this as "epistemological access". They wish to re-educate instructors and learners to think and learn in new ways, ways that will allow them to make more effective use of new technologies, as communications technology becomes available across South Africa.

Along these same lines, Nomusa Dlodlo and Nompilo Sthole, from Zimbabwe, take a look at the impact the Internet has had on education on the African continent. The focus of their research lies in how to make best use of the Internet to improve the educational systems of Africa, without increasing the divide between those countries that already have good information infrastructure and access, and those which are still struggling to grow and develop technologically.

Anthony Adams of the University of Cambridge brings us news of Ennis, a small town in Ireland, which won a competition in 1997 to become the first 'Information Town' in the republic of Ireland. Dr. Adams outlines changes that occurred in the town, as well as changes that did not occur, particularly among the town's schools. He discusses the need to change the way schools define themselves and their curriculum, if they are to continue to best meet learner needs. Maria Verdu and colleagues from the University of Valladolid in Spain also take a look at this changing definition of education. They propose restructuring education to focus on auto-learning, active learning, and pedagogical aspects of learning.

Janice Hinson leads a group from Louisiana and Connecticut addressing the issue of access and race in the
USA. They examined two very different fourth grade classes, and the effect that access to the Internet has on these two groups. They look at the effect that access could have on learner self-image, their reading scores, and their performance on a cross-curricular research project.

As previously noted, the second main theme addressed in this section is one of content. What should the content of online material look like, and how can it be best presented to users? In this vein, we have several authors presenting new applications and tools designed to improve the online learning experience for both learner and instructor.

Firman Gunawan of Indonesia provides insight into providing foreign language instruction via the Web. This paper looks at how to best build the interactivity as well as the content needed to address the needs of foreign language learners. Similarly, Jorge Kinshita of Sao Paolo University in Brazil introduces us to a tool he has developed which allows instructors to easily produce lecture slides for online courses. Kathleen Bacer from Azusa Pacific University looks at the issue of how to develop and nurture an online community. She addresses issues such as breaking down technological and communication barriers.

For a slightly different look at the issue of providing an effective, user-friendly online environment, Fannie Cox from the University of Louisville takes a look at the virtual library. She takes a look at the services offered in a digital research library, and how that information differs from what is found on the Internet and concludes that students and educators need to recognize that differences and similarities do exist between the University Library's gateway, online catalog and the Internet. Norshuhada Shiratuddin and Shahizan Hassan of Malaysia provide a look at CikguNet, a government designed Web site aimed at improving the online learning environment. The goal is to provide a location where learners can easily access the information and resources they need. The authors provide guidelines and criteria for evaluating and critiquing the effectiveness of a Web site to meet user ease-of-use and learning needs.

The final group of contributions describes several services that are available to support the development of service centers and their trainers. Joaquin Vila, Barbara Beccue and David Doss, from Illinois State University, present information on an interactive tutorial guide to ASP programming. Active Server Page (ASP) is a hot topic in Web design, and is commonly used to provide a variety of interactive Web functions. Dennis Sharpe provides feedback on a user needs assessment conducted last summer at Memorial University of Newfoundland, Canada. He has examined a series of changes which were made, and the subsequent improvements in support services. A team from the Labein Technological Centre in Spain describe an unusual training system that focuses on critical emergency situations, developed within the European Community's ETOILE project. This may be of interest to teacher educators who are designing simulation-based training that integrates Intelligent Agents, Virtual Reality and Shared Mental Models for learning from actions on equipment and management decisions.

Corporate demonstrations round out this section. Sandy Mills from WebCT introduces the WebCT Certified Trainer Program. Joyce Bokuniewicz provides a look at the services offered by Centra and its efforts to provide intuitive, sophisticated online learning environments. Steve Korin from BASCOM Global Internet Services offers information on the issue of filtering and managing Internet content.

Developing and Nurturing a Dynamic On-line Learning Community

Kathleen Bacer, Ed.D
Advanced Studies, Educational Technology

Kbacer@apu.edu

Abstract: This paper addresses the issues surrounding the creation of a dynamic on-line learning community. The development of an effective external and internal environment that embraces/capitalizes on the learning process and nurtures the learner is essential. Two components in developing the external environment are the design of the interface and the effective delivery of the curriculum. Effective communication and the creation/sustaining of a partnership in the learning community are the key components in developing the internal environment. Basic strategies for nurturing and maintaining the on-line learning community are delineated.

Introduction

Critical to any on-line learning community is the ability to create an environment that not only embraces/capitalizes on the learning process but nurtures the learner as well. While this is critical for any learning community, the on-line community sports a new arena of challenges as the dynamics of the human interface are facilitated by methods of telecommunication rather than the physical presence/interactions of students/teachers. The explosion of the internet and access to telecommunication tools has released the learner from the walls and boundaries of a physical building in which they are no longer restricted by specific time and place. This explosion is changing the way we are able to collaborate, problem solve, access and disseminate information, and engage in what is recently known as e-learning. Distance education/learning, online courses/learning, net courses, or e-learning is sweeping across the business and educational marketplace bringing to the forefront the many complexities of developing and nurturing an effective on-line community of learners. We as educators are being asked to take all of what we know so well in the face-to-face (f2f) instructional paradigm and translate it into an on-line paradigm. It is an exciting and daunting challenge. The purpose of this paper is to help with the translation!

What exactly is a Dynamic Learning Community?

A dynamic learning community (whether f2f or online) creates a sense of buy-in, pride, and ownership of the learning. It inspires and motivates thinking, creativity, problem solving, reflection, inquiry, and constructive collaboration among all the learners. The environment created can either promote or inhibit the learning dynamics of the community.

According to Merriam-Webster environment means “the total circumstances surrounding an organism or group of organisms that affect and influence the growth and development of organisms.” (1956, p.276). I consider environment quite a powerful word and concept that is known to sustain life and in this case sustain learning! Throughout my K-U (Kindergarten to University level) teaching career, I have experienced first-hand the influence of the environment (good or bad) upon student learning. I consider the learning environment the canvas, the background, the supporting foundation upon which everything else is built and influenced. I have watched students’ behaviors/learning patterns at all different levels drastically change just because an environment was modified and/or created that supported and encouraged what I consider a dynamic learning community.

So how do we create an effective environment that will develop and nurture a dynamic on-line learning community? Well, I’m glad you asked. If you didn’t, there is still time. Hopefully by now you
have noticed that although you are surrounded by text, much like many e-learning experiences, papers also have environments that are either effective or ineffective in creating a teaching/learning partnership. Notice I have written this paper in first person. Not typical for research papers I realize, but appropriate for the objective of this paper. Although I am restricted to a single-spaced 10pt black font, no graphics, sound or video, and limited interactivity, if you are able to continue to persevere through this paper in its entirety hopefully you will learn how to capitalize on the online environment and utilize its wealth of resources! So how do we create an environment that will develop and nurture a dynamic on-line learning community? First an understanding of the external and internal environments is necessary.

Developing Environments within the learning community

Within any learning community there is an external and internal environment. Both of these environments are equal in value and must be developed and nurtured effectively. To be able to create an effective external and internal environment online, it is important to first gain an awareness of what its role is in the schema of learning.

External Environment

The external environment is the place, so to speak, where the learning revolves. For f2f it is the usually a physical classroom/building. For on-line or e-learning it is the interface that the course is housed within and the manner in which the content is delivered.

Generally speaking, K-5 teachers are incredibly gifted with creating an effective external environment in a physical classroom. You walk into their classrooms and you are surrounded by a rich and stimulating environment, lots of evidence of past and future learning, celebrations of accomplishments, and reminders of content begging to influence young minds. What happens to this external environment as we progress to High School and College? The external stimulus slowly disappears and/or changes to a more stoic or what we might refer to as a "professional" look. Why? Do we not need it anymore? Is it no longer an essential component? As educators we silently justify the absence of effective external environments. We may believe students no longer need it, they have learned to control themselves, it is a distraction or we do not need to entertain them, so to speak. At the university level there are some logistics that stop the feasibility of being able to create an external environment that aligns with our courses as our classrooms are shared among disciplines. Yet I have experienced the amazing impact of creating external environment at the higher levels. For example, in a math/science methods class for pre-service teachers, together we created/decorated our own external environment. We weren't sure what impact it would have on the other classes, nor how long things would stay up, but decided as a class that we would try it. The results were amazing. I watched a whole transformation take place as students walked in the class. Students were excited to come to class, they were proud; they shared with their colleagues. Does this have an impact on learning? Absolutely! Word spread and I learned that the other classes that met in that room were also impacted. The inquiry process was stimulated, a sense of belonging and ownership in learning was fostered, and a realization that external environment is vital wherever we are learning was reinforced. So...move this into e-learning, take the awareness that it is just as important – if not more so, as you design the external environment – the interface and the development of methods of content delivery.

Developing the External Environment

Two essential components of developing this external environment are the design of the interface and the effective delivery of your curriculum.

The design of the interface is very important. It is your vehicle for not only communicating the content of the class, but also creating an external environment. Choosing and working with the correct tools is critical. There are now many providers and course managers for on-line courses to assist in the development of a course. The most common ones are listed in the resource list. It is not my purpose here to provide a critique of each, but to equip you with strategies and concepts that will empower the utilization of any tool. Remember, it's not the tool, it's how you use the tool to create an environment (interface) and communicate your message (curriculum/content) that is important. There is always the option of building your own website/portal for your on-line classes. There are many web authoring tools and collaborative software that you can download onto your site. You need to be aware of advertisements though and the
servers that they may be housed on. Of course this requires a bit of experience. Ideally this would be the best route, but not the most likely. When considering the design of an interface, realize that no matter which one you decide to use, there will be limitations. I have found it beneficial to work around the limitations so that I can still communicate through the interface effectively. When selecting an interface to communicate and support your curriculum, consider these issues:

- **Does the interface have a lot of layers to get at the information?** If so, how can you eliminate them and work around them so the course is “push” technology and not “pull?” For example, there are many different interfaces for discussion groups/forums. Do they allow you to view all messages in an expanded form, view the question that is being asked in your response posting, email participants when you have responded to a posting? All of these are issues that reduce the layers of an interface and add to the usability of the learning experience.

- **Is the interface transparent or is transparency easy to master?** In other words, is it user-friendly and intuitive so that the interface does not hinder the learning? After one session will students no longer think about the technology and focus on the content?

- **Do you always have to be on-line to edit the course?** Whose server does all your work reside on?

- **Do you have a complete copy of your work and is it copyright protected?**

- **Consider the tech support issues for the student and for yourself as the designer. Are they readily available?**

- **Is the interface flexible enough for you to be able to communicate effectively?** Can you customize it to create the environment you want?

- **If you are using a variety of collaborative tools, are they on stable servers?** Are their advertisements running through them? What’s the tradeoff?

In the development of my external environments I sometimes use a variety of tools to create the environment needed. For example, I utilize parts of providers and course managers that best meet my needs. I utilize ecollege for one of my on-line classes. Once I customized the environment, I found the collaborative tools very usable and students felt comfortable by the second session. I turned off the gradebook and chat room features though. I need a much more robust gradebook and virtual synchronous classroom. I prefer to utilize a dynamic virtual environment. I have created a virtual classroom within a thriving learning community called TappedIn. http://www.tappedin.org. My virtual office and classrooms are located on the 9th floor, Rm 915. TappedIn has very powerful collaborative features that allow me to move beyond the scope of a mere chat room. We can for example, creatively express ourselves (show emotions), work in groups at tables, write on whiteboards, post notes on bulletin boards, record our conversations, share resources, or create “bots” to enhance our environment. It also connects students with an active on-line learning community.

For my f2f classes, I utilize blackboard as a front portal and build supportive websites that link to appropriate sections within blackboard. Many times I stretch the interface to meet my needs. For example, I wanted a front-end in blackboard without all the layers – information that was in the face of the learner so to speak – so I built an attractive front-end website and attached it as a permanent announcement. You will find as you gain experience that the external environment will emerge. You don’t have to have a “canned” environment that looks the same as all the others. Can you imagine the on-line learner that is faced with the same interface over and over again?

A dynamic on-line learning community actually allows those in higher education to have that external environment back – virtually of course! Remember environment stimulates inquiry.

Part of the external environment is also in the delivery of the content. In delivering the content on-line, variety is the key. Use a variety of ways of presenting information – audio and video clips, interactive pdfs (portable document formats) students can print and interact with offline, short presentations, and of course the utilization of web resources. I cringe when I see colleagues scan their lecture notes, videotape whole lectures, and type pages of information to present on-line. The effective ways of presenting your curriculum f2f may not be effective at all in the on-line environment.

As you utilize a variety of ways to present the information, implement a variety of activities for student response also.
Nurturing the External Environment

- Make sure your external environment is accessible to all your students. Create a support site with helpful resources and tools they will need to successfully execute all parts of the course (i.e., quicktime, realplayer, adobe acrobat)
- Create a photo website with short bio information
- Make available upon request online office hours in a virtual office.
- Believe it or not, brevity reinforces attentiveness, especially in an on-line environment. I emphasize the use of what I refer to as “powerful paragraphs.” Everything that is posted, including my own content, needs to be a powerful paragraph - short, concise, and to the point. Remember, everyone has to read everyone else’s work.

Internal Environment

The internal environment is all the inner workings of the learning community. This is the part of the environment we create to allow for risk-taking, intellectual challenges, creativity, the construction of new knowledge, motivation to excel, and support of the life-long learning quest. It is the internal environment that affirms and challenges the learner in collaboration with other learners. In a f2f classroom the effectiveness of the internal environment can be seen, felt and heard. Good pedagogy focuses on many strategies that lead to effective internal environments. In essence this is the heart of teaching. In the on-line environment, the “inner workings” are not easily seen, visual clues are almost non-existent, and gaining a sense of presence is more difficult. Effective ways of communicating and the development of a sense of community become essential and foundational. Providing different ways to communicate synchronously and asynchronously are important. There are many different interactive communication tools you can utilize. In creating the internal environment consider these:

- **Email** is the most transparent. Usually everything in a class centers around that basic communication tool. It is first layer, “push” technology.
- **Threaded discussions** allow for asynchronous communications, reflection, and interactive discussions. Author editing and being able to view all conversations/threads at the same time should be a part of this interface.
- **E-journals** are very useful for one-to-one student/teacher reflections. They are “private” and I have found them an excellent tool in establishing an effective relationship and gaining valuable insight into individual learning.
- **Virtual classroom** – while this is part of the external environment, it is also essential for building the internal environment. It becomes the synchronous environment where community is built that supports the internal environment.
- **Webliographies or data collection resources** – a place where students can share good ideas and “finds.” Allows for networking to begin to emerge which strengthens the internal environment.
- **Shared documents** – All part of collaborating with each other and reflecting/learning from one another’s work.
- **Videoconferencing** – If everyone has the technology and baud rates are fast enough, this has the potential of adding the human interface depth to the course.
- **On-line gradebooks** – Essential feedback tool if used to continue to allow for risk-taking, and motivation to excel.
- **Interactive quizzes and activities** – Creatively engage learners in problem solving, and construction of knowledge. Accesses the power of on-line learning.

Developing the Internal Environment

Effective communication and the creation/sustaining of a partnership in the learning community are the key components of developing the internal environment. Think of how you can add richness to your interactions both between students and with yourself. If students do not collaborate with each other you will have for example twenty isolate learners. They will be robbed of networking which is so much of what
learning is. When we share and reflective in a collaborative environment our perspective in chaos or at peace with others allows us to construct our learning.

In developing the internal environment work towards providing an atmosphere that is

- Affirming
- Motivating
- Stimulates inquiry
- Nurturing
- Open, accepts, values and directs opinions
- Keeps students focused
- Draws the student into the process

Organize and integrate all your best practices into the course. Invest time to create a safe environment with lots of one on one and group interactions. The process will make you a better teacher.

Finally in developing your learning community build activities to create a sense of belonging, value, and foster collaboration. I utilize a virtual classroom filled with environment and ability to “emote” (express emotions textually) to encourage the development of the learning community.

Nurturing the Internal Environment

Nurturing the community can be challenging but also the most enjoyable. Some basic tips to get your started...

- Get to know each student. You will actually get to know them better than in a f2f class because they can’t blend in with the crowd! Intimidation is less and everyone has an equal voice with equal access to you. Many times students will open up much more on-line than in a f2f class.
- Let your personality shine through – sense of humor, intellect if you will, etc… Make sure your emails reflect a warm and caring attitude.
- Email can get overwhelming so provide students with “filtering” strategies. A simple one is to have all email subject areas start with the course number.
- Take your best classroom practices and re-think them – how can you put them on-line? Take your worst classroom practices and either make them better on-line or throw them out!
- Use technology to nurture the community and environment – not frustrate it.
- Provide constant feedback that validates/encourages and challenges/promotes further learning. Do an “attitude” check on your responses making sure they reflect the personality and support that is conducive to learning. Email and postings can easily be misunderstood.
- Maintain a sense of flexibility – things will go wrong with technology!
- Protect the community – just like you would do in a f2f classroom. Discourage inappropriate comments/actions and encourage appropriate ones.

Conclusion

In working in an online environment, don’t forget to consider possible barriers such as servers down, bad connections, download time, computer crashes, and URL’s here today and gone tomorrow. Students will invariably encounter technology issues that will hinder their progress. I always encourage my students to not let the technology stop them. If anything, they get real creative!

Don’t put something on-line if you can do it better f2f. Many times we give in to trends in education without thinking about the ramifications. On-line is a trend right now. If you can use the presence of the web, Internet tools, etc… to reach a depth of teaching and learning that you cannot accomplish f2f, then by all means embrace it. I have! If you can’t, then don’t. If you do not know how, then seize the challenge and learn – it is worth it. For example, I can not imagine teaching my “Emerging Trends in Technology” class f2f. I could never provide the depth of the learning f2f. Students would not be able to experience the immersion into the trends without being immersed on-line. I knew with this class that the
technology would empower the learning process. That’s what it is all about, isn’t it? On the other hand, I still didn’t put it totally online. I firmly believe in initially creating the learning community f2f, making sure we experience each other’s physical presence, voices, personalities and interests while establishing a common starting point with the utilization of the technology. I also have found it just as important to celebrate the accomplishment f2f at the end of the learning journey. I am teaching in an educational technology program, do you realize how much more vital this strategy is in another discipline?

By all means, give yourself time for the process of reinvention to work!

As some final thoughts to create and maintain a dynamic learning community, work towards an environment that:

- Stimulates research, reflection, responses
- Motivates participation and the learning process
- Engages and facilitates the construction of new knowledge and emerging ideas.

Your curriculum coupled with a dynamic external and internal environment, interwoven in a supportive learning community is the optimum. If your online environment is richer than your f2f environment, then you have accomplished your goal and have a viable learning community.
Abstract: Like so many other university libraries, the University of Louisville Libraries is creating an environment where the university community, its students, faculty and staff can access information from "virtually" anywhere in the universe. No longer does one have to physically go to a building and search the card catalog. One can search the University Libraries electronic resources from home as well. But, with this new level of access come pitfalls. Faculty and students were already amazed with the abundance of information available from the Internet and now the University Libraries has increased the level of access by making electronic resources (journals, books, and databases) accessible using Internet technology through the University Libraries gateway and online catalog. This paper will discuss the differences between the Internet, the University of Louisville's gateway and the online catalog, by demonstrating a few of the major electronic resources accessible through the Internet. And, it will enlighten faculty and graduate students on the differences and similarities of searching the Internet, the University Library's gateway and the online catalog to become knowledgeable and efficient searchers for information in today's virtual library.

Introduction

Searching for information today, whether it is via the Internet, the public library or university library website, can be an overwhelming experience and a daunting task. Library users expectations have changed as computer technology changed. The "Virtual Library" has become a standard way of describing libraries that provide access to digitized information using numerous computer networks such as the Internet and the World Wide Web (WWW). (Saunders, 1999, p.2) Just when you think you understand all there is to know about searching the Internet, or your favorite library, something changes, or does it? The Internet and the online catalog have never been the same. Because of web technology, researchers and students looking for scholarly resources, no longer have to physically travel to the library. Instead, almost anyone can use the library's proprietary information resources from the Internet. Web technology allows the university community to search the library's web pages for its information or services at the University of Louisville (U of L) from anyway in the world. Anyone can search and find very diverse information on the Internet and anyone can also publish on the Internet. But in an academic environment, librarians have researched, evaluated, and in the case of electronic resources, contracted that information to make it accessible to library users. Library users have the convenience of using the library at home.

At U of L, one can enter the virtual library through its main web page, the gateway or the Research Center. From these two entry ramps, the patron can browse or search the online catalog and the Internet. They are not the same. But they are similar. To harness the power of the search, you begin by planning a search strategy. The goal is to take control of your time and become efficient, by planning an effective approach and understanding how it all works, whether it is the online catalog, the main library web page or "Research Center", which will be discussed later or the Internet. Each has a distinct purpose and its own computing structure and once that is understood, searching any type of online system, should become easier and more efficient, without ever having to become a computer scientist or a librarian.

Access to the Libraries Information and Services

U of L's Libraries' main web page (see Fig. 1, http://www.louisville.edu/library/) functions as a kiosk, pointing to sources and resources of information and services provided by the libraries for the U of L community of faculty, staff and students. Examples of the type of information available from the main web page are: the hours of operation, the online catalog (Minerva 2000), ZoomText to magnify images for people with low vision, along with...
other services for patrons with disabilities, frequently asked questions, library locations, job opportunities, interlibrary loan information and online request, distance learning services, instructions to access online resources from off-campus, information literacy instructional classes and much more.

Figure 1: The University of Louisville Libraries' main web page to information and beyond

The Research Center

Another information kiosk and entrance into the virtual library at U of L is the Research Center web page. It is accessible from the main page or directly from the Internet, because it has its own Internet address or URL (Uniform Resource Locator) http://www.louisville.edu/library/research (see Fig. 2). When accessed from the main library page, it is a subset of the main page and you are in a different, but specialized virtual realm. As you virtually enter the Research Center, the University communities, its faculty, staff and students have accessed yet another layer of information. The Research Center is the initial step in doing scholarly research. Librarians organize and evaluate scholarly resources both in paper and electronic to create a web page specific to a particular subject based upon the library's holdings, special collections, archives and subscriptions. From this web page, the libraries provide the user with access to digitized information: books; searchable databases; electronic journals; specialized collections; other libraries on campus and around the world. Access to full-text journal articles are available from four access points: 1) the Research Center; 2) searching the online catalog; Minerva 2000; 3) from a publisher's website and 4) an aggregator's website, most commonly known as a database. A similarity is that they each use Internet technology, but differences begin when searching and retrieving an article, abstract, or a citation. As at many other Universities and Colleges, members of the community prefer full-text articles, over abstracts or citations. Library patrons prefer to be able to do a search and have the article in a matter of minutes. Technology has made it possible and users have these expectations.
Searching

Earlier we discussed the attributes of both the main page and the "Research Center." Both are portals to sources of information and services for members of the U of L community, at the library and beyond. This digitized information is stored in computers networked around the world on a publisher's or aggregator's search engine. An aggregator will broker for many journals and bundle them to sell to libraries. Due to competition for library business, publishers and aggregators will create their own platform or search engine to provide access to the journals they sell. Each search engine is similar, but unique. These characteristics will be discussed later. They all use the Internet as their vehicle to disseminate information, but that is where the similarities end and the differences begin.

At the Library

At U of L, the main page and the Research Center are very easy to use. If a patron can point the mouse and click, then the user is already off to a good start. To use either of these web pages, a user must be able to read, use a mouse or equivalent equipment, be able to choose a button or hyperlink and click their choice. These web pages were created to be user-friendly. On the Research Center web page, each subject web page was created with the content for the web page provided by librarians to aid users in their quest for information. Librarians use reliable sources and critically evaluate the content of all the web pages available through both the library's main page and the Research Center.

Minerva 2000

Several different online catalogs are on the market today. U of L has the same type of online catalog that is currently being used by the Library of Congress. Many university libraries name their online catalog. At U of L, it was named after Minerva, the Greek goddess of wisdom. There are several ways to search Minerva 2000 such as: author/title/call number, journal title, keyword, phrase, etc. Minerva 2000 also allows limits to be set to restrict the results to various preferences such as format (paper, maps, electronic, microfiche) library location, and date.

Minerva 2000 is unlike the old paper card catalog. Gone are the days when a library patron's search was physically limited to using a card catalog and paper indexes. A search in Minerva 2000 will guide users to holdings of books, periodicals, video and other media, and special collections. (see Fig. 3, http://minerva.louisville.edu).
In contrast to searching a library for its proprietary scholarly holdings, searching the Internet provides users with information that is diverse; it goes from being scholarly to advertisements. Anyone can publish on the Internet and searching the Internet can be overwhelming.

![Interface to Minvera 2000](image)

**Figure 3:** Interface to Minvera 2000

**The Internet**

All search engines are not the same, plus there are other web sources to begin the search process, such as a web directory. Web directories use subjects to classify websites. (Fonseca and King, 2000, p.40). Similar to the Research Center web page where librarians have classified information for its subject web pages or the online catalog that allows subject heading searches. Two popular web directories are The Librarians' Index to the Internet (http://sunsite.berkeley.edu/InternetIndex) and Yahoo (http://www.yahoo.com/). Both web directories websites are different, but they both direct users to specific information. Librarians not only research and evaluate content for subject web pages, but also search engines (see Fig. 4). Another website that can assist users in choosing search engines or web directories is Search Engine Watch (http://www.searchenginewatch.com), which also provides the

![Selected types of search engines](image)

**Figure 4:** Selected types of search engines
latest news on search engines. The table below describes the differences in features and search capabilities for searching Minerva 2000, three popular databases: ProQuest Direct, Nexis-Nexis Universe, EBSCOhost, the U of L's main library web page and Research Center, Yahoo - a web directory, and Google - a search engine. All search engines have a help button for assistance. Becoming an efficient searcher takes practice, planning, and understanding that all search engines are not built the same. In general, search engines whether they search a database, an online catalog, or the Internet, all share some commonalities. What makes them different is how they are designed to search, access and deliver information.

THE INTERNET AS A TOOL FOR A REVOLUTION IN EDUCATION IN AFRICA: A DREAM OR REALITY

Nomusa Dlodlo, Nompilo Sithole*

Abstract
In this paper, the author looks at how the Internet can help Africa develop educationally. The research highlights the benefits that can be derived from access to the Internet for educational purposes in Africa and the problems which have caused the slow growth of Internet access in education in Africa. The author then suggests solutions to these problems in an effort to bring full Internet access to Africa as quickly as possible, thereby improving the quality of education.

1. Introduction
Before the Internet was introduced in Africa, (Osburn, 1999) observes that there was no other method capable of transmitting the same information and at the same time to both industrialised and developing countries. With the Internet, the people of Africa have, for the first time the opportunity to have access to the same information, and at the same time, as people in industrialised countries.

Other than giving Africans the same development opportunities as the industrialised world, the Internet is the fastest growing communication technology. According to (Molosi, 1999) it took 38 years for the radio to have 50 million listeners, 13 years for the television to reach the same mark and only 4 years for the Internet to cross the same line. By the end of 1998, more than 100 million people were Internet users. With the ability to grow so rapidly, one wonders why more people in Africa have not been able to gain access to the Internet, and have not been able to use it as an educational tool.

As the use of the Internet continues to grow, this will have profound implications on education in African countries. According to (Africa on the Internet, 2000), there are fears that if Africa does not 'connect fast enough' the growth of the Internet will only accelerate marginalisation of the African continent. As the pace of growth accelerates even more, the gap between those who are linked up and those who are not grows larger. These dangers and fears are real and should not be underestimated. Lamenting them will not stop the growth of information technology. Instead, Africa's civil society, governments and entrepreneurs need to be challenged to take advantage of the information technology revolution now gripping the rest of the world and bring the Internet to Africa.

2. Applications of the Internet towards the development of education in Africa
(Deutsh, 1956) states that, what we see happening today, that is, the networking of developing nations, generally began in the universities and research communities. The advantages of networks to academia were,
and still are obvious - databases are shared, conferences organized, papers circulated and discussed, collaborative research and writing undertaken, and so forth.

Universities and research in developing nations are strengthened, and the "brain drain" diminished as the Internet reduces pressure on professionals to move abroad. (Deutsch, 1956) further observes that early in the 20th century, physics research was only concentrated in a few centers, but increased international communication - journals and conferences - led to worldwide dispersion of physics research. The Internet will actually accelerate the spread of information for educational purposes to even the remote areas, which have access to the Internet.

Electronic Distance Education (EDE) is the process of extending learning, or delivering instructional resource-sharing opportunities to locations away from a classroom, building or site, to another classroom, building or site by using video, audio, and computer communications technology including the Internet. At its most basic level, EDE takes place when a teacher and a student are separated by physical distance, and technology is used to bridge the instructional gap. As a result EDE can provide adults with a second chance at college education, reach those disadvantaged by limited time, distance or physical disability, and update the knowledge base of workers at their places of employment.

3 Internet resources for education

In EDE students can engage in electronic discussions with each other via facilities that are available over the Internet such as newsgroups, bulletin boards and chat groups and e-mail.

Newsgroups allow students to engage in discussion groups on areas of interest. A student subscribes to a discussion group and messages to and from subscribers are distributed via electronic mail (e-mail). An electronic mail message is a document that is created, dispatched and received on an electronic mailing system. Electronic bulletin boards on the other hand store messages on central computers and users must log onto these computers to read messages that are sent to these groups.

A chat group is a service in which participants around the world can talk to each other by typing in real-time on hundreds of channels. In an example where students are encouraged to actively participate in EDE seminars, the student leading the seminar prepares a paper and submits this by e-mail to a group for consideration. Some electronic discussion follows, prompted where necessary by the tutor. After a few weeks the student presenting the seminar summarises the discussion and presents a revised paper. Management of such seminars requires skill from the tutor in judging just when to contribute a comment in order to keep the discussion going.

In organisations where e-mail is available, both tutors and students are offered an efficient and straightforward means of communication. One such application is to use e-mail to remind students of impending deadlines. Even students who are absent when the message is first posted are certain to receive the message when they next access their e-mail. Similarly any changes, revisions to assignments or hints can be delivered to all students through e-mail.

The increased numbers of students and the corresponding increase in time spent by staff on assessment has encouraged interest into how technology can be used for assessment purposes at various levels. In a fully automated assessment system all aspects of the system from the assessment which the student completes to the processing and administration of the marks, including overall management of assessment information is technology-based. Perhaps the most immediately obvious and most easily accessible use of technology to assist the assessment process is in the recording, analysis general storage and management of results. A wide range of spreadsheet packages (e.g. Excel, Lotus123) and database packages (e.g. Access, Oracle) is available over the Internet. A package is a collection of computer programs to achieve a particular purpose. Spreadsheets are used to expedite record keeping involving mathematical calculations. The numerical data can be mathematically calculated and presented in an easy-to-understand format. A database is a collection of information that can be organised, sorted and printed in various report layouts. A database package assists in collecting information into a database. Examples of information, which may be collected and stored in a database, include personal student information, records of classroom resources and student academic information.
There is a growing interest and increasing practical experience in the use of computers to deliver objective tests. Objective testing is often taken to imply the use of multiple choice questions. The creation of a bank of questions on the Internet invites the possibility of each student being presented with a paper made up of different questions, but of an equivalent standard. It is possible to use the computer to generate different tests automatically from the bank of questions. It also offers the interesting possibility of an instant computerised marking facility that allows immediate feedback for students.

Computer technology is there to aid those doing research. Communications packages that provide access to databases and archives on the Internet and explore the World Wide Web can assist with research and information retrieval. Communications software is used to search library catalogs, search electronic journals and text, and retrieve text, graphics, audio and video files.

4. Problems Causing Africa's slow Growth in Internet access

Internet access in Africa has slowly improved over the years, but many people in the continent are still unaware of the Internet and those who may be aware of its existence don't know how it may be of benefit to them. There are several reasons why Africa's Internet infrastructure has remained so fragile, therefore slowing down the rate at which people are able to access the Internet.

4.1 Interference of state-owned PTCs

According to (Adam, 1993), the state-owned Posts and Telecommunications Corporations (PTCs) involvement and approval is usually required to proceed with networking plans in the area of telecommunications in most African countries. Because, in most cases, the PTCs have rigid policies and poor management and computing capabilities, the need for approval by the PTC to proceed with any networking plans frequently hinders the progress of networking in Africa.

4.2 Computing Equipment in Short Supply

(Adam, 1993) highlights the fact that both hardware and software are difficult to source in Africa in terms of cost. Therefore, equipment is usually in short supply. If it is available, it is either obsolete or under utilised. In an institution, one may find mainly old mini-computers and low-end personal computers with limited application software.

One is convinced that if the policy makers appreciate the importance of computer literacy, the resources would be made available to purchase computers for schools. The policy makers would also see to it that computer education is included in the school curriculum.

4.3 Low Investment in Research and Development

Statistics indicate that African universities and governments invest only a small percentage of their budgets in research and development. The policies implemented by the governments may only be short-term and do not take into account any long-term research options. As (Adam, 1993) put it, "the research staff work under extremely difficult conditions. Salaries and incentives are limited and not sufficient to promote the use of modern technology for research". Usually an individual researcher or a research department in an organisation or an institution is not able to afford the costs of using computing technologies in research and development. A lack of understanding of the impact of electronic communications on the telecommunications infrastructure and the impact on research and development is one of the persistent challenges to network development.

4.4 Extreme Dependence on External Technological Sources

There is an extreme dependence on external donors in the area of information technology. This dependence could be in the form of finance for purchasing equipment or computer hardware and software donated to an institution. According to (Adam, 1993) this has a few disadvantages. The use of information technology is mainly limited to themes selected by donors, consultants, etc. If the donors have donated equipment which they
want to be used in the engineering department of the school, then even if there is a greater need for the
equipment in the computer science department of that school, the equipment cannot be shifted there.

Despite these disadvantages, external sources are very important in bringing the Internet to Africa. They have
the financial resources, which are needed in order to purchase equipment and train the system operators and
users. Without them it is not feasible to try and implement a network plan in Africa which will benefit a greater
part of the population. So there actually has to be a trade-off between the resources which have been donated by
these external sources and the control that they have over the use of equipment.

4.5 Journals in short supply

Most information technology journals and magazines, with a broad range of technology assessments and
updates on computers and networks are procured outside Africa. They are therefore, expensive for individuals
to obtain and are generally in short supply. According to (Adam, 1993), “while journals in various fields can
sometimes be found in libraries of universities and research centres, journals and proceedings on various tools
for networking are generally unobtainable”. This means that it is difficult to have access to the most current
developments in networking.

4.6 Lack of formal training in the area of networking

There is an observable slack in the area of formal training in computer networking. Because of the lack of
training in network design and management, and the fact that those who are skilled in the networking area
move to places that offer better salaries which is usually in foreign countries, there is, therefore, a shortage of
human resources in the field in Africa. In order to curb the brain drain, industries should be challenged to give
salaries and conditions of services, which are comparable to those in countries, where the experts in computer
networking are moving to. To curb the brain drain, industries should be challenged to give salaries and
conditions of service which are comparable to those in the countries where the experts in computer networking
are moving to.

4.7 Lack of culture for sharing information

In academic institutions and industry there is the problem of lack of a culture of sharing information, which
should exist mainly in these circles. There is an unwillingness to share information and resources, maybe
because of the competition for foreign resources.

With companies which are competing, this is understandable. Each of the companies wants to get ahead of
the rest of the competitors by improving services and, therefore, increasing their customer base. In
academic institutions, this problem leads to non-progression in the area of computer networking. If one has
an idea, or information that they have been able to source, then sharing it with others will also improve
their understanding and maybe bring in new insights which they had not realized before.

4.8 Telecommunications Costs

If the state monopolises telecommunications, there are no controls to the prices which they will charge for
accessing the Internet. The problem is even compound in Africa because of the few telephone lines, which
exist. (Cohen, 1999) puts it this way: “A few statistics illustrate why the basic requirements of access-a-
telephone-line presents problems for less industrialized countries. Globally, 49 countries, 35 of which are in
Africa, have fewer than one telephone per 100 people”. The lack of telephone lines in some areas makes it
difficult to cultivate an Internet culture, as there is need for a telephone line and a computer in order to be
able to gain access to the Internet. Besides not having reliable telephone lines which are necessary for
usage of the Internet, cost is also inhibitor to Internet access

4.9 Counter Regulation

The governments at times try to regulate the content of the information accessed over the Internet.
According to (Cohen, 1999), this happens in countries where telecommunications are monopolized by the
state. Governments can also restrict access for political purposes and economic gain.
5. Suggested Solutions

The problems, which have been listed in the previous section, have seriously affected the connectivity of African countries to the Internet. Although the Internet is essential, building intensive Internet connections require a thoughtful plan, long-term commitment, financial support for sophisticated Internet technology, sufficient human resources to run sophisticated networks, and in-depth knowledge of networking.

5.1 Sensitisation and Teaching

Sensitisation and teaching are important activities in networking. Continuous sensitising and teaching theory of networking costs system operator’s time, but is most useful during the first stages of building a national network. There are several ways in which people can be sensitised on the use of the Internet.

5.2 Frequent Updating and Change

Networking is a dynamic area that needs frequent updating and change. Realising the fact that there is a continuous change in computer technology, there is a grave need for frequent upgrading of the equipment that an organisation has, and an improvement in the skills of the people in the field.

5.3 Collaborate with PTCs

Government-owned Posts and Telecommunications Corporations (PTCs) have been one of the major stumbling blocks to networking in Africa. PTCs actually claim to know much about networking than they do. If policy makers and key industry players collaborated with PTCs, they would be able to encourage each other in networking technology. PTCs should also acknowledge that electronic networking will not threaten their networks or reduce annual telephone bills but would rather improve their capacity and generate demands for newer services. In essence, this would be an advantage for the PTCs. If they have improved services, they are better able to compete with new players who come into the telecommunications market. Thus, long-term collaboration schemes should be established between community and government PTCs.

5.4 International Cooperation

The networking map indicates that Africa lags behind all other continents in the use of data communications technology. While the global Internet is growing at a phenomenal rate, its potential changes to society are becoming immense, and the creation of a truly global internetworked research village is becoming evident. Isolation from this global movement is still very much in evidence in Africa. African network enthusiasts can only become self-sufficient through learning from the experience of the international community.

5.5 Institutional Support

Institutions play a major role in promoting networks. Lack of institutional support and political will to promote a network initiative are, according to (Pimienta, 1993) major stumbling blocks to networks in the region. To quote him directly, “Building of network user groups, supporting official structures for academic institutions such as science and technology commissions, and involving active researchers to obtain political backing from their institutions, are ways of improving institutional support.

5.6 Organisation

Centralizing network activities using some appropriate organization that deals with plans, projects, results and impacts of activities is very important. Effective organisation saves money and effort in dealing with governments and different institutions. One has a set out plan and is able to follow it through sequentially.
5.7 Financial Resources

Technical plans and network architectures should be based on available financial resources. (Pimienta, 1993) lists the following as major costs of a network: the coordination of a network from conceptualization to implementation, the installation and configuration of a network, network support, including training (user support), the maintenance both at user level and at nation level and communication costs. Dependence on foreign assistance to cover all of the above costs makes national network overly dependent. When such donors withdraw, national networks may be jeopardised. (Pimienta, 1993) suggests methods of building cost recovery tools into the national network to help to support it. Some of these tools include institutional subscription fees, additional fees for conferences or other Internet services and training and support fees.

5.8 Technical Plan

A sound technical plan is also a critical element in sustaining a network. Networks should match national infrastructure and user requirements. (Pimienta, 1993) further suggests that concentrating efforts toward building large national hosts (rather than numerous smaller nodes) allows for better transmission media and continuous support for the improvement of bandwidth.

5.9 Wireless Technologies

Wireless technologies are actually being seen as one of the most important ways of addressing the needs of a continent with the least developed telecommunication systems in the world. (Jensen, 1996) though argues that “although wireless systems can offer far more rapid roll out times, greater reliability, lower maintenance costs and better security, wireless Internet connections are also not inherently more viable than wired networks – they are more appropriate in applications where traditional solutions for some reason are not feasible or cost-effective. These traditional solutions would include access to the Internet via a telephone line and a modem.

6. Conclusion

The Internet is a communication tool that should not be confined to industrialised nations and begs to be utilised now to address Africa's chronic need for communications and development of education. The ushering of Africa into the new information age will be realised through a partnership of African governments, private business and donor agencies. The desirable outcome is a sound telecommunications infrastructure, decrease in access costs and equipment costs, proliferation of telecentres in rural areas, heightened computer awareness and improved communication.

Bilingual Web Based Learning:
“To know the world and to be known by the world”

Firman Gunawan
Teleeducation Laboratory
Divisi RisTI PT TELKOM Indonesia
Bandung, Indonesia
firgun@risti.telkorn.co.id

Abstract: Web is a simplest and a cheapest technology to deliver a knowledge to all over the world. This presentation paper would tell you about our concept about bilingual web based learning (our way to know the world and to be known by the world), type of services, research and development steps in developing bilingual web based learning, development time-line, how the human resources organized in development and operational stage, collaborative work with other institutions, and our future plan in web based learning concept.

Introduction

Invention of the Internet technology make everything change and move fast. Information flows very fluently make us very easy to get all information and knowledge we want and also we can share everything we know to others. We believe that to follow the change we can not move and work alone anymore. We have to collaborate with other parties, otherwise the changing will destroy us. To be have a good collaboration we need a good communication with others. Not only good communication but also we have to increase our knowledge. In order to achieve all above statement we try to build a distance Learning system through the web. Web is a simplest and a cheapest technology to deliver a knowledge to all over the world. We try to convince people especially in developing country like Indonesia that the technology is not as far as they thought before.

The course were made is a general informal English course especially for Indonesia or Local community. We aware that English language is a world language and to be able to communication we should have a good skill in English. Some of the courses are free to take, every body can take it whenever and where ever they want. That’s the advantage of the Web!! And if you want to ask the expert you can contact them by e-mail. Another course is Indonesia language course. The course is intended to every body who want to learn Indonesia language. But at the first time, it is intended to help any foreigner who working in Indonesia because to be able communicate with Indonesia community it would be better if they know a little of Indonesia language. So this is the way to know the world and to be known by the world.

Web based Learning Concept

Technology based Distance Learning is defined as a system and a process that connects learners (students) with knowledge centers (Instructor, Database) who are separated in distance and need to interact in real time or non-real time. And Web based Learning is a technology based Distance Learning that used web as interface. And some people said that web based learning have made many changes in knowledge material delivery. For some parties point of view this is the most effective way compare to other distance learning media alternatives. Up to now there about three training or learning program which is delivered through web both on the internet or intranet such as computer/technical training program, business program, and languages.

There are many classification of web based learning. This article will explain some of this classification. The first classification was according to the media type:
1. Text and Graphics Web base Learning
   Text and Graphics is the simplest web based leaning application. Instructor only put the courses material on the web and student can access it very easy. But this Web based Learning type present text and graphics only then interactivity level is very low.
2. Interactive Web based Learning
   In this type, the web based learning is equipped with a quiz, self-test, text entry test, and other. The interactivity level is higher than the first type.
3. Multimedia Interactive Web based Learning
Most of training program used this model as their web based learning model because this model has a highest interactivity level. Student and teacher can communicate in real time situation, audio streaming, interactive web discussion.

Interactive Multimedia Web based Learning have the highest level of interactivity but to achieve that level we will have a highest cost than others. In order to achieve that we have to use step by step work, first of all we could build the Text and Graphics Web based Learning then we enhance the capability step by step until we achieve the highest level of interactivity.

According to instruction type there are two kind of web based learning:

1. Synchronous
   Student could communicate with their teacher and other student at the same place and time

2. Asynchronous
   Student could communicate with their teacher and other student at the same place but not always at the same time.

Finally there are four type of business model in web based learning:

1. Free courses with commercial advantage
   Usually learning institution or provider provide a free courses and everyone could follow the course without pay it. Commercial advantage could be afford with advertising or form other content provider

2. Commercial course
   This course's mode is replica of conventional courses but use web as its media. Conventional process such as registration, placement-test, and others has to be passed before student could access the material and of course the student have to pay the course.

3. Learning Application Service Provider
   Mostly, this type of web based learning business model is provided by learning tool producer. Beside sold their application they also offer a leased service. Every party could used their software and host in their application on the basis per hour and per concurrent user.

4. Learning Portal
   Like another type of portal, learning portal is also a collection about any resource to learning. It could be learning material, web based learning home page, and learning information.

**Idea Generation**

The idea comes up when my colleague try to enhance our English capability by send us one material a day. It was a good beginning but too bad it's not consistent because it stop when we get busy. When we busy we don't remember that we have to send our friend a the web, we could reach all people that connected to our LAN/INTRANET. So I told this to my manager, he agreed and told me to start build this application. Then we start the idea about bilingual web based learning. We defined bilingual web based learning as a web based learning system that content or delivery process used an English and Native language as a main language. We develop a web based learning that content consists of English Language and Bahasa Indonesia with delivery language both Indonesia and English.

**Implementation Steps**

**Prototype I (Oktober 99- February 2000)**

**Our Course Features**

**English.**

In English feature we have a number of features. Those are:

- **A grammar**
  We deliver this section because we aware it is a difficult part of English beside the vocabulary.

- **Idiom**
  This feature was made to help people learn about idioms, what is the meaning and how to use it.

- **Conversation**
  To help student increase ability in any conversation style like at the office, at school, in the meeting, and occasional live

- **Scientist story**
  We try to make our community close to science. One of our weakness is that most of our student don't have a good capability in basic science. We try to attract people through the scientist story.
Networking Terminologies
We work in Telecommunication and Information technology field. Then it is important to know all about networking terminology.

To deliver this course we have two step, first we give the student a brief theory then we ask them to answer a simple question on the web. This is a weekly program then we will update the course every Monday.

Indonesian Course
In Indonesian course the features are:

- **Grammar**
  In this section we try to help people learn about Indonesia grammar, how to speak, how to read. We are aware that the difficulties in Indonesia language is how to spell in Indonesia. To we think that it would be better if we add a sound feature in every Indonesia word

- **Vocabulary**
  The feature were intended to help people to increase their indonesia Vocabulary.

This is also a weekly program then like the english course program we will update the course every Monday.

Type of Question
As we mention in above paragraph, the course will preceded by a short material or lessons and follow by the question. There is a lot of type of question that we give to learner but in general the question flow is depicted in this figure.

Multiple Choice Question Types
There are two program that used in this type, first a program from Hot Potatoes Software and second is developed by RisTI using Java script. The First Program is more complicated and more sophisticated that the other. It's a user interface program. And if we work with the second program, we should working from the source program but the function is same and the advantage is we don't have to buy it. We used this type of question if for Reading Comprehensive Test and Networking Terminology test, but it is possible to use this type to the other item.

Short Answer Type
There are two program that used in this type, first a program from Hot Potatoes Software and second is developed by RisTI using Java script. The First Program is more complicated and more sophisticated that the other. It's a user interface program. And if we work with the second program, we should working from the source program but the function is same and the advantage is we don't have to buy it. We used this type for Vocabulary test, Scientist Story, and any other items which appropriate.

Matching Answer Type
The matching type now is only from Hot Potatoes software but in the future as the other type we will develop our script to make this type question. For a while we used this type question for vocabulary test and Idioms test.

Prototype II (July 2000- February 2001)
In this second prototype we enhance the capability of our application. First, we do an assessment of First prototype. Second, we do a development process based on analysis result. We have to know and understand the system specification before we design new system which will be developed. Through system specification we will get information about processes that needed and involved in system.

Web based learning could be specified from a different point of view:
**User Point of View**

From user's point of view, the system consists of two service type:

1. **Free System**, this system is intended to user who not or not subscribed to become a member of commercial course system. The user just only need to register but he/she doesn't have to pay anything but the facility is not as much as commercial system..

2. **Commercial System**, this system is intended to user who want to became a member of commercial course. User have to register first and pay for the course. We will give more feature for this user.
Facility Point of View

From the facility point of view our web based learning are consists of:

1. User Management System is a System that function to manage user and content data base. System is consists of:
   a. Registration is a processes that consists of user items.
      i. User authorization which consists of:
         i. User ID
         ii. Password
   b. Payment method. There are two payment system: on-line and off-line

2. Interaction Facility, is a facility that function to provide interaction media or communication among instructor and student, instructor and instructor, or student and student. Interaction System is consists of:
   b. Chatting
   c. E-mail/mailing list

3. Teaching Facility, a facility that used to support teaching and learning system.

4. The content is consists of:
   a. Daily Lessons, this is a content that will change everyday. The contents are consists of:
      i. Idiom
      ii. Proverb
      iii. Vocabulary
      iv. Antonym
      v. Synonym
   b. Weekly Lessons, this is a content that will change everyday. The contents are consists of:
      i. Idiom
      ii. Grammar
      iii. Vocabulary
      iv. Reading
      v. Scientist Story
      vi. Networking Terminologies
   c. Sample Class, this is a class sample of commercial courses that consists of following material:
      i. Conversation
      ii. General
      iii. Business
      iv. TOEFL Exercise

5. Evaluation and Scoring Facility.
   This is a facility that used to evaluate especially student who take the commercial course or take a weekly lesson. This evaluatio system is consists of four types:
   - Examination (Quiz)
   - Exercise/Homework
   - (Student Progress Tracking)
   - Report and Certificate

6. Supporting System,
   This is a facility that used by system administrator to administer the system, user, include create the material, quizzes, exercise, etc.

Resources

Development

First step is to obtain who is the member of the development team. Development team is responsible to develop web based learning. This team build a web based learning from the beginning, integrate the software which is needed to develop the web or customized web based learning application software that available in the market. The development team are:

1. Project Manager
   The project manager will lead this development project, he oversees the assignment and flow of tasks and coordinates development schedule. The project managers might fulfilled other roles on the project in addition to management and supervision.
2. Instructional Designer

Instructional designer for the web based learning project is the person who responsible for the teaching and learning process in web based learning that will be built. He/she should define need analysis, overall design, and often actual writing of storyboard. Storyboard are graphical and text presentation of the information that goes into each screen of the program.

3. Programmer and Database Expert

Programmer is the one who responsible to encode the system that have been designed into a language that understood by the machine/computer.

4. Software quality assurance

Once the programming step in place, the team needs to test the applications. Software quality assurance may be apart of programming but in a large web based learning development there are some specially people responsible to maintain the software quality.

5. Subject Matter Expert

Subject matter expert acts as a consultant in the actual of curriculum. Clearly, different subject matter expert are needed for each content. The SME are chosen from their expertise area, and work with writer and instructional designer to create the actual curriculum and training method that will be used.

6. Writer and Editor

Writer crafts the text of the learning material. It require communication with Subject Matter Expert and Instructional Designer. And Editor is needed to verify the grammar in the text of the curriculum and control all the material and exercise.

7. Web and Multimedia Developer

Web and multimedia developer are responsible to design the web page, audio, video, and animation according to the result of Instructional Designer and Subject Matter Expert proposal.

Operational Human Resources

In the web based learning operation we need a different team or different human resources.

1. Manager

Manager Responsible for web based learning operational. He/she should maintain the web based learning operational.

2. Instructor

Instructor responsible for delivering courses. She or he has to answer all the student question and if there is a discussion session the instructor should be able to moderate the discussion.

3. Web Master and Administrator

Web master and Administrator handles the day to day technical support related to delivering the content over the network.

Lesson Learned

From the experience, we have several lesson that might be good if you consider it:

a. Be detail with Design
b. Be careful when evaluate
c. Do a Beta Test and Pilot Project
d. Watch your Content Development
e. Consider your Resources (Both Content, Financial, HR, etc)

Future Plan

In the future we plan to continue develop bilingual web based learning by collaborate with other institution which have a different expertise (such as language expertise). And we try to enhance our facility like add some feature like bulletin board system, conferencing tools, web synchronized, etc.

Suggestion and Summary

As we mention above bilingual web based learning is a web based learning system that content or delivery process used an English and Native language as a main language. We hope we could make it as good as possible so people from out country could learn our language easily and people from our country will learn International Language easily anywhere, anytime. From the experience we have learned, I would like to conclude:

- Technology just a medium
  The technology is just a medium then we couldn't say it bad technology or good technology. But the important thing is what the technology which appropriate for our condition and situation
- Need collaboration with other institution
In globalization era we have to know that we can live by ourselves anymore, we need to collaborate with others.

- Need a subject matter expert
  For the content, if we don’t have any resources for this field, feel free to collaborate with other who has these expertise

- Allocate Resource to the fit position
  Put your resource to an appropriate place.

- Next development: Desk Top conference, virtual library
  Desktop conference is a synchronous model of Distance Learning technology. This time we are not using this technology but we still do research about this technology. We believe that desktop conference technology will growth follow the internet technology growth especially voice over IP technology. And virtual library as the supporting system for our distance learning will be developed. It is possibly a joint partnership with other library who have very good expertise in this field

A Lecture Generator in the Web

Jorge Kinoshita
Department of Computer Engineering
Polytechnic School of São Paulo University
Brazil
jkinoshi@pcs.usp.br

Abstract: We made a tool to generate presentations as HTML pages from a simple input text which can be generated in any text editor. This tool is available for public usage through a CGI script at http://www.pcs.usp.br/~jkinoshi/lecture. This paper presents how a text given in a simple notation can create useful presentations.

Introduction
It is common to use a computer tool (e.g., PowerPoint [1]) in order to prepare a presentation. The material generated by the tool is a sequence of slides where each slide consists of:
- One title
- Many topics, organized in a hierarchical way.

In this paper we present a "lecture generator" tool that transforms a single text into HTML pages (slides) to be used in a lecture. Our approach is simpler than "PowerPoint":
- The input text has a very simple notation that can be created in any text editor.
- The output is HTML pages that can be seen in any browser, hence, in most platforms.

The tool is available for test in [2].

Input text and output slides
Each line of the input text basically corresponds to a title or a topic of some slide. The first character of the line tells the difference:
- title: A line beginning with '*'.
- topic: A line beginning with '-'.

Example 1:
* Title of Slide 1
  - the first topic inside Slide 1
    - the second topic inside Slide 1
* Title of Slide 2
  - one
  - second topic.
  - the last topic.

The input text from example 1 generates two slides:
- Slide 1: The slide "Title of Slide 1". See figure 1
- Slide 2: the slide "Title of Slide 2".

Observation: The link to the former and next page is automatically generated at the head of the slide.
Example: In figure 1, the link to the next page is "Title of Slide 2".

The hierarchy: Topics in a slide
Each topic line can begin with one or more '-'s. The more '-'s, the lower it will be in the hierarchical structure, as it can be seen in example 2. The first slide of presentation in Example 2 is seen in Figure 2.
Example 2: Hierarchy in topics

* Title of Slide 1
- 1. the first topic inside Slide 1
   -- 1.1. the sub-topic of 1
   --- 1.1.1 the first sub-sub-topic of 1
   --- 1.1.2 the second sub-sub-topic of 1.
* The second slide
- some topics inside

The hierarchy: Slides in a Lecture

A lecture can correspond to a sequence of slides organized in a hierarchical way. Each title line begins with one or more '*'s. The more '*'s, the lower the slide will be in the hierarchical structure of the lecture.

Example 3:
* Title of Slide 1
  - one topic
** Title of Slide 1.1
  - another topic
** Title of Slide 1.2
  - one topic more
which generates three HTML pages. The first HTML page is in figure 3:

**Figure 3: First slide of Example 3**

**Links to the "sub-subjects"**
The tool creates links to the slides at the immediately lower level (sons in a tree structure) at the bottom of the page. This is done because:
- it is common to present the great sub-subjects under some slide and
- it enhances the navigation during presentation.
Example: The Slide 1 in Figure 3 has two "sons". The two links "Title of Slide 1.1" and "Title of Slide 1.2" (bottom of figure 3) are automatically generated by the "Lecture Generator" tool.

**The table of contents**
The tool automatically creates the HTML page pa0.html that displays the table of contents. The figure 4 shows the table of contents of the example 3.

**Commands to the Lecture Generator Tool**
We created a special notation in the input text (commands) that enables figure insertion, comment insertion, etc. The commands are:

1. mark a portion of input text as comment
   **syntax:**
   ```
   :rem
   some comments
   :/rem
   ```
   The lines between :rem and :/rem does not appear in the output.
Figure 4 - Table of contents of table 3

2. keep the text as it is (ex: example of code)
syntax:

<pre>
some text that must appear as it is at the output
</pre>

The lines between :pre and :/pre must appear as a text at the output HTML pages. It is useful to show programming code.

3. insertion of figure
syntax:

+img:file
Example: figure 3: +img:florida/ex3.jpg

The Lecture Tool creates the HTML tag 'IMG' from this notation.

4. insertion of a HTML link.
syntax:

+http:anURL

If the user adds the character '+' before an URL (in this context, a sub-string that begins with "http:" ) then the HTML tags A and /A are automatically generated.

5. insertion of a sub-window. It is possible to show some text during the presentation of a particular topic.
syntax:

+{some text}
Example:
+{this is an example of a sub-window}

When the sub-window is declared then a HTML link to a window containing "some text" is generated in the slide. This is done by a javascript function. In figure 5, the command: +{this is an example of a sub-window] generated the link "[*]" to the yellow window containing the text.
Figure 5: Example of a sub-window. The sub-window appears when user clicks the link [*]

6. insertion of any HTML tag
Any HTML tag can be inserted using the normal HTML tag notation.

Example:
   this is a text in <b>bold</b>

The tool development
The tool was created in Perl in a Linux machine.
The tool in http://www.pcs.usp.br/~jkinois/lecture uses two Perl-scripts:
- the script palestreia.pl that takes the text and converts it into HTML pages.
- a CGI script that deals with the user-interface. Basically it:
  - receives the text and user email from a form,
  - applies palestreia.pl, compacts it and,
  - sends the compacted lecture to the user.

Usage Examples
A presentation of the Lecture Generator Tool is in http://www.pcs.usp.br/~jkinois/lecture/paO.html
and its corresponding input text is in http://www.pcs.usp.br/~jkinois/lecture/ig.txt

Conclusion
The Lecture Generator Tool creates slides as HTML pages from a very simple input text. It is available to public usage through a CGI-script. It has some advantages and disadvantages over powerpoint.

Advantages over PowerPoint
- Our tool organizes the slides in a tree structure instead of a linear structure.
- PowerPoint can display presentations in the web, but it becomes photos that are heavy to send. The Lecture Generator Tool generates presentations in HTML format. The HTML tags are very powerful and can be used to enhance a presentation.
- Free of charge usage by [2].
- The input text can be generated in any text editor. I recommend emacs [3] in outline-mode. In fact, emacs outline-mode inspired me to construct the lecture generator tool. A description extracted from the help of emacs is:

   editing outlines with selective display.
   Headings are lines which start with asterisks: one for major headings, two for subheadings, etc. Lines not starting with asterisks are body lines.

   3255
Body text or subheadings under a heading can be made temporarily invisible, or visible again. Invisible lines are attached to the end of the heading, so they move with it, if the line is killed and yanked back. A heading with text hidden under it is marked with an ellipsis (...).

Disadvantages over PowerPoint

Powerpoint has many facilities that are not yet supported by the Lecture Generator Tool; for instance, it enables to create some special "effects" during the transition from one slide to another.

Future

I hope to enhance this tool and license it under GPL [4].

Abstract: Educators and parents across the country have been grappling with ways of making the Internet a safe extension of classroom learning. While many schools have implemented a filtering methodology to screen "inappropriate" or "non-educational" content, there is an emerging backlash that has come to view filtering as restrictive, unreliable and counterproductive. This paper discusses the benefits of another approach: curriculum-based content management. This approach enables educators to pre-select websites that are in line with a particular lesson or in accord with that district's overarching educational objectives. Moreover, curriculum-based content management promotes focused, proactive learning. Students do not "surf the web". Within such a system, students are presented with thousands of categorized, pre-evaluated websites, turning "search time" into "learning time." Curriculum-based content management maximizes the educational value of each school's Internet investment, allowing teachers and students alike to realize the power and efficacy of Internet-enhanced learning.

Introduction

Over the past thirty years, the Internet has grown from its beginnings as a military communications system to a tool used by individuals and organizations worldwide. Among its many supporters are students, educators, and administrators who benefit not only from broadened access to information resources, but from the ability to discuss and collaborate over any geographic distance. Among its many applications, the Internet can enhance daily lesson plans and teaching in the classroom environment. This study examines ways the Internet can be used effectively in a classroom setting. Educators can use and accept the Internet not only as an alternative to attaining research materials in the library; but as another tool that creates interactive, higher-level thinking for teachers and students in the classroom. Educators can take advantage of the Internet in the classroom yet still remain focused on the information needed for an effective learning objective. For many reasons, educators may approach the use of the Internet in the classroom with slight apprehension. One reason is that we may be unclear as to what the Internet is and what it does. We have heard the raves about the Internet as this tremendous "superhighway" that allows teachers and students to access a vast amount of information, but sometimes educators are still uncertain as to where it fits into the classroom. The word "Internet" refers very generally to the global network of hardware and cabling that hosts information and carries it from place to place. There are many different types of information traveling through the Internet at a given time, (from electronic mail (e-mail) messages to Web pages). For K-12 schools, Web pages are doubtless, the most frequently used form of Internet information. This is most likely due to the similarity of Web pages to the pages in the textbooks that you use in the classroom. Web pages offer a way for textbooks to be taken to another level because the Internet provides a dynamic new way to create interactivity. Educators are familiar with using traditional textbooks inside and outside of the classroom environment. At times a main objective for an educator may be to find interesting and dynamic ways for students to become engaged in the texts and provide a way that will create the students' willingness to read and absorb the information. On the other hand, students may feel that the textbooks are unexciting or not interactive. Interactive tools and materials make it easier for students and teachers to relate mutually to the information conveyed. The Internet provides an interesting and unique way for students to relate mutually with each other and with their teacher. Students respond to the Internet with great enthusiasm because of its ability to be an interactive form of traditional textbooks.
Harnessing The Internet

The Web, a world community on the Internet has proven to be a tremendous tool for conveying information that can be used to facilitate learning and convey knowledge which can then be used for learning activities. However, there IS a common, major problem for educators. There is so much information that attaining a grasp on it may be difficult. The system is disorganized and teachers may feel as if there is no way to control it for classroom use. Educators are left with a giant system that provides information but in a disorganized and confusing fashion. It's like a library where all the books have been placed randomly in the stacks. The solution is a simple one..... creating software which organizes Internet content and makes it a beneficial tool for the classroom, computer lab and library. The development of content management software, thus allows for the "educational" shaping of the Internet within the school environment and provides educators with the ability to select Internet based information based upon classroom curriculums. Pre-selected, focused, content replaces the timely and cumbersome practice of "searching" for appropriate content while precious classroom time passes by. Students reach appropriate content FAST, maximizing their online time through "on task" learning. Websites can be selected from the vast volumes of Internet information and presented to students based on appropriate State Education Department K-12 curricula, across the breadth of subjects taught in our nation's schools. How can we develop FOCUSED resources and present them to students in the educational setting? Rather than use a "shotgun" approach by providing a "friendly" or "kid-safe" search engine as the vehicle, educators can offer pre-qualified Web-based curriculum resources via a drill-down menu system allowing students to get to the information they need quickly. This results in a more motivated student and a learning environment where students CAN complete the assigned tasks. The Internet was NOT designed for classroom use, a fact that explains many of the difficulties schools have had in trying to integrate its various offerings into their existing curriculums. As rapidly as schools are being wired, so too have rumors spread of functional weakness, perilous legal exposure, and loss of CURRICULUM FOCUS. Superintendents are often overwhelmed by the challenges of integrating Internet content into established methods of supporting school curriculums. And few vendors seem to have an answer that meets the educational requirement of supporting currently accepted curriculums. Yet, no one can deny that, properly deployed and managed, the Internet provides dynamic educational opportunities that extend far beyond the borders of classroom walls. When you think about it, your school is better prepared than you think to deal with Internet access issues: You already choose the books to include in your library and the materials to fill out your curricula. Thus, you have always managed educational content, in one form or another. Internet access will be no different, provided that you have the correct technology and a forward-thinking attitude. In planning for this new technology, superintendents may find themselves having to think about technical issues in addition to curriculum and overall administration of districts. Among the technical issues are: Integrating technology, while... Addressing parents' and school boards' concerns, while... Handling repercussions of educationally-inappropriate content being accessed on school grounds. Facing the threat of litigation through exposing students to "inappropriate material", while... Budgeting for the cost of setting up and maintaining a system, Dealing with the fear of the changes that such a system will mean for your well-established curricula. As most of us are aware, schools across the country (and around the world) are scrambling for Internet access in order to take advantage of the rich content and communication ability this medium offers. More and more schools are integrating Internet content into their curriculum for some very simple reasons: It makes learning fun and interactive. It dramatically expands classroom resources. It makes students comfortable with research and reference sources. It opens students to cultures beyond the classroom, and breaks down the walls inherent in any learning situation. It enables communication with the global learning community. Internet access bridges the gap between technology and education. In general, it provides three elements that are crucial to bringing a school forward, arming it for future developments in curriculum delivery: 1) Effective and managed Internet access with content security, electronic mail, chat communication for community-building and peer strategizing, and access to educational materials and environments far beyond the classroom. 2) Network technology along with the connectivity, infrastructure, and speed necessary to effectively compete for bandwidth now and in the future, wiring a school for its Internet and Intranet needs. 3) Dynamic curriculum integration that fulfills a school's educational objectives for the next millennium, reducing preparation costs while providing students with dynamic, fun, and effective educational value. Web sites perform a similar function to textbooks but in a dynamic new
that prevent access to specific Web site addresses, or to key word approaches that remove or block-out pre-determined words appearing in the text. Defined as such, filtering software provides a partial response of removing a danger. But what is added with this approach? It has no curriculum-based goals, it does not provide an alternate solution, and it adds no educational value. With all of the resources available to educators on the Web, the filtering response unfortunately approaches Web technology in the classroom as a formidable force that can only be managed through reducing a teachers' choice. Curriculum-based content-management is, however, a positive educational choice. This choice is in order for an Internet solution geared toward the educational community: *Guided, classroom-focused and curriculum-appropriate access* only to previewed sites either self-defined by a school, or tested and approved by the guidelines of an educational advisory board. This system uses a different strategy than filtering software: A school starts by defining their “Allowed List” of sites to support their curriculum. These sites naturally are linked to State curriculums for K-12 across subject areas and naturally lead students down a path that fits the school’s learning objectives, and keeps students focused on lesson plan objectives. This philosophy mimics the way in which educators have traditionally selected books and other printed materials for classroom discussion and library use. It places Web access accountability on educators and schools. A distinct benefit here is that a COMMUNITY DEFINES IT'S OWN STANDARDS for Web access, rather than accepting a corporate definition often found in filtering software solutions. It's simple to define access. A school can do this by using one or more of the following methods: 1) Use an educational portal such as an educator-developed school website as a rich access point, with sites broken down by curriculum area. Unfortunately, this is a time-consuming task and considerable effort must be given to development and maintenance of such a site. 2) A school can create its own “Allowed Lists” of sites which students can visit, and make these lists available to students in a number of ways without creating a school website. Lists can be tailored for different schools within a district, or different subjects within a school. However, giving students “allowed lists” as word processor documents with hyper-links is perhaps an inefficient solution. 3) Make use of the many educational sites already in place by universities, museums, government entities, and other schools themselves. Many educators and organizations have already constructed Web pages containing multiple access points into educational Web sites. Curriculum-based management removes concern over what content will enter the school environment. It's always up-to-date, dynamic, and channeled into age- and curriculum-appropriate educational objectives, just like any other classroom resource. Let's look at some of the common questions and concerns people have when implementing an educational solution as discussed above. Your educational and community peers are concerned about a definable number of important issues: 1) Are sweeping policy changes required? Teachers and parents are often concerned that the Internet will radically change the way schools operate. Given what’s been written about the dangers of the Internet (and the dearth of information on the sometimes overwhelming benefits of
access), it’s no wonder. One of your roles in guiding your peers through this process is to reassure them that there is, in fact, nothing to fear with this new technology. Whether it’s administrators concerned about content or teachers concerned about learning new technology, you’ll know how to choose a system that will keep their students safe and give them dynamic content that seamlessly integrates into their curriculum and your school environment. 2) What policies must we put in force? Choosing curriculum-based management over filtering software provides an easy, painless solution that really requires no particular policy, and no definitions of what is inappropriate for your students. Educators merely pick and choose what they need from the Internet (with help from a K-12 categorized library of sites) appropriate to the curriculum, age group, and study topic of your students. There’s no need for educators or parents to worry about what will enter the classroom environment: educators have gained true management of the Internet. 3) Who defines what is “appropriate,” and doesn’t this vary by the student’s age? Through a curriculum-based management system, you define where the students go, no where they shouldn’t go—just like the way you’ve always done it. There is a distinct advantage to this since your “allowed” sites are not defined by a software company, but by educators in your school. Sites are agreed upon by those within your community. This approach enables educators to present educational Web content in a manner consistent with the way support materials have always been selected and used. Overall, this is the most natural way of dealing with Internet access. Furthermore, a solution such as one based on an Internet Communications Server offers group management, letting educators set up classroom groups, or choose content for labs and individual computers on the school network. This powerful feature assures are-, curriculum- and topic-specific Web content. 4) How is such a system maintained? Maintaining the system is extremely simple. An “administrator” program lets educators easily set up “allowed” sites, and can make use of the sites chosen by educators who review and select sites based on State and Regional curriculum guidelines. If students attempt to access a site that has not yet been “allowed”, they see a friendly message; then they have the option to send a message to their teacher requesting the site’s addition. Teachers can then examine the site and, if it is valuable, quickly and easily add that site to the Allowed List. This feature demonstrates the flexibility of an Internet Communications Server. Anyone who has ever operated a computer can easily pick and choose their options using the tab-driven tools in the user software. With the use of exclusive passwords, educators can use full Internet research capability on computers they choose. Choosing a curriculum-based management solution over filtering software automatically reduces concern over liability by allowing educators to choose sites just as they choose books for their library or curriculum. This gives educators comprehensive management of Internet content, while using password protection and a secure, server-based design to assure that only educators access the management settings.

**Child Safety on the Internet**

Like any highly populated community, the Internet has a dark side. Along with the positive contributions—online libraries, interactive museums, and access to cultures far beyond the boundaries of the classroom—there are negative influences: individuals who use the Internet harmfully to serve their own ends. Fortunately, managing the risks can be much easier here than it would be in an actual community. The challenge for educators is to replace the negative influences with true educational value. Filtering solutions used in school settings cannot always provide a totally “safe” solution because must always update so-called “not” lists based on the ever-growing number of undesirable sites found on the Internet. This is tantamount to the little boy whose finger in the dike is all that stops the onrush or the North Sea! Sooner or later, that type of approach will fail. Content-management, therefore represents a proactive approach: educationally valuable content, locally controlled, FOUSED on specific K-12 curriculum as opposed to the old “reactive” approach. As an added measure of support for applications where educators choose to use selected computers in an “unrestricted” mode, popular “filtering” technology works transparently within the system to shield users from these common inappropriate areas: 1) Violence/Profanity, 2) Partial Nudity, 3) Full Nudity, 4) Sexual Acts, 5) Gross Depiction, 6) Intolerance, 7) Satanic/Cult, 8) Drugs/Drug Culture, 9) Militant/Extremist, 10) Sex Education, 11) Questionable/Illlegal/Gambling, 12) Alcohol & Tobacco. Also, filtering is provided on sites deemed to be “productivity reducing” in the educational workplace: Sports, Entertainment, Games, and Humor. Any site on the Internet, however, can be “allowed” globally, or on a computer work group basis as well as on an individual computer. Therefore, for instance, a Physical Education teacher might choose to have certain
Sports related sites "allowed" on computers within his supervisory area. A librarian might also choose to have certain Health related sites available in the library, not generally allowed to the school population. This type of proactive solution allows educators to control their own preferred Web sites and to map out a safe pathway through the Internet. Another feature allows teacher the ability to create electronic "worksheets" called PROFILES, which present students with a learning task and the appropriate targeted websites the teacher has chosen for student use. Only those sites as well as textual instructions for the students are shown on workstations. Profiles are an additional way youngsters are kept on target and maximum focus can be maintained during a limited classroom or lab period. Providing such a "safe-harbor" for learning allows the Internet to be a wonderful resource for learning and exploration as it revitalizes the educational setting. As in many other facets of life, care must be used when introducing children to this resource. Using a content-management approach to provide educational resources supportive of accepted educational curricula provides a proactive solution to this challenge.

Creating Empowered Learners

In today's media-saturated world where children of all ages passively feed on an array of disjointed images and messages, furthering proactive and focused learning has become perhaps THE biggest and most important challenge facing our nation's schools. Rather than having students sitting in a classroom while teachers "lecture" and a few "motivated" students participate while the rest merely mark time, it is imperative that we turn teachers into "facilitators" and students into inquisitive learners. Teachers acting as "-guides" facilitating "learning adventures" using Internet technology has been shown to promote active learning. How, then, can we foster such learning? A curriculum-based approach to Internet-enhanced learning patterned along the lines outlined in this paper, will go a long way toward facilitating this process, creating dynamic classrooms brimming with energized teachers and proactive learners.
An Application for Training and Improving Co-ordination between Team Members, Using Information Technologies.

Abstract: As most of the daily situations are handled by teams in the current world, the necessity of training teams which collaborate in order to solve situations in time-pressure scenarios arises. This type of training is complex; it may also be difficult to carry out periodically and besides, crucial information can be lost with the existing training systems. In order to increase the effectiveness of systems that promote learning by individuals, teams and organisations involved in the emergency resolution and to raise the frequency and quality of trainings. We present a training system based on a methodology, which integrates Intelligent Agents, Virtual Reality and Shared Mental Models for learning from actions on equipment and management decisions to be performed in emergency scenarios. We describe its application to the resolution of an underground fire emergency developed under the ETOILE project funded by EU. The system can be applied to other scenarios.

Introduction

In an increasingly complex world where most of the daily situations are handled by teams, the importance of the team training in the task of overcoming emergency situations is well known. The value of employing information technologies in these scenarios, for completing the existing training systems, leads us to present a methodology which integrates traditional trainings, individual computer based trainings (CBTs) and live emergency drills with collaborative training systems for teams, based on advanced information technologies.

Training individuals and teams that must work in emergency situations is complex for several reasons: the number of people involved in the situation can be high, the disruption caused may be expensive and the equipment involved costly to operate. It may be infrequent for similar reasons and also
because agreeing on a common training date is not easy when the people involved belong to different organisations.

The most common existing trainings in complex time-pressure scenarios and emergency situations mainly consist of: theoretical trainings, specific trainings for each role and situation, and real drills. Most of the times, real emergency drills are considered the best way to improve co-ordination between the people involved in the emergency situation, however the high level of complexity of the trainings, the low frequency and the lack of realism are the reasons that make convenient for these drills to be complemented with another training systems. So the purpose of the developed training system is not to substitute the existing ones, but only to compensate the known drawbacks of the existing trainings and complete them.

Technologies Integration

The paper is based on the work developed in the ETOILE project (Environment for Team Organisational and Individual Learning in Emergencies). The project is funded by the European Union in the context of the ESPRIT programme. ETOILE proposal consists of technologies integration and the system proposes to apply jointly three raising technologies: Virtual Reality, Intelligent Agents and Shared Mental Models. The ETOILE system is designed as a distributed virtual 3D environment where trainees cohabit with intelligent agents.

Virtual Reality

In order to make the user (trainee) feel like in the real world, the training takes place in several computers, one for each of the trainees, and a 3D view of the participants and the environment is shown to every trainee (Fig. 1). In the Virtual Reality, the user has the possibility to navigate through the virtual world, interact with objects and participants represented in the scenario and even simulate communications by clicking on the corresponding devices. Changes in the environment and scenario are easy to perform and there is no need to use costly equipment. With the Virtual Reality interface, the trainees can be located at different places, connected by a network, and all they work together into the same virtual world in order to solve the emergency situation.

Figure 1: Virtual 3D view of the Train Driver in his cabin during the training session.
Intelligent Agents

Intelligent agents are software systems that can act by their own and react on incoming events or messages. In the ETOILE project two different kinds of these agents are included; behavioural agents and pedagogical agents. Behavioural agents are agents whose behaviour in the system is described as human-like, they plan and react like humans participating in the emergency situation. In the training system, not all the roles in the emergency situation are taken by humans but intelligent agents are used to take them over. These agents substitute humans and make the system available even when only some of the people involved in the emergency are available. Pedagogical agents are agents with didactic functions whose main task is to help the users to perform the tasks and achieve the goal in the emergency situation. Pedagogical agents increase the system ability for the communication between the trainee and the computer by giving assistant and advise during the training session.

Shared Mental Models

When humans do not work alone but together with other people in a team the concept of shared mental models appears. Shared Mental Models describe how the single team members proceed in developing a common “mental simulation model” that allows the team to make predications and estimations of the current situation. Shared Mental Models are implemented in the behavior of the agents. Two kinds of these models appear most frequently in the ETOILE demonstrator scenarios, compensatory and anticipatory knowledge. When messages between participants are passed by a third party, this intermediary has the opportunity to compensate for missing or incorrect information. Besides, people sharing information received by other participants or equipment are in the position to anticipate request to actions. Knowing that all the participants have a shared mental model of the training session, one of the participants can receive a feedback message from any other one when the action is not the appropriate one. The usage of these models significantly improves the training benefit. These ideas are taken into account for the communications between participants. Based on the same ideas, the system includes learning support tools, these tools help the trainer to make an evaluation of the training and the trainees after the session.

System Development

The technologies described above are used in the ETOILE project in order to develop two demonstrators. The system aids to complete the training of the personnel involved in the resolution of two specific emergency situations: an incident in a power plant and a fire emergency in an underground tunnel. Labein is developing the application for the second scenario, this scenario has been chosen due to its complexity and completeness. In this scenario lots of people belonging to different organisations are involved. Metro Bilbao personnel, security guards, paramedics, fire brigade and the emergency services dispatching centre. The aim of the system is to complete the training of the Metro Bilbao personnel who are in the emergency central dispatching room and the train driver of the train on fire. In a training session the trainees and the trainer are seated in front of their PCs. The trainer selects the scenario, the situation, the role of the participants and the current conditions of the training before the session starts, the trainer can also start, stop and pause the session and even introduce external events during the session. Every trainee enters in a 3D environment (Fig. 2) where a detailed representation of his workplace is shown, every participant in the session is represented by an avatar either the humans or the agents. The humans interact with the environment to perform their task during the emergency situation, task performed by each of the participants are updated in every of the VR windows. There are mainly two kinds of actions: equipment manipulation and communication with another participants. The main communications devices are simulated by the system, in this case (telephone, talk channel, megaphone, train-ground system, etc.). The system also includes a pedagogical agent, the assistant. This agent is in charge of monitoring the participant actions and give advice and assistant to the trainees. The training support tools included in the system give support for the evaluation of the training done by the trainer when the training session is over.
Conclusions

The use of the system facilitate the trainees to improve their co-ordination and decision making during the emergency situation. The application features enable the simulation of equipment malfunctions, which would be tedious to reproduce in a live emergency drill. All the main tasks involved in an emergency situation are reproduced during the exercise. The trainer can choose between the emergency scenarios provided in order to cover different situations and achieve a complete and adequate training. Different means of communication are used between the participants in the session and all these communications and devices are simulated by the system. Complementary learning support tools are provided by the system for the monitoring, supervision and evaluation of the learning. At this moment the project is in the phase of integration of the partners developed work.

The ETOILE consortium consists of two Spanish companies as final user, Metro Bilbao (Underground company of the city of Bilbao) and Iberdrola (Spanish electricity provider). Two German institutions as authoring tools developers, research institute Fraunhofer-AGC and the company STN Atlas Elektronik. Two Spanish centres as leaders developers, the authoring tools are used to develop two applications or training scenarios one by each of the Spanish centres. The first one developed by LABEIN Technological centre, deals with a fire emergency in a Metro tunnel. The second one, about an emergency in a nuclear power plant, is developed by Tecnatom and Iberdrola, two Spanish companies. The other partner of the project is the University of Lancaster located in the United Kingdom, as learning support tools developers and they also evaluate the benefits of the system.
Acknowledgements

The paper is based on the work developed in the ETOILE project (Environment for Team Organisational and Individual Learning in Emergencies). The project is funded by the European Union in the context of the ESPRIT programme. The ETOILE consortium consists of the following institutions: LABEIN, METRO BILBAO, IBERDROLA and TECNATOM from Spain, Fraunhofer-AGC and STN-Atlas Elektronik from Germany and the University of Lancaster from the United Kingdom.

The Secretariat of State of the Universities, Research and Development, Inter-ministerial Commission of Science and Technology funded the activities described in the paper through the reference TIC1998-1711-CE.

Virtual reality interface and behavioral agents defined in the Underground Demonstrator are based on Metro Bilbao procedures.

The WebCT Certified Trainer Program: Modeling Online Teaching and Learning with Industry Driven Standards

Sandy Mills
Educational Program Manager, WebCT
United States
sandy.mills@webct.com

Abstract: Written by professionals with extensive online teaching and learning backgrounds, the WebCT Certified Trainer program goes beyond typical technical training and was designed for those who are tasked with teaching others how to use WebCT and how to create instructionally sound courses. This discussion-based program focuses on the techniques, strategies and methods for integrating teaching and learning principles, learning styles, building online communities, and includes discussion on other topics such as intellectual property, copyright, academic honesty, and accessibility. This paper explores the research and educational philosophies behind the program, and highlights why over 90 institutions around the world have become involved and what they are saying about the program.

Introduction

The WebCT Certified Trainer Program is a program that extends beyond typical technical training and explores the world of teaching and learning online. It is a full-bodied program that is designed to give professionals who are responsible for delivering WebCT training an opportunity to discuss best practices and expand their skills in several learning environments. This paper provides an overview of the WebCT Certified Trainer Program, including why it was created, a description of the characteristics of the target audience, the educational philosophy that forms the foundation of the program, and the outcomes of the first year of the program. Included is an analysis of pre and post assessment data from 156 workshop participants.

The Purpose

Developed by Murray Goldberg and a team of students in 1995-1996 at The University of British Columbia, WebCT was one of the first fully web-based examples of software that provides a set of tools that enable instructors to perform typical instructional tasks through a Web browser (Goldberg et al., 1996). Early adopters of WebCT and other programs were typically technically savvy instructors who were seeking to "push the teaching envelope" in some way, by providing online communication pathways, self assessments, self-paced tutorials, or collaborative learning spaces. They tended to have a high tolerance for learning new methods. As the popularity and importance of teaching with online courseware grew, institutional early adopters turned into trainers and/or mentors for the next wave of instructors. There is evidence that instructors in this "second wave" learn differently. They commonly need to have the benefits explained in concrete terms to their personal situations and have different professional development goals than the "entrepreneurs" (Hagner, 2000). There has been a lag in further developing faculty to use technology in teaching. This "chasm" has been defined as the gap between "visionaries"--customers who seize on new gadgets--and more mainstream "pragmatists" who need convincing before they buy (Moore, 1999). To further complicate matters, many of the early adopters were self-taught and were not formally trained in instructional design, Web design, accessibility or teaching and learning research. Therefore, there is also often a gap between their training agendas and what the instructors need to learn.

As WebCT educational specialists traveled from campuses to conferences in 1999 conducting training and consulting, it became increasingly apparent that while institutions everywhere had committed to online education, they were voicing the need for higher quality online course development, and the need for higher quality training.
Understanding that individuals tasked with explaining the software to instructors have a perfect opportunity to spread strong online teaching and learning practices, WebCT developed a program to certify individuals who could exhibit such strengths. Since many institutionally based trainers may not have had formalized trainer training, certification was seen as an effective way to ensure trainers practice a structured training delivery method that allows for awareness, practice and feedback (Walter, 1998). A development team of WebCT professionals was formed, and the problem was defined: how do we help others become effective WebCT trainers while also contributing to the improvement of the overall quality of teaching and learning online?

The Target Audience

The team was able to categorize institutionally based WebCT trainers into three groups and identify potential strengths and weaknesses with each type. For example, the first group was defined as those who are considered “techies” and have been chosen as trainers because they have knowledge and experience with the technology. Often they receive little training on educational foundations or effective training techniques. Many of these folks do not have experience teaching with technology, but instead have been expected to maintain it. They know all about the buttons, and enjoy showing all of them. Their knowledge and passion for the technology is often their greatest training strength. With appropriate coaching and training, they can become empathetic to those who are not as technologically savvy, and can build a repertoire of teaching and learning examples for their WebCT training duties. The second group identified consists of instructional designers or curriculum specialists who are responsible for supporting technology needs of faculty along with helping them to design instructionally sound courses. Often these individuals must work hard at staying informed about new advances in technology fast enough to stay ahead of their faculty. They believe in instructional design and pedagogy, and are excited to use technology as a vehicle to transport their teaching and learning messages. They typically want to know best practices for introducing technology, and best design for delivering training. The third group of institutional trainers for web-course development consists of faculty who have learned how to use the product, and because of their early adoption of online teaching, they are often volunteered to aid with the professional development of their peers. These early adopters often have enthusiasm for and knowledge of the product based on experience, but lack a well-rounded set of technology skills that are necessary for training faculty. Most understand innately what works and what doesn’t, but they may or may not have matched their techniques for online teaching with current research.

Understanding that these three groups of trainers have varying skills, competencies and needs, and there is an overlap of job responsibilities, WebCT defined four competency areas for achieving certification status. They are: 1) Presentation Ability, 2) Audience Concern and Empathy, 3) Knowledge of WebCT and Related Technologies and, 4) Pedagogical Understanding. Industry standards for similar programs were researched, and research on online teaching and learning and corporate technical training was utilized. It became clear that this program fell in the middle of teacher education, online teaching and learning, and technical trainer training.

The Program

Step 1-WebCT Knowledge Test

The program begins by gaining experience using WebCT and building online teaching environments. Since content knowledge is crucial for any trainer, the program is designed for advanced users and not to bring beginners up-to-speed rapidly. For this reason, it is highly recommended that one spend at least one semester working with WebCT before entering the program. A study area with sample test questions and study aids is available to help guide candidates who seek greater knowledge of WebCT. The WebCT Competencies for Online Facilitation and Course Design (http://webct.com/certify) is available to help individuals prepare for this test and the subsequent step, the Train the Trainer Workshop.

The WebCT Knowledge Test (WKT) is designed to test both product knowledge and a basic level of proficiency with instructional design, Web design, and teaching and learning principles. The test consists of 2 parts. The first part is a practical test, where each test taker is given two hours to put together a sample WebCT course based on a specific set of directions. The second part is a multiple choice, short answer, and matching test. To obtain a passing score, one must obtain a score of 75% or more on both parts.
Step 2-WebCT Train the Trainer Workshop

More important than the actual web course platform is the need for teachers to understand the pedagogy that drives each course. Simply teaching instructors to "point and click" may increase the number of teachers using technology, but will not improve the quality of online learning environments, or the quality of online teaching. Best-practice organizations claim to keep their focus on teaching and learning issues, and not just on the technology, and see faculty development as a series of steps that include addressing pedagogical application of technology (APQC, 1999). The workshop portion of this program focuses on online pedagogy, and begins in an online environment, where exemplar online course design and online facilitation are modeled. The curriculum involves research and discussion on the topics of: building online communities, good teaching practices, learning styles and theory, as well as important issues such as copyright, intellectual property and accessibility for the handicapped. The exit requirement for the online component is a portfolio that is uploaded into the Student Presentations area of the course. The portfolio deliverable is a job aid that the participants can use after the workshop at their own institutions to integrate teaching and learning resources while training others to use WebCT.

The face-to-face portion of the workshop is led by a WebCT Master Trainer, and comprises two days of discussion-based activities that emphasize the online materials. In addition, participants have the opportunity to demonstrate effective presentation and teaching techniques while receiving feedback from peers and the WebCT Master Trainer. The competencies used for final evaluation are further investigated, and the participants are asked to reflect on the workshop and their training skills before scheduling the last step for certification, evaluation.

Step 3-WebCT Certified Trainer Evaluation

The final phase of the WebCT Certified Trainer Program is evaluation, where the certification candidate conducts a live training session, incorporating and demonstrating very specific program competencies for this summative evaluation. The candidate either requests an onsite evaluation or submits a videotape of a live training session. A WebCT Master Trainer then evaluates the trainer against the 4 competency areas. A detailed evaluation report is written with suggestions for improvement. A team of master trainers then decides upon the certification status. Since the entire process is intended to facilitate mentoring and coaching of trainers, if the candidate is not successful during an initial evaluation then a second evaluation is granted with more feedback and more suggestions for improvement.

The Outcomes

The individuals who registered for the Train the Trainer workshop consisted of individuals who support faculty, instructors, administrators or managers, network or server administrators, and others. Of the 156 who were surveyed, the participants consisted mostly of individuals whose job it is to support faculty. The makeup of the participants indicated that network and server administrators comprised only 5% of the entire group, whereas faculty maintained 17% of the group.

<table>
<thead>
<tr>
<th>Role</th>
<th>Percentage</th>

</tr>
</tbody>
</table>

Figure 1: 156 participants were asked, "What is your primary role?"
Participants were asked what percentage of their current role is dedicated to training, including time spent coordinating, conducting, producing materials and planning for training. Only 15% of the 156 participants appear to be full-time trainers whereas 82% of the participants have other responsibilities besides training. It is interesting to note that 3% have no recognized responsibility for training, but were interested enough to enroll in the program anyway.

![Figure 2: 156 participants were asked, “What percentage of your weekly duties involve training? This includes coordinating, conducting, producing training materials, and/or planning.”](image)

Participants indicated very favorable growth in comfort levels for incorporating the philosophies of learning styles, good teaching principles, and building online communities while conducting WebCT training. These comfort levels were assessed at the beginning of the workshop, and then again at the end of the workshop. Positive growth in comfort levels was seen in specific survey questions, as well as in the comments area of the survey. The area of content that showed the greatest increase was learning styles while conducting WebCT training. The Percentage of respondents for each comfort level is outlined in Figures 3, 4, and 5. Anonymous comments submitted from the participants also indicated an extremely consistent perception of growth from the experience. A few comments have been included below:

- *This workshop provides many good examples from both the course designers(s) and the other participants that are very beneficial. Talking about “good teaching principles” is no more helpful than simply lecturing students - engaging the participants and providing concrete examples is as essential for WebCT training as it is for courses delivered in any other setting.*

- *It put my focus back on WHY we use these tools and not just the HOW of the tools. I will now include these practices in my future trainings.*

- *I do not have a lot of experience in teaching. This training has really helped me to focus on things other than technology.*

- *This was very good information for me. I feel much better about my knowledge base. I have so many great links and now feel like I belong to a great community of trainers... to all in the class and the great facilitators. Thanks!!*
Figure 3: 156 participants were asked how comfortable they were discussing learning styles with instructors while conducting WebCT training in an introductory survey and then again upon exiting the workshop.

Figure 4: 156 Participants were asked how comfortable they were discussing and illustrating Good Teaching research with instructors while conducting WebCT training in an introductory survey and then again upon exiting the workshop.

Figure 5: 156 Participants were asked how comfortable they were discussing ways to build online learning communities with instructors while conducting WebCT training in an introductory survey and then again upon exiting the workshop.
Summary

The outcome of this program is the creation of a community of certified trainers who not only teach the "how" (button-clicking) but also the "why" (educational purpose) when teaching others about WebCT and online learning. Access to a private discussion and document sharing area is one of the benefits of attaining certification, and within this area continued community building, educational materials and best practices are shared. The program is definitely unique, and is determining what the industry standards are for certified trainer programs in education. The impact this program has on the world of online teaching and learning is being tracked through close communication with its graduates and continued assessment and evaluation of the program.

References

Acknowledgements

The WebCT Certified Trainer Program was built by a team of dedicated educational specialists at WebCT, and through continuous feedback from a very special group of WebCT users around the world. Special acknowledgements go to the following for their continuous contributions to the program and for helping to improve the overall quality of online teaching and learning: Murray Goldberg and Sasan Salari and their talented team of WebCT developers; Steve Kelner and Michelle Lamberson, Program Directors; Barb Solberg for authoring the original online workshop; Kim Zartman and Beth Stinson for ongoing development of materials; Bonita Bray, Margarita Santiler, Laura Sederberg, Bob Boufford, Estelita Young, Robert Serrano, Jacque Carlson, Marvin Britto, and Heather Kelley, for ongoing facilitation of the T3 Workshops; Michelle Lamberson for her editing brilliance; and Chris Huggins and Monica Bouchard for their many hours spent nurturing and coordinating the program.
Using Information Technology Applications to Support Distance Learner Services

Dennis B. Sharpe
Faculty of Education
Memorial University of Newfoundland
Canada
dsharpe@mun.ca

Abstract: This paper presents a brief summary of a comprehensive report that documents the results of a needs assessment of a sample of university distance education students engaged in degree courses during the 1999-2000 academic year. The intent was to examine the current use of available student services and to determine, based on the expressed needs of distance learners, the kinds of multimedia, interactive support services that should be developed to enhance student success and retention in an increasingly competitive market.

Introduction

Post-secondary institutions in North America are rapidly expanding distance program offerings through both traditional print/mail formats as well as through variations of tele-learning that include video-conferencing, tele-conferencing and on-line web-based courses. Such approaches are being driven by escalating advances in information and communications technology. The demand for distance delivered programs continues to increase nationally and internationally, with institutions competitively reaching out to clientele who do not want the inconvenience of more conventional on-campus full-time programs. However, despite these trends, the provision of services for distance learners has tended to receive much less attention, yet such services are considered a vital component in linking students with the institution and helping to ensure student success. Almost all universities and colleges maintain web sites that enable current and potential students to access a wealth of information. The use of on-line course registration systems also continues to grow. Many other students support systems, however, tend to be less evident; and individual distance course support services vary widely by both institution and program. A review of such services is both appropriate and timely.

The Project

For over 30 years, Memorial University of Newfoundland through its School of Continuing Education has had an extensive (and expanding) involvement with distance education. Current annual course registrations are over 11,000. In July 2000, the School conducted a needs assessment of distance support services as part of the initial phase of a project to ascertain: (a) the use of current services by students taking distance delivered courses; and (b) the kinds of services and support structures such students would like to see developed. The results of this assessment, it was anticipated, would then be used to inform the second part of the project. This would involve the development and testing of new and/or improved distance learner support services that appropriately utilise current interactive media technology. The overall intent was to further enhance the delivery of distance programs and courses, provide exemplary services to students regardless of time and location, focus on products that are learner oriented, and to increase student retention and success.

The needs assessment survey involved an extensive phone interview of a random sample of approximately 200 distance students engaged in one of a number of degree programs, but with a primary focus on students who were located in Labrador and/or were completing courses toward a Bachelor of Technology degree. The semi-structured interview included questions pertaining to respondent technological competencies, their access to technology, use and evaluation of current support services, and the kind of resources they considered would be of help to them and to new distance learners.

A profile of study participants reveals that 43% were taking correspondence courses, 23% web-based only courses, and 34% at least one course by each of these methods during the 1999-2000 academic year. Their ages ranged from 19 to 54 years (average 31.7 years), 48.7% were female, 53.6% were single, and 82.9% were working full-time in addition to studying. The number of years that had lapsed between their current program and any prior one ranged from
zero to 29 years, with over 27% saying it was at least 10 years. Over 92% had access to basic internet technology, however the quality of this service was generally considered poor in the remote areas of the Province. In terms of the use of basic computer-based technology (email, word processing, using on-line resources and web searches), 80% felt fairly comfortable. Many though, were less certain about their ability to send or receive files, configure software or take part in on-line forums.

Some Identified Needs

As a group of distance learners, respondents expressed a wide variety of individual needs. Where applicable, these were grouped under common themes for analysis and discussion purposes. The most frequently identified need was for help with time management. This was not surprising given the work and/or family commitments of many respondents. Also it is not an uncommon problem with many other groups of adult learners, and points to an area in which to develop appropriate support services. Other identified needs were more detailed course outlines for program planning and course selection purposes, personal and program counselling, a toll-free help line, continuing education contact information, and improved communication and feedback during courses. Most respondents also indicated that they would make use of CD or on-line resources that addressed such things as research writing skills, library orientation, more advanced internet searching, and preparing for tests; and over half said they would make use of, if made available, on-line services such as a frequently asked questions@ web site, a campus bookstore merchandise catalogue, a peer mentoring system, and a virtual student lounge. It was also apparent that a fair number of respondents needed help simply adjusting to university courses as well as many of the fundamental aspects of "being a learner". A few also expressed feelings of isolation as a student and not being part of the university community. The latter perception was, however, greatly reduced where there was frequent interaction between students and with course professors through, for example, email, chat groups, and on-line forums.

Issues and Challenges in Developing Distance Support Services

Whilst there were commonly identified needs, it is apparent from the survey (and other research in this area) that distance learners represent a diverse group when combinations of personal competencies, life style and geographic circumstance are taken into account. For those with the requisite technological competencies and tele-communications access, the development and provision of quality support services is much less onerous, and enable service providers to make use of a variety of current technologies, typically internet based. For some learners, the development of basic technological competence will almost certainly need to precede engagement in interactive computer and/or web-based services, and could perhaps be embedded into the introductory sections of a university program or course. By contrast, for those students with the competencies, but with, for example, poor internet access, alternate technological solutions for some support services would be appropriate. In particular, CD-ROM based delivery might partly address some of the identified needs of distance learners, especially if such multimedia was interactive, user friendly and adult learner based.

Despite advances in asynchronous communication, most respondents expressed a need for a combination of live (person to person) and on-line forms of communication, depending on the kind of service or help they were seeking. It was also evident that such support mechanisms need to be available at times other than during regular work hours. Ideally, this could involve a central contact source at the university, easily accessible by two or three communications means, who can either deal directly with diverse student issues/problems, or point the student to a source that can help (but not give that student the "run-a-round"). Communication with distance learners can also be enhanced with up-to-date web sites that are appropriately cross-linked, catalogued and referenced within an institution. This would likely reduce the demand for personal communication.

Overall, the results of this needs assessment affirmed the need for a number of existing student services and also revealed a number of new directions to take. Evidence of varying levels of technological competence and availability, as well as diverse student backgrounds and needs, suggest that a "one solution, one approach" perspective is neither appropriate nor advisable. Many of the services that respondents expressed a need for could be made available through the application of appropriate technology. Some of these services might obviously be linked to, or integrated into, existing services; whilst others would require fairly extensive development, especially to meet the needs of a diverse group of distance learners.
Web Sites Usability Evaluation Guidelines for Teachers: A Case of CikguNet On-line Environment

Norshuhada Shiratuddin
Shahizan Hassan,

School of Information Technology, Universiti Utara Malaysia, 06010, Kedah, Malaysia
shuhada@dis.strath.ac.uk
shahizan@mansci.strath.ac.uk

Abstract:
Web usability is one of the important factors that determine the success of a web site of any type, especially web learning environment sites. Teachers, who have the intention of developing on-line teaching materials, must take into consideration the issue of usability not only during the development process but also when the web site is being implemented. This paper describes a usability-testing model, which is then applied to evaluate CikguNet web site. CikguNet (at http://www.cikgu.net.my), is one of the well-known web sites for teachers in Malaysia maintained by a governmental agent MIMOS and is designed as an environment to assist teachers in producing quality teaching and learning materials especially materials that are technology based, for teachers to exchange their educational ideas or materials and serve as a resource centre for academics and teachers. CikguNet proves to exhibit a high usability level with only few usability problems. The usability-testing model proposed in this paper is intended as a guideline for teachers to adopt.

Keywords: web usability, usability criteria, usability model

Introduction
As the number of web sites on various subjects is increasing over times, the issue of web usability has become very important. Publishing a web site is a very easy job to do even by a primary school children, but to produce a usable and useful web site would not be as easy as one would think. Usability is a concept that is related to the design aspects of web pages that not only make sense to people who use them, but also allow users to easily get the information they look for. Usability problems should not be considered as a minor issue as there are many examples of cases to prove that usability problems could affect on-line sales and customer visits to a particular web site (Rowland, 2000; Seminerio, 1998).

Considering these, web designers must take into consideration the issue of usability not only during the development process but also when the web site has been published. This means that designers should regularly evaluate their sites to maintain and improve the level of web usability. To perform the evaluation, however, designers need to measure their site against relevant usability criteria. However, many web design guides differ between each other in terms of coverage and level of technicality. In addition, some of them are too exhaustive and difficult to follow by the non-technical people. With this in mind, this study attempts to propose a model of web usability criteria for teachers who intend to develop a web site for their teaching purposes. This model was tested on CikguNet web site, one of the well-known web sites for teachers in Malaysia.

Methodology
Content analysis method was used to analyse the usability literature such as web design guides, textbooks, and journal articles. Based on the analysis, a total of 40 generic usability criteria were identified as suitable for teachers web sites. These criteria were then grouped into 7 main categories, abbreviated as SCANMIC (Screen Appearance, Content, Accessibility, Navigation, Media Use, Interactivity and Consistency). This model was then tested on the CikguNet web site. The evaluation on CikguNet was done on 22nd November 2000 involving two expert reviewers. In the first stage, the experts spent 1 hour exploring the CikguNet site so that they could get familiar with the site. Then, in the second stage, they reviewed the site for 1 hour by using the listed criteria. During the review, both experts will determine the score (0-5) for each usability
Two Pentium Personal Computers were used, one with Local Area Network Internet access and the other with 33Kbps modem Internet access.

**Web Usability: the SCANMIC Model**

Gathering from various literatures on web design and usability, the researcher has identified 40 generic criteria of web usability. These criteria are then clustered into seven main factors, abbreviated by the researcher as SCANMIC. These factors are as follows:

1. Screen Appearance
2. Accessibility
3. Navigation
4. Media use
5. Interactivity
6. Consistency
7. **Web Site Usability**

![Figure 1: Seven categories of criteria that determine the usability of web sites](image)

### a) Screen Design

Screen Design can be divided into 4 sections: space provision, choice of colour, readability, and scannability (Shirley, 1999; Morkes and Nielsen, 1998). Space provision refers to proper allocation of space for web page elements such as menus, advertisement banners, and content display to help users focusing their attention. Choice of colour, emphasises the need to use proper colour in web page design not only to attract users but also improves learnability and ease of use. Readability concerns with the issue of providing a readable content within web pages. This is not easy to be achieved because reading from a computer screen is different from reading from a paper. Nielsen (1997) argues that users read 25 per cent slower from a computer screen than a paper. Therefore, designers must take into consideration issues of online writing including type of fonts, leading and legibility, page appearance, word and letter spacing, and typographic colour. Apart from readability, designers should also consider the issue of scannability, the concept whereby contents are chunked into smaller parts so that the users could skim rather than read (Morkes and Nielsen, 1998).

The proposed criteria for screen design in this study are shown in table 1 as follows:

<table>
<thead>
<tr>
<th>Criteria</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sharp colour contrast between text and its background</td>
<td></td>
</tr>
<tr>
<td>Use of fonts that are easy to read and commonly used</td>
<td></td>
</tr>
<tr>
<td>Different text sizes to differentiate between titles, headings and texts</td>
<td></td>
</tr>
<tr>
<td>Clear page titles</td>
<td></td>
</tr>
<tr>
<td>Clear headings and sub headings for general text/document</td>
<td></td>
</tr>
<tr>
<td>Short paragraphs (not more than 6 short sentences)</td>
<td></td>
</tr>
<tr>
<td>Use of typography and skimming layout, for example, bold fonts and highlighted words</td>
<td></td>
</tr>
</tbody>
</table>

Table 1: Web criteria for Screen Design

### b) Content

The question of what should be on a web page depends largely on the goals of the web site. Some intend to sell products and service, some offer free entertainment, some provide government information and so on. However, one should bear in mind that providing content in a web page is not as easy as providing a printed page in a book. Yet, a designer should not run away from the basic elements of a document to ensure a web site's usefulness.

There are four basic elements of traditional document design; *who, what, when, and where* (Lynch and Horton, 1999). *Who* here refers to information in a web that tells who the owner is. *What* refers to the question of "what is a web site offering?". This means that users must have some kind of ideas of what to browse when they are at the main page of a web site. The third element, *When*, highlights the need to specify the date a piece of information and a particular web page are published. It also emphasises the issue of currency or timeliness of an information in a web page. Finally, the *Where* element that relates to the
need to inform users on the whereabouts of servers they are browsing from. The criteria for content design use in this study are shown in Table 2 below.

- Language used is suitable for audience
- High quality writing, for example, good grammar and no typographical error.
- Information of authors of articles and other text documents is provided (e.g. names and affiliations)
- References or sources of articles and other text documents are provided
- Background information of the site's publisher (site's owner) is clearly stated i.e. logo, name, address, phone number and email address
- Resource date
- Choices of language for multi-ethnic audience
- Links to other relevant sites (list of schools, education authorities etc)

Table 2: Web criteria for content designs

c) Accessibility
One of the goals of having a web site is to attract visitors as many as possible from various locations. The basic way to achieve this is to ensure that the site is accessible to target users. By the word 'accessible', it means that users would not only be able to get connection to a web site but also able to browse all contents available. The higher the degree of accessibility, the higher the level of usability. There are three elements of accessibility: loading time, browser compatibility, and search facility. Loading time is the time it takes for a network PC to download data and files from a server. Apart from loading time, designers should also consider different browsers used by surfers across the world. Although users might use two popular browsers of Microsoft Internet Explorer and Netscape Navigator, the browsers might differ in terms of their product versions. The proposed criteria for web accessibility are shown in Table 3.

- Acceptable loading time (10 - 20 seconds depending on the contents of the page)
- Compatible contents for all main browsers (e.g. Netscape and Microsoft Explorer)
- Compatible contents between different versions of the same browser

Table 3: Web criteria for accessibility

d) Navigation
Some people believe that the best site contains lots of graphics, animation, and colours. However, not many realise that the basic of an effective web site is its navigability. In her 'Designing Electronic Material' article, Parker (1999) states that good navigation in a Web site is comparable to a good road map. With good navigation, users know where they are, where they've been, and where they can go from their current position. In short, navigation is the key to making the experience enjoyable and efficient. The criteria for navigation are listed in Table 4.

- Main menu/ list of key categories of contents in the main page is provided
- Links to the main page in all sub pages is available
- List of key categories of contents in all sub pages so that users do not have to go back to the main page to browse other pages
- Contents should be grouped into a small number of key categories (not more than seven)
- Small number of steps/ links to arrive at a particular information (not more than 3)
- Accurate/ unbroken links
- Use of sitemap

Table 4: Web criteria for navigation

e) Consistency
There is an element of 'fear of the unknown' when users visit a web site for the first time. Although they might be familiar with the browser and hypertext application environment, the design of a web site is different from others. Some web sites might put the menu bar at the top of screen, while others might use a
horizontal hypertext button at bottom of the screen. Some websites prefer using frames to divide functional areas while others merely use colour boxes. Therefore, there will always be some elements of unfamiliarity on behalf of users when the visit a website for the first time. In considering this, design consistency is important to speed up user's learning. The main criteria used for consistency are shown in Table 5.

- Consistent page layout, for example, screen size for content display, banners, and menu bar.
- Consistent use of text in terms of its type, font size and colour.
- Consistent use of navigational aids, for example, menu bar, buttons and links in terms of graphics metaphor, size and colour.

Table 5: Web criteria for consistency

**Interactivity**

Interactivity is a broad term and can be misleading. However, the researcher is referring to features in a website that facilitate a two-way communication between users and site owners or other pre-assigned personnel. Additionally, the features allow users to give feedback and comments on any issues raised by the website. The introduction of the interactivity features such as email, guestbook, online forms and net conference might enhance a website's worthiness. The key criteria for interactivity are listed in Table 6.

- Availability of features for users' feedback about the site, for example, webmaster's email address and online form.
- Availability of features for sharing ideas and discussions, for example, e-forum, net conference, and net chatting.

Table 6: Website criteria for interactivity

**Media use**

The use of media such as graphics, images, animation and audio in web pages distinguishes it from information presentation on papers. Studies on online electronic materials have shown that the integration of this media keeps users attention and, when used effectively, can enhance usability. However, designers should take extra care when introducing all these elements as improper use of them may distract users and affect usability. Additionally, heavy utilisation of media elements consumes website server's hard disk space and lengthens the downloading time. The main multimedia elements are sound, graphics, images, audio and video (Web Workshop, 1999). The list of criteria for media use are suggested in Table 7.

- Use of continuous/time-based media (audio, animation and video) to suit context, for example, demonstration, instruction, speeches, and songs.
- Alternative access to any information presented through continuous/time-based media (audio, animation and video).
- Use of static media (graphics and images) to enhance the information being presented.
- Non-excessive use of static media (graphics and images) in all pages.
- Use of thumbnails to display photos with the option available to see a large image.
- Information or warnings on file type and size for downloading.

Table 7: Website criteria for media use

**Case study: Usability Evaluation of the CikguNet Web Site**

The proposed SCANMIC evaluation model was used to evaluate the CikguNet website (http://www.cikgu.net.my). CikguNet is a portal site specially developed for teachers by Mimos Ltd., one of semi-government IT-based companies in Malaysia. This site can be considered a one-stop-centre for teachers who are looking for teaching related materials as well as general education news. In addition, this site also provides a platform for teachers to share ideas and discuss on certain important issues pertaining to teaching and education in primary and secondary schools in Malaysia. As a portal site, CikguNet also provides opportunities for teachers to register for free web space, email facilities, web development tools and discussion forum.

In general, it can be said that CikguNet website has a high level of usability with a total score of 71 percent. Three factors; interactivity, screen design, and consistency contribute significantly towards this with 100, 91, and 87 per cent score respectively. This is followed by navigation and accessibility that score
fairly well with 77 and 73 per cent respectively. Two more factors fell below 70 per cent level with 56 per cent score for content and 54 per cent score for media-use, the lowest of all. The summary of the results is presented in table 1 and figure 1 as follows.

Table 8: Summary Results of CikguNet Web Usability Evaluation

Note: each criteria was given a score between 0 to 5 by the experts

From the evaluation, it can be concluded that in general, CikguNet was properly designed and well maintained. The choice of colour for this site is appropriate and suitable for the audience. Similarly, the use of fonts and their sizes, the arrangement of paragraph and the space allocation for text lead to high level of readability. In addition, the level of scannability is also considerably high due to clear titles, headings and sub-heading in each page, the use of short paragraph and effective typography and skimming layout. Apart from this, CikguNet is also easy to be accessed by users who use different type of browsers. The other good aspect about CikguNet is the availability of contact addresses, online forms, online survey and forum facilities that constitute towards a very high level of interactivity. Also worth mentioning is the use of graphics and images that are effective and not too excessive.

Despite its strengths, CikguNet also has some usability problems that might affect its usage. The major problem comes from the screen design structure of the main page that is too long, scattered and could be confusing. From our study, we found that the main page is as long as 6 screen pages and the list of contents are scattered on the left and right-hand side of the screen. To make things worse, the main page is jumbled up with links and advertisement banners. In addition, the news section (Berita Pendidikan CikguNet) is also included in this page with several broken links. Using the lowest modem connection with 33kbps and a pentium 133Mhz personal computer, the main page took about 5 minutes to load, which is too long and unacceptable.

Apart from the main page, this site also has some usability problems affecting the design of the whole site. The major problem is the content design that scores only 56 per cent as shown earlier. The lowest score is caused by several criteria violations such as no authors are stated in the news section (Berita Pendidikan CikguNet), no reference or sources in some articles in several sections, for example, teaching tips section (tip mengajar), no resource date (except news section) and no page revision date. Another aspect of
usability problems that needs improvement in this site is navigation. The low level of navigation was contributed by the poor design of the main page. In addition, there is no site map available for this medium-size site. This study also reveals that Cikgunet has a low level of accessibility for text-only browsers because there is no labels (alt tag) for graphics files.

Discussion and Conclusion
This study reveals that the proposed model could easily be used to evaluate any web sites including the sites used for educational purposes. This is because all the 40 criteria used in this model are generic in nature and therefore they are applicable to all type of web sites. Also worth mentioning is that the usability criteria proposed in our model are designed to be used by both non-technical and technical people. Hence, teachers who are not very good at web publishing can use the model to evaluate their sites. The outcome of the testing shows that CikguNet is highly 'usable' contributed by high level of readability, scannability, consistency, interactivity and accessibility. This study also identified a few major usability problems found in CikguNet that need urgent attention to improve its usability. Nonetheless, this study also has its limitations. First, the content analysis of the usability literature was based on the interpretation and judgement of the researchers. Second, 5 out of the 40 criteria used to evaluate the site are subjective criteria, which means that the interpretation of one reviewer might differ from others. Finally, this study only employed two expert reviewers.

Abstract: Information and Communication Technologies have changed the way we work, the way we live and the way we learn. One of the things that should be updated regarding the new educational context is the tutorship support, that is specially important in a learning environment. In this communication a definition of the educational system of the Information Society for primary and secondary education is proposed, what is called Educational Intranet. Next, it focus on how should the tutorship support be offered by such Educational Intranet. So, this document describes and proposes an original tutorship support system to be incorporated to an educational intranet for primary and secondary education. The tutorship support can be performed face-to-face, that is to say, in real time using a video-conference system (Synchronous Tutorship Support) or it can be carried out by means of a text-based messages or queries electronic mailbox (Asynchronous Tutorship Support).

Introduction

A New Space of Education and Communication is coming, which is driven by the culture of Information and Communication Technologies. Schools should be aware of this change and should set up the new objectives and educational methodologies inside this new context. One of the things that should be
updated, regarding that new educational context, is the tutorship support, that is specially important in a learning environment.

The tutorship support plays an important role in the learning process. This fact is true in each learning context in general, but in some cases, such as rural schools, the tutorship function is specially complicated.

Castilla y León, in Spain, is a rural, vast and sparsely populated region, with a lot of small towns and villages. This fact makes difficult to offer the minimum public services. Regarding education, children in rural areas suffer too many drawbacks: larger distances from home to school, a poorer educational offer, remoteness from other educational and cultural services, such as Universities, libraries, museums and Research and Development Centers. It has to be emphasized the fact that teachers have also a lot of added problems: they have to teach children of different ages, with few resources, ...

The use of Information and Communication Technologies (ICT) at primary and secondary schools could decrease the differences between children from rural and urban areas regarding the access to sources of information and services. Moreover, it introduces teachers and students into the Information Society, contributing also to the development of this New Society.

So, in the last decades, the educational infrastructure in the rural areas of our region has changed from a centralized model into a more distributed model based on what is called the GRS or Gathered Rural School, with classrooms distributed in the area of the GRS and some centralized services. The newest element incorporated to this model is the Rural Center of Educational Innovation, where students stay for a long period of time and study some especial matters such as Technology, Music or Art.

The fact is that the tutorship support in the GRS model plays an important and critical role and it must be considered from the perspective of the possibilities of ICT.

So, this document is referred to the use of ICT as a support to the learning process, that is to say, an instrument for teaching and learning, in contrast to the use of ICTs as a subject or as an aspect (Plomp et al. 1997). ICT must be an instrument integrated into the educational process: it is not a substitute for either the teacher or for any other educational tools. Moreover, since technology will actively change the learning process and the pedagogical relationships, ICT should be considered as an important point in the foundation of the learning environment, as the learning theory and the social organization of learning (Pulkkinen, 1999).

In this paper the authors describe their vision about how should the tutorship support be offered by an Educational Intranet for primary and secondary education, which concept is defined below.

**Educational Intranet**

Our concept for Educational Intranet is related to an education strongly based on the use of computers. It consists in the fact that students use computers and the Internet (together with some traditional tools) as the cornerstone of their education.

This model is based on the fact that knowledge requires learning by experience, so students should take a more active role in the learning process.

The teaching methods and learning processes are very different from the traditional ones: the traditional curriculum-based education evolves an education based on objectives, guided auto-learning, active learning and cooperative work. It involves a complete change in organization of contents, learning process and pedagogical aspects.

The Educational Intranet defines what we think the educational system of the Information Society should be: a new way of learning, a change in the students and teacher’s roles. One of the main advantages of Educational Intranet is that it facilitates a collaborative learning versus the traditional and more competitive one. At traditional schools students were motivated by competition. At new schools, the schools of the Information Society, this objective should be reached by cooperation.

Cooperative learning has a lot of advantages, for example, it increases the motivation and the productivity and it is a good training for future professional team works (Mühlhäuser, 1995). When students work in small groups, school time and space are better employed. Teachers can dedicate more time to the least advanced groups or work on different subjects with each group, according to the students’ necessities. These strategies are efficient and proven against school failure. Consequently, a more efficient and less expensive learning process can be achieved, due to a decrease in school failure.
Therefore, the Educational Intranet can be defined as a new educational system, where computers, networks, multimedia materials and telecommunication services are basic tools and where new learning methods are used. These new methods are based on guided auto-learning, active learning and collaborative learning.

The Educational Intranet should be based in an Educational Server that offers some distance services:
- Construction of communities around some matters.
- Communication among teachers and students.
- Control of work streams in the educational area: homework, revisions and tests.

This document deals with the tutorship support as a specially important way of communication between the student and his/her teachers. We will describe how the tutorship system should be implemented in an Educational server and we will show an example of pilot project.

The Tutorship Support System

The tutorship support system we propose for an Educational Intranet is based on the tutorship system implemented by the authors in the pilot project Internet for Schools (see Rodriguez et al. 1998): this pilot consists in different Internet-based services for teachers and students of primary and secondary education. Some of those services are electronic tutorship support and communication among different scholar centers.

The objective of our electronic tutorship system is to put students in touch with teachers of different subjects. Students can ask questions to teachers and obtain answers from them.

Therefore, it is necessary that different teachers from different schools participate as electronic tutors for one or several subjects, in a way that students can communicate with each of them.

The tutorship support can be performed face-to-face, that is to say, in real time using a video-conference system. That is what we call Synchronous Tutorship Support. Or it can be carried out by means of a text-based messages or queries electronic mailbox: Asynchronous Tutorship Support. Both types of electronic tutorship support are being implemented together in a new educational server.

![Figure 1: A tutor accessing to the queries about Language introduced by several students. All questions have been answered by other teachers and the tutor could see the answers or introduce a new one.](image)

Figure 1: A tutor accessing to the queries about Language introduced by several students. All questions have been answered by other teachers and the tutor could see the answers or introduce a new one.
The Asynchronous Tutorship Support

Asynchronous communication provides freedom from the constraints of time and place and it involves more reflective thinking (Pulkkinen, 1999), so it is a powerful aid for the tutorship support in an open learning environment.

The Asynchronous Tutorship Support proposed makes use of a text-based messages electronic mailbox. In order to facilitate and make more flexible the work of teachers and also enrich the tutorship support process itself, the system works as described below: a student send a query to the electronic mailbox established for a certain subject. All teachers that have been subscribed for that subject can deal with the query, introduce his/her answer and access to the answers introduced by other teachers. That is, it is possible for a student to obtain more than one answer to a query. This system was implemented and tested in the pilot project Internet at Schools (Fig. 1 and Fig. 2).

![Figure 2: A student accessing to the answer to one of his or her questions. The student can see data about the tutor who dealt with the query (including a photography) and communicate directly with him by e-mail.](image)

The Synchronous Tutorship Support

The Synchronous Tutorship Support proposed is based in a desktop video-conference system. The video contact provides a human face and dimension to the distance communication, which is so important in an educational environment (Wright & Cordeaux, 1999).

The system proposed works like a web call center. More than one teacher can be available to contact with. A student will be able to select the teacher who he wants to communicate with using video-conferencing, from all of them being on-line. The communication will be established on a peer-to-peer basis between the student and the selected tutor (Fig. 3).

Students can always make use of other communication tools, also synchronous or asynchronous, like text conferencing, e-mail or the asynchronous messages electronic mailbox.

Conclusions
This document describes an original tutorship support system to be incorporated to an educational intranet for primary and secondary education. The combination of a synchronous and an asynchronous tool provides accessibility and flexibility to the distance learning environment. Both of them involves a group of tutors which students could communicate with, the first one by means of a desktop video-conference system and the second one by a text-based messages electronic mailbox. This asynchronous part of this system has been used before in a pilot project, and has been demonstrated to be a completely new and efficient method of tutorship support.

That model of tutorship support and its practical implementation have been included in the curriculum of a doctoral course at the Faculty of Pedagogy of the University of Salamanca (in Spain).

Abstract: This paper describes a web-based Active Server Page (ASP) Tutorial that provides an interactive online guide for ASP programming. The application was created using a variety of technologies including ASP and Macromedia Flash to implement the interactive segments of the tutorial. All the sample codes written in ASP can be demonstrated online. Flash movies are used to provide online, side-by-side ASP code interpretation. This site is intended to provide an easy-to-follow, step-by-step tutorial for inexperienced ASP programmers. The ASP Tutorial introduces ASP syntax and the basics of ASP programming. Using an interactive style, this tutorial provides fully commented easy to follow examples, programming techniques, and quizzes. Both linear and random navigation are provided on every page so the user can easily find topics of interest.

Introduction

The ASP Programming Tutorial (http://138.87.169.64:2012/index.htm) was developed to provide an interactive online guide for Active Server Page programming. The target users include undergraduate and graduate students who are interested in ASP programming. However, anyone interested in learning ASP could benefit from this tutorial application. For years, faculty members have relied on textbooks and assignments to cover and drill programming language specific concepts and syntax. However, some of the difficulties faced by the students in grasping these concepts are the limited scope of the assignments and the lack of opportune feedback. In order to strengthen students’ understanding of these concepts and syntax, they need to have more immediate feedback when solving assignments than traditional textbooks and teaching methods can provide.

In order to provide students with a different type of learning environment, it was decided to develop a supplemental tool for teaching ASP scripting. Providing students easy and convenient access to the information both at school and at their place of residence was also an objective of the project. To meet these objectives, a web-based tutorial was designed and implemented using HTML, ASP, and Macromedia Flash.
Active Server Page (ASP) is one of Microsoft's Web server application development technologies. Web developers can use ASP technology to dynamically generate browser-neutral content using server-side scripting. An ASP file is usually an HTML file that includes one or more scripts (small embedded programs) that are processed on a web server before the page is sent to the user. The ASP code can be written in a number of scripting languages including JavaScript, JScript, VB script and Perl (Practical Extraction and Report Language). However, the default scripting language for ASP is VBScript.

Contents of the Tutorial

ASP Programming Tutorial consists of primarily textual content explaining the basics of ASP programming. Some of the topics covered in the tutorial include:

- What is ASP -- Definition, servers supporting ASP
- Client/server -- N-tier model
- Scripting -- Scripting vs. programming, compiled vs. interpreted.
- Why ASP -- Advantages, characteristics
- Structure of an ASP application
- ASP Objects and Server Variables
- User Interaction (HTML forms)
- Web Database Connectivity
- ODBC and DSN System
- ActiveX Data Object Connection
- Cookies and Session Control
- Interactive Examples
- Interactive Quizzes

The ASP Programming Tutorial is divided into the following 5 major topics: What is ASP, Getting Started, User Interaction, Session Control, and Web Database Connectivity. A consistent organizational template is used to structure each topic so that people taking the tutorial quickly become familiar with the procedure followed in the tutorial. First, the user is presented with a coherent, progressive set of lessons that cover the current topic. The lessons are followed by an interactive programming example that elucidates the concepts covered. And finally, an interactive quiz is provided for self-testing.

The lessons are normally text-based presentations of the topics. However, when appropriate, Flash movies are included to help the user visualize the concepts being presented. For example, the client/server architecture lesson includes a movie. This movie steps through the interaction between client and server using animation and voice over narration. See Figure 1.

![Figure 1: Client/Server Interaction Movie Implemented in Macromedia Flash](image)

3287
The interactive programming examples have been implemented using Macromedia Flash. These program examples illustrate ASP code structure, user interaction, server variables, session control, cookies, and web database connectivity. Each of these programs introduces ASP syntax via meaningful examples that are explained in detail when interacting with the program. The event of a user placing the mouse over a section of code triggers the display of a window which explains that code segment. In addition, all of the examples can be downloaded and executed upon request. Figure 2 is a screen capture of one of the example programs with added explanatory labels.

Figure 2: An Interactive Programming Example Implemented in Macromedia Flash

Both linear and random navigation are provided on every page so users can easily find topics of interest. Figure 3 shows the typical screen layout and navigation options. At the left of the screen a navigation panel shows the major sections of the tutorial and highlights the user's current location within the tutorial. Using this panel, the user can navigate the tutorial in a non-linear or random fashion by selecting the topic he/she wants to visit. Linear navigation has been implemented by traditional arrow icons pointing left and right for previous page and next page navigation within the tutorial. Additionally, a horizontal menu bar listing commonly used utilities, such as a glossary of terms, site map, and links to relevant ASP sites, is included at the top right most corner of the screen.

BEST COPY AVAILABLE
Active Server Pages (ASP) is one of the Microsoft's Web server application development technologies. An ASP file is usually an HTML file which includes one or more scripts (small embedded programs) that are processed on a Microsoft Web server before the page is sent to the user. Web developers can design web applications that interact with the users by using ASP.

ASP is primarily a server-side scripting technology. The users on the client side do not have access to the actual scripts that implementing

Figure 3: Screen Layout and Navigation Options of the Tutorial

The utilities referenced in the menu bar provide an effective way for the user to interact with the web-based tutorial. For example a full-text search function is available to the user for finding available references within the site. An interactive site map utility allows users to visualize the content and provide hyperlinks to any of its sections. Figure 4 shows the graphical site map.

Figure 4: Tutorial Site Map
The glossary function for this site contains a navigation panel with a tree-like structure where the user can select the term he/she wants defined. See Figure 5.

**Figure 5: Glossary of Terms**

Conclusions

There are numerous books available that cover these ASP Programming topics thoroughly. However, books have their limitations in a learning environment. For example, they are static by nature. Though they may be able to explain concepts in great detail, they still do not present students with an opportunity to study and learn concepts in an interactive fashion. Actually using or applying the concepts helps students improve their understanding of the subject matter. This limitation of textbooks can be effectively rectified by using interactive instructional multimedia technology like the web-based tutorial presented in this paper. Another advantage of this type of application is that students can effectively interact with a web-based tutorial anytime and anywhere when connected to the Internet.

Abstract: South Africa is on the threshold of drastic changes in the field of education. The ideal is to move away from the stereotyped teaching methods and passive learning to a learner-centered approach. This is linked to efforts to address inequalities in education and to overcome historical disadvantages. One of the major stumbling-blocks, however, is the relatively underqualified teacher corps and the massive undertaking of the retraining of ten thousands of teachers - many of them in remote areas, far from the larger training centers. A lack of basic infrastructures further complicates the situation. The major issues addressed in this paper concern the availability of the necessary infrastructure and technology for the delivery of effective learning opportunities, and the nature of several innovative projects inclined to create learning communities of educators and learners that use Information and Communication Technologies (ICTs) to enhance education.

Orientation

South Africa is on the threshold of drastic changes in the field of education. The outcomes-based education (OBE) model, Curriculum 2005, is in the process of being implemented in South African schools. The ideal is to move away from the stereotyped teaching methods and passive learning to a learner-centered approach according to which the pupil is actively engaged in constructing his/her own knowledge and comprehension. This ideal is linked to efforts to address inequalities in education and to overcome historical disadvantages.

Other important initiatives are currently being launched in the country. As far as technology in education is concerned, an example is a ministerial investigation into technology-enhanced learning [Technology Enhanced Learning Investigation (TELI) 1996] which has synchronized with the development of Curriculum 2005 since 1995. Special emphasis is placed on the role of technology and other resources in the process of reconstruction: "...old and new technologies have the potential to help tackle critical problems of access, redress, flexibility, and relevance" (TELI 1996 p.7).

One of the major stumbling-blocks in the process of change, however, is the relatively underqualified teacher corps and the massive undertaking of the retraining of tens of thousands of teachers in the OBE mode of thinking, as well as the upgrading of their qualifications to the accepted standard of a four-year tertiary qualification. Many of these teachers find themselves in remote areas, far from the larger training centers. A lack of basic infrastructures such as electricity, telephones and adequate transport facilities further complicates the situation. The nature and extent of these problems were clearly revealed in several national surveys like the National Teacher Audit (Hofmeyr & Hall 1996), the School Register Needs Survey of 1996/97 with regular updates [Research Institute for Education Planning (RIEP) 1997], and the Science/Mathematics Teacher Survey undertaken by EduSource (1997).

But can the introduction of computer technology in any way promote the process of change? Is it realistic to consider on-line education as a mode of tuition when principles such as cost-effectiveness and equal opportunities for all are at stake? What about the availability of the necessary infrastructure and technology for...
the delivery of effective learning opportunities, i.e. the issue of access? And what is being done to bring teachers and learners in contact with the new on-line world of information?

The Issue of Access

For many countries, and particularly those in the developing world, the lack of network and telecommunication infrastructure is considered the major obstacle to Web-based education. In his set of guiding principles and practices for the design and development of distance education, Ragan (1999 pp.3-4) states as principle that the selection of instructional media and tools should reflect their accessibility to learners. In countries like the United States, quality concerns are more likely to relate to the lack of capacity or band-width within their computer/telecommunications networks. Institutional needs for network and desktop hardware, software, support and training are also considered as major factors in the growth of on-line distance education in the developed world (Broad 1999 p.8).

Like many other developing countries, South Africa is battling with the challenge of harnessing information and communication technologies effectively to accelerate social development. Most debate in this regards tends to center on the extent to which the adoption and use of these technologies can contribute to reducing the massive inequity that exists among and within societies. These debates often tend to reflect a simplistic conviction that Africa will benefit from the development of advanced communication. This type of observation is sometimes tempered with some awareness of the danger that the explosive growth of these technologies may serve to entrench disparity rather than eradicate it [South African Institute for Distance Education (SAIDE) 1999 p.1].

It is important to note that, of the 750 million inhabitants on the African continent, only about 2,85 million are using the Internet on a regular basis - with 1,82 million linking up from South Africa. This is perhaps an encouraging figure, indicating a high level of technological advancement in the country in comparison with the rest of the continent, but it also means that roughly only 6% of the South African population link up regularly. The cost of computer equipment and the lack of basic infrastructures are held as the most important reasons for the relatively slow growth figure of the Internet in South Africa, but it is expected that, in future, cordless Internet (WAP) can play a major role to bring the Web to the masses by means of cell phones and handheld computers (Sake 2000 p.3).

But what about epistemological access? Lelliott, Pendlebury and Enslin (2000) rightfully warn that physical access is not sufficient; at the very least, epistemological access to on-line education requires students and their teachers to become computer literate as well as conventionally literate and numerate - and even more so in the field of teacher education with its very special demands.

These are the challenges. Information communication technologies clearly do have the capacity under appropriate circumstances to reach large numbers of learners through a few well-qualified tutors using materials developed by specialists. It does not ask for an Internet connection to each household, because a properly equipped learning center within walking or cycling distance from every household, no matter how remote, can serve a similar purpose. We must also remember that, at present, the prerequisite of access can be met by very few countries, even in the world.

Availability of Infrastructure and Technology

When the realities of the South African education are regarded, the picture for a possible technology-enhanced approach in education does not appear bright at all. The picture becomes even bleaker when the possibility of on-line education is considered. In the first place one must realise that South Africa has a very big and extensive education system which is governed by a National Department and nine provincial education departments. In 1999 there were approximately 12.3 million learners in South African schools, attending 29 386 schools with just over 375 000 educators. [Department of Education (DoE) 2000]. The majority of these learners (more that 80%) can be considered as from developing communities.

The School Register of Needs Survey (first conducted in 1996/97 by a consortium of research-based institutions) provides a comprehensive database of the physical facilities, equipment, resources and services available at almost 28 000 primary and secondary schools in the country. It was, for example, found that more than half of the schools lack basic administrative equipment like typewriters and computers. A shortage of
more than 57 000 classrooms nationally was reported, while learner laboratories in secondary schools showed acute shortages (RIEP1997; The Teacher September 1997). Fewer than half of the schools (43%) nationally had an electricity supply. With the exception of the Northern Cape, Western Cape and Gauteng, most schools had no telephone lines. In the Free State it was found that only 25% of the more than 2900 schools had a telephone; duplicating facilities were only available at 17% of the schools; with a 19% availability of overhead projectors, 11% video recorders; and 6% computers (RIEP1997). All this information indisputably indicates only a limited applicability of the ideals of technology-enhancement in education. "What this means is that in a world increasingly wired up and becoming a global village because of advanced technology...there are thousands of schools and millions of South African children who are getting left behind in this information era simply because they cannot be reached" (The Teacher September 1997 p.3).

The School Register of Needs is regularly updated. The most recent data for the Free State province (made available by the Free State Department of Education) shows some improvements in electricity supply, telephones and also in the availability of computers at schools. In 2000, 83% of the schools now have an electricity supply. Telephones are available at 43% of the schools, with mostly rural and farm schools who are missing out in this regard. Just over 5 100 computers are in use in 600 of the schools (24%). This still means that 76% of all schools in the province (1334 rural and 600 other) are still without a single computer! Furthermore, an analysis of the designation of the 5 100 computers shows that most of these computers reside in well-equipped laboratories in schools in wealthy urban and semi-urban communities. These laboratories were mostly established by school governing bodies who used their private school funds for this purpose. Roughly 150 of the schools with computers are linked up and has Internet and/or E-mail facilities to facilitate communication with the provincial department of education. About 15 schools also have their own Web-sites.

The above statistics highlight the major inequalities that still exist among schools in different communities in this province, and it can be accepted that the pattern will not differ much throughout the country.

During interviews with officials of the Free State Department of Education, several of them clearly stated that computers and computer education are not priorities at this stage. This viewpoint can be understood when it is taken into consideration that education in the province suffers from a shortage of funding and that there is still a battle to erase the effects of the unequal distribution of money in the apartheid era. According to the TELI report, inequalities have to do with many aspects, inter alia, the poor physical infrastructure in many areas, poor communication, insufficient provision of library services and other resources, poor training facilities, people who are not yet ready for high technology strategies, and a lack of a supportive learning environment for pedagogical and professional development. The fear is therefore expressed that the introduction of technology will further broaden the gap between the urban and the rural areas (TELI 1996 pp.34-36). There are, however, also other views. Other officials, however, feel that all learners and teachers have a right to be introduced to the new technologies and the new world of information yet unknown to them. In accordance with the views of Carl (1995 pp.2-3), they believe that technology can be the bridge to equality for all and that advanced technology can make a "quantum leap" possible.

When it comes to higher education in South Africa, research shows that most students in the formerly disadvantaged communities do not have access to basic technologies such as the telephone and audio recorders. Beneke (1998) reports on the availability of technology to students studying through Vista University Distance Education Campus (more than 60% in teacher education programs), as determined in successive surveys undertaken in 1989, 1994 and 1998 (see Tab. 1). He shows that limited numbers of students had access to computers and, with a mere 20 - 40% accessibility to telephones, it is quite obvious that online education, for example, would not have been possible for most of these respondents.

Table 1: % availability of technology to Vista University distance education students in 1989, 1994 and 1998.

In accordance with the research of Beneke, the authors conducted a survey among three groups of students at the Free State Technikon and Vista University. Group A represents 47 second-year students in the
IT department and Group B 150 first-year students in a Computer Literacy class in the Faculty of Management at the Technikon Free State. Group C represents 43 final year teacher education students at the Bloemfontein campus of Vista University (see Tab. 2). All the students are from formerly disadvantaged communities. Although the high accessibility figure to electricity (93%+) looks encouraging, a situation like this is unthinkable of in a developed country, namely that more than 60% of a group of students in a second-year computer science course and more than 90% final year teacher education students did not have access to a personal computer. The 10% and lower linkage to Internet and E-mail respectively, indicates that on-line education is at present just a far-off dream to these three groups of students. This is despite the fact that all these students are basically computer literate, because all students in non-computer science courses have to follow a one-year computer literacy course at their institutions.

Table 1: % availability of technology to students at Technikon Free State and Vista University

In further surveys undertaken by the authors, teacher education students and practicing teachers were asked for their views on the possibility of INSET and PRESET programs offered at a distance by means of Internet/E-mail. Most students reacted positively to the possibility of on-line education, but great concern was expressed regarding the inaccessibility to computer equipment and the cost involved. Another great concern involves the lack of an "ever-present" lecturer as well as a possible lack of contact with other students. The important aspect of the technological literacy of tutors as well as students was also mentioned. A fundamental principle was touched upon by one respondent who wrote: "All people must be given a chance to know more, also about computers". This remark again highlights the burning issue of equal opportunities to all in a country where such great disparities between the richer and the poorer still exist.

But what is the solution? Nobody really knows. In South Africa the problem is addressed by means of deliberate efforts by tertiary institutions, industry, the private sector, the national and provincial governments, international agencies and others to make money available and introduce innovative projects that may break this vicious circle of ever-increasing disparity.

Projects and Other Initiatives in Progress
National level

SchoolNet SA (at www.school.ac.za) is the most important national organization that has to be mentioned. It is linked to the National Department of Education in the country and organizes and coordinates on-line activities on school level or, in its own words: "... an organisation formed to create Learning Communities of Educators and Learners that use Information and Communication Technologies (ICTs) to enhance education" (www.school.za/about.htm). It has core funding from the International Development Research Centre (IDRC) - a Canadian donor organisation - and Open Society Foundation for SA, with project funding from the World Bank Institute and a range of corporate partners. SchoolNet SA is currently involved in initiatives and projects such as the national Minister of Education's Tirisano Project, the Telkom 1000 Schools Internet Project, the Thintana i-learn Project, the Nortel Phumelela Networks Project, and several others.
Special mention needs to be made of the Thintana i-Learn Project. It is funded by Thintana, a consortium of the national communications network, Telkom, and its strategic equity partners - SBC International and Telkom Malaysia. The consortium provided R21.2 million ($3M) to set up computer centers in 200 disadvantaged secondary schools equally distributed in all the nine provinces and to train a minimum of ten educators per school. Each of these schools will receive between ten and twenty networked computers with Internet connectivity. This project will be implemented over a two-year period. The strength of the project has attracted the partnership of the world-wide computing software leader, Microsoft, funding the cost of software to the value of R5.9 million ($0.75M). The project, which will be managed by SchoolNet SA, forms part of Thintana's commitment to invest R120 million ($15.5M) from 1997 to 2002 on a series of educational programs that will improve technology learning and bring future generations to a knowledge-based society.

Free State Initiatives

The Department of Education in the Free State province is also involved in several projects to provide schools in developing communities with computers and get them linked up. In 2000 the national telecommunications company, TELKOM, provided 133 schools with a computer and provided some training to a few teachers at each of these schools as part of its national Telkom 1000 Schools Internet Project. The idea was to get each school connected via E-mail and the Internet. In 2001 further training of teachers will be undertaken by SchoolNet SA through 28 so-called TELKOM Super Centers. Many of the farm schools in the province still lack essential facilities like electricity and telephones. In the eastern part of the Free State (near the Lesotho border) private companies are planning to get rural schools connected via satellite communication. In one remote area an innovative project is even using solar energy to get computers and the Internet going!

From the side of universities, colleges and technikons in the Free State, the possibilities of on-line education in reaching students in remote areas are slowly being exploited. Several on-line programs have been implemented or are in the process of implementation - with the Technikon Free State (at http://eswot.tofs.ac.za) that has taken the lead in this regard. Other innovative projects between institutions and schools are opening the new world of ICTs to teachers and learners in these schools. Two of them are briefly discussed:

The Thutamahlale Upliftment Project at Vista University in Bloemfontein forms part of the South African Science Education Network (SASEN), a project sponsored by the Flemish government. Four South African Universities and the University of Leuven in Antwerpen, Belgium, are the partners in the project. The purpose is to develop interest and enthusiasm, as well as to provide teachers with teaching strategies and computer literacy skills they can apply in the context of the outcomes-based Curriculum 2005 in Grade 7-8 classrooms. The project is aimed at establishing science, technology and computer laboratories on the university campus, and at presenting workshops to 90 teachers and providing 32 teachers with computer literacy skills. The SASEN computer laboratory was completed during 2000 and the computer literacy part of the project could be implemented. The participating teachers are now attending workshops one afternoon per week and they already received training in basic computer skills and application software. The progress of the teachers is carefully monitored. The challenge, however, is to assist these teachers in utilizing their newly-found skills effectively in environments where one computer has to serve a school with more than a 1000 learners!

With the aim of playing an active role in the community and in support of the National Education Department's Tirisano Project 2000-2004, the Technikon Free State (TFS) launched its TFS/Lereko Adopt-a-School program in September 2000. In the first phase of the program, the emphasis has been on the professional and personal growth of Lereko's teachers, with computer literacy as one of the main objectives. The TFS equipped a computer laboratory with Internet facilities at the school, and is now providing training to the teachers. The Department of Information Technology at the TFS handles the IT component of the program. It will carefully monitor the progress of the teachers over the next twelve months and will adapt its training to the teachers' needs.

Concluding thoughts

This discussion has provided a rather bleak picture of the possible large-scale introduction of computer technology and on-line education in South African schools and institutions of higher education.
access - informed by a lack of funding, the high cost of technology and the unavailability of basic infrastructures - seems to be the major stumbling-block in this regard. And if the possibility of on-line teacher education is considered as a viable option for INSET and PRESET purposes in South Africa, the issue of access (including epistemological access) clearly constitutes a major challenge. With the rapid growth in the use of the information communication technologies in the more advanced section of the South African community, fears that the gap of inequality in this regard is rapidly widening, need to be addressed. Projects to counteract this vicious trend need to be supported. More funding, also from international donor communities, need to be attracted. The country's progress can only be served if educators are open to innovation and change and willing to tackle all the challenges, including the issue of access, in a creative and innovative way. As far as the aspect of equality is concerned, it is appropriate for all those concerned with education in South Africa to pay attention to the warning words of Apple (1992 p.86): "... The new technology is here. It will not go away. Our task as educators is to make sure when it enters the classroom it is there for politically, economically, and educationally wise reasons... We should be very clear about whether or not the future it promises our students is real and not fictitious. We need to be certain that it is a future all of our students can share in, not just a select few".

References

Educational Technology is not an oxymoron, and yet there is a continuing struggle to find the blend between education and technology. Perhaps part of this struggle occurs because research over the past half a century continues to modify the conceptions of how teachers teach and how learners learn. At the same time, technology has changed and expanded in ways beyond expectation. The development of technology has altered society, creating new cultures and shifting individual perceptions of the world. Technology has influenced language by providing new words and phrases or new meanings to old words and phrases, for example, hardware, software, and multi-tasking. The message delineated from the articles presented in this section indicate that as education shifts with the advancing technologies, the theoretical constructs of teaching, learning, and evaluation must continue to guide this process.

There are twelve articles that are referred to in this introduction. These articles can roughly be placed in the categories of a) ethics, b) paradigm shifts, and c) lessons learned from the implementation of education and technology. All of the articles provide thoughtful considerations for educators as they continue to grapple with the integration of technology and education.

Banister’s article, “IT with integrity” speaks to the fundamental issues regarding the ethical use of technology in education. Instructional technology provides an abundance of opportunities but certainly can be misused. Teachers have a greater understanding of the needs of their students and the promotion of appropriate classroom environments than does the corporate world, therefore, Banister believes that teachers must be at the forefront in ensuring that technology is implemented with integrity. For example, teachers should be involved in the design and choice of software rather than just using what is available thus depending on the persons who may profit from the use of software. Cassidy’s article, “Historical perspectives on teachers, technology, and American public education” complements Banister’s article by stressing that educators should develop a sophisticated sense of how to integrate technologies. Cassidy provides an historical perspective to relay the message that theories of curriculum and pedagogy have influenced the complex process of technology integration more successfully than social, political, and economic interests. Educators in the present can learn from the lessons of the past as they implement new communication technologies in the classroom.

The second group of articles concentrates on paradigm shifts that incorporate teaching, learning, and/or evaluation theories to provide new understandings of the integration of education and technology. The authors of each of the articles convey concepts related to the continuing effort to enhance communication and learning through the blending of education and technology.

Barner-Rasmussen’s article, “Designing tasks for networked technologies using intentional acts” merges the taxonomies of interactivity and communicative events to provide a model for designing tasks related to online courses that foster interaction. The shift to the new taxonomy presents four intentional acts (informative acts, applicative acts, reflexive acts, and evaluative acts) that produce successful interactive communication. The implementation of the new taxonomy should also provide documentation and evaluation of why certain interactions succeed and others fail.

Holmes, Tangeny, FitzGibbon, Savage, and Mehan’s article, “Communal Constructivism” introduces an expanded definition of Vygotsky’s social constructivism that is dynamic and adaptive in trying to understand how to teach and learn effectively with technology. The authors have developed an approach in information technology that they call ‘communal constructivism’ that assists students to construct their own knowledge as well as knowledge for others. They use a river analogy to depict this type of learning. Parton’s article, “IT practice from theory” also draws upon Vygotsky to present a paradigm shift beyond constructivism. Parton uses Vygotsky’s Zone of Proximal Development to show how teaching and
learning can be transformed through the social context of instructional technology. Kayashima’s article, “A tutor’s advice trains a student’s self-regulation skill” presents for tutors a new paradigm of learning also based on situated constructivism as well as Soviet socio-cultural theories and situated cognition. Tutors do not give answers to questions posed by students but instead regulate how knowledge is to be attained by providing advice and modeling of their self-regulation skills. This provides the opportunity for students to develop their own self-regulation skills to gain knowledge.

Thampi and Mantha’s article, “Creation of a new paradigm for the roll of educators through in service training that facilitates innovation and improves the process of imperfectly seeking emerging technology in tandem with the evolving market place” utilizes a case study approach to explain innovations needed for individuals to learn skills to keep pace with emerging new technologies. The authors apply the ABC analysis model in training to enhance the teaching-learning process of new technologies.

Connel’s article, “Applications of knowledge based evaluation in educational technology” presents a paradigm drawn from formal evaluation theory that will improve research and evaluation in a field with an emerging knowledge base. Educational technology is just such an emerging discipline that can benefit from evaluation conducted based on the link between knowledge and justification systems. Lenaghan and Choate’s article, “How do we know whether to plug in or plug out?” provides a paradigm shift for evaluation that departs from Connel’s model by focusing on technology-based activities related to brain-based learning. Drawing upon the theoretical perspectives from brain operations research, Gardner’s Multiple Intelligences, and three types of thinking (Bloom’s Taxonomy, Scriven’s Critical Thinking, and Ouch’s Creative Thinking), Lenaghan and Choate offer a foundation for how to implement and assess teaching and learning with technology.

The next group of articles focuses on lessons learned in the use of technology that can be incorporated in education. Robinson’s article, “Instructional technology: Practical application alignment with theory in student teaching field placement” describes a case study of a buddy system configuration between student teachers and cooperating teachers in order to appropriately integrate technology in the classroom. The findings indicated that time is the greatest obstacle in integrating technology. The lessons learned from this study were that in order to have a successful merging of technology theory with practice, student teachers need preservice training that enhances collaboration, self-directed learning, and coordination of equipment.

Solovieva’s article, “Communication technologies: Post-industrial infrastructure. This model depicts the lessons learned so that humans can find their position in the complex world of technology and the interplay between society and technology. On the other hand, Neto’s article, “Virtual worlds, real minds: An investigation about children, videogames and cognition” investigates the lessons that can be learned from investigating children’s learning processes involved in skill acquisition in video games. This research project provides analyses that indicate how children learn in video games that can be incorporated into educational technology implementation in the classroom.

Ultimately, the articles presented in this introduction have provided a picture of how research and theory related to teaching and learning guide the integration of education and technology. Education will continue to provide answers for the expansion of technology and technology will likewise aid in the development of education. Eventually the struggle to find the blend between education and technology will lessen as the paradigm shift stabilizes.

Dr. Paula Christensen is an Assistant Professor in the College of Education at Northwestern State University of Louisiana. Her areas of expertise in teaching and research are gifted education and counseling. Recently she has developed an online workshop in gifted education for teachers.
In the past three decades, the use of computers in education has continued to grow and develop. With the introduction and expansion of the Internet, K-12 schools, as well as colleges and universities are tapping into the resources of the World Wide Web. "Technology" is the buzz word on the lips of educators across America and few seem to question its appropriateness. There are, however, signs that the manner in which technologies are impacting education is not always as positive as many claim (Olson, 2000; Stroh, 1999). It is time for teachers to critically examine the phenomenon of instructional technology with a commitment to honestly relating the shortcomings and dangers, as well as the benefits. Decisions based on such examination have the potential to focus the use of computers in education more productively (Bromley, 1998).

Areas for consideration include an emphasis on teacher and learner needs, rather than computer system needs, an awareness of environmental consequences of our computer technology habits, and an acknowledgement of the economic factors that drive many of the choices being made today in the educational technology realm.

Analyzing these areas with a keen eye for disparities and inequities and then translating these discoveries into catalysts for action begins to foster an atmosphere of dedication to the process of education, rather than a commitment to increased technology, regardless of consequence. Such work is not easily accomplished and requires a willingness to sometimes question the authorities spreading more propaganda concerning the use of computers in the classroom, than productive advice. To embark upon such a task is pursuing instructional technology with integrity.

There is evidence to suggest that American educational institutions have rushed to include computer applications in their curriculum too quickly, with little evidence to demonstrate that these applications will provide more benefits than drawbacks. We have launched a huge national experiment that in years to come may prove to have been detrimental at many levels, including placing children at risk (Cordes & Miller, 2000). Teachers must take a stand and be vocal about what computers do well in their classrooms, and what they cannot do (Fabos & Young, 1999). Realistically evaluating these functions allows for a more balanced role of technology in the classroom.

Needs of Teachers and Students

Firstly, focusing on teacher and learner needs must be paramount, as technological "solutions" are made available to classrooms. Cuban (Cuban, 1986) examined the use of various technologies offered to classroom teachers since 1920. Historically, technologies such as the motion picture, radio, and television have been heralded by those outside the classroom as being "the answer" to improving the curriculum and transforming the schools. Once the technologies were placed in the schools and promised outcomes did not materialize, teachers were traditionally blamed for resisting the newest educational technology and attacked for not implementing the technology effectively. Cuban offers an alternative to this typical interpretation.

Teachers commit to working in an environment that is filled with complex expectations and multiple restrictions. Over the years, teachers have developed various strategies that effectively allow them to navigate through this environment and accomplish their work - teaching students. Teachers, for the most part, are astute and very capable people who will adjust and adapt outside intrusions to meet their needs and the needs of their students. In his argument, Cuban affirms a belief in the trustworthiness of the teaching profession. If instructional technologies are truly going to improve teaching and learning, then the best process for achieving this improvement will involve harnessing the expertise and the energies of those who are in the classrooms. Their knowledge and skills need to be respected and acknowledged.

Currently, most software is developed and produced with little or no input from classroom teachers. Why is it surprising that much of this software, once purchased, collects dust on classroom shelves? Perhaps if software developers more actively sought to involve teachers in product design and construction, and pursued innovative ways to recruit and compensate these experts, educational software would become a more integral component of classroom instruction.

Teachers can provide additional insights as to how computers in the classroom honestly help or hinder the work of teaching and learning. While dedicated "technophiles" bemoan the use of computer applications in the classroom that provide practice or review of skills introduced in the curriculum, dismissing them as "kill and drill", classroom teachers value some of these programs. Teachers know that students need practice and repetition over quite a long period of time to master certain skills or content, and using the computers to accomplish this, sometimes, mundane necessity is quite helpful. Rather than mocking educators as "out of touch" or "short-sighted",
proponents of informational technologies in schools should cultivate an attitude of understanding and respect in this area.

Many advocates of computer-based education claim that students benefit from this method of instruction by experiencing a greater comprehension of the material being taught. The success of American classrooms has traditionally been measured by standardized tests, so linking technology to increased test scores is an attractive assertion. A multitude of research studies exists to demonstrate technology’s positive effects on achievement (Fabry & Higgs, 1997). Many of these studies are quantitative in nature, operating with both a control group and an experimental group and comparing the educational results through the use of pre- and post-tests. Control groups received instruction through more “traditional” teaching methods (i.e. lecture, textbooks, worksheets), while the experimental groups participated in computer-based instruction. Meta-analyses, consolidating the results of hundreds of these studies, revealed that the average student in the experimental group performed about .3 standard deviations better than the average person in the control group.

Though the amount of research demonstrating technology’s ability to increase student achievement seems compelling, a closer look reveals cause for skepticism. Most of these studies have been short-term and have focused on drill and practice applications. The issues of higher-order thinking skills and influences other than the technology specifically were not addressed. Dillon and Gabbard (1998) report that, after reviewing quantitative studies of hypermedia technology applications, the results were inconclusive. While the use of technology to teach various skills did not cause a decrease in student achievement, most achievement levels were similar to those in the control group (Dillon & Gabbard, 1998). To date, research does not conclusively demonstrate that introducing technology into the classroom environment will measurably impact student achievement and those who are championing the cause of instructional technologies must take care to not overstate the abilities of computer applications to impact this area.

Some longitudinal studies have been done which suggest that improved learning occurs when teachers and students have access to computers whenever needed. The Computers Helping Instruction and Learning Development (CHILD) research done in Florida from 1987 until 1992 revealed statistically significant changes in standardized test scores for all participating grades and schools. The Apple Classrooms of Tomorrow (ACOT) project, from 1985 until 1993, also demonstrated that technology significantly increases the potential for learning (Fabry & Higgs, 1997). However, though both of these studies spanned several years, they also contained elements that could account for the student achievement results, other than computer access. Monies spent to train teachers and provide additional guidance and support in the classrooms, as well as the interest and excitement generated by the addition of so much new equipment into the educational settings of these students, were influences not directly addressed in the research.

Other advocates point to the motivational characteristics of computers in schools. In a review of the Buddy System Project, teachers, students, and parents reported that the computers placed in the students’ homes as a component of the project motivated the children to do homework. “The computers are fun and the children not only don't mind, but often enjoy doing homework.” (Duffy & McMahon, 1992)

The excitement of being allowed to do something apart from the normal school routine, such as work on the computer, can be very motivational for students. The use of multimedia programs or presentations can increase attention and students report that they are more attentive to classroom presentations that incorporate these elements (Yaverbaum, Kulkarni, & Wood, 1997). Using a computer is heralded as a favorite activity of students (Cummins & Sayers, 1995) and teachers are eager to tap into their students’ natural interest in technology (Quesada, 1996). The motivational qualities of multimedia make it the instructional material of choice in many classrooms (Roblyer, Dozier-Henry, & Burnette, 1996).

While the motivational characteristics of technology use are important to educators, we need to consider the appropriateness of the computer being used as a reward for students, a type of recreational or diversional unit. Is this the proper use of technology in educational settings? Also, will computer use still prompt excited reactions among students once the novelty of the technology begins to fade? Experts in the realm of instructional technologies need to openly admit that the motivational characteristics of computer use have been a curiosity since the 1960’s. Early studies by the military in using computers to train personnel noted that automated instruction could elicit “sustained performance from students with little independent motivation for the particular task posed”. (Noble, 1991, p. 124) It is clear that the computer can be a powerful medium for capturing the attention of students, but this characteristic alone can be as dangerous as it is beneficial. To truly promote the use of instructional technology in an honest way, we must be willing to caution teachers to not always equate student interest in the computer with an improvement in instruction.

Since schools are expected to increase the amount of information available to and understood by students, it is not surprising that technologies that promise to deliver a broader base of available information would be attractive
to schools. Public school libraries have been renamed “media centers” and card catalogs have been replaced by databases. The fastest growing budget in the list of school technology expenditures is telecommunications, increasing thirty-three percent in the 1997/1998 school year to $266 million (Felix, 1999). Interest in assuring that students and teachers have access to the legion of informational resources available through internet connections is high among government, business, and community leaders. Thirty-five percent of our schools had some sort of Internet access in 1994, growing to ninety percent by 1998 (Becker, 1999).

Statistics continue to provide evidence of continued additions of hardware and software to U.S. classrooms, but “an account of technology in terms of circuits and processors alone is sorely lacking” (Garner & Gillingham, 1996). A closer look at the distribution of Internet resources in schools reveals grave disparities. American school districts in affluent areas with a high tax base also are equipped with high-speed modems and the newest computers. Most inner-city and rural districts are not so fortunate. Even with additional government grant monies and the recently added “E-rate” provisions, most poor and minority populations in the United States had no internet access in their classrooms in 1999 (Burns, 2000). In order to pursue informational technology with integrity we must admit the disparities that exist in our nation and around the world when the issues of access are considered.

Finally, it is hard to argue against giving students access to more information relevant to their interests or the curriculum they are expected to master. Educators committed to promoting the process of inquiry welcome resources for students to explore. However, unlimited access to everything available on the World Wide Web is another unrealistic vision for our schools. Providing access to multiple sources of information without screening inappropriate material or guiding students’ evaluative processes to determine what information is useful or applicable to specific areas of study, is counterproductive. Very little empirical evidence exists linking Internet access to student learning and researchers are being asked to help fill the gap in this area. Again, accessing information alone, may not be a sufficient reason for investing in educational technology.

Besides the interest in increased achievement, motivation, and information accessibility, computers in the classroom are being promoted as tools of collaboration and communication with those beyond the walls of the school building. Students and teachers are being encouraged to exchange ideas, work on projects and develop relationships with those who are accessible through the technologies of email and the internet. Barab and Duffy (1998) discuss the benefits of developing these “communities of practice” and cite several examples of schools demonstrating this type of development.

Judi Harris (Harris, 1998) has devised a category structure based on the kinds of classroom activities which utilize telecollaboration. She outlines three broad areas of telecommunications activities which she entitles interpersonal exchange, and information collection and analysis and problem solving. Within these broad categories she groups eighteen types of activities used by teachers and students to incorporate internet resources into the classroom curriculum.

The National Geographic Kids Network is a telecommunications project that involves students in geographically dispersed classrooms working through real research processes in their communities and sharing their results over the network. Scientists review the data collected and organized by the teams of students, and participate in the conversations over the network by giving their interpretation of the data. This program is only one example of the type of communication and community of practice that can be nurtured through the use of technologies in the classroom.

However, teachers must also help students recognize the limitations of telecommunications. Much of what happens over the networks is a metaphor – we chat without speaking, smile without grinning, and hug without touching. While e-mail does have conversational qualities, it also possesses limitations, and those limitations are magnified when communicating with people from different cultural backgrounds. It is interesting to note that, even after months of online communications between the students of Joliet, Illinois and Tununak, Alaska, the Joliet students still held stereotypes about the Eskimo children, which were shaken loose only after viewing video tapes of the Yup’ik (Fabos & Young, 1999).

While computers offer a valuable way for students to share their ideas and thoughts with others, a few drawbacks should be considered. Communication is necessarily limited to those who are economically advantaged enough to possess the technologies required to make the exchange possible. Postal services and telephones are available to a greater percentage of potential collaborators, and some projects may be limited, if only those with internet access are included. Also, not everyone willing to collaborate may be capable of offering valuable feedback to the project at hand. Care must be taken to monitor projects to insure productive and meaningful work.

If those of us who are convinced of the value of using computers in the classroom can communicate with teachers in a respectful manner, freely admitting that the use of instructional technology has limitations, we might be able to begin to develop productive collaborative efforts. Efforts that help instructional technologies to become a
more vital, rather than peripheral, part of the classroom work of teaching and learning. Focusing on the needs of teachers and students can help to accomplish this goal.

In order to be advocates of computers in the classroom from an ethical perspective, we need to admit that computers cannot meet all the needs of students. In fact, it is possible that channeling so much money into placing computer hardware and software and Internet connections into classrooms is harming students, by depriving them of resources that they need far more. Money invested in nutrition programs, health care, high-quality child care, and early childhood education for low-income families could perhaps yield better results in the area of academic success than placing more computers in a classroom. Students also need more opportunities and resources provided through the updating of the traditional school library, and expansion of art, music and foreign language curricula.

Teachers, for example, continue to call for smaller class sizes so they can give their most challenging and disadvantaged students the personal attention they deserve. They ask for more human resources of all kinds — more aides and volunteer mentors, more tutors in reading and other subjects, more social workers and counselors, to help meet children’s emotional and remedial needs. (Cordes & Miller, 2000, p. 87)

Environmental Consequences

Considering the environmental consequences of the choices we make concerning educational technologies is also necessary. A constant upgrading of hardware leaves countless “outdated” machines filling up landfills across the country. Is it possible that the needs of the classroom can be met with computers that don’t always have the fastest processor and maximum memory? Or can more pressure be placed on manufacturers to produce units that can be upgraded internally, eliminating the cost and waste of replacing hardware in 2 or 3 years? A sensitivity to the tax base that is supporting public education, also would demand that we evaluate the monies spent in this area.

It is impossible to purchase a new computer or piece of software without an updated, better, faster, more powerful, more versatile product not just about to be marketed. Our ability to continually produce these improved high-tech products may be overpowering our ability to discriminate what is truly needed in the classroom, and how the constant practice of upgrading can sabotage instruction, as well as the environment. I faced an example of this dilemma in my own teaching last year.

Being an elementary music teacher at an inner-city school, I have limited financial resources available for equipment purchases. When the computer monitor on one of my classroom machines went out, the corporation technology staff suggested I go “slumming” and look over the equipment that had been discarded by other teachers. I was told that most of this hardware still worked, it had just been replaced by newer equipment and schools didn’t have space for all of it. I was directed to the “basement” of one of the corporation’s larger elementary schools, a building that was originally designed as a junior high school. I entered what was fondly labeled “the dungeon, a huge open area underneath the building, complete with a dirt floor. As I wandered through the piles of outcast pieces which included stacks of chairs, tables, chalkboards and even a piano, I spotted a mountain of computer equipment in one portion of the area. I began to crawl over the piles of computer monitors, printers, and CPU’s, hoping to find something that I could use. Taking advantage of a nearby electrical outlet, I began testing the units and found many to be in working condition. I was really enjoying “the hunt” until I lost my footing in the mass of technology and was nearly caught in the avalanche that ensued. Realizing that being alone down in this huge mound of equipment was probably not safe for me, I left quickly, without finding the monitor I desperately needed.

On the drive back to school, I began to reflect on what I had seen...stacks of computer equipment, some in disrepair and some not, waiting to be eventually transported to the landfill. If this was a sample of what is happening in our schools, as well as our homes and offices, as we continue to purchase new machines year after year, will we soon be living on top of such mountains? Is upgrading our system to provide more power and memory really worth the expense of creating such waste?

If we are able to continually manufacture these more powerful machines, can’t we figure out a way to use existing units and just replace processors and memory cards to improve their performance, without constantly acquiring completely new units? In schools especially, where tax dollars are supporting the operating budget, wouldn’t it be more ethical to try to make computer units last as long as possible, considering the needs of the classroom? Isn’t it possible that the applications teachers and students find most useful don’t always need the fastest processor speeds available or the maximum memory (Bromley, 1998)?

It’s very possible that we undermine teachers’ abilities to experience optimal success in using computers in the classroom by constantly upgrading. Teachers have tremendous demands placed on their time and energy, and
working with a certain operating system or application may require years of use before a comfort level is reached and real curriculum integration achieved. Changing the hardware and purchasing upgraded versions of software every year or two may serve only to keep teachers feeling uncomfortable and ill-prepared to use these resources. As advocates for instructional technology, we need to concede that the newest "tech-toy" on the market is not always going to be of great advantage in the classroom.

**Education or Economics?**

Finally, considering the classroom environment over the corporate world is crucial if instructional technology is to be implemented with integrity. A strong interest in preparing students for the work force of the future drives one segment of the educational technology proponents. Business owners want students to learn the skills necessary to function in their job markets. They believe that placing computers in the classrooms will encourage the development of these skills (Jamison, 1992).

This concern with training students to meet the economic needs of the business community reflects the social efficiency model developed by Kliebard (Kliebard, 1995) in his writings on the American curriculum. For nearly one hundred years a segment of the American populace has advocated that the public schools train students to efficiently join the working world with practical skills. Vocational education programs are now being reconstructed into "tech prep" programs in high schools across the United States in order to satisfy this demand. "Computer literacy" is a term that is tossed about in this dialogue, though a clear definition of what is meant by the phrase is difficult to articulate.

Students who are adept at manipulating digital information through the use of a computer are a valuable commodity in the job market. Corporations are eager to contribute computer hardware to school systems when they believe that they will receive a substantial return on their investment. Those in the business of producing and marketing computer hardware and software have a vested interest in the use of technologies in the schools, profiting most from the growing budgets for computer equipment in education.

Though training students to use computers to prepare them for the adult working world is a strongly supported rationale in the American culture, educators must evaluate their goals in the classroom and the overall context of their curriculum in order to decide what needs to be taught. Jonathan Kozol (Kozol, 2000) discusses the dangers inherent in a mindset that views young people as our future workforce. Spending time and money in the schools to produce students who possess computer skills alone is unrealistic and dangerous.

Especially at the elementary school level, it is difficult to argue that students really need to be able to effectively use the office applications of the workplace today. Technology is changing at such a rapid pace that it is ludicrous to believe that constructing a PowerPoint presentation in the third grade is somehow going to prepare students for the working world of tomorrow. Yet teachers, parents, and school board members are being lured by the business world to see such activities as exciting and highly desirable. Just the image of a child sitting at a computer seems to provide adults with the false sense that something wonderfully educational is happening, and those in the business of selling technologies are taking full advantage of this phenomenon.

Hardware, software, networking, and telecommunication companies have gotten directly involved in financing and/or taking leadership roles in groups like the Consortium for School networking, TECH CORPS, and the CEO Forum on Education and Technology. The press frequently quotes such organizations without mentioning their close links to companies with a financial interest in high-tech schools (Cordes & Miller, 2000). Before taking the advice of these groups on how to transform education through the use of powerful technologies, we need to acknowledge that their opinions are heavily based on their hopes for increasing corporate profits.

Even government commissions are susceptible to the propaganda espoused by corporate America. For example, the Web-based Education Commission, established by Congress, has conducted hearings at the headquarters of Sun Microsystems in Silicon valley. At the hearing, the commission heard testimony from Sun's vice-president, Kim Jones who testified, "There may be only a handful of, say, third-grade math courses that are the best in the world. A robust network that links schools and students to those courses ensures that any third-grader anywhere can benefit from the best course, no matter where it originates. This is why Congress must invest not only in such a network, but also in the best educational content." (Jones, 2000) Is Congress also considering the dismal track record of the last 30 years of computers in education?

The business of distance learning is booming across the country, not because all universities have embraced the great educational benefits of such programs, but because distance learning offers revenue potential previously untapped. Again, this is a national experiment that has yet to demonstrate effectiveness in producing well-educated citizenry. Are educators being duped into believing that their "business partners" are truly interested in the development of well-educated minds, or do we see the "dollar signs" in the eyes of those who view schools as customers who will keep paying for the products they develop?
Conclusion

Teachers who want to use information technology with integrity must come to grips with these issues and push to create learning environments with technology that genuinely meet the needs of their students, while protecting the environment and frugally making use of the tax dollars being spent in the classroom. Those in the business world must be influenced to tailor their products and services to better match school needs and goals. We must be honest about what computers in classrooms can do and what they can’t. We must demonstrate courage in openly acknowledging the disparities that exist between what we envision and what currently is happening. If we can discuss the weaknesses and dangers of computer use in schools, as well as the benefits, then we are on a better path. When these practices become the norm, instructional technology will function with integrity.

Designing Tasks for Networked Technologies using Intentional Acts

Michael Barner-Rasmussen
DMM - Distributed Multimedia Technologies and Applications, WP3: Distributed Education
Department of Information and Media Science, University of Aarhus
Denmark
nthrman@nethotel.dk

Abstract: Teachers all over are finding that designing tasks for networked technologies requires more than setting up a web-server with class schedules, a few links to related materials, e-mail, discussion areas and so on. All too often on-line-materials are not read, on-line-discussions die out and teacher-mailboxes remain empty.

What is happening, when no mails to the teacher arrive? When a conference dies? When a carefully prepared volume of on-line-papers is not applied to the student-task at hand? We need a better way to model/understand/connect the various elements of the on-line learning experience to understand these failures in more detail.

The theoretical framework described in this paper greatly expand the analytic understanding of student-student and student-teacher interaction in the educational context to allow for a better founded planning of these when designing online courses or course-support.

From this outset a number of specific teaching situations using networked technologies are analyzed in order to show the depth and breath of the frameworks capabilities.

Introduction

Teachers all over are finding that integrating networked technologies into the educational setting requires more than setting up a web-server with class schedules, a few links to related materials, e-mail and discussion areas - All too often on-line-materials aren't read, on-line-discussions die out and teacher-mailboxes remain empty.

What is happening, when no mails to the teacher arrive, when a conference dies, when a carefully prepared volume of on-line-papers aren't applied to the student-task at hand? We need a better way to model/understand/connect the various elements of the on-line learning experience to understand these failures in more detail.

This article explores a pragmatic linguistic approach to understanding how communicative failures can lead to such breakdowns and how to avoid such failures in the design of electronically mediated communications in the teaching situation. By combining Bordewijk and van Kaam's theory of modes of interactivity (Bordewijk & van Kaam, 1986) with an adaptation of Ole Togeby's theory of communicative events (Togeby 1993), the constitutive rules governing the success of communicative events can be used to formulate the success-criteria, which must be met in order to turn an intention to interact into an interaction. Incidentally this leads to a much more general model of interactivity, since communicative events can be affected by anyone with access (students, teachers, third parties), thus opening up the field to a plethora of socio-institutional relationships other than the 'traditional' teacher-as-center-student-as-periphery-relationship.

Assumptions

Three assumptions or claims underlie the proposed framework:

1. All interactions starts with an act, which, importantly, is the only thing, the one intending to interact has any control over (Sperber & Wilson, 1986)
2. Due to the opacity of computer-mediated communications most if not all acts through networked media can be considered intentional and purposeful communicative events
3. Technology assisted/delivered courses can be viewed as being comprised of series of sequences of communicative events, which only retrospectively can be seen as a series of interactions.

The interesting bit, from a linguistic viewpoint, is what happens 'in-between' the abovementioned events: What
makes a communicative event successful in affecting interaction? How does one facilitate the turning of communicative events into the intended gainful interactions? To answer the question we need a usable taxonomy for communicative events as well as a taxonomy of interactivity in order to combine them into a theory of affecting interaction.

A Taxonomy of Interactivity

When dealing with communicative events, that are mediated through some electronic delivery channel or other, differentiating the interactions, that takes place by looking for different traffic patterns seems logical. Bordewijk & van Kaam (Bordewijk & van Kaam, 1986) arrive at such a taxonomy by posing two questions to Interactive Mass Media:

1. Who is the producer/owner of the content? The Center or the Consumer?
2. Who controls the delivery and use of the content? The Center or the Consumer?

Which, when placed in a matrix, yields the four basic modes of interactivity:

<table>
<thead>
<tr>
<th></th>
<th>Content owned (produced) by Center</th>
<th>Content owned (produced) by Consumer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Center controls choice of content and time</td>
<td>Transmission</td>
<td>Registration</td>
</tr>
<tr>
<td>Consumer controls choice of content and time</td>
<td>Consultation</td>
<td>Conversation</td>
</tr>
</tbody>
</table>

Both the explanatory power and weakness of this taxonomy lies in the fact that the power-relationship is built into the understanding from the outset. In today's networked interactive media, and particularly in the educational setting, problems arise with understanding who is fulfilling the role of Center and who the role of Consumer. Modern teaching methods casting the teacher as anything but a information-controlling center In addition, the model makes no determination as to why and when a consumer might choose to view a transmission, supply information, consult the center and so on, and when he or she might choose to ignore the 'difference' made.

That is all somewhat well and good for Interactive Television, but not so good for Interactive networked media. Here success (meaning the event is received as intended and has the intended consequences) is not granted the initiator in the same 'easy' fashion as an information controlling and -disseminating center. Interaction is what happens when personally initiated events has the intended consequences, not the acts in themselves; Bordewijk and van Kaam model is descriptive, simultaneous or (more often) after-the-fact, and what we need is a heuristic for creating tasks that are more likely to succeed in the electronic classroom. However, the four interactivity-modes identified still reflect different basic modes of availing information for perception and inference, and are, for the educational setting, quite all-encompassing, so it should be possible to analyze them to deductively reformulate the model in terms of sender(initiator)-intentional acts instead of in terms of content- and temporal control.

- **Transmission**
  To transmit something means the uninteruptable transfer of signs - The purpose of transmitting must then be to inform about some point about the state of affairs by means of availing the information in its entirety to the receiver before allowing any transmission-interrupting interactions to take place.

- **Consultation**
  To consult is basically to ask a question, again about the state of affairs, to some authoritative source. The purpose of consulting can then be said to be the wish to apply the sought for information to some problem or deliberation.

- **Registration**
  Registration is an inverse consultation, where the information sought doesn't concern the state of affairs (since the consumer isn't an authoritative source) but instead concerns the consumers personal attributes - e.g. views, opinions, knowledge, skills in order to evaluate the questioned attributes on some scale or other.

- **Conversation**
  Conversation is the free exchange of ideas, information, knowledge etc. between equals (consumers). Since we have already covered the intentions of informing, applying and evaluating, what remains in the domain of conversation, and that is not covered by the first three intentions, is the individual purpose of achieving a better understanding of ones own views, knowledge, feelings, etc by means of reflecting on what is known, thought, meant etc., against a peer intellect.
Thus, the four basic modes of Interaction can be shown to subsume four basic purposes/intentionalities with acting to attempt to initiate an interaction, by means of creating a communicative event for perception and inference by the receiver. The:

1. Informative
2. Applicative
3. Evaluative
4. Reflexive

Communicative events.

A Taxonomy of Communicative Events

Communicative events are what the actants produce to ‘create a difference’ in the environment of their intended receivers (Sperber & Wilson, 1986), thus, a text event is ... not an object which can be recognized in physical or mental space, but a historical event in time. (Togeby, 1993, p. 819). In Togeby’s taxonomy of these events five outside contributing factors of the text-event are linked to their related functions by a constitutive rule for each function (Togeby, p. 819-845) in the following manner:

<table>
<thead>
<tr>
<th>Function</th>
<th>Constitutive Rule</th>
<th>Factor</th>
</tr>
</thead>
<tbody>
<tr>
<td>Expression</td>
<td>(must be) Sincere</td>
<td>(of) Sender (views and opinions)</td>
</tr>
<tr>
<td>Use</td>
<td>(must be) Correct &amp; Comprehensible</td>
<td>(in the chosen) Sign System</td>
</tr>
<tr>
<td>Contact</td>
<td>(must be) Regular &amp; Fair</td>
<td>(through the) Channel</td>
</tr>
<tr>
<td>Information</td>
<td>(must be) Relevant</td>
<td>(to the) Receiver</td>
</tr>
<tr>
<td>Proposition</td>
<td>(must be) True</td>
<td>(about the) State of Affairs</td>
</tr>
</tbody>
</table>

I’ll briefly explain the terms used to denote the factors and, where relevant touch upon their related functions and constitutive rules:

- **Sender**
  The initiator of the text-event. The initiator creates the difference in the intended receivers’ environment for some purpose or other. It is the fulfillment of this purpose that is the intent with creating the difference, not the transferal of the informational content of the communication. For this intent to succeed, the sender’s expression must be regarded as sincere.

- **Sign System**
  The semantic and structural content of the text-event. This is the code-level of the taxonomy. For any message to succeed the use of the sign system must be correct and comprehensible. Meanings exist at the code level – Togeby’s taxonomy is definitely not purely inferential, but ‘the meaning’ can only be unequivocally/unambiguously determined by looking at all the other factors present in the specific historic communicative-event.

- **Channel**
  The social-institutional and technical arrangement, the channel, that enables and constrains the contact to be made. That contact must be regular denotes that the relationship between sender and receiver must be well defined and be within societal-institutional norms. That contact must be fair denotes that no undue/unfair social-institutional demands or requirements may be placed on any of the communication partners through the arrangement. Note that regularity and fairness must be fulfilled both for the technical and the socio-institutional arrangements.

- **Receiver**
  Whom or what the text-event is intended for. Human decoding of text-events is not perceived as happening at a code-level only, but also at an inferential (often abductive) level at which the receiver infers the intention of the sender and selects the domain of optimal relevance (Sperber & Wilson, 1986).

- **State of Affairs**
  The knowledge-domain treated in the text-event. Determining the truthfulness of the proposition is a process involving not only knowledge within the domain, but also knowledge of that particular domains epistemology and (scientific) methods.
Merging the two Taxonomies

We now have both a taxonomy of text-events and a taxonomy of the accompanying purposes of initiating them. Integrating the two different optics can then derive the success-criteria; the constitutive rules in Togeby’s taxonomy with the four base intentionalities derived from Bordewijk & van Kaam:

- **Informatives**
  
  Since the purpose is to inform a ‘receiver’ the foremost demand must be that of relevance, to that receiver, and secondly truthfulness/consistency in respect to the state of affairs.

- **Applicatives**
  
  With the intent of gaining a usable answer, the foremost concern when affecting applicatives must be to supply a correctly posed question to make a more success likely. Thus focus of attention becomes that of correctly and understandably using the sign system.

- **Reflexives**
  
  Here, the purpose is ‘achieving a better understanding of ones own views, knowledge, feelings, etc by means of reflecting on what is known, thought, meant etc., against a peer intellect’. Thus, one must have the feeling of being in the presence of peers and for that feeling to present itself, the initiator must primarily ensure that the communicative event created is a sincere expression of his or her views etc.

- **Evaluatives**
  
  Much the same way as Reflexive-interactions, a certain level of trust is required for an Evaluative text-event to turn into an Evaluative interaction. However, here trust is established through a formal system since the trust is directed towards the institutions/initiators formal right to evaluate the receiver. Thus focus is foremost on the social-institutional arrangement, the Channel, so, for an evaluative communicative event to succeed it must be regular and fair.

A new matrix can now be proposed. Whereas Bordewijk and Van Kaam concentrates ownership and temporal control, we now instead ask only the initiator, why he or she attempts to affect the interaction. Is it to avail or to get something? And is that something declarative conceptual knowledge or is it the views, attitudes, understandings, etc. of a certain individual or entity?

A matrix of potential purposeful acts intended to affect interaction (foremost success-criteria parenthesized):

<table>
<thead>
<tr>
<th>Purpose is to avail</th>
<th>Purpose is to get</th>
</tr>
</thead>
<tbody>
<tr>
<td>Declarative conceptual knowledge</td>
<td>Informative (Relevance)</td>
</tr>
<tr>
<td>Views, attitudes, understandings, etc.</td>
<td>Reflexive (Sincerity)</td>
</tr>
</tbody>
</table>

We now no longer have the problem of determining a center or periphery. The four types of acts can be undertaken by all actants present in the situation, and every act can be interpreted or misinterpreted freely by the receiving actants.

Designing Tasks using Intentional Acts

Coming all the way back to task-design we can now begin designing tasks by designing the communicative events intended to affect the undertaking of the task. With the proposed taxonomy of four different intentions with affecting a communicative event, we can uniquely fit each communicative event to the whole and thus create a learning experience that at least will fail in a document-able manner or will succeed and we will know why. The rest of the article therefore discuss a number of common task-elements in relation to the new taxonomy.

How to make Informative acts succeed

Where the other three concepts of the proposed taxonomy somewhat subsumes their own purposes an Informative act does not. We must always ask: in relation to what, the informative act should be relevant.
Informative acts are always the answer to (interaction with) some previous communicative act or setting the stage for something that comes after.

Examples of Informative acts, that sets the stage:

- If the Informative act is a lecture, it implicitly fulfills the need of the students to prepare for the upcoming exam, i.e. the informative act must be relevant in relation to preparing for the upcoming Evaluative act.
- If the Informative act sets the stage for some exercise of task, it must be relevant in relation to the implicit Applicative act of asking, "How do I do the exercise?"
- If the Informative act is followed by discussion, it must be relevant in relation to the upcoming Reflexive act of relating the knowledge presented to one's previous views, opinions, feelings etc.

Examples of informative acts, which are answers to previous acts:

- Interactions with Applicative acts
  - The student signs up for an exercise by clicking a button on a web-page, thus interacting with a previous applicative act initiated by a teacher.
  - The teacher answers a question using e-mail regarding a previous lecture, some administrative procedure, previous task etc., thus interacting with a previous applicative act initiated by a student.
  - A student does the same thing as the teacher in the previous example, thus interacting with a previous applicative act initiated by another student

- Interactions with Evaluative acts
  - A student fills out an online examination questionnaire, thus interacting with an Evaluative act initiated by the teacher.
  - A teacher answers a question regarding his teaching style or choice of content, thus interacting with an Evaluative act initiated by a student.

- Interactions with Reflexive acts
  Most of the time, interactions with Reflexive acts will take the form of new reflexive acts, but sometimes it becomes necessary to 'short-circuit' or stop the discussion and put forth an Informative act to achieve that end.
  - The teacher informs a student, that there is not enough time left to continue a discussion started by the student, thus interacting with a previous Reflexive act.
  - A student informs another student or the teacher, that he or she cannot participate any further because of other duties, thus interacting with someone's previous Reflexive act.

How to make Applicative acts succeed

I probably interpret Togeby's factor, 'the sign system', in a somewhat wider sense than anticipated by Togeby himself. My reasoning is that often the biggest problem with asking questions is not that there aren't things one isn't clear about, but that phrasing the question itself is too demanding of one's present capabilities.

The Applicative act, requiring correct and comprehensible use of the sign system, can in the educational context be analyzed to require of the 'sign-system-use', that the question posed must:

- correctly and understandably use the terms/concepts specific to the subject being taught
- correctly and understandably pose the question within the subject being taught's area of inquiry.
- correctly use the subject-being-taught's epistemology in the determination/description of the 'problem'

It seems obvious, that in order to pose 'good' questions the asker must have a good grasp of the sign systems concerning the 'state of affairs' that the course presents.

So, to ask questions 'correctly', one must have at least partially appropriated the specific concepts and concept-relationships of the domain - the correct and understandable use of the sign system in the specific domain.

In most teaching situations, Applicative acts are most often enacted by students asking questions of a practical nature to their teacher, but as this analysis shows, often are stumped because many questions cannot be phrased correctly at the time, where their answer has any usefulness. Understanding this brings focus to the demand on the teacher or 'availing institution or technology' of supporting the 'correct and comprehensible' asking of questions.
How to make Reflexive acts succeed

This mode of interactivity is often more difficult to achieve than the others due to the fact that affecting it puts the initiator a risk of being labeled or judged by peers and tutors. The competitiveness of many school environments naturally inhibits any personal display of preference or depth of knowledge.

The level of risk can often be coupled to the way a course is evaluated. In the Nordic countries we have a tradition for using oral examinations of a discursive nature, making the teachers opinion of ones 'standing' an important factor. In this situation, it can prove impossible to achieve a true state of Reflexive interactions – the students will rather attempt to say, what they think the teacher wants to hear.

For the Reflexive act to succeed it must be interpreted as sincere, but it is exactly the sincerity of the expression that gets to be questioned, when the institutional and/or social context, that the Reflexive acting out is taking place within, is not sincerely addressed in the initial Reflexive act!

Reflexive acts can then be encouraged along two dimensions:

- Controlling the audience
  - Providing students with private and/or anonymous forums for having such discussions
  - Dividing classes into smaller units, that can have private discussions (as in the point above), that maybe later is brought into plenum as a 'group-

- Controlling (or understanding) the potential consequences
  - Addressing the problem directly to get discussions started
  - Asking teams to discuss rather than individuals, thus 'smearing' responsibility across multiple persons
  - Require participation as a part of the course-completion-demands

Not addressing these issues leads to insincere, and therefore failed Reflexive acts. Resolving the social and institutional barriers is a real challenge to educators today, since their resolution may entail concrete changes to the formal and cultural side of conducting a course, the way it is evaluated and the way it is taught.

How to make Evaluative acts succeed

In the examination-situation, ensuring that the Interaction takes place is most often not a problem, however, there are many situations, that are not exams, where Evaluative acts are in order. Self-evaluations are more and more becoming de rigueur, and can often prove useful for modifying a course to the level and wishes of the students taking the course.

For the educational setting we can explicate the general requirements of regularity and fairness:

- Constituting regularity
  - Make obvious, that the answer is needed for a relevant task, e.g. giving a grade or modifying an upcoming lecture.
  - Assert, that the initiator has the necessary social standing and -relationship to be able to ask the question

- Constituting fairness
  - Ascertain, that the answers sought are (or has had the chance to get) 'inside' the person or persons queried
  - Ascertain, that the answers sought can be fully communicated through the used technical arrangement (technical side of the channel)

In technologically mediated situations, this can prove a real problem. E.g. where a model or prototype is required many a times it is much easier to build that in the real world.

Making sure, that regularity and fairness is communicated properly in the evaluative act can often be a good authors tool in determining whether one really knows, what it is one whishes to know about; what the purpose of requesting the input is.

Historical Perspectives on Teachers, Technology, and American Public Education

Margaret Cassidy
Adelphi University
Communications Department
Blodgett Hall, NY 11530
cassidymanther.adelphi.edu

Abstract: New technology is one of the most frequently named components in, or rationales for, school reform. Many of the hopes expressed today for educational technology sound reasonable and desirable, but history suggests that integrating technology into classroom practice is a very complex process, profoundly affected by trends in educational policy, curriculum theory, and pedagogy. This paper points out some of the common themes that run through the history of educational technology, with particular attention given to overlaps with trends in educational policy and theories about curriculum, teaching, and learning.

Introduction

It has been a characteristically American response to new media to see them as reasons for changing schools, and to hope that their introduction into classrooms will revitalize education in one way or another. Hopes for the educational potential of new technologies abounded throughout the twentieth century, and continue to dominate policy talk. Film was so vast in “its possibilities for the instruction... of humanity that did it not already exist we should, if we possessed enough imagination, pray for its invention” (Forman, 1935, p. 1); once fully understood, films would, “no doubt, be considered as necessary a part of school equipment as are textbooks, maps, charts, and blackboards” (Ellis & Thornborough, 1923, p. vi). Radio was predicted to raise the human mind “to an entirely new level of precision and efficiency” (Darrow, 1932, p. ix). Television was hailed as “the power tool “the greatest vital force in modern education” (Long, 1952, p. 417). Computer-assisted instruction would “march relentlessly into our instructional lives” (Goodlad, 1968, p. 7). Each of these media was embraced by many education reformers of its day, and argued to be compatible with then-current ideas about pedagogy, curriculum, and the purposes and priorities of schooling. And yet, despite some very high hopes about the potential uses of these media in schools, they rarely saw extensive use in typical classrooms.

A common response to this troubling history is to claim that today’s computers will be differently received by schools, because they occupy a different role in social life than did those earlier technologies. There is some truth in that claim; however, one of the common themes running through the history of twentieth century educational technologies is that some difference in the new technology is always named as the reason why the new one will succeed where the older one failed. Mere difference is not enough to ensure different outcomes.

The differences in these various attempts to bring new communication technologies into the school environment are in the details—for example, in the particular social problem people hoped to solve by using a new technology in schools—not in the basic, underlying assumptions—for example, that social problems can be addressed by using technology in schools. We need to be more consciously aware of the assumptions being made today about technology and education, so that we can think harder about their validity and usefulness. A good place to start—and, it sometimes seems, a rare one—is in the past, where we are not quite so emotionally invested in what people were thinking and doing, and are therefore more likely to be able to establish some critical distance. From there, with any luck, we can apply our newly honed skills in critical distance to the present, along with some different ideas against which we can compare our own. What’s more, we come back to the present with a better understanding of where our ideas came from, what circumstances brought them into being in the first place, and how they have changed over time.
The story of educational technology must be more thoroughly and deliberately intertwined with other aspects of school reform if the repeated attempts to transform schools with technology are to be more adequately understood. That is, what happens to new media in schools is—and has always been—mediated by theories of curriculum and pedagogy, prevailing beliefs about the purposes of schooling, and the relationship between technology and the work of teachers. For example, educational film and radio were closely tied to the child-centered progressive movements of the time. These media were advocated for their appeal to multiple senses, for their capacity to arouse students’ interest, and to connect children to the world outside the classroom—all hallmarks of child-centered progressivism. At the same time, some of the social efficiency reformers of the time also advocated the use of these media, believing that children would learn more quickly and efficiently through film and radio than through conventional instruction.

Similarly, instructional television was tightly bound up in educational policy of postwar America. After World War II, American public schools suffered from intense overcrowding and a severe teacher shortage. Instructional television was developed, in large part, with the aim of spreading out the teaching force by providing mass instruction by master television teachers. The idea was that television-taught classes could be much bigger than conventional classes, and would only require a teacher’s aide for supervision. Furthermore, television lessons could make up for the inadequacies of underqualified teachers.

Other aspects of postwar educational policy were related to the development of teaching machines and computer-assisted instruction. As the Cold War intensified, Americans became increasingly concerned that their public schools were inferior to the schools of the Soviet Union. In particular, there was great anxiety that American instruction in math, science, and foreign languages was inadequate. There had been a great deal of military research during World War II on the use of various audio-visual devices for training, which brought together audio-visual educators and psychologists. In the 1950s, behaviorism, and the teaching machines that went with it, were popularized, where the material to be learned was broken down into its smallest components and “dispensed” to the learner. Also popularized in this period was the “systems approach” to education, another inheritance from military research and practice, which involved conceiving of the learner as part of a human-machine system, where each was to be adapted to the other to streamline training. Computer-assisted instruction was developed in the context of these efforts to make learning efficient and failsafe.

Some of the more recent modifications to computer-assisted instruction are a product of further psychological research and the development of information-processing models of human cognition. For example, computer simulations arose largely out of an interest in modeling the workings of the human mind and, in turn, using those models to shape human learning. Much of the current “constructivist” focus of educational technology arose out of these developments.

Hopes to improve American public education though the use of new technology need to be informed by the historical context in which those hopes are embedded. In the process, we can develop a more sophisticated sense of how to integrate new technologies into schools, and a better understanding of the factors that can work so powerfully against such integration.

Applications of Knowledge Based Evaluation in Educational Technology.

Michael L. Connell, Ph.D.
Curriculum and Instruction
University of Houston
USA
Mkahnl@aol.com

Abstract: In an emerging system, one of the primary functions of the founders should be to explore acceptable justification systems. Consider, for example, intuition, logic, or causality. In doing this, it is helpful to recognize that each choice of systems—even if only made on a temporary basis—will have significant impacts on which true items may be proven and which false items may be disproved. When this is done a case is easily made that a meaningful evaluation is possible with only a shared justification system present. Items of truth and belief, although of extreme interest to the parties of most evaluations, are shown to be irrelevant to the advancement of knowledge that may come about as a result of the evaluation itself.

Introduction

I use the term Knowledge Based Evaluation to refer to a conceptual framework that arises when one uses an epistemic perspective to examine the dynamics of performing an evaluation within an emerging, or ill-structured, domain. A full description of this framework is beyond the scope of this paper, but may be found in a future volume of the Journal for Technology and Teacher Education.

As was suggested in the abstract, one of the primary functions of the founders in an emerging discipline should be to explore and legitimize various acceptable justification systems for use within the emerging discipline. This does more then just legitimize a research paradigm, at a foundational level it serves to frame the broader parameters of what knowledge may and may not be found within the discipline and how such knowledge claims are to be contextualized.

Application

Within an epistemic tradition knowledge has often been expressed by the rather formal relationship K=JTB. In this expression K refers to Knowledge, J to justification system, T for truth, and B for beliefs. These are all to be thought of in the perfect idealized form. In actual applications we are not dealing with abstracted perfection, however, but rather with a localized and specific area of inquiry. I will use the lower case k=jtb to refer to this contextualized set of features.

Thus in an actual evaluation, from the perfect set of all knowledge, K, a subset, k, would be selected to for the basis for creating areas of evaluation. Although not previously noted, k is also contextualized by the institutional constraints of the target audience, as influenced by the evaluators. This points to the need for an extensive period of development between all parties to the evaluation to develop a mutually meaningful k. Thus, expectancy management is not only important for the nature of the deliverables, but also to set up the epistemic foundation and philosophical arena within which the evaluation will function.

Once a shared understanding of what is to be measured is determined, this item of measurement is the k-knowledge item, which may then be explored and measured by examinations of the systems of justification accepted - j, the truths shared by the parties to the evaluation - t, and the beliefs expressed - b. Each k needs to be justified by the holder or knower of that k, using a j-system of justification appropriate for the system at hand. This j is comprised of the acceptable methods of defense for the domain from which the k was drawn. This j should be the subject of significant debate, particularly in the case of emerging systems, or ill-defined realms of inquiry such as technology and teacher education.
Within education, for example, two paradigms—each with their respective j's—might be classified as qualitative and quantitative research methodologies. Should these be blended in evaluation, great care must be taken to ensure the developing j's reflect the k under consideration. This often creates situations within which selected items of knowledge are intuitively obvious, yet must be classified as an unknowable k within j—the acceptable system of proof. A poignant example currently exists in education in the struggle with paradigms concerning which j's will be accepted and institutionalized. Such struggles are characteristic of an emerging discipline, but distract from the nature of what specifically the systems should be able to measure. It would make more sense to first decide the true nature of k and the select an appropriate j for the task at hand for each study.

In an emerging discipline, such as educational technology, there may not be a well-established and institutionalized method of justification for k claims. In mathematics, on the other hand, there are well-established systems of proof that are acceptable within that discipline. This has an impact on the nature of the knowledge claims that can be made. Clearly justification systems, once accepted and privileged within any system, determine not only what a good defense should look like, but also what a knowable item is and under what circumstances knowledge advancement may be claimed.

Apart from the advancement of knowledge within a field, this has a direct implication on the evaluation in progress. If an element (i.e., an individual, system, institution, or whatever can make appropriate use of the accepted j) is under evaluation, then that fact itself can be an item for evaluation. When that is done, the following are examples of the type of inquiry that this conceptualization might generate:

- How well does the j used by the element correspond to the j accepted by the system performing the evaluation?
- How well is the j used by the element implemented by that element?
- From the potential j available, was the element able to select one appropriate to the problem under investigation?
- From the potential j available, was the element able to select one that was acceptable to the field?

It should be noted that whether the k is true or false, knowledge could still advance within the system. The state of knowledge advancement is only determined by the selection of an appropriate j. The selection of k, that is the form of knowledge to be evaluated, is critical to guide subsequent evaluations. Its own universal truthfulness, however, is not itself subject to universal verification. All that is required is that it is acceptable as a k—a knowable item within the field or audience conducting the evaluation.

Although there is not room to develop this argument here, it is sometimes the case that at one level, even the localized t becomes unimportant to the evaluation. Thus, a k can be held to be universally true or false for all of the potential knowers who are members of the discipline conducting the evaluation. Indeed, the system of justification can be independent of the truthfulness of the k. An item may or may not be t—true at the individual or institutional level, but this decision is independent of the evaluation. Similarly, b—beliefs held by the institution or individual only impact the evaluation to the extent to which they are instantiated in the j—justification system in use by the individual or institution. Thus, when conducting an evaluation using this knowledge-based approach, we can express the "space" within which we are concerned by filling in the necessary assumptions and limitations.

An emerging field or discipline, such as teacher education and technology, defines itself by creating the linkages between k and j. It is through this mechanism that we define the forms of knowledge that will be known and knowable within the emerging field. It is also through this mechanism that we may discover what legitimate items of inquiry might look like.

Communal Constructivism:
Students constructing learning for as well as with others.

Abstract
We believe there is a need for an expanded definition of social constructivism that takes into account the synergy between the more recent advances in information technology - which are increasing our potential for communication and the ability to store a variety of data types - and advances in virtual learning environments. In particular we are still at an early stage in trying to construct knowledge as to how to teach and learn effectively with ICTs. What we argue for is a communal constructivism where students and teachers are not simply engaged in developing their own information but actively involved in creating knowledge that will benefit other students. In this model students will not simply pass through a course like water through a sieve but instead leave their own imprint in the development of the course, their school or university, and ideally the discipline.

Introduction
The most interesting effects of the advent of Information and Communication Technologies (ICTs) in teaching is they force the teacher to undertake a radical re-assessment of the way in which they teach. The use of ICTs raises a whole series of questions ranging from the appropriateness of the ‘chalk and talk’ paradigm, through the role of assessment, to the need to cater for different learning styles. This paper describes how the authors, who are themselves both teachers and learners, are re-assessing the way in which they teach and learn in light of the enormous flexibility being offered by ICTs.

The context for the discussion is a 2-year, part-time Masters program in the area of ICTs and Learning - Master of Science in Information Technology in Education - in which a wide variety of techniques, many old but some new, are being used in an attempt to enrich the learning experience and have begun to fundamentally change the way in which we envision education. The theme, or educational philosophy, underlying our approach is one we call 'communal constructivism', by which we mean an approach to learning in which students not only construct their own knowledge (constructivism) as a result of interacting with their environment (social constructivism), but are also actively engaged in the process of constructing knowledge for their learning community.

We argue that the modern education process is too like a sanitized pipe system through which large numbers of students are pushed through to emerge from the far end ‘educated’ but without leaving any discernable trace on the system they have passed through. The ‘communal constructivist’ philosophy is more akin to a river that shapes its own environment as it flows forward. We draw upon a diverse range of educational inputs ranging from the constructivist theories of Vygotsky to those of Cognitive Apprenticeship, through techniques used in one-teacher rural Irish primary schools to the Japanese han system. Of particular interest is the way in which ICTs can be creatively used to bring new life into these diverse ideas and how it can combine and synthesize many previously separate initiatives.

A search for an appropriate model of education
Our current classroom model is largely a product of the industrial revolution whereby groups of students of the same age come to a single physical location to be instructed in the same subject matter at the same pace. By comparison, earlier models of learning were much more tailored to individual learners and stressed high-level interaction between the tutor and student. Indeed modelling the process of learning was considered as important as imparting facts and information. A stress on skills of speaking and rhetoric has been largely lost as delivery was increasingly restricted to the teacher. Assessment plays a defining role that results in students being conditioned to learn only what is of direct relevance to examinations and often only then in a superficial manner. Although it varies somewhat from country to country, for the most part the education system acts as a shrinking pipeline with students being channelled into greater and greater specialisations at earlier and earlier ages1. The emphasis is on an individual learning by oneself, for oneself, and even where learning is within a wide group or social context, the goal of learning is still for ones own benefit.

1 In Ireland for example many undergraduate degrees are specialised, or professional in nature. Entry to university is highly competitive and judged on the results of a single set of nation-wide exams and students are encouraged, and in some cases are required, to pick between language and science courses as early as fourteenth.
Not only are the processes of learning narrow, but the products are also boxed in. School subjects are increasingly standardised and defined. Science subjects, for example, have been delineated and divided while the field is increasingly connecting and evolving. Developments are moving so rapidly that whole areas of knowledge are increasingly obsolete. What is needed is a reflection of the growth and expansion of the knowledge of the discipline within the subject being taught in the classroom.

Pouts-Lajus and Riche-Magnier (2000) argue that new educational technologies give us an opportunity to rethink educational relationships as we reflected on what was presently being offered to students as an educational experience as well as best practice, both from our own tradition and internationally we began to evolve a new theory of an approach based on building a community of learners with a focus on the community itself rather than on the individual learner.

Our ideas on ‘communal constructivism’ derive from a wide variety of sources. Theories of social constructivism, combined with advances in ICTs are introducing new ways of learning. Social Constructivism is defined as a process by which students make meaning, and the central role their community, through culture and language, plays in this process. Learning is seen as a social and collaborative activity that is facilitated rather than directly taught by the teacher. Building on constructivist theories, where students are involved in building their own knowledge, social constructivism adds an interactive dimension. This approach is influenced by the work of Vygotsky who believed that children learn from within themselves and as well as from influences in their social or cultural environment. Although Vygotsky focused on the role of speech and not on the role of new technologies, the fact that communication is increasingly supported by computers, e.g. e-mail, discussion boards, chat rooms, MOOs, MUDS and Virtual Worlds, has lead to his work influencing theories of learning in the information age.

We also have been influenced by the concept of cognitive apprenticeship and the work done in designing supporting computer environments to test theory (Lajoie & Greer, 1995). Essentially teachers offer students cognitive apprenticeships by working with students and modelling key aspects of learning until the students are able to work unassisted. The teacher is responsible for passing on knowledge of the process rather than simply focusing on content. Earlier models of apprenticeship learning underlie the theory.

Before schools appeared, apprenticeship was the most common means of learning and was used to transmit the knowledge required for expert practice in fields from painting and sculpting to medicine and law. Even today, many complex and important skills, such as those required for language use and social interaction, are learned informally through apprenticeship-like methods - that is, methods not involving didactic teaching, but observation, coaching, and successive approximation (Collins, Brown & Newman, 1989; p. 453).

The great educator Cardinal Newman argued in his classic The Idea of a University that people learned more from being in contact with each other than from formal classes. “If I had to choose between a so-called University which dispensed with residence and tutorial supervision and gave its degrees to any person who passed an examination in a wide range of subjects, and a University which merely brought a number of young men together for three or four years... I have no hesitation in giving the preference to the later...” (Newman, 1852; p. 35). This is very much the same thinking that underpinned the classic British Boarding School model for many years. In both these cases, however, the collective aspect of learning is in the area of socialization, or in Newman’s case becoming a ‘gentleman’, rather than on traditional subject-based learning that was still done in a conventional classroom.

An in-depth study by one of the authors, Holmes (1998), of a rural Japanese community in the Hiroshima area identified many practices which have given us ideas as to how our view of teaching and learning can be expanded in a Western context. In Japan, for example, Grade 6 students primary school collect the younger ones walk with them to school each morning and home each afternoon. This is obviously a valuable exercise in socialisation but of even more interest is the use of han groups within school. A han is made up of 3 or 4 students within a class and it is the responsibility of the han to make sure that all members are able to move forward through the materials. This is radically different from Western education where the individual is paramount.

The han system in Japan – from an interview with a Japanese teacher.

It looks like in the UK that students should not disturb other students; but in Japan, in such a class, it is encouraged. One plus one is usually more than two. Partly because of this, students turn to each other for help before turning to the teacher. Since the class moves at the same pace they will help each other to move forward. Students rarely compete with each other in class.

Students working individually– from an interview with a British teacher.

We do not deliver skills from the front, but instead, we are allowing people to develop skills at their own rate.

(We are very much encouraged to look at differentiation and we are asked to provide extensions of tasks for those people who are able to move more quickly.

3316
Group-work is also of course prevalent in Western education and much has been written on the advantages of group-work and project-based learning (Papert, 1993; Rotherenberg, 1999). A related concept is that of peer tutoring which has been shown to have benefits for the tutee. We are particularly interested in the benefits for the tutor in such arrangements.

Closer to home small rural Primary schools, of which there are still very many in Ireland, where two or three teachers take the full range of ages from 5 to 12 years old, offer very interesting models of education. Enormous creativity is required in timetabling subjects and extensive use must be made of both group project work and peer-tutoring. Economies of scale argue that such schools are not viable units but the power of ICTs to extend the horizons of such schools is seriously challenging that assumption.

At the other end of the educational spectrum, the concept of a learner making a contribution to the field within which they are learning is at the core of what it means to do Ph.D. level research. Ph.D. students attempt to expand knowledge of a discipline and are encouraged to publish their results so that their own work is recorded and helps develop the field of knowledge. At this level in the formal education system delivery, and reception, of information is replaced by the process of building new knowledge and making it available to others. This we argue is one of the best learning experiences but applies only to a select few. We shall explore how it can be delivered at other levels in education.

Courses in the formal educational system are predominantly static in that a teacher covers the same material year after year. At the same time new technologies are impacting with subject disciplines and teaching pedagogy to evolve present fields, such as biology into new areas such as biotechnology. The syllabi of many courses could be constantly rewritten and still be almost always out of date.

External pressures are also calling for change in the education system as employers are more and more looking for people with good teamwork and communication skills. There is a real challenge for an education system to ensure its graduates have relevant and applicable knowledge and skills. Partly in response to such issues, large-scale organisations such as the OECD are stressing skills of knowledge management and creation rather than simply memorization of content materials.

**Communal Constructivism**

Many of the previous proposed solutions to challenges faced by educators today involve more time and more money. Teachers are increasingly pressured to provide more of their own time to training and updating their skills while governments are obliged to keep increasing educational budgets. What has not been considered is a way to build on the knowledge, skills and energy of those at the heart of schooling—the students.

We believe there is a need for an expanded definition of social constructivism that takes into account the synergy between the more recent advances in information technology—which are increasing our potential for communication and the ability to store a variety of data types—and some of the educational ideas outlined above. In particular we are still at an early stage in trying to construct knowledge as to how to teach, and learn, effectively with ICTs. What we argue for is a communal constructivism where students and teachers are not simply engaged in developing their own information but actively involved in creating knowledge that will benefit other students and teachers. In this model students will not simply pass through a course like water through a pipe but instead, river-like, leave their own imprint in the development of the course, their school or university, and ideally the discipline. This will result in a gain for the institutions or course, but more importantly the students themselves will benefit.

We argue that a diverse range of techniques can, and should, be used to enrich this type of learning environment within which the focus is on learning with and for others. Peer tutoring and project-based learning are obvious techniques but we also advocate the ideas of cognitive apprenticeship, the publishing of information, flexibility in the time table, a radical look at the way in which assessment is done, and so forth.

Our pipe and river analogy derives from the observation that presently much of the student learning that happens in one year of a course is lost for the next. The pipe can not be enriched by water travelling through it, indeed over time the pipe may need repairs, whereas water flowing through a river will leave rich mineral deposits and slowly influence the course of the river. Obviously the students have learnt material during their studies, and the teacher would have learnt from the students, but there is little or no year-to-year transfer of knowledge between students. If the student learning processes and their work could be captured then courses might instead build on knowledge rather than simply repeat it.

To create an environment where students leave their imprint on the course, and the field, as an integral part of their learning not only benefits their own learning, the learning of their colleagues in their classes and those that will come after, them but more importantly creates a vast number of graduates who will be well aware of the importance of teaching and education and thus communal constructivism also provides a teaching apprenticeship for all those who come through the school system. The profession would benefit from a rich pool of people who understand the concerns and support new initiatives.
Putting Ideas Into Practice aided by ICTs

We are now seeking to explore ways in which these ideas of communal constructivism could be developed by applying them in a classroom setting. The course in question is a new two-year, part-time Master's programme in the area of Information Technology in Education. The students, or learners, on this course are predominantly teachers themselves who are involved at some level in using ICTs in the classroom. The course has an intake of 25 and the first year is made up of a taught component with the second year being devoted to a research dissertation. The first in-take was in October 1999 and at the time of writing we have now both the taught year and the dissertation year up and running.

The Communal Constructivist approach requires that the course be dynamic and adaptive. As the field itself (ICTs and Learning) is so dynamic it is necessary that both the course content, and more importantly the method of delivery, be capable of adapting to new information and new techniques as they emerge from within the course itself and from the discipline at large.

The potential of information and communication technologies (ICTs) in the area of learning are well known. Aspects which are particularly relevant to our subsequent discussion include the potential to allow students to become publishers, and not just consumers, of information through the use ICTs, for example, word processing, web and multimedia authoring tools. The use of Email, list servers, discussion boards, virtual chat rooms, MOOs and so forth greatly enhance communication capabilities and cut across divisions of space and time. Digital audio, video, web cameras, on-line logs can capture and disseminate classroom experiences for research and reflection. Databases, referencing packages, statistical and text analysis packages allow the storing, structuring, and analysis of information. On-line tracking, monitoring software, adaptive learning environments, for example, aid in the structuring and analysis of one's own learning.

Our approach also requires that from the very outset students see themselves as producers and not just consumers of information. Students are given instruction in various technologies for presentation to their peers, ranging from PowerPoint tools to produce slides to sophisticated Web design. All coursework and projects have presentation built in as a fundamental part of the exercise. The students must present their work to their peers and also place it on the Web for use by students in subsequent years and for inspection by the wider community. Students are actively encouraged to submit their work to national and international conferences, not just at the end of the degree but during their study and not simply as an addition but as an integral part of their studies. All proposals for research topics must include a section on how the work could make an impact on their field and an outline of plans for publication and dissemination of the research. Students are encouraged to write research papers with the academics and to jointly present their work at conferences, specific individuals are not encouraged but rather the entire class is prepared. This is not just a passive participation but an active collaboration in both the preparation and the presentation. It is probably best summarised by our experience at the students first outing at a national conference where one first year student, who was asked to videotape a presentation being given by some students from the second year, felt compelled to come forward and give the audience the benefit of his views on the topic. Students are also required to write their dissertation proposal in the form of a grant application and to actively pursue (with some success) real research contracts.

Within the course a wide variety of techniques are used to instil in students the idea that they are involved in a process of constructing knowledge and that that construction is a communal affair. Of particular interest are the following.

1. Extensive use is made of **group work and project-based learning**. Assignments are done in groups of 3-4 for first term and then in groups of 2 for the second term. The final term assignment is an intensive individual project by which time the students are much more confident with the technology and the subject matter.

2. The initial specification of the course had built in assessment by examination. A realisation that the learning taking place in an exam is purely focused on the individual lead us to adopt a portfolio approach assessment process that would both benefit the individual, their peers and learners that followed them.

3. Student work has developed into a portfolio allowing for reflection on their year-long learning process and also allowing for future students to see the progress of knowledge acquisition.

4. **The lecture format** used varies somewhat between modules but typically involves making reading material available on the web a week in advance with a modest amount of "lecturing" in any class. Students engage in project work and discussion during lecture time.

5. Extensive use is made of **peer tutoring** and mentoring. There is considerable diversity in the backgrounds of the students on the course so peer tutoring arises naturally within the class. More formally each student on the 1st year negotiates with a student on the 2nd year of the program to act as their mentor.

6. 2nd year students are encouraged to engage in an apprenticeship lecturer role by being given the opportunity to: deliver part of a lecture; lead a discussion group; develop course content; adapt and expand on a lecturer's notes; act as a technical assistant; act as a general helper (there is always a need for someone to answer questions in the hands on session); develop related tasks for students to undertake in the hands-on sessions and add relevant links into the lectures.

---

3 The specification for the end of year capstone project is "Do something interesting that showed you learned something".
Conclusion

There are a number of down stream effect of the flow of students through the course. Although it has taken time and effort to set up a system the benefits are already apparent, numerous, and include the building of a dynamic and well-researched body of course material. This material will be continually updated and thus new directions for the course will evolve. Already there is a to expand the course into new areas such as distance learning and we hope to be able to offer the course for the blind. The active participation of students in the course has created an internship for university teaching as well as strengthening their own understanding of the 3rd level learning environment thus increasing their metacognitive and reflective skills. Having student work available also drives up the level of the course as other students can more easily understand what is expected of them and thus build on a high standard rather than reinvent the wheel.

The fact that we had a student population of adult learners who had already demonstrated responsibility in their learning and professional lives was of benefit to us. We were interested in how this model might be rolled out for learners of other ages. One of the most interesting effects observed in the first year of the course was, therefore, the extent to which students on the course began to replicate the learning environment they themselves were part of in the classes that they in turn were teaching. The most dramatic example was where one of the authors, herself a primary teacher, employed both peer-tutoring and Web-based publication with her class of 10-year olds. The class were taught how to use a simple story-authoring package and gained experience in its use. They then were given the task of going into the classes of 9-year-olds in the school and teaching not just the students how to use the package but also the teachers of the other classes. The whole process was documented on a Web page that the students took great delight in showing their parents. The teacher in question would have described herself as barely IT literate at the outset of the course and what is interesting is to see how she felt empowered to apply her own experiences from the Masters course to her very different classroom situation. Other examples include the accompanying papers in this proceedings by Dearbhaill McKibben and Sharon McDonald on their experiences in the course and as well a paper by Eileen Brennan on how she is conducting research into public policy in ICTs.

Dewey (1916) argued at the turn of the century that learning is a building process, we believe that education as a whole should also be considered as a in the same light. It is early days yet but we feel that we have much to learn, or rather much to construct, in this communal approach to constructivism. Luckily we are not alone in this rather daunting endeavour but have the human resources to regularly expand and update the course as we are presently supported and aided by over 25 master's students and will soon be aided by 25 more and so on and so on... With their aid we will enrich the course and our own ideas with resources. Not just the identification of more useful information but we are investigating developing software that supports interactive student input to the course. Ubiquitous computing we believe will ease applying communal constructivism ideas to classrooms. When students all have lightweight, wireless laptops that are connected to the Internet they are able to download lectures, visit resource, and post material to the lecturer while engaging in group work or listening to lectures. As our own students reflect on and record their experiences in the course we will also research on our own learning in order to build back into the course. This will aid future students and record the evolution of the modules, future teachers understand the work to date and indeed the discipline itself.

We are also meeting a need to identify and train 3rd level instructors as the course provides an apprenticeship and internship for lecturing at university. As each of our own students returns to influence teaching practices in their own schools communal constructivism is impacting the community and thus supporting lifelong learning.

The biggest benefit of communal constructivism, however, is to the learners themselves. At present their role in the education system is akin to a charity case. They receive benefits from the state and/or their parents for years and have very little input into what they learn, as well as when, where and how they learn it. This has created passivity not only in the learners but within the whole system. A sense of community has been lost. Communal constructivism is about empowering the learner to allow them to reclaim a role in their own education. The advantage to the learner is in taking part in deep meaningful and allowing them to have a role in society throughout their formative years and not just after graduation. Giving students responsibility will train them to be responsible.

Communal Constructivism stresses that learners should be listened to and to be important to others. We believe that they should be useful and have some say in their own lives. They must be included and their work should be valued by others. Their learning tasks should be useful and recognised as such. They have a right to be needed.

A Tutor's Advice Trains a Student's Self-regulation Skill

Michiko Kayashima

Tokyo, 194-8610 Japan
kayasima@lit.tamagawa.ac.jp

Abstract: We propose that a tutor's appropriate advice trains a student's self-regulation skill. Through analysis of the tutoring interaction between academic departments, we discovered that a tutor's advice transformed a student's questionings. Our hypothesis by the analysis is that this transformation indicates an appropriation by the student of the tutor's self-regulation skill. We propose a training model of a student's self-regulation skill, which is based on the appropriation by the student of the tutor's self-regulation skill.

1. Introduction

Currently, a new paradigm of learning incorporating three distinct theories is emerging - social constructivism, Soviet socio-cultural theories, and situated cognition. This new paradigm brings these social issues to the foreground as a central phenomenon for study (Koschmann 1996 p.11). Under this new paradigm, the emphasis in research on collaborative learning has shifted from the study of the conditions under which group members learn more effectively, to the collaborative interactions themselves. Chi and VanLehn have shown that specific kinds of interactions may engender specific kinds of outcomes (Chi and VanLehn, 1991). The outcomes of these studies led collaborative learning research to show that the interaction must be structured in order to promote effective discourse (Cohen 1994). Some researchers have developed the structured interaction model in order to force the group members to mediate each other's learning. For example, in Reciprocal Teaching (Palincsar & Brown, 1984), the interaction is structured to promote a specific discourse pattern: questioning, summarizing, clarifying, and predicting. Reciprocal Teaching has been found to improve the ability of understanding prose. The ASK to THINK – TEL WHY (King 1999) model of peer tutoring also relies on structuring the interaction which consists of a question and answer component. In the Reciprocal Teaching and ASK to THINK – TEL WHY, the discourse pattern promotes interactive cognitive activity as well as metacognitive process such as monitoring and regulating the cognitive activity.

On the other hand, effective discourse has a common factor. It involves metacognitive processes such as mutual regulation and reflection (Brown 1987). This indicates that effective discourse plays the role of controlling a group member's thinking or causing him to reflect upon his thinking. In other words, effective discourse temporarily supersedes a student's self-regulation skill. From this, we can see the possibility that structured interactions composed of specific utterances can fulfill the metacognitive processes of interlocutor-regulation skills and self-regulation skills.

The purpose of this study is to explore an appropriate advice, which train a student's self-regulation skill. In this paper, we propose that a tutor's advice trains students' self-regulation skills. We will first focus on the discourse pattern: a question-answer methodology using structured interactions, and we describe how the use of appropriate questions trains a student's self-regulation skill. Next, we will describe how a tutor's advice trains a student's self-regulation skill. Finally, we will describe a training model for self-regulation skills.
2. Training the student to use of appropriate questioning

In both the Reciprocal Teaching method and the ASK to THINK – TEL WHY model of peer tutoring, students were trained to use appropriate questions. This is indicative of a students’ self-regulation skill training.

In the Reciprocal Teaching method, students as well as teachers take on the role of guiding other members in a group through the processes required to understand texts. In the initial phase, the teacher modeled effective monitoring strategies and feedback. In the intermediate phase, students became much more capable of playing their role as dialogue leader, and by the final phase they provided sophisticated paraphrases of the text and asked sophisticated questions (Brown 1987). One reason for this effect is that the teacher introduced students to their role as a dialogue leader through explicit instruction about appropriate strategic directives (Wertsch 1998).

In the ASK to THINK – TEL WHY model of peer tutoring, the student who is in the tutor role also constructs a more accurate student model through the student’s feedback. And the tutor could select the appropriate question on the basis of the student model. If the student’s answer to the tutor’s question is incomplete, the tutor asks another question. This methodology of training using appropriate questions causes the student who is in the tutor role to construct a model of another student’s knowledge and to control another student’s acquisition, integration and organization of knowledge through asking appropriate questions. From these analyses, we can conclude the following.

- Through explicit instruction in appropriate questioning technique as described in Reciprocal Teaching and the ASK to THINK – TEL WHY model, the student could be trained to see an interlocutors’ thinking as an object of his cognition.
- These methods imply that the teacher advises or appropriate questions give students a demonstration of the proper self-regulation skill.
- The students who are in the tutor role or group leader role could be trained to control the interlocutors’ thinking with the basis of appropriate questions.

It should be emphasized that these processes indicate that the students who are in the tutor role took the meta-level role for the interlocutor’s cognition. In other words, the student’s ability to use appropriate questioning indicates the [interlocutor]-regulation skill.

3. A Tutors’ advice transforms student’s questions

Now we are ready to consider our main problem. We regard both Reciprocal Teaching and the ASK to THINK – TEL WHY model of peer tutoring as an indirect training of self-regulation skills. In this section we will analyze research of student’s spontaneous questionings and a tutor’s advice. We will consider that a tutor’s appropriate advice can directly train a student’s self-regulation skills.

We analyzed the interaction between advisers and students during tutoring sessions among different academic departments. And we observed that the students’ questionings prior to receiving a tutor’s advice were different from questionings after receiving advice.

In the initial phase of the tutoring, all students asked similar questions such as “What is a modem?” However, tutor’s advice transformed some of the students’ questions into a confirmation-question or another what-question. The former students were asking for justification of their own assumptions that were based on an explanation encountered in their reading. The latter students were asking for information to integrate their understanding of what they read. For example:

Confirmation-questions:
- “I suppose that all information is represented as one or zero. If so, is hiragana or katakana represented as

What-questions:
- “Let us know more information about it, for example, the merits or the demerits and so on.”
3.1 A classification of user's questions

In order to account for this transformation of students' questionings, we categorized the various questionings. As there were many factors encountered in students' questions, it was very difficult to determine their classification. Moore (1995) classified students' follow-up questions according to previously given explanations and communicative goals. As student's questions are spontaneous and random, we decided to follow her classification. Our adaptation of this classification is shown in the following table.

<table>
<thead>
<tr>
<th>QUESTION</th>
<th>PREVIOUSLY GIVEN ADVICE</th>
<th>COMMUNICATIVE GOAL</th>
</tr>
</thead>
<tbody>
<tr>
<td>What?</td>
<td>None</td>
<td>Acquisition</td>
</tr>
<tr>
<td>Is it true?</td>
<td>Make uncertain things clear</td>
<td>Comprehension</td>
</tr>
<tr>
<td>What?</td>
<td>Make uncertain things clear</td>
<td>Integration</td>
</tr>
</tbody>
</table>

Table 1

As table 1 shows, the communicative goal of student's questions was changed. This transformation of the user's communicative goal leads us to consider the student's knowledge transformation. The initial questions: What—question (Goal: Acquisition) indicate that a student was only cognizant of an unknown thing in the subject matter. Also he did not regulate his knowledge. However the communicative goal of questions after receiving advice, which is Comprehension or Integration, was changed. The latter questions indicate the student's attempt to regulate their knowledge.

On the other hand, it is known that low ability performers are deficient in both knowledge and the resources for controlling that knowledge. And knowledge differences reflect processing differences. Poor learners are deficient in knowledge because of poor learning skills, in particular, the self-regulation skill (Campione 1987). Furthermore, there are many degrees of self-regulation skill but the distinction has not been made as clear. And conscious awareness and direction of thought rank lower than self-correction and regulation that can proceed below the level of consciousness (Brown 1987).

From these, we can see that the transformation of students' spontaneous questions indicates how they regulate their thinking.

4. A tutor's advice trains students' self-regulation skills

Here we will describe how a tutor's advice trains students' self-regulation skills from the viewpoint of the relationship between advice and the transformation of students' questionings. Before describing this claim, we will analyze the relationship between advice and the students' transformed questions.

4.1 What is advice?

There are three typical advice patterns in response to students' questions in the initial phase of tutoring.

Advice #1: You should be more specific when you ask somebody a question.
Advice #2: You should be more specific when you ask somebody a question. There are explanations about CPU's in magazines. Please read them. If you have questions after reading them, I can help you.
Advice #3: You should be more specific when you ask somebody a question. If you make the things you don't know clear, you will be successful and will enjoy learning.

This advice is representative of a tutor's own self-regulation skills, which are informed by the student's questionings and which regulate student's cognitive activities (Kayashima and Okamoto 1999a).
This is made clear when we see that all of the advising statements include the same phrase: “You should be more specific when you ask somebody a question.” This phrase means that students should perform conscious cognition of their thinking. In other words, this phrase gives students insight into how a tutor regulates a student’s thinking.

4.2 The relationship between advice and the transformation of students’ questionings

Here we describe the relationship between the advice and the transformation of student’s questions. We claim that the transformation was triggered by the student’s appropriation of advice. This claim is not new and can be found in various studies (Rogoff 1991, Wertsch 1998).

The tutor’s advice indicates his monitoring and control: i.e. how the tutor monitored the student’s knowledge structure, and how the student should regulate his knowledge structure if the roles were reversed.

What is important is whether students engage in conscious cognition when they receive this advice (Kayashima and Okamoto 1999b). This is important because metacognitive experiences are most apt to occur whenever one engages in conscious cognition (Flavell 1981). By engaging in conscious cognition, the student’s thinking can become an object of his cognition. Some students, who engaged in conscious cognition, were aware of their deficient monitoring and then appropriated the tutor's regulation itself. Others did not appropriate it. Although the former student was transformed, the latter was not transformed in the light of questionings. The appropriation of a tutors’ regulation might lead to modification of the student’s knowledge structures, which then might transform his questioning. In other words, the transformation of students’ questions does not necessarily mean that the student’s self-regulation skills have developed. However, the development of self-regulation skill requires the appropriation of a higher self-regulation skill.

5. The training model of self-regulation skills

Now we shall describe how a student appropriates a tutor’s self-regulation skill, using the following description:

Monitoring: monitoring (Agent, Target, Level) (1)
Control: control (Agent, Target, Level) (2)

Here we describe how a learner (Agent) monitors his own or another’s cognition (Target) through some monitoring level (Level) as shown in (1) above. Additionally a learner (Agent) controls his own or another’s cognition (Target) at some control level (Level) as shown in (2) above. The agent is a person who monitors or controls. The target is knowledge structures that are monitored by the Agent. The value of Agent or Target is shown as T and L, in which “T” refers to tutor and “L” to learner. The value of Level is “L,” meaning that monitoring level is i, and “Li+1” means that monitoring level is higher than “Li”.

We describe a learners’ questionings and a tutors’ advice as follows:

Questioning: tell (Agent, Others, To do) (3)
Advice: want (Agent, Others, To do) (4)

We describe that a learner (Agent) asks a tutor (Others) a question as shown in (3) above, because a learners’ questionings imply that they tell tutors their immediate antecedent cognitive actions (To do). As tutors (Agent) want learners (Others) to engage in proper cognitive actions (To do), they advise. Therefore we describe advice as (4).

As students’ questions at the initial phase of the tutoring represent their awareness of incomprehensible concepts, we describe them as (5). This monitoring level is “L0”, because students were only cognizant of incomprehensible concepts. The advice received from their initial questions represents that tutors want learners to regulate their knowledge structures in the same way the tutor regulates learners’ knowledge.
structures. It is a higher level than one that was initially seen in their questionings. We describe it as "L_i" (i＞0). This we also indicate as (6).

\[
\begin{align*}
tell (L, T, \text{monitoring}(L, L, L_i)) & \quad \text{(5)} \\
\text{want} (T, L, \text{control}(L, L, L_i)) & \quad \text{(6)} \\
\end{align*}
\]

Now, we describe how a learner appropriates a tutor's self-regulation skill; especially regulation as follows. We describe that the learner appropriates the tutor's regulation skill following a learner's questioning and the subsequent tutor's advice as shown in (7) below. That is to say, the learner appropriates the tutor's regulation skill: control (L, L, L_i). It should be noted that "control (T, L, L_i)" is the same as "control (T, L, L_i)" in "want (T, L, control (T, L, L_i))". Thus the appropriation might engender the learner to modify his knowledge structures. The transformation of his knowledge structure leads the learner to ask a question that has a different communication goal from that of his initial question. This is shown as (8) below.

\[
\begin{align*}
tell (L, T, \text{monitoring}(L, L, L_i)) & \quad \text{(8)} \\
\text{<-tell} (L, T, \text{monitoring}(L, L, L_i)) & \quad \text{(5)} \\
\& \text{want} (T, L, \text{control}(L, L, L_i)) & \quad \text{(6)} \\
\& \text{control} (L, L, L_i) & \quad \text{(7)} \\
\end{align*}
\]

This model of training self-regulation skill indicates that learners use appropriate questions by the appropriation of the tutor's self-regulation skill.

6. Conclusion

We propose a prototype model for training self-regulation skills. This model is based on question-answer dialogue, and is also based on the view of a user's internalization of another's self-regulation skills as users appropriate them.

If we develop the model, we can create a new, effective advice discourse and improve learning through changes in a student's self-regulation skills.

In further work we intend to explore what advice encourages a students' appropriation of a tutor's self-regulation skills, specifically, what advice becomes the object of conscious cognition. Solving this issue, we could then utilize more effectively this model for training self-regulation skills.

How Do We Know Whether To Plug In Or Out: The Quintessential Question for Education/Learning Enhanced Through Technology?

Dr. Donna Lenaghan, Educational Computing and Technology, Barry University, USA  dlennaghan@mail.barry.edu

Dr. Angela Choate, Educational Computing and Technology, Barry University, USA  achoate@mail.barry.edu

Abstract: How do we know whether or not to Plug-in or out” is the most important question educators must answer before the first dollar is spent on technology. And if money was spent on technology without improving learning, the plug should be pulled. Insights and criteria for such a decision are provided within this paper’s analysis of brain operations, technology enhanced learning opportunities, research study comparing learning styles with technology self-efficacy, and a review of assessment strategies. The two guiding questions for this paper are: What technology-based activities are associated with brain-based learning and how is the effectiveness of technology assisted learning measured. The authors assert that technology can be a powerful tool for teaching and learning and more and different ways to assess technology’s effectiveness are needed.

Brain Boosting with Technology

Brain boosting (analogous to rocket boosting) is the process of harnessing the natural powers and functions of the brain for effective and efficient learning. Brain Boosting requires an understanding of brain development potential components (multiple intelligences, brain operations, and types of thinking). The following tables offer a review of these components and link them with technology activities. They illustrate how technology can be an additional brain booster to launch the potential of students.

Multiple Intelligences

Howard Gardner revolutionized educators’ understanding of the brain’s potential through his Multiple Intelligences theory. He redefined intelligence as “the ability to solve problems or to make something that is valued in one or more cultures” (Checkley, 1977, p.9). According to Gardner, students are smart in a combination of at least eight different areas. Multiple Intelligences theory and categories within it should not be used to classify people, but should assist in understanding, planning, and evaluating the teaching and learning process. Each person has two or three dominant intelligences that he or she uses to complete daily tasks, solve problems and respond in stressful situations. Teachers should provide multiple opportunities for students to learn and demonstrate their learning through all these intelligences. Numerous opportunities to explore and develop different intelligences are found on the Internet (Table 1).

Brain Operations

Through brain mapping (observing and analyzing the neuron firings in human brains) the biological paths and processes for learning are defined. When these paths and processes are linked with variables of learning with technology, certain strengths of learning with technology appear and the surface validity of incorporating technology into the teaching and learning process is revealed (Table 2).

Types of Thinking

When types of thinking are added to the mix of understanding of brain capacities (intelligences) and how it works (brain operations), the foundation for knowing what and how to assess begins to appear. Bloom's Taxonomy, Scriven's Critical Paradigm, and Ouch's Creative Thinking steps are excellent schemas to provide an overview of types of thinking. Think of each of these as three rocket boosters to launch aspiring stars—your students.

Bloom's Taxonomy

Bloom's Taxonomy, an educational benchmark of concept mastery for years, prescribes levels of thinking. These levels are matched with technology activities in Table 3.

<table>
<thead>
<tr>

Critical Thinking

Critical thinking is defined as a set of characteristics and steps to process and generate information. (Scriven, on-line and Elliott, 1966). Universal characteristics and steps for critical thinkers with potential technology activities are listed in Table 4.

Table 4: Describes Elder’s and Paul’s characteristics and steps of critical thinking and list activities for technology integration.

**Creative Thinking**

Creative thinking (third rocket booster) is related to critical thinking (second rocket booster) but not the same. Critical thinking does not require creative thinking. A comparison of the components of critical and creative thinking finds two clear distinctions. First, there is the presence of emotion in creativity and its controlled absence in critical thinking. Secondly, creative thinking requires divergent thinking (generating a range of acceptable ideas) and critical thinking process requires convergent thinking (one acceptable solution). These distinctions are critical to assessment and evaluation process and outcomes measures and instruments.

Howard Gardner describes a creative person as "one who regularly solves problems, fashions products, defines new questions in a domain that is considered novel but that ultimately becomes accepted in a particular setting" (1993, p. 35). Creative thinking includes problem solving, initial novelty, and ultimate acceptance by others. Eight stages of the creative process are identified and listed with technology activities in Table 5.

Table 5: Describes Oech’s creative thinking steps and potential technology based learning activities.

**Learning Styles and Technology**

When traditional learning style theories are applied to teaching and learning with technology, it is expected that linguistic, visual, kinesthetic, global and specific learners will succeed with computers. An interesting study went beyond these traditional expectations and compared conceptual thought processes with computer usage.

In this study, three instruments (a computer technology questionnaire, a computer user self-efficacy scale, and a learning style inventory) were given to 152 employees (mostly teachers) in a large metropolitan school district who were enrolled in computer training. The findings included a significant relationship among
Convergers (people who prefer abstract conceptualization and active experimentation) and computer efficacy and no significant relationship between learning styles and a most or least preferred software application.

Interesting implications for staff development and integration of technology in teaching and learning activities emerged from this study. Among these implications are questions about how to effectively measure technology assisted learning activities.

Assessment/Evaluation Strategies (process & outcome) to Measure

How do we know if the teaching and learning process is conducive to brain potential, operations and types of thinking (rocket boosters) is the purpose of process (formative) assessments. Outcome (summative) assessments measure the learning outcomes. (Did the rocket boosters work and was the rocket successfully launched into the appropriate orbit?) Traditional assessments—essays, multiple choice tests, true-false tests and standardized normed tests—were and are frequently used to assess learning with technology. Traditional assessments are adequate in measuring some levels of thinking but need to complemented with newer assessment strategies to capture the variety of learning possible with technology enhanced learning. With new technologies in the teaching and learning process, there appears an emphasis on non-traditional forms of assessment such as authentic assessments (portfolios and journals), project based learning products, and rubrics. Different types of assessments are matched with types of thinking in table 6.

Table 6: Current assessment strategies matched with types of thinking.

</table>

As noted in the table 6, the traditional assessment will measure most types of thinking, but the reliability and validity with a variety of learners and learning outcomes are often questioned. Non-traditional assessments are critical for measuring creative thinking. The current practice of predominately using traditional assessments for basic skills and the non-traditional assessments to assess creative and problem solving products reflecting learning with technology creates a disbeneficial dichotomy.

A need for a new paradigm of assessment emerged with the integration of technology in the teaching and learning process and the predominance of constructivism theory or techniques in technology integration. As we are teaching and learning in new ways, we need to measure the process and outcomes in different ways. In order to fully
capture the richness and vastness of teaching and learning that integrates technology, a bridge connecting the traditional assessments for convergent thinking and the nontraditional assessments for divergent thinking is needed. Normed quantitative tests measuring concept recall and understanding often miss the unexpected insights of creative problem solving. From another perspective, too often, qualitative portfolios and projects fail to explicitly assess basic concept mastery. Since standardized objective competences are predicted to remain an emphasis in school achievement, they need to be explicitly addressed in the constructivist and project based learning assessments.

Conclusion

How do you know when to plug in or plug-out? The plug-in or out decision should be made by examining whether or not the teaching and learning process is more effective and efficient (complementary to brain potential and processes and types of thinking) with technology. (Did the rocket boosters work to their full potential in combination with each other and was the human spirit—rising stars—students launched.) Individuals should make this decision based on: 1) the process and types of learning to be assessed and 2) findings from outcome instruments that measure basic skill competencies as well as creative meaningful application. Thus, the decision of Plugging-In or Out is an informed decision based upon assessment data and the potential of launching our students as all-stars!

IT Practice from Theory. The Need for a New Paradigm.

Nigel Parton, Dept. of Educational Theory and Practice, University of Edinburgh, Scotland.

Abstract: IT is seen as having the power to transform teaching and learning. Extensive commitments have been made to its use throughout education. In some ways IT has been successful but it has not always achieved its intended aims. It can be argued that this is because IT's introduction and implementation has not been based on an appropriate pedagogy. IT's power renders aspects of existing pedagogical understanding obsolete. What is required before we can be truly successful is a new paradigm. Within the area of electronic communication a social constructivist position can illuminate our current position and show how best to use the technology to support teaching and learning in undergraduate degrees in the future.

This paper is intended to be of interest to individuals involved in initial teacher education.

Learning Technology Dissemination Initiative (LTDL), (18997), BrTe Ideas, Edinburgh, Herriot-Watt University.

Throughout the Scottish education system extensive investment has been made in Information Technology (IT). A number of reasons have been given for making greater use of this. Not only is it viewed as being cost effective it is also seen as encouraging flexible and independent student learning. Increasingly IT is used as a medium for delivering significant parts of degree programmes. More widely there appears to be an ever growing consensus that IT will continue to expand its role as a medium for learning. Often though claims regarding its efficacy are not fully substantiated. It is not uncommon for little detail to be given. At times it can seem that it is enough to describe the proposed practice without offering either an overarching rationale or an examination of the proposed pedagogy. Even when a theoretical justification is given it can be less than rigorous.

For example, Fischer (1997) argued that work was an increasingly collaborative effort among colleagues and peers and this process was being accelerated by the use of ICT. Learning was becoming, “a new form of labor.” (p 9). Although the notion of the development of, “collaborating communities of practice,” is appropriate the paper tends towards a restricted view of the nature of learning. Knowledge seems to be seen as a series of facts and the transmission of knowledge is emphasised. Fischer argued that the effective use of ICT allowed the delivery of the, “right knowledge at the right time to the right person and in the right way.” (p 12). Although IT systems do allow access to vast numbers of facts, an overemphasis on this not only devalues knowledge itself, it also suggests a limited view of both the nature of learning and the complexity of the relationship between learner and teacher. Astleitner and Sams (1998) explain that there are numerous examples of such limited expectations and argue that the majority of World Wide Web sites designed to support student learning either directly or indirectly seem to equate learning with the transmission of facts. They go on to suggest that what is needed is a, “firm foundation based on pedagogical principles in order to provide the theoretically founded knowledge necessary for extensive and high-quality support for teachers.” (p 85)

Personal experience suggests that although the use of IT in both schools and universities has made some impression it has not had the impact on learning and teaching some of its loudest proponents have anticipated. In Scotland a rationale for the introduction and use of IT in higher education was outlined in the MacFarlane report (1992). This initiated a series of developments throughout those institutions involved in initial teacher education (ITE). These included the development of policies confirming a commitment to the role of IT within teaching and learning settings, extensive investment in both hardware and software for academic staff and the introduction of relevant staff development programmes. Further provision was made to allow students access to both IT facilities and appropriate support. A number of innovative developments resulted including, SPRITE (1993), STARS (1997) LTDI (1997). It has been subsequently argued by Simpson et al (1998,99) that the innovative expertise developed by individuals through involvement in these activities has not been widely disseminated amongst staff in the institutions and that impact on the organization and structure of teaching activities has been limited.

Within the Edinburgh undergraduate ITE programme IT has been successful in changing the experience of students in lectures. For example the publication of notes in an electronic format means that students no longer need to take extensive notes and can focus on the lecturer. The lack of frequent pauses to allow for students completing note taking has meant that there can be more effective interaction with the content of
the lecture. Students and staff now have access to a wealth of information so extensive it could be held by no traditional library. Email has proved to be a highly effective method of conveying administrative messages to students and dealing with their questions of a similar nature. Although somewhat reluctantly students have been prepared to use email to describe aspects of their professional activities. However the introduction of the technology has not proved to be as successful with the more academic aspects of student work. Students have not been prepared to use email to hypothesise, discuss or attempt to refine their understanding of professional issues. It would appear that this is not because they are unsure of how to use the technology, there is a lot of evidence of a high degree of technical proficiency in using the medium. It appears that young people use informal networks to effectively develop their skills in the use of this technology, at times innovatively adapting them to meet their own needs and priorities. Nor is it because students are unaware that it can be used for open-ended discussions, even a brief examination of student bulletin boards will show evidence of spontaneous discussions about a range of non-academic subjects. Some of these can show evidence of development in the participants’ understanding. It can be argued that Astleitner and Sams (ibid) view that a stronger theoretical underpinning is required if IT is to be used effectively to support academic work, is correct.

An essentially Vygotskian perspective seems to be able to offer this theoretical underpinning. Vygotsky (1978) defined the zone of proximal development (ZPD) as the distance between the, “actual developmental level as determined by independent problem solving and potential development as determined through problem solving under adult guidance or in collaboration with more capable peers.” (p 86) This implies not only that the mind has a potential for development but that it can develop in a range of different ways. The manner and direction of this development depends not only on the assistance given by adults and more capable peers but also on the socio-cultural environment. Tulviste (1991) argues that within any given society thinking develops in accordance with the types of activities in which people engage. By engaging in culture specific activities people develop higher mental processes that are appropriate for culture specific tasks. The mind itself constantly evolves as individuals find themselves facing new challenges.

According to Tharp and Gallimore (1988) to understand learning in the ZPD three concepts are important; situation definition, intersubjectivity and semiotic mediation. In any given situation an experienced practitioner may define it differently from a novice. For example, an experienced teacher tends to be more perceptive as to what is important in classroom situations and shows more sensitivity to the subtle characteristics of the classroom than a student teacher. This is situation definition. Once the novice has reached an understanding that allows him to generate a definition of a situation that is in tune with that of the experienced practitioner intersubjectivity has been achieved. This is a qualitatively different understanding of the situation to that held previously. Intersubjectivity is achieved through semiotic mediation, that is through dialogue between the experienced practitioner and the novice. It is through this that the novice’s understanding of what needs to be done develops. With the experienced practitioner’s support the novice moves towards their mentor’s understanding of the situation. Intersubjectivity is achieved when their understandings overlap.

It is possible for the novice to progress through the ZPD. Tharp and Gallimore (ibid) suggested that this progression goes through two stages. Initially assistance is provided by the, ‘more capable others,’ who explicitly advise and support the learner. Over time intersubjectivity develops and the support becomes less explicit with the novice taking more responsibility for the situation. Eventually the processes become, “internalised, personalised, adapted and owned,” by the novice. This is the end of the first stage.(p 252). Stage two is when the, “assistance is provided by the self.” The responsibility for the task has shifted from the experienced practitioner to the learner. At this point the relevant processes are not automatic. Tharp and Gallimore argue that this stage is, “intermediate between external regulation and full individual competence. It may also be seen as the stage in which the voice of the regulating other is gradually acquired by the learner so that the regulations may be stated self to self, gradually taken underground, transmuted into thought and eventually discarded as behaviour becomes fully developed and adaptively automatic.” (p 253).

Vygotsky (1986) suggested that intellectual development takes place on two planes. The first is the inter-mental plane which is between people in social and cultural situations and the second is the intra-mental
plane which is the internalisation of the inter-mental processes. The implication of this is that higher mental functions are carried out in collaboration with others in a range of settings. Language, therefore, must play a central role in their development and internalisation. Vygotsky considered language to be an important tool for thought and problem solving. “Thought is not merely expressed in words, it comes into existence through them.” (p 128) Language allows individuals to examine thought, clarify it, explore contexts, solve problems and identify connections. It is an important aid in structuring and refining thoughts.

Learning is a complex process. It is about developing understandings and making links rather than just the transmission of facts. It is influenced by the culture of the society in which the learner resides. It is not a solitary experience but something that happens in a social context. Interaction with others is central to the learning process. Language, both oral and written, has very close links to learning. Not only is it used as a means of communication but it is also central to the thought process and hence to learning itself.

As IT can be used to facilitate communication it could be seen as having a role to play in supporting this type of learning process. As with all activities that lead to learning its structure needs to be appropriate to its purpose. Electronic communication opens up possibilities for dialogue that could be used to support effective learning. It is not as spontaneous as oral language and does not contain the non-verbal cues that are involved in verbal interactions. It is less formal and more flexible than traditional methods of written communication. Although arguably not a totally new genre of communication it does have advantages over more traditional methods. These include:-

- allowing communication over distances that would otherwise be prohibitive;
- allowing access to expertise that would otherwise be unavailable;
- allowing groups of individuals with shared interests to exchange views in a common forum;
- helping the writer to express views they would be reluctant to share in a ‘face to face’ exchange;
- facilitating communication through its asynchronous nature.

It would seem therefore that it should be a highly effective medium for supporting learning and helping the learner progress through the ZPD. It has the potential to be used to develop thinking as well as communicating with both mentors and peers. Within the context of initial teacher education (ITE) there would seem to be potential for using electronic communication to develop student understandings during their times in the Faculty when they are not being directly taught. It would also seem to be an ideal medium for supporting students when they are involved in school placements outwith the Faculty.

This potential for IT to transform teaching and learning within educational establishments has been widely predicted. For example, Lewis (1999) argued the emergence of a pedagogy arising from, ‘constructive learning,’ stressing learner choice and multiple routes to outcomes. Pellegrino and Altman (1997) amongst others have speculated upon the processes of change, the forms these changes may take and their potential desirability or otherwise.

In the past it has proved difficult to bring about significant change in educational practice and, as stated previously, there is some evidence that pedagogical change relating to the use of IT is not unproblematic. In practice centrally planned initiatives tend to have only a limited impact on teaching and learning. Brown and McIntyre (1993) argued that within education, professional practice involves complex judgements, the process of which experienced practitioners have internalised to such an extent they appear to operate with a superficial simplicity. In contrast to a centralized approach to change it can be argued that a different approach is needed if a lasting change in educational practice is to be achieved. Within this model the educators themselves generate new concepts and frameworks through their roles as reflective and controlling participants in innovation.
It is not enough to introduce electronic communication into any learning situation and expect it to transform learning and teaching. Although applying existing pedagogical principles helps its effective use what is needed is a further exploration. The technology does have potential to transform but before this can truly happen we need to revisit our theoretical understandings. What is needed is a new paradigm.
Instructional Technology:
Practical Application Alignment With Theory In Student Teaching
Field Placement

Carole S. Robinson
Curriculum and Instruction
The University of Montana
United States
CSR_MT@email.msn.com

Abstract: This case study explores what student teachers learn about practical classroom instructional technology applications within their elementary field placement and any underlying influences on student teachers implementing instructional technologies in the elementary are described along with their cooperating teachers' accounts of factors in the school that either promote or inhibit professional technological growth.

Student teacher/cooperating teacher participants were placed into buddy system configurations. These pairings served to investigate a) What effects do instructional technology using educators have on non-instructional technology using educators? And, b) What effects do non-instructional technology using educators have on instructional technology using educators?

When looking for ways schools of education can successfully merge instructional technology theory with classroom practice, three themes emerged: a) collaboration and rapport; b) self-directed learning; c) equipment: time and availability.

Introduction

Seventeen years ago, A Nation at Risk (United States Department of Education, 1983) addressed the need for secondary students to take a computer course prior to high school graduation. Standard course work emphasized programming in BASIC. Computer literacy was rarely considered in preservice education curriculum. Today, The Department of Education officially views technology as a change agent for public school systems.

With a new century upon us, educators are witnessing a convergence of brain-based research, technological innovations, a new culture of students, au courant learning theories, and a federal agenda to place computer-based technology into the nation's K-12 classrooms. This notable amalgam of developments combined with the exponential growth of the World Wide Web and newly published National Educational Technology Literacy Standards (International Society for Technology in Education, 2000) for teachers and students provide promising new implications for teaching and learning. As a result, schools of education are becoming points of egress for encouraging, modeling, and training preservice teachers to effectively synthesize computer-based technology into their newly developing classroom methodology. "The effect of computer-based learning technologies in facilitating student learning and performance is seen only when participants have the knowledge and skill to use the technology" (Fulton, 1998, p. 1).

The United States Department of Education (2000) found 66% of public school teachers integrated technology into classroom curriculum "compared to 47% of teachers who reported feeling somewhat prepared and 14% of teachers who reported feeling unprepared" (p. 89). However, schools of education infusing the technology standards to already overcrowded teacher certification programs have developed into a slow course of action. According to Thomas, Larson, Clift, and Levin (1999) technology is best infused in all preservice education coursework. The "autonomous course model" subtly promoting learning technology applications was "not valued by students" and they were "seldom able to incorporate technology into their own curriculum" (pp. 4-5).

A predominated inconsistency exists between many schools of education faculty technology
knowledge base and what they are training preservice teachers to do. Only 40.4% of faculty members indicated moderate to high proficiency in instructional methods for integrating technology (Vannatta, 1999, p. 1485). Queitzsch (1997) discovered major technology concerns directed toward faculty curriculum integration and student field placements. Students deserve teachers who model the best that technology can bring to learning (Topp, Thompson, & Schmidt, 1994; Jinkerson, 1995; Kortecamp, 1995; Queitzsch, 1997).

How can schools of education successfully merge instructional technology theory with classroom practice? This study is primarily concerned with investigating the student teaching practicum from the student teachers' viewpoints of being prepared to effectively integrate computer-assisted learning and instruction into their classroom practice. This will include underlying influences on student teachers implementing instructional technologies in their classroom practice. Emphasis will be directed toward revealing any internal and external support mechanisms and/or curriculum methods to better encourage appropriate proficient integration.

The Study

Participants for this naturalistic case study consisted of three elementary education student teachers enrolled in their final student teaching semester and their respective cooperating teachers. The field experience study site has a national reputation of being one of the premier school districts in the area and a reputation of one of the best and most progressive especially in the area of technology. Each classroom teacher is equipped with a personal use windows platform networked computer. All classrooms has four or five additional networked computers as well as a color printer. Teachers have access to the school server for bulk license purchased educational software, Internet access, and student project storage.

By placing student teachers in the same field placement elementary school site, participants had access to the same technology. This was important in investigating individual views of a technology-enhanced teaching environment and its underlying influences on implementing instructional technologies during the student teaching practicum. Noteworthy student teacher study outliers included technology experience prior to admission to the education program, school of education instructors, and cooperating teacher designation.

Paring was in a buddy system configuration (Carlson & Gooden, 1999). It intended to provide insight into how partnering of differing technology competencies translated into practical classroom application as well as the advantages and disadvantages of these field experience pairings. Individual cooperating and student teacher technology ratings were determined by unbiased evaluators served to establish commonalities as well as distinct technology abilities - a key in considering their field placement classroom pairings.

Table 1: Study Participant Pairing Configuration by Instructional Technology Competencies

Patton (1990) subscribes that there are three classical methods of generating qualitative data: reading (document analysis), talking (interviewing), and watching (observation). The general design of this study incorporated all three classical methods.

The first phase of the case study is biographical in nature. Participating preservice and cooperating teachers participated in an informal interview early in the student teacher's field placement experience. The informal interview introduced the study and allowed the researcher to better understand each participant's interests and concerns regarding the study. Interview questionnaires and informal interviews were also used throughout the semester to gain some perception into what teaching and computer-based technology means to each interviewee.

To better understand the participants' classroom experiences and gather first hand information
necessary to furnish detailed accounts, student teachers were observed in their classrooms during the second phase of the study. The primary observational resource was videotaping and the observer remained as non-participatory as research conditions allow. The first observation was made on the first week the student teacher took over the classroom from the assigned cooperating teacher. The middle two videotaped sessions were equally spread as circumstances allow between the first and the last formal week of the student teachers’ field placements.

The third phase of the case study entailed reflection and comparison. Student teachers and cooperating teachers were asked about their involvement with technology following their student teaching semester. Additionally, each student teacher’s School of Education Summative Assessment of Student Teaching, filled out by both their cooperating teacher and university supervisor prior to teaching certification and filed in the Office of Curriculum and Instruction, was studied for any pertinent commendations (strengths) and recommendations (weaknesses) significant to this study.

Data analysis was the fourth and final phase. After perusing and careful analysis, the themes that became the foci of this report emerged from the data. Even though key factors at times coalesced, overlapped, and intertwined, themes remained distinct. After constructing a matrix of tables delineating the themes and the number of times each of them was backed by the data, I focused on the three that were most heavily supported: a) Collaboration and Rapport, b) Self-Directed Learning, and c) Equipment: Time and Availability.

Findings

The study recognizes that many of the student teacher participants’ field experience perceptions correspond to substantial national data regarding obstacles to and facilitation of a national thrust toward technology literacy. Time quickly emerged as an overlying theme. Data became predisposed to a multiplicity of participant time perceptions influencing technology integration decisions on many levels. The present analysis is congruent with existing research findings citing time as a critical implementation component (Beggs, 2000; The United States Department of Education, 2000; Mitchell & Hutchinson, 1998; Nantz & Lundgren, 1998; Kane, 1994; Sheingold & Hadley, 1990).

Since the first day of the study, participants wrestled with a responsibility overload. Weekly research focus groups were scaled down to bimonthly scheduling. I opted to end the focus group in favor of preceding or following each video observation with informal student teacher interviews as well as conversing with participants when I was visiting the study site for supplementary data. However the overlying issue throughout this study was how much time influenced the field placement experience (c.f. Fisher and Dove, 1999; United States Department of Education, 1998).

During many classroom video observations, I witnessed schedule conflicts with technology-enhanced projects. Student teachers related that it is not uncommon for technology acute teachers to sacrifice other content areas for a technology-integrated assignment. Further investigation using informal interviews revealed a pattern of the teaching staff engaging in unofficial reprioritizing of subject area scheduling.

The need and motivation to integrate technology during the field experience waned for two of the three student teachers as the semester progressed (c.f. Thomas, Larson, Clift, & Levin, 1996). Lesson planning was time consuming enough and incorporating goals and objectives involving technology made a demanding endeavor even more so. I witnessed a student teacher’s good intentions overridden by not enough time to effectively integrate technology into the lesson plan, to choose software content to supplement the subject area, to prepare the computers for the project, and apprehension about not enough time in the schedule to work all the students through the computer station component (c.f. Medcalf-Davenport, 1999; Larson, Clift, & Levin, 1999; Queitzsch, 1997).

Each student teacher often became frustrated over the amazing amount of time it took their young students to work through technology-integrated assignments and to use technology not typically located in their classroom. A majority of student and cooperating teachers often spoke to considering the time it took to locate and set up technology into viable working mode as a major consideration when integrating it into his or her curriculum.

The preoccupation with time led to a parallel investigation into what factors contributed to these student teacher’s coping mechanisms (support system) during their field placement experience.
bonding element between the participant pairs in the study underscored the heavily researched and proven phenomenon of student teachers readily implementing their cooperating teachers’ classroom practices in lieu of the university professors’ with which they have spent two years of preparatory work (c.f. Calderhead, 1988; Pratt, 1993; Merriam, 1993; Richardson-Koehler, 1988). I observed a direct connection evolve between this study’s participant pairs’ collaboration and rapport and their individual self-directed learning characteristics. Classrooms became settings for experiential learning - self-directed learning activities involving gleaning and synthesizing knowledge placing student teachers with personal responsibility for their own learning.

Cooperating teachers served as the student teachers’ fundamental ongoing transitional support system toward becoming skilled educators. Field experiences provided a mentored trial-and-error authentic learning environment where, hopefully, theory may connect to practice. Participant pairs became collaborators working together in real time, not just in theory - a missing element in their university-based teacher education program. Feedback was immediate. These elementary classrooms represented the bell jar wherein student teachers had daily opportunities to synthesize previous academic coursework, including two previous semesters of school observations, on a conscious level.

Pair One complemented each other’s contributions toward increasing curriculum technology integration. The technology literate novice student teacher and nearing proficient cooperating teacher expanded each other’s technology literacy base and energized further learning toward a common goal – creating and facilitating a challenging engaging learning environment.

Pair Two’s experiences appeared more one-sided. The cooperating teacher’s proficient computer-assisted learning and instruction integration methodologies put theory into action for the student teacher. The proficient technology literate cooperating teacher largely affected the nearing proficient student teacher by making him an active participant. Even though the cooperating teacher greatly appreciated her student teacher’s technology abilities and contributions to her classroom, she did not learn from the student teacher.

Pair Three’s proficient technology literate team appeared an anomaly to this research. The student teacher did not flourish in this technology-rich professionally modeled learning environment. Eventually he reengaged his self-directed learning abilities to become better prepared for class. However, neither the student teacher nor the cooperating teacher grew exponentially in technology integration. Both voiced frustration about the experience.

Recommendations

Teacher educators and administrators working in technology accommodating university environments are ultimately responsible for working toward setting functional integration priorities in motion throughout preservice curriculum. Implementing priorities will emphasize focus on a necessary goal of the educational institution – preparing teachers for the new century of students. Largely, classroom technology integration debates have shifted from if to how in the last decade – How can schools of education successfully merge instructional technology theory with classroom practice? How cannot possibly be approached until priorities shift to facilitating the process.

Recommendation 1: Begin Now

Appropriate computer technology integration should become an automatic response to specific methodological needs prior to student teaching. Teacher educators must begin to transition their own curriculum design toward facilitating this goal. Once the student teacher enters his or her field placement experience, time elements are often weighed against exploring technology integration. Unless more student teachers establish a better comfort level with the latter, integration is often bypassed. So, if and / or when a student teacher becomes overwhelmed from his or her field experience demands, with the proper preservice training, integrating technology should not be interpreted as an overwhelming additional curricular chore.

Recommendation 2: Infuse Technology Into Every Course

Holistic integration is the key. Systematically infusing educational technology into the every teacher education course in some way will assist the curriculum transition toward graduating technology competent new teachers. As teacher educators enhance their own technology-based skills by connecting
computers with each facet of school curriculum and instruction, preservice students will begin to connect with technology to contextual learning activities involving age-appropriate, competency-building learning experiences to be used in student teaching. Even beginning observation could require students to locate instructional technology within the building site and establish a familiarity with reservation procedures.

Educational technology courses estranged from the main body of educational coursework further perpetuated the notion that technology is an entity to be dealt outside the mainstream academic courses. A danger lies in isolating technology from an authentic learning environment. Isolating may translate primarily into a computer application course. However, courses of this type could be renovated to include authentic learning environments where preservice students design and implement technology integrated activities in K – 12 settings.

Recommendation 3: Do Not Assume Assimilation

It is doubtful that teacher educators teach curriculum methodology and content standards around machines. Think of the disservice to education if teacher educators certified new teachers who built lesson plans around equipment, like pencils or color markers, not concepts. Laughable perhaps but novice educators need to be able to assimilate the difference between computer technology applications and integration. Just because preservice teachers can assemble a PowerPoint presentation does not guarantee that they can conceptualize and construct a curriculum implementing PowerPoint that engages higher-order thinking skills. Teacher educators should never assume preservice students have the ability to assimilate theory into practice. The ability to assimilate is not a given for every undergraduate - especially since they have most likely spent at least 13 years in educational systems primarily entrenched in drill-and-practice and memorization.

Recommendation 4: Model, Model, Model

Research proves its importance in student teachers' ability to integrate technology into their classroom curriculum. School of education instructors and administrators must evaluate how to make prevalence in every preservice classroom every day - then set the practice into action as soon as possible.

Virtual Worlds, Real Minds: an investigation about children, videogames and cognition

Antonio Simão Neto, M.A.
Pontificia Universidade Católica do Paraná BRAZIL
4simao@uol.com.br - simao@rla01.pucpr.br

Abstract
The Virtual Worlds, Real Minds project aims to investigate and understand the cognitive processes that take place when young people play videogames and to provide educators with some insights based on this understanding. Preliminary findings show that traditional, Cartesian ways of thinking can be perceived, along with new, more emotional and interactive forms of viewing and making sense of external stimuli.

Children resemble more their times than their parents
Ibn Kaldum, Arabian thinker, XIV century

Introduction
This research project started when my nine year-old boy asked me to go with him to a videogame rental shop. A new game had just arrived from Japan and he wanted to get it ahead of his friends. He didn’t know exactly what the game was about. Needless to say, neither of us knew a single word in Japanese, spoken or (of course), written. This basic fact didn’t stop him at the least. He rented the game, we went back home, he inserted the cartridge in his console and wonderfully started playing. Just like that.

How? It became immediately clear to me that important mental processes were being mobilized at that moment. He was enjoying himself, he was having a good time, but he was learning as he played.

In order to be able to play a new and still “uncracked” digital game, in which written and spoken word were in a different and unknown language, my son had to rescue and apply everything he knew about games and how to play them. And he had to do it “on the fly”. The pace and sheer speed of the game didn’t allow him time to think. Or maybe it is better to say that he couldn’t think in cartesian ways, racionalizing everything as he went along.

It was then that I decided to investigate the processes of thinking and learning that are involved in the act of playing videogames, in the hope of reaching further understanding about the ways the new generations think, communicate and interact. If we could advance our comprehension of the young minds, maybe we could devise more efficient educational methodologies. In other worlds: it is time to develop educational systems that are “in sync” with the generation we are supposed to teach – or to help in their learning.

Videogames were chosen as a particularly relevant subject also because they are pervasive: kids’ main use of technology.

The research project
The research has been going on for a little more than an year and some results are being obtained. These preliminary results are the topic of this paper.

The research is part of a broader project being conducted at the Pontificia Universidade Católica do Parana, a private-owned university in south Brazil. It is a medium-sized institution by Brazilian standards, with about 20,000 students and 1,500 staff members. The Faculty of Education started in 1998 a new area of research called “the Centre of Tomorrow Education”, with the aim of studying new educational technologies and methodologies, of evaluating the
impact of these innovations in different educational environments and of helping teachers and academic staff in the
difficult task of applying new technologies and methods in their day-to-day work as educators.
The “Virtual Worlds and Real Minds” project is one of the projects presently being carried on at the Centre. It started
formally in the beginning of the 1999 academic year (which in Brazil is March) and is expected to take on more year
to reach final results.

Methodology
The project comprises field work and analysis. Field work is being done in three different environments: home,
videogame rental stores and arcades. The Home environment is itself divided into two categories: console-based
videogames and computer games.
The first part of the observation was directed towards videogame home users. Young people from 4 to 14 years old,
mainly middle class, living in three different neighborhoods. They were observed and interviewed, both at their home
and at six videogame rental shops which agreed to cooperate with the researcher, allowing an interesting comparison
between these two playing environments. All in all, the universe of this first stage totalized 54 “regulars” (50 boys and
4 girls) and about a little more than a hundred other kids who contributed to the research in more open ways (some
were interviewed but not observed while playing, others were observed only once or twice and were not follow-up, for
a number of reasons). Data were collected and registered in a spread-sheet/data base/graphics integrated software. A
control group of 8 kids who claimed not to play games at all was identified and interviewed regularly.
Apart from direct observation and interviewing, a large number of materials was selected and analysed, such as
specialized videogame magazines, fanzines, web sites, books, posters and other related stuff which belong in the
gamers universe. Videogames of many different types and systems were seen in detail and played by the researcher
(as far as I was able to go...).

Preliminary Findings
For explanatory reasons, preliminary results are shown in three groups:
- classical processes and patterns of thought
- non-cartesian and emotional intelligences
- social behaviour and sociability patterns

Thinking Digital
First, it could be observed that many ways of thinking that educators put a lot of effort into to develop in their students
are already being employed by kids when they play their games. Association, generalization, analysis and sintesys,
transfer, projection, simulation, trial and error and a number of others forms, alone or combined, are put into action by
the gamers all the time.

It is not in the scope of this paper to present and discuss all those “ways of thinking” and how they operate in the
gamers minds and actions. But let’s take generalization, for instance. One of the main components of
Cartesian/Newtonian processes, generalization occurs when there is not enough data to proceed – so we start from
what we have and try to extrapolate the ideas we consider as generic enough (and so, applyable) to the new situation;
generalization also happens in the opposite direction, when we have too much data and must discard what is not
relevant (for not being generic enough) in order to proceed within a safety error margin. Well, that is what we can see
young people doing when they put a new game in their favorite console or when they get to new phases of a game.
They advance by grasping – in a wink of an eye – what is relevant and what is not, what must be discarded and what
must be fulfilled so they can deal with new situations. Surely educators would love to see their students doing the
same when they tackled the contents of a traditional course...

One of the aspects which may present teachers and educators with food for thought is the way gamers deal with error.
They are not afraid of making mistakes, of following the wrong turn or of choosing a bad weapon. They know that to
err is to learn: error is a natural, necessary part of a learning curve. How different from what they get in schools,
where they are taught that to make a mistake is something bad, something to be ashamed of. No wonder they accept a
passive role as students while they are so very active playing games.
Thus, kids are not discouraged to play a new game. On the contrary, they love the challenge, they yearn for the new and are not afraid of facing new obstacles. When dealing with a new game or screen within a game, they think – fast – and they act, without hesitation, on the basis of what they decide, after considering, with mind and body, what should be done.

Emotional Intelligence on the Fly

This complex structure of trial-and-error, of thinking and acting, of seeing and doing, of feeling and knowing, of risk and feedback, is quite amazing for an adult who were raised believing in the power of rational, logical, processual thinking.

For emotions, intuition, sensibility play a very important part in the world of the gamers. Many times, when a problem arises which is not solvable by association with past experiences, by generalizing, analyzing, transferring, previewing or any other rational way, they trust their feelings, their intuition. "I don't know how, but I was sure I should go that way". They also know that you must keep a delicate balance between being "cool" and relaxed and being keen, attentive, adrenaline-driven if you want to be a good gamer. Emotional intelligence applied...

Sociability in the gamers' world

Other interesting considerations in the educational point of view can be made at this point. For instance, research is very important in the world of videogames. Gamers publish and read magazines, web sites, fanzines and other printed materials. They look into these materials to find and share tricks, suggestions, opinions, open and secret codes, even illegal or a least unauthorized information that show how to defeat a tough enemy, how to get more money or new lives, how to go faster, how to find that secret passage. They also consult more experienced gamers (nothing to do with age: experience is measured by the time one have already spent playing); they build and use a highly integrated network of players; they interact.

In a way, gamers tend to form a kind of “urban tribe” as defined by French sociologist Michel Mafesoli: a post-modern pattern of sociability, in which individuals behave in certain pre-defined ways accepted and valued positively by the group, who derives its own identity as a group from these shared values. This pattern affects the way kids play (and the way they learn) since the ones who interact tend to be more effective in reaching their goals. The isolated individual gamer must rely on his own abilities and often they are not enough to win (“to zero”, to “tough game. Thus, we may be facing a very interesting case of cooperative, collaborative learning environment. This may conflict with the highly competitive nature of games, digital or not. In the specific case of videogames, it seems that competition is seen more like a dispute against the machine than against the other players. We can see that in a boy’s party (if there is a videogame console available, there is where kids will gather around): young and older kids helping each other to defeat the mean phantom. They don’t really care if a friend killed the monster in less time (they will try to better their scores latter); they want to learn how to do it, or how to do it faster or more efficiently. There is a lot more to games than simple hand-eye coordination. Among other capacities, it can be observed a gain in visual understanding, in media awareness and in the development and use of a multimedia, interactive language.

Problems over the horizon

On the other hand, an educator can easily see a number of problems in the games kids play. There is violence, for sure. A kind of sublimated violence, as some psychologists argue, or at least the representation of violence. Videogames – a boy’s world, for sure. Many games are “politically incorrect”, since kids look into virtual worlds usually through the eyes of a white-macho-american hero, who kills everything that moves. They go beyond a sexist view. Here are Nazi fundamentals: everyone who is not like me wish to do me harm; better to eliminate them before they get a chance to eliminate me.

This arguments are nor to be discarded lightly. They suggest a deeper investigation on the sociological and psychological aspects of videogaming, which are beyond the scope of this research. Even so, it can be pointed out that violence, racism, sexism are not inventions of the games industry and would not disappear from the world if games were abolished (as some propose). It is out task as parents and educators to contextualize these issues, to discuss them, to amplify the world of references and values children have access to – then they will be able to make right choices. Is
was noted in this research that some very violent and bloody games are popular, but not played as much as other, more involving and challenging games. Other negative aspect perceived during this investigation was a tendency, shown by some kids, of over-self-valueing. A good gamer considers himself “the best”. He can always find a way to defeat his enemies, to win a challenge, to find hidden treasures. He is so good that nothing is beyond his capabilities. Life outside the game must be the same. He will always be a winner. There are some considerable dangers here, from a narcissistic isolation to a self-centered, egotistic individualism.

Next Steps
Field work will continue with the groups mentioned above and with two new groups: computer-game players and arcade gamers. Those two groups were left out of the first stage of the research because they tend to involve kids older than 14, and in the case of arcade players, from other social stratus. Analysis of data will be carried on with more attention to statistical procedures and methodologies. Observation and interviewing will continue, with special attention to the control group. Cognitive aspects will be the main issue to be tackled, in the hope that we will be able to deepen our understanding about the ways the new generations think, communicate and act.

As author Douglas Rushkoff pointed out,

“To look into the children’s world is not to look back to what we were. Is is to look into the future”.

Communication Technologies: Post-industrial Infrastructure

Tatiana Solovieva

Abstract: This work addresses the complex relationship between the post-industrial society and communication technologies. This interaction results in the acquisition and the codification of theoretical knowledge and information that influences the key aspects in the social and technological development, namely: social, political, economic changes. A model was developed to represent the balanced coexistence of technical and human infrastructures in our information era. As a result of the presentation of this model, the readers will gain a new perspective on their position within the multi-level human-technology infrastructure.

Introduction

Technique possesses a universal significance, for through it a new cosmos comes into being.
Nicholas Berdyaev.

This work investigates the relationships between the two essential components of the technological infrastructure: technical and human factors, represented, respectively, by the communication technologies and the post-industrial society. The paper presents the conceptual macro view of the infrastructure and its surrounding issues discussed in the historical and analytical works by contemporary thinkers in the field of technology and culture. Technology reshapes traditional society, its values, and its routines. Most of the contributors recognize the potential benefits of technology, however, they also express the genuine concern about human mind and freedom. Alongside the infrastructure related topics, the writing introduces multiple interpretations of the impact of modern technological world on the nature of human experiences in social aspects of life. In order to address contemporary issues about communication technology, it is essential that we define what is meant by technology in modern world. The illustration of the evolution of its definition will give us a better picture of the subject matter of our discussion.

What is Technology?

Feibleman defined technology as “the name for the invention and employment of artifacts, and artifacts as materials altered through human agency for human uses. Another name for artifact is tool” (Feibleman, 1982, p. 74). Neil Postman (1997), the author of the article “Defending ourselves against technology,” makes a distinction between a technology and a medium. He states the following: "As I see it, a technology is a medium as the brain is to the mind. Like the brain, a technology is a physical apparatus. Like a mind, a medium is a use to which a physical apparatus is put. A technology becomes a medium as it is given a place in a particular social setting, as it insinuates itself into economic and political contexts. A technology, in other words, is merely a machine, a piece of hard wiring. A medium is a social creation” (p.229). He also presents the idea that it is possible for a technology to be used in a manner in which “its social, economic and political consequences are quite different from one culture to another” (p. 229). In different cultures and languages, philosophers defined technology in different ways.

The French word technique, and German Technik, are usually put into English as “technology” (except by Lewis Mumford, who calls it "technics"), and the English word “technique“ means something else: "a technical method of accomplishing a desired dream" (Webster). Ellul's usage of technique in both French and English is vastly broader still: the totality of all rational, efficient methods in every field of human activity. In other words (those of his translator, John Wilkinson), technique is “nothing less than the organized ensemble of all individual techniques which have been used to secure any end whatsoever”(Susskind, 1973, p. 89).

Jacque Ellul (1964) sees technology, la technique, as an ensemble of technical means, a totality of means that operates at its best efficiency. Langdon Winner (1977) in Chapter II “widely recognized work Autonomous technology views technology in the following way:
A technique is a structure of human behavior designed to accomplish a definite outcome. A technical organization is an assemblage of human beings and apparatus in structured relationships designed to produce certain specific results. A technical operation, to the extent that one engages in it, determines what one does (p. 75).

It is certain that technology does not exist in a vacuum. The interaction between humans and technology is taking place at many levels. The technological phenomenon is a constant of human history. The paradox is that culture cannot exist without technique and technique will not exist without culture. According to Marx, humans make their world, but they are also made by it. The idea of paradox, the dualism, "the double edge sword" type of relationship is the characteristic of the interaction between humans and technique of modern era. This very idea of paradox, the dualism is one of the central themes of this work.

To Ellul, the greatest wonder of our time is the integration of people and society into the complexity of the technical world. The final definition of the technology in this paper can be formulated as a multi-complex interrelation with life, society, and the environment. Lewis Mumford (1983) in the article "Technics and the nature of man" refers to the classic Greek usage for technics that "makes no distinction between industrial production and art; and for the greater part of human history these aspects were inseparable, one side respecting objective conditions and the functions, the other responding to subjective needs and expressing sharable feelings and meanings" (p. 81).

Technique may be understood in a broader and narrower way. One word stands for both industry and art: another means to make, to create with skill. We speak not only of an economic, industrial, military technique, a technique of transport and the comforts of life, but also of a technique of thought, versification, painting, dancing, law, even of a spiritual technique (Berdyaev, 1983, p.203).

In connection to the definition of the technique that contributes to the understanding of its meaning, it appears necessary to present its defining characteristics in the context of modern time due to its special position in our life.

The Characterology of Modern Technique

According to Jacques Ellul (1964), "the technique of today has the same characteristics as all preceding techniques" (p.62). Yet, "primitive techniques have no reality in themselves; they are merely the intermediary between man and his environment" (p. 63). Modern phenomenon is that due to the advancement of its features" today's technical phenomenon has nothing in common with the technical phenomenon of the past" (p. 78). Rationality and Artificiality are two obvious characteristics of the technical phenomenon. Self-augmentation "can be formulated in two laws: 1) in a given civilization, technical progress is irreversible; 2) technical progress tends to act, not according to arithmetic, but according to a geometric progression" (p. 89).

Winner (1992) writes: "any suggestion that there be a slowdown, limitation, or moratorium on scientific inquiry, research, and development is unthinkable at present" (p. 66)."Technological determinism stands or falls on two hypotheses: 1) that the technical base of a society is the fundamental condition affecting all patterns of social existence; (2) that changes in technology are the single most important source of change in society" (p 76). A restricted technology does not exist.

The Technological Imperatives show instrumental and economic requirements. "Vertical integration is the state of affairs in which the output of one operation becomes input for the next. Ellul labels the same phenomenon "monism" and "the necessary linking together of techniques" (Winner, 1992, p.101). The technological systems have an inherent tendency to set a complex of linkages that continues beyond society's original anticipation. We do not know the outcome. We are not able to decide what is best, or what should be. For Winner, technological advancement is characterized by industrialization means in social, technical, economic structures to support the large-scale production of goods, mechanization, rationalization, modernization (dynamism, extension, size and concentration, division, complex interconnection, interdependence, centralization, apraxia, universality, pervasiveness, irreversibility, inevitability, positive destiny), growth or "progress". Langdon Winner, altogether with the characteristics of modern technique, presents one aspect of the paradox, the master-slave paradox, the issue of control. He asks why technology is problematic. And he answers: "It changes itself and its development generates other kinds of changes. The major concern is the issue of human autonomy and the loss of mastery. One idea is that technique is believed to be a reality in itself and to have its own special laws. On the other hand, the modern history of technological change
is "a diverse collection of patterns rooted in the specific choices that individuals, groups, and nations have made for themselves and imposed on others" (p. 54).

Ellul agrees with Winner that in technological society we are all technicians who do not have much of a consciousness, which puts us into a position of peasants who could not control their destiny. The rules of the game have changed. Technology has a trend to be a new God. Technological impact is so great and complex that men no longer can cope with it as a means, and therefore, it is more an end-in-itself. Men must adapt themselves to it.

Winner is also concerned about this very issue of reversed adaptation and the dual nature of technology that is not neutral in his view. It is ambivalent. Technology is not neutral. It is both, good and bad. It constantly interacts with humans who are praising it and trying to escape from it at the same time. It always produces "winners" or "looses." Postman (1997) is in agreement with Winner in his statement: "Only those who know nothing of the history of technology believe that a technology is entirely neutral or adaptable" (p. 229). To Ellul, however, technique is about the choice of its use. It is human responsibility to make ethical choices, which becomes more plausible if we, as a post-industrial society, gain a better understanding of our place within the complex, multi-level communication technology infrastructure.

Post-Industrial Infrastructure

In order to develop a successful network, the members of a global society need to know the core components of a complex system called communication technologies infrastructure. This infrastructure is a multi-level system where all its parts are interconnected and function together to achieve common goals.

Originally, 'infrastructure' referred to the military support system (e.g. Roman roads, city walls, etc.) The concept of infrastructure includes technical and human aspects. According to Byrd, Turner (2000), "Information Technology (IT) infrastructure is the shared IT resources consisting of a technical physical base of hardware, software, communications technologies, data, and core applications and a human component of skills, expertise, competencies, commitments, values, norms, and knowledge that combine to create IT services that are typically unique to an organization" (p. 167). Sometimes there are three aspects of the communication technologies infrastructure specified, namely: hard, soft, and economic. In The technopolis phenomenon: smart cities, fast systems, global networks (1992) infrastructure is seen as a comprehensive three-tier integrated system comprising hard, soft (education, government), and economic components. Table 1 demonstrates the conceptual model of communication technologies infrastructure signifying a more detailed strategic approach to establishing a deep hierarchy of inner systemic relationships among all the core elements of the infrastructure.

Post-Industrial Society

The boundaries are very likely to be marginalized between the Post-Industrial Age (1950-1969) and the Cybernetic Age (1970-present). Why then are we talking about 'the post-industrial society and not about the information society, the knowledge society, the professional society, maybe? Bell (1973) writes: "In Western society we are in the midst of a ...change in which old relations, existing power structures...are being rapidly eroded...What the new social forms will be like is not completely clear" (Dordick, 1993, p. 11) From the model [Table 1], we gain an understanding that there are five groups of knowledge-producing activities: education, research and development, media and communication, information machines, and information services—constituted what Bell defined as the knowledge industry. Post-industrialization is a process with new technical, social, cultural components where the integral parts are professionals as the established ruling class, risk, and control (Nelson, 1998). "Despite early predictions that information workers would be riding high in an information economy, they are often the first to lose their jobs as firms consolidate their activities and relocate work, made less valuable by information technology, to low-wage-rate countries" (Dordick, 1993, p.5). There is no contradiction of terms in the remarks about the leading role of technical elite and its unstable market value due to increased competition resulting from rapid diffusion of postindustrial innovations.

Communication Technologies

According to the conceptual model of infrastructure [Table 1], communication technologies are to be examined at different levels. The first layer is the four core elements: telecommunications, computers, visual and acoustical technologies (Maughan, personal communications). No nation can expect to maintain a technological
advantage for too long. What will matter is how well that nation can utilize the market to its advantage and for how long. This requires marketing skills, organizational innovations, and educated workforce. These are the "technologies" that are crucial in the twenty-first century. Dordick (1993) notes that technology, then, should be seen not in terms of hardware or software alone (the next level of information objectification) but also as a way of managing, educating, and organizing which is a macro level of communication technologies structural analysis.

The end product of all information service markets is knowledge. The link between the post-industrial society and communication technologies, the "axial principal" if we use Daniel Bell's expression, is the acquisition and codification of theoretical knowledge. Information itself has three dimensions economic, scientific, and behavioral. The key idea of the social life is development. Its progressive nature is best described through the examination of the numerous variables that comprise development.

Table 1: A model of communication technologies infrastructure in the post-industrial society.
Development Variables

Contemporary problems of the well-established and developing nations are caused by several factors, for example, the cultural differences among nations, money constrains, time constrains, and inadequate training. Economic growth is a necessary but not sufficient condition for development. Development is more than economic growth. Development is a complex process that encompasses economic, social, and political changes. Development requires attitudinal changes, cultural adaptations, a trained and educated work force, and a political structure. Communications and communications technology are agents of economic, social, and political change.

Economic Change: Technology is a significant determinant of economic growth. The measurements of the economic scope in the information society are: 1) the size of the information force (as a percentage of the total labor force), 2) its contribution to the nation's Gross Domestic Product, by sectored analyses of labor force and contribution to GNP. Within the economic pyramid, the shift to a more balanced economy in which an agricultural sector and a diverse manufacturing sector are key factors in the development process. Social Change: For development to continue, there must be a trained and educated work force, an effectively functioning government, public investments in basic infrastructure, communications, and transportation, and a positive attitude toward progress. Political Change: There has to be a well-understood national policy that encourages the development of high-value industries, and there must be a policy that encourages competition among firms, emphasizing innovation and invention. In order to encourage long-term investments there must be political stability and a favorable tax climate. The following points help explain the variables associated with political change.

Innovation / Invention in a postindustrial world is more process-oriented than product-oriented. Carley (1995) notes: "mass-communication technologies that enable greater competition among messages and greater message complexity will enable faster information diffusion than those technologies that inhibit competition and message complexity" (p.547). Companies differ in the speed with which they adopt innovations.1) Innovators-the first firms to adopt a new idea 2) Initiators-the firms who adopt the idea soon after the innovators 3) Fabians-the firms who adopt the idea only after its utility is widely acknowledged in a particular industry 4) Drones-the last firms to adopt new ideas" (Mueller, 1971, p. 54) There are four states in the process of innovation: 1) The scientific discovery, when the theoretical principle behind an innovation is discovered. This results from basic research; 2) the invention, when it is for the first time made clear that the production of a given product or process is possible. This results from applied research; 3) the innovation, when the product or process is for the first time applied successfully in practice. The innovation is the result of product development; 4) the innovation diffusion process, by which an innovation spreads from the first innovator to other potential innovators" (Pedersen, 1975, p. 74) Informatization is an important determinant of development. It is a process of change leading to an information society. There is a relationship between informatization and the global economy, and national development and economic growth.

The Role of Communication Technologies in the Post-industrial Society

Nowadays, people question the domineering role of technology in their social organization. Strijbos (1997) in the article "The paradox of uniformity and plurality in technological society" illustrates the duality of the human and technology relationship: social unification and pluralism at the same time. There is no doubt that a technological universalism in a geographical and a qualitative aspect is a fact of life. There are two distinct visions on the results of technological influences. Some people believe that a growing pluralism and disintegration is a distinct characteristic of our time.

However, the contrasting phenomenon of uniformity, mechanization might be just the other side of this technological culture we live in. The author examines the relationship between technology and culture from a historical perspective beginning with the early rise of technology in the tenth century in Europe to the present. The author warns us that technocracy realizes its potential in a totalitarian technology. Technology in its modern form becomes a reality to the laws of which man doesn't have access. At the same time there is another angle: the level of uniformity rises in parallel with the advancing technology. The works of different philosophers, including Ellul, Mumford, Postman, Winner present the paradox that technology makes us uniform in our thinking and at the same time gives us opportunity for diversity.
Conclusions

The key to the effective utilization of newly produced objectified information is access to that information. The National Information Infrastructure is a measure of this access. The maturity of the infrastructure is measured in terms of hardware/software purchase patterns, policy (access, control), real/perceived value, skills of information workers (knowledge workers, data workers) and users, maintenance and upgrade, leadership, change acceptance or resistance.

The negative aspects of postindustrial technological autonomous expansion are the separation between labor and private life, an enormous social mobility, and the identity crisis. Technology makes our life easier but it also makes it extremely complex. The complexity of our relationship with technology makes us seek direction: Where are we going? Who is in control: man or machine? These issues are highly disputable in regard to the direction we are taking technology vs. it is taking us. The answers to these and many other questions the readers are called to seek for themselves. " In a complex technological society, "almost every one, in fact, can find his niche in a public world where all things must work somehow together" (Feibleman, 1982, p. 87). Despite the marvelous paradox of the world we live in that is characterized by ambivalence, dualism of the nature of technology and its interaction with humans, we exist in a dynamic, yet a balanced system.

Abstract  
Change is the name of game in the hyper-competitive international market place - radical, unrelenting and ever accelerating change. It is not an event. On the contrary, it is a journey that has no end. In this whirlwind of change, only such educational institutions of higher learning that are prepared to take the leap beyond the traditional hierarchies would thrive and survive. Educators should understand the deeper forces that operate on the Teaching Learning process and the market place. The paper attempts to find this synergy through a case study.

Introduction  
Observations  
* In depth and complete knowledge of subjects are not sacrosanct.  
* Academic excellence is a myth.  
* New treatise is to be evolved.  
* Educational system churns out hordes of "one dimensional" people.

The advent of the new technology is creating unprecedented, yet fleeting opportunities. The educational Institutes that fail to act now and build newer Teaching -Learning methodology that capitalize on these opportunities will find themselves relegated to mediocrity or will obsolesce in the emerging market place. There are some critical challenges that incumbents need to overcome to succeed in the global market place. The incumbents fail to attract the right talent by crippling the new Teaching -Learning process with old educational models and methodologies. The world is complicated, demanding and unforgiving. It is clear that the complexity of building a sustainable educational -training model will only increase.

New imperatives  
Educational process is the source of almost all value creation, knowledge based industry thrives on this; the efficacy of intellectual capital depends on the training model one choose to implement. What is new is that the stakes are now much higher and competition is intensifying dramatically.

Leaders of education should give focus and direction to the process of innovation even at cost of in depth knowledge of any one subject. Design of curriculum should be with a mission statement. It needs to take a holistic approach of Teaching Learning process and training to develop skills and disseminate information.

"Instead of fixing problems, the millennium humans will chase opportunities, they will not seek to optimize. Instead, they will be hard wired to innovate. They will not seek to perfect the known. Instead they will seek to create wealth by
imperfectly seeking the unknown", quoted in a leading newspaper, which manifests the attitude of all and sundry. Keep
this in mind while preparing the course and training material.

The time has come to terms with "Education by objective". The curriculum design process should be left to market
force, but then the roll of educationist should be to develop physical content and logical sequence to satisfy the market
aspirations, which dictates that, "Content is the king". The practice of concurrent engineering can be applied in the
curriculum design by simultaneous interaction with the interested and all concerned parties. The technological
innovations like video conferencing, chat facility through internet and dedicated web sites for university curriculum
design department, facilitates and gives thrust to holistic approach to the training program.

Our study shows that this improves the perception and participation of teaching learning process by all concerned
parties involved. The market appreciates the removal of the process of "reinventing the wheel" and appreciates the
cultivation of temperament for the emerging technology and the proactive role of universities in bringing about a
cultural revolution in the name of technology integration in all walks of life.

The paper discusses ways and means to create a skill set to enable the teachers to change gear to innovate and
assimilate the emerging information technology and evolves a practice to figure out the non-essential part of the subject
domain to optimize the creative energy of the people involved.

Case Study
A technique like ABC analysis in the realm of inventory control is to be discussed in the paper at large. Most
importantly the paper address the pedagogy involved in the Teaching-Learning process of computer programming
languages such as Object Oriented Programming in C++, JAVA and other Internet technologies and methodology to
innovate to understand and follow the technology, with out a time lag, so that state of art technology can be offered to
trainees and students.

Programming languages are the pace setter for developing mastery over the emerging technology in the realm of
technology convergence. Object Oriented Design, Analysis, and Programming introducing students to a new paradigm
in implementing and practicing any of problem solving strategies.

It is observed that teachers handling the programming language classes tend to distanced away from newer languages
and related technologies and exhibits inertia to be comfortable with ongoing process of pushing technology to it’s limit.
On the contrary the market dictates to produce more and more technology savvy educators and administers. Our
experience in conducting refresher courses for teachers, introduce them to a new paradigm in seeking knowledge and
capability to study and assimilates newer and ever unfolding technologies. The teachers were told to give priority to
certain areas rather than trying to master every bit of the available forms and literature on the subject. They were
advised to give importance to the process of “conversion of problem to logic”.

The need not elaborate on data types, Compatibility, Portability, Multithreading Capabilities of the language or even
java virtual machine. There is a lot of parallel between previous programming language and newly evolving
programming languages, try to figure out the similarities in the newly created language or software packages. Teach
and learn in the mould of previously developed methodology, but with new constructs. Develop computer program for
same set of exercise problem definitions which were developed for earlier languages. The fundamental understanding
in interdisciplinary subjects, data structure, Numerical methods, Operations Research techniques, mathematics of
Graphics and human behavioral psychology gives us a deeper understanding and helps us to translate the nuances of
any problem definitions. These self sufficient modules not only contained, tried and tested code but also had
programming capabilities built in to make holistic ‘building blocks’ that make application development easy.

ABC Analysis approach applied to innovate Teaching – Learning process of fast emerging
technology.
This is a classification which attempts to distinguish the ‘Vital few from the trivial many’. In inventory management the
basis is annual value. A, B and C are categories of importance. Different controls are adopted for each category. ABC
analysis is the widely used approach for classifying the inventories on the basis of cost and use in the realm of Industrial Engineering practices. This is a type of Pareto analysis and some times also referred to as Always Better Control approach. We created categories of varying importance amongst Object Oriented Analysis, Design, programming in Java and C++ and interdisciplinary subjects which cater to the supply of problem definitions to be converted in to computer program.

Findings
One cannot overemphasize that the single key priority for Teacher educators is to rapidly reposition themselves for extreme competitive preparedness without any further delay. The direction of flow of value, whether into or out of the educational Institutions, will depend upon the relative competitiveness of the Institute. Educational process of an institute needs to be calibrated for there ingenuity on the basis of the net value that they capture for the national economy. It is the Institutions endeavor to continuously explore opportunities for growth by establishing synergy and blending its multiple core competencies to create new epicenters of growth. The market mechanisms are essential to engender efficiency and add value to the Teaching Learning process. Yet, they must be supplemented with a much broader growth strategy to create and retain value to uplift the Standards of institutions of higher learning.

Application of ABC analysis like technique on training model, witnessed a sharp response from among teacher’s undergoing refresher course on Object Oriented programming in C++ and Java programming languages. Majority of the incumbents (92%) embraced this technique to improve their ability to assimilate newer technology at a faster pace.
Last year there was a great deal of press discussion around a report produced by the Alliance for Childhood entitled *Fool’s gold: A critical look at computers in childhood*. The report was critical of the amount of funding spent on introducing and consolidating the use of computers and other media in early childhood classrooms, when, in their view, the funds should have been diverted to maintain the traditional format of early childhood curricula. In particular, the authors of the report claimed that “... the benefits of computers for preschool and elementary school children were being vastly overstated.” And that “... the costs - in terms of money spent, loss of creative, hands-on educational opportunities, and damage to children’s physical and emotional health - were not being accurately reported.” (Alliance for Childhood, 2000, p.1)

Some contradictions in their findings cause us to question the Alliance’s conclusions. First, the authors contended that those who supported the use of computers by young children had a vested interest in marketing the machines while at the same time the Alliance has strong ties to Waldorf education, a pedagogical approach which focuses on sensory motor learning and regularly does not teach reading systematically until children are in the 3rd or 4th grades of school.

The second contradiction concerns their either faith or lack of faith in research concerning curricular tools. The Alliance criticized the lack of research to support claims that computers can enhance early childhood learning contexts and cited research where it specifically did not (classrooms in which drill and practice software were blamed for poor test results in the basic skills). This was somewhat ironic since at the same time they made contentious claims expressing their own viewpoint which were not supported by any research at all. Near the end of the report they stated “... there is absolutely no evidence that a lack of computer technology in elementary school poses any threat at all to a child’s development.” (p. 87) Yet many of the tools of the early childhood curriculum they support, have no foundation in research. Certainly, there are no studies either which examine the effect that lack of jigsaws, blocks or collage pose to a child’s development - which serve to indicate the futility of asking such questions.

To be sure, there are uses of technology which are not effective or appropriate, but same is true of any curricular material. So it is important to know how to use the curricular material. In addition, there is a lot of low quality software on the market which doesn’t afford many opportunities for learning. Even so, this fact cannot justify the condemnation of all software.

Thirdly, though the Alliance attacks the misallocation of funds toward the use of technology, the paltry amount given toward early childhood cannot be compared with the general misallocation of society’s resources in America. How many citizens question the amount of foreign aid allocations, or the billions of dollars spent on fighter aircraft or missiles, to the detriment of American children who are homeless, have poor nutrition and whose schools are devoid of adequate funds. Certainly, in American society which according to the The State of America’s Children (Edelman, 2000) is number one in medical technology yet one in six have no health insurance; number one in millionaires yet 20% of children are poor and at risk of malnutrition; number one in military yet over 80,000 children have been killed by guns since 1979; any attack on the misallocation of funds must be examined in the context of incredible misallocations national resources.

The publicity that the report received was considerable and worrying. Each year those teacher educators who prepare students to become early childhood professionals come to SITE to discover ways in which they might extend and improve their practice in order to ensure that teachers of the 21st century are confident and competent in the use of instructional technology. In this way children in our classes are provided with opportunities to become effective learners in new and dynamic ways. We believe that the use of instructional technology enhances teaching and learning opportunities for young children and can cite research to support our viewpoints, including our own.
This year, the presentations in this section all review and consider important issues related to the use of instructional technology by teachers and learners.

The paper by Ragan considers the ways in which the use of computers is appropriate in a pre school environment and highlights what knowledge teachers of young children need in order to design environments that are characterized by the appropriate use of computers when necessary. The notion of competency in terms of technological fluency is an integral part of this discussion as well as the clear articulation of what knowledge and skills are needed for exemplary teaching and learning with instructional technology.

Bell and Crawford ask us to consider levels of comfort with technology for preservice students, since they contend that confidence and competence with technological devices, and the ways in which they may be integrated into teaching and learning contexts is an important pedagogical skill for the information age. They suggest that computer literacy is only developed in supportive environments when both children and teachers are afforded with opportunities to explore and problem solve in versatile ways. They continue the dialog in their second paper by considering the use of technologies in a variety of different educational contexts such as museums, after school programs and learning centers. Bell and Crawford contend that when children are given autonomy and control over their learning in interactive displays they are more likely to return to engage with it and other displays. They suggest that such contexts for learning with technology provide exemplars for learning in diverse environments and should inform the ways in which we organise teacher education courses that are related to curriculum applications both in school and in out of school contexts.

Next, Christina Han examines the attitude of principals to the use of instructional technology by young children. Principals are key people in terms of the provision and support of computers in schools and Han discusses the results of her survey with principals in Hong Kong which elucidate the key features of computer use in their schools.

He and Zhang provide a variety of examples of interactive learning contexts for teachers. They contend that the use of instructional technology with students can enhance their attitude to learning in a positive way and that this has a beneficial effect on the education process. Their results indicate that the use of instructional technology can assist in raising students' abilities in abstract thinking, analysis and synthesis of ideas and when practiced in a context of exploration can yield additional benefits associated with becoming autonomous learners.

Nancy Yost explores the use of videoconferencing with kindergarten aged children. Her project involved two classes who became involved in a weather project. The two teachers included a range of technologies for the successful sharing of ideas and communication and the paper discusses the issues and outcomes of the interesting project.

Abstract: Building upon the young child's prior knowledge and developmental level, computer literacy must be addressed early in each child's educational career. A comfort level or disposition is important to develop for both young children and as well as early childhood teachers, which is why the importance of instructional technology is stressed within the pre-service teacher's educational experience.

Preservice Teacher Preparation

Pre-service teachers focus an immense amount of time on the classroom experience, as well they should. The learning opportunities associated with real-world, student-centered classroom environments should be strongly emphasized during the methodological design and development of the preservice teacher's training. Individuals preparing to be early childhood teachers, generally are offered a wide variety of experiences working with young children. These experiences range from simple observation in pre-primary and primary grade classrooms to taking full responsibility for successful, authentic learning experiences for young children during the final stages of their preparation. Students experience tutoring individual children in content-oriented skills, facilitating learning experiences for young children in small groups, as well as planning and implementing educational activities for as many as two dozen young learners in self-contained classroom. Significant challenges arise for these pre-service teachers. Planning lessons and managing relatively large groups of young, dynamic learners, aligning authentic educational experiences with mandated objectives, and promoting application of skills and knowledge in relevant ways for the purposes of student assessment are just a few of the major concerns.

Pre-service teachers should develop dispositions that they are decision makers and have a genuine part in developmentally appropriate classroom activities. Integrating technology into the pre-service teacher's training must occur so that they will have developed a well-rounded set of skills when taking responsibility for their own classroom. The support of the early childhood and instructional technology faculty members offer the preservice teachers a supportive environment through which to design, develop, discuss and revise a lesson plan. Such a learning experience offers the preservice teacher the opportunity to think through the real-world process of integrating instructional technologies in appropriate and successful manners.

Integrating Technology

In the last fifteen years, early childhood teacher educators have moved from wary speculation of the appropriateness of instructional technology in pre-primary and primary grade classrooms to a greater understanding of the operations and integration of technologies into daily classroom practices (Anselmo & Zinck, 1987). With current public interest in effective early childhood instruction at a high level, it is appropriate to prepare the next generation of teachers to use technologies with young children. Currently, pre-service teachers bring varied experiences with technologies to their course work and experiences. Yet, the trend toward heighten awareness and positive dispositions toward technologies among pre-service teachers is apparent.
Planning and Implementation

The opportunity to develop an understanding of the early childhood classroom environment adds to the preservice teacher's conceptual framework, which in turn aids the preservice teacher in further developing a repertoire of skills that offer opportunities towards the integration of technology. The integration of technology into the young child's learning environment offers experiences that may not otherwise be available, and supportive environments offered by the early childhood and instructional technology faculty members aid the preservice teachers in further developing the necessary skills associated with a superior repertoire of experiences.

Pre-service early childhood teachers should be encouraged to view instructional technology as not simply a means of delivery of learning experiences, but a means for young children to represent their understandings and to creatively express their interpretations of the world. (Charlesworth, 1997) It has long been held among early childhood educators that children should learn through "hands-on" instruction of three-dimensional materials. Integrating technologies with those fundamental "hands-on" experiences should be evident in lesson planning. This blend of experiences should nurture individual learning styles, promote autonomy in young learners and to augment typical classroom assessment strategies.

Interpreting the scope and sequence of early childhood curriculum in relation to individual child development will compel pre-service teachers to balance expectations with individual learning needs, as well as the context of the community. Clearly, effective early childhood education does not take place in a social or cultural vacuum. Lesson plans that are developmentally appropriate will reflect an understanding of instructional expectations, child development and community. (Lubeck, 1998) Does the use of instructional technologies in early childhood classroom influence this delicate and ever-changing balance? Using computers or other interactive technologies with young children will not fundamentally change effective classroom practices. Teachers that consistently and creatively use technologies, model a disposition toward new learning contexts, methods and information. Young children will interpret these experiences and develop their own understandings and dispositions toward instructional technologies. If a climate of acceptance is fostered in early childhood classrooms and is evident in pre-service teachers' dispositions, lesson planning and daily implementation, then young children will be influenced by these authentic and meaningful experiences. Ultimately, pre-service teachers should view instructional technologies as a means of fostering a sense of independent practice, collaborative learning relationships among peers and empowering our youngest learners to independently interact with various media and gain new understandings.

Summary

The components of appropriate and effective early childhood classrooms must now include emerging technologies specifically for young children. Also, the definition of the early childhood classroom teacher as "nurturer-facilitator" will be altered as children gain independence and a broadening worldview through their experiences with technologies. Lesson planning for developmentally appropriate classrooms will assuredly become more complex in the coming years, yet the opportunity awaits for more dynamic classroom experiences for young children, growing autonomy for young individuals, and expanding the horizons of information for young children will yield notable benefits for students, as well as professional satisfaction for those teachers that develop well-planned learning activities.

Abstract: The support of the early childhood and instructional technology faculty members offer the teacher candidates a supportive environment through which to design, develop, discuss and revise a lesson plan. Such a learning experience offers the teacher candidate the opportunity to think through the real-world process of integrating instructional technologies in appropriate and successful student-centered manners.

Introduction

The integration of technology within the young child educational environment can present significant levels of difficulty for teacher candidates, as well as master teachers with numerous years of experience. The conceptual framework pertaining to the appropriate and successful implementation and successful, appropriate integration of technology within a learning environment can grow exponentially when the teachers integrating technology have a nurturing, supportive environment available through which to think through such a difficult task. Further, the support of university faculty and instructional designers adept at the appropriate and successful implementation of technology lends an environment wherein the educator can develop a level of comfort with the technology while developing the skills and conceptual framework necessary to integrate technology into a lesson plan. An environment that emphasizes a nurturing, supportive environment for the educator will also maintain such an environment when the implementation of technology reinvents itself within the young child learning environment. The modeling associated with instructional technology within a learning environment is of utmost necessity.

Teacher Candidates and the Young Child

Teacher candidates focus an immense amount of time on the classroom experience, as well they should. The learning opportunities associated with real world, student-centered classroom environments should be strongly emphasized during the methodological design and development of the preservice teacher’s training. Students experience tutoring individual children in content-oriented skills, facilitating learning experiences for young children in small groups, as well as planning and implementing educational activities for as many as two dozen young learners in self-contained classroom. Significant challenges arise for these teacher candidates. Planning lessons and managing relatively large groups of young, dynamic learners, aligning authentic educational experiences with mandated objectives, and promoting application of skills and knowledge in relevant ways for the purposes of student assessment are just a few of the major concerns.

Instructional Technology
Teacher candidates should develop dispositions that they are decision makers and have a genuine part in developmentally appropriate classroom activities. Integrating technology into the teacher candidate's training, more specifically supporting the appropriate instructional design associated with designing a lesson plan, must occur so that they will have developed a well-rounded set of skills when taking responsibility for their own classroom. A significant opportunity may be realized through the integration of technology into lesson planning for early childhood classrooms. The support of the early childhood and instructional technology faculty members offer the preservice teachers a supportive environment through which to design, develop, discuss and revise a lesson plan. Such a learning experience offers the preservice teacher the opportunity to think through the real-world process of integrating instructional technologies in appropriate and successful manners.

In the last fifteen years, early childhood teacher educators have moved from wary speculation of the appropriateness of instructional technology in pre-primary and primary grade classrooms to a greater understanding of the operations and integration of technologies into daily classroom practices (Anselmo & Zinck, 1987). With current public interest in effective early childhood instruction at a high level, it is appropriate to prepare the next generation of teachers to use technologies with young children. Currently, teacher candidates bring varied experiences with technologies to their course work and experiences. Yet, the trend toward heightened awareness and positive dispositions toward technologies among teacher candidates is apparent.

Planning and Implementation

Where in the milieu of teacher education courses does the early childhood preservice teacher have the opportunity to integrate technology in an appropriate and successful manner? Of course, the requisite instructional technology course is emphasized as a core requirement, but what of the integration of instructional technology within the learning environment? The focus of learner-centered educational environments must be emphasized, and the technology must be integrated in an appropriate and successful manner. The opportunity to develop an understanding of the early childhood classroom environment adds to the preservice teacher's conceptual framework, which in turn aids the preservice teacher in further developing a repertoire of skills that offer opportunities towards the integration of technology.

Pre-service early childhood teachers should be encouraged to view instructional technology as not simply a means of delivery of learning experiences, but a means for young children to represent their understandings and to creatively express their interpretations of the world. (Charlesworth, 1997) It has long been held among early childhood educators that children should learn through "hands-on" instruction of three-dimensional materials. Integrating technologies with those fundamental "hands-on" experiences should be evident in lesson planning. This blend of experiences should nurture individual learning styles, promote autonomy in young learners and to augment typical classroom assessment strategies.

Conclusions

Issues surrounding pre-service teacher training, creating understandings of the importance of comprehensive lesson plans for early childhood classrooms and implementation of those plans in effective and developmental classroom settings abound. The components of appropriate and effective early childhood classrooms must now include emerging technologies specifically for young children. Also, the definition of the early childhood classroom teacher as "nurturer-facilitator" will be altered as children gain independence and a broadening worldview through their experiences with technologies. Lesson planning will assuredly become more complex in the coming years, yet the opportunity awaits for more dynamic classroom experiences for young children, growing autonomy for young individuals, and expanding the horizons of information for young children will yield notable benefits for students, as well as professional satisfaction for those teachers that develop well-planned learning activities.

Abstract: This work shows a propose of teaching computer science for children. It is intended that the “Information Technology Teaching” sharpens the critical sense and capacitate students to learn not only to use currents technologies, but to understand how it works. To find out which Computer Science Topics are more suitable to teach children, it was realized a quiz, answered by Computer Science and Information Technology teachers which thought disciplines. A solid basis to the practice of Computer Science has the objective to develop the demanded abilities to think, to express clearly and precisely, to answer problems and create concepts.

Introduction

Many efforts are being developed to use today's technologies into the teaching-learning process. These efforts are aimed at the use and classification of educational software products, distance communication techniques, the use of multimedia and virtual reality resources to aid teaching, and also in the construction of computer environments that could change the educational paradigm, though from all known papers up until know there is none focusing on the basic Computer Science concepts involved.

Between all the aspects involved during the learning process, the development of logical reasoning has fundamental importance, thus it is proposed that the teaching of fundamental concepts of Computer Science could enhance the basic school learning and develop today's demanded abilities.

This article is organized in three sections: the discussion of teaching concepts, the aspects of work in the teaching of computer science or children and the final conclusions.

Teaching Concepts

According with Menezes and Diverio (1999) the computer theory is very important to the Computer Science, because it gives a right theory support requested to a correct and great learning of the science involved on computers, creates the development of a logical and formal thinking, and also, introduces fundamental concepts that are developed in other areas.

To find out which Computer Science Topics are more suitable to teach children, (Fernandes and Menezes, 2000) it was realized a quiz, answered by Computer Science and Information Technology teachers which thought disciplines like: Software Engineering, Data Bases, Programming Languages, Math and General Systems Theory, in many public and private institutions of Brazil.

It was asked, independent of the application to answer in an intuitive and objective way which are the basic fundaments of Computer Science. The identified concepts where separated and summed in relation to the quantities of answers.

From all the concepts cited, the top ones where: Algorithms, Programming, Formal Languages and Automatons, Computability, Complexity, Formalisms and Machines. It is noticed that those comprehend the basic formation in the Computer Science area.
It is intended that the "Information Technology Teaching" sharpens the critical sense and capacitate students to learn not only to use this technologies, but to understand how it works.

This vision is corroborated by many authors such as on (Esmin, 1999) and (Silveira, 1997) in which there is evidence that the traditional methods of teaching math bring the student to use most of the time to elaborate calculations as opposed to build concepts and develop abstract reasoning.

Therefore, as math does not teach how to manipulate a calculator, the teaching of Computer Science cannot be limited to be a training or to teach how to use a tool, like a specific text editor. Because if something changes in this type of editor this training must be restarted. Additionally as it does not fit in this context, the teaching of typing and shorthand writing.

Aspects of Work

After identified the fundamental concepts of computer science it is necessary to study how they will be introduced and how to approach them in conformity with the existing disciplines. We are studying on the history of education and how today's disciplines where introduced to the actual school curriculum for to be based.

History is the understanding of the transformations made by men during time. Pedagogy is the art and the science of teaching, or the action of men when transmitting its knowledge. It is focused on the man in its whole and it is centered on the formation of thought. Thus Pedagogy in the teaching of Computer Science can help the formation of computational though, use other's science methods, and identify and eliminate learning obstacles. The path to the teaching of Computer Science must be worried on the solution of problems and must be centered on the student's experience to act in a specific knowledge domain.

Understand and study the history of computer is before all understand the evolution of mathematics. The result of building techniques that allowed us to calculate in the past, for example, area and tangent coincides with the technological development of mankind. Thus the first year of Computer Science must be based on the teaching of mathematics, for example: basic in logical math and conditional idea of Computer Science.

Conclusions

The data collected with the teachers on the institutions researched shows the basic requirements for Computer Science, what mainly comprehend the basic formation in the Computer Science area.

These concepts must be worked in a multidisciplinary matter, focused in mathematics. Thus, algorithms are used for development of calculus, logic' notion, of theory of set etc.

The transformation of these concepts in useful applications is of fundamental importance, bringing motivation to children for the computer science' study.

Technology and Character Education of the Younger Generation

Shujia He
Qibao High School
Shanghai, P. R. China
qibnozx@online.sh.cn

Yuehua Zhang
Education Department Washburn University
United States
zzyzhang@washburn.edu

Abstract: This paper intends to provide a variety of examples for teachers to recognize the possibility of utilizing technology to create a student-centered interactive learning environment and to show how some high schools in Shanghai, China have been successful in cultivating in their students healthy personalities and strong characters, so as to produce a generation of young people who are ready to contribute to their society. The presentation will include a variety of ways in which to apply technology to create this beneficial learning environment, which will not only enhance students' learning of basic knowledge and skills within subject areas, but also to enrich their self awareness and capacity to strive for success.

The Impact of a Technological Learning Environment on Character Education of the Younger Generation is significant. Discussions centered on character education, spiritual growth, and moral development continue to punctuate the educational landscape. Indeed, throughout history, the question of how the environment impacts each child's growth has always been an important issue among the educators. From the ancient Chinese philosopher, Confucius, to modern educators in China and all over the world has been the belief that the environment makes children who they are when they grow up. Chinese folk wisdom says that children living near the sea learn how to fish, whereas those living in the mountains learn how to gather logs for fire. In recent years, those schools able to afford the costs are building an environment in which modern technology reinforces teaching and learning, and therefore provides a measurable contribution to character education.

The Internet learning environment provides limitless opportunities for students to access useful and interesting information, and encourages them to search for and discover the unknown. While still relatively new, the Internet has long since outgrown its novelty, and is now seen as a crucial tool for fast access of timely information. Navigation through the World Wide Web is facilitated through search engines connected with each other making available vast amounts of highly focused information, especially when used through effective keyword searches.

In Shanghai, at QiBao High School, a private school, there are three laboratories with a total of 168 computers with full access to the Internet. In addition, there is an electronic reading room in the library and networked computers in each classroom. All the science labs and school offices are networked with LAN (Local Area Network) and WAN (wide area network). This well-planned electronic infrastructure provides students with opportunities to access the Internet whenever necessary to search for new information, to discover new solutions to problems, or to communicate with someone in another part of the world. Indeed, for students at this high school, utilizing networked technology has become part of their daily lives.

In 1999, Qibao High School students were given an opportunity to develop an open-ended theme-study unit. Students were divided into 72 project groups, and utilized the Internet not only to select their themes but also to search out the necessary information and to determine effective modes of approach to solve the problems. This special project and the students' learning experiences were recognized by the city government to serve as a model and high schools across the country have been encouraged to follow this model.

Multimedia learning environments and a variety of computer software has enhanced students' interest both in science and in the humanities. When placed in this active learning environment, these students show a heightened interest in their coursework, even in the traditional science and humanities courses that have often had difficulty in cultivating student interest. The curious mind and the desire to discover have led to great scientific inventions and truth, as well as providing greater insights into our own humanity. It is our conviction that making full use of the
information-technology environment, as a catalyst for promoting students' characters is one of the important strategies.

Jianping High School in Shanghai has more than ten teaching laboratories, and the school administration requires all teachers to utilize at least two computer software packages in their teaching every semester. Qibao High School has hosted five multimedia technology workshops that provided training for more than 200 teachers. In addition, it held four contests for multimedia projects; some of the resulting multimedia teaching tools were impressive enough to have been published by Baida Electronic Publishing House.

Distance-learning and online courses make it possible to create a student-centered learning environment, therefore enhancing the production of personnel with creativity. The student-centered teaching model utilizes situational learning, collaboration, and communication, all of which help to encourage students' creativity and then to flesh out this creativity in real-world situations. In this environment, students are actively constructing their knowledge through multimedia technology, while teachers are the organizers, the facilitators, and promoters. This is the model that will produce the next generation who can meet the challenges in a world whose technical and social landscape is changing at an ever-increasing rate.

A learning environment that applies computer-aided instruction (CAI) can also train students for high-level thinking. Internet and multimedia learning environments provide opportunities for students to research and discover. Students are an active part of the learning process. CAI also provides situational learning in which students search the problematic situation, form the problem, and derive their own solutions. Therefore, students have the practice to recognize how the relevant phenomena and workable strategies finally lead to problem solving.

Information technology utilized in the classroom brings a variety of rich cultures from all over the world into a virtual global village and provides opportunities for creating a new culture, one that enhances each student's ability to analyze and critique. Internet and multimedia environments have already helped to create this culture that nurtures the students in their ability to analyze, make connections between classroom learning and real world applications, to construct their own knowledge, and to think critically.

The open learning atmosphere invites students to participate in interactive networked learning activities and therefore to develop and turn students from having a mere presence in a society to having the ability to serve the society. The use of instructional technology can help students in their training of high level thinking, therefore encourage them to have healthy personality and characters. The use of instructional technology can increase students' desire for learning and therefore enrich their experience in discovery. The use of instructional technology can widen students' view of knowing, therefore help them to build a solid foundation for basic knowledge and skills. The use of instructional technology can help raise students' abilities in abstract thinking, analyzing facts into constituent parts and synthesizing diverse knowledge into a coherent whole. The use of instructional technology can provide new opportunities for students to practice their skills in experimenting with new concepts. The use of instructional technology can train students to be self-regulated learners.
Technology in Early Childhood: A Model for Teacher Training

Professional Program in Education
University of Wisconsin-Green Bay
United States

Abstract: Changing perspectives for the use of technology in early childhood education lack explicit standards, based on a sound theoretical and empirical foundation, to generate changes in teacher practice and student learning. Funded by the university system and working in partnership with PK-16 area school districts and community-based childcare centers, this project developed technology standards for young children and the teachers who work with them and used those standards to develop competencies that define what young children and their teachers need to know and be able to do. These competencies were then integrated into pre-service teacher coursework and piloted in a workshop series offered at a local childcare center. The data collected from this pilot is now being used to develop a workshop series for early childhood professionals in the region to be applied collaboratively in early childhood settings. Anticipated outcomes include changes in teacher beliefs about and skills in technology, technology-enriched early childhood classrooms, more equitable access to technology for all young children, greater continuity between the preschool and elementary years, and enhanced student achievement.

Introduction

In partnership with local childcare centers, public school districts, Head Start programs, and neighborhood family resource centers, the UW-Green Bay Professional Program in Education was awarded a 3-year grant for the development of an on-site Early Childhood Teacher Preparation Program that matches program competencies with PK-12 school and community needs in a collaboratively supported, community-based model. Students now engage in performance-based learning in community-based early childhood settings with culturally, linguistically, and ability-diverse young children and their families. They receive mentoring support from master teachers, accessing course content through WebCT core modules. The project created an innovative response to the national call to reform teacher preparation and additionally provided an opportunity to improve student achievement by recognizing that quality child care is and must be a part of a system of learning that impacts child development. UW-Green Bay Early Childhood Program course content has been converted into clearly defined competencies. These competencies are now being cross-referenced with the high standards developed by the state of Wisconsin and early childhood professional organizations, and adapted to respond to the diverse and changing needs of the young children and their families in the community.

Missing from this process were technological standards from which to develop competencies in the area of technology in early childhood curriculum. The use of technology with young children and in early childhood settings has been controversial, with strong concerns being expressed about whether it is developmentally-appropriate and compatible with the learning needs and styles of young children. However, previously held beliefs about the limited abilities of very young children are now being challenged, and current research on young children and technology reports that integrated technology activities can increase student learning and achievement. Children from earliest infancy are reported to form categories (Gelman, 1996) and encode concepts in the form of 9 new words per day by 18 months of age (Carey, 1978). They are also reported to use
those categories to extend knowledge (Carey, 1985). Computer activities have been shown to enhance the development of these early cognitive competencies when they integrated into the curriculum, and coupled with relevant off-computer activities. Cognitive gains in significantly more areas are reported (Haugland, 1992). How young children are asked to use software also affects the development of their conceptual skills (Clements & Natasi, 1993). Outcomes are more positive when they are assigned open-ended tasks or projects requiring problem-solving rather than left to explore freely (Lemerise, 1993). Socially, young children are reported to spend nine times as much time talking to peers during computer time than when doing puzzles (Muller & Perlmutter, 1985), spend 95% of that talking time discussing the work (Genishi, et al., 1985), and exhibit greater peer teaching and helping when using computers (Clements & Natasi, 1992). Computers appear to serve as catalysts for social interaction rather than isolating children, as once believed. To be effective, young children need to learn to use technology in new ways - for exploration, creative problem solving, and self-guided instruction—and the teachers who work with them need the knowledge and skills to effectively integrate technology into the curriculum and use it to support social interaction.

Access to technology is also poor in early childhood settings and for the diverse families they serve. It is reported (Coley et al., 1997) that children attending low-income and high-minority schools have less access to most types of technology. With technology now permeating learning at all levels and in all areas of development, standards in the area of technology at the early childhood level and their application in the early childhood curriculum are critical to establish quality and continuity between the early childhood and elementary years and address issues of equitable access. While acknowledging and respecting differences, all young children need exposure to a common body of knowledge and skill that includes technology so they can be challenged to reach their full potential.

In response to these needs, this project identified standards and competencies for the children and for the teachers who work with them that recognized that the appropriate use of technology differs for preschool age children. Additionally, opportunities were provided or are being developed for teachers to gain the knowledge, and develop and apply the skills and positive attitudes needed to create technology-enriched early childhood classrooms in developmentally-appropriate ways and share that with the diverse families they serve.

The Project

The collaborative development and implementation of a competency, performance, and technology-enhanced early childhood teacher preparation program and the existence of a strong University/community partnership for the improvement of student learning, provided a strong and innovative collaborative base in which to identify and implement these missing standards in technology. The following project goals and activities drove the design and implementation of the model:

**GOAL 1**: This project will develop appropriate educational technology standards for young children and for those who teach them, based on the premise that the appropriate use of technology differs for preschool age children.

The development of these standards was guided by a Developing a Curriculum (DACUM) process. A workgroup was identified to select participants for the DACUM and gather existing research/resources to support the process. Fourteen early childhood and technology professionals from across the state gathered to identify what preschool children should know and be able to do with technology before they enter elementary school AND what teachers should know and be able to do with technology in early childhood settings. The end-product of the DACUM workshop was a chart listing essential job duties and tasks of teachers working with young children in the area of technology. Before conversion into outcome/competency statements, it was important to have consensus on the views of those in the early childhood and technology professions from the region. To this end, we asked an additional 84 early childhood/technology professionals in the state to complete a verification survey to validate the importance and the frequency of use for each task identified by our panel of experts.

**GOAL 2**: Working in collaboration with teachers, librarians, and other experts from the community, the UW-Green Bay faculty will use the DACUM standards to identify competencies appropriate for integration into the early childhood minor coursework as well as activities requiring pre-service teachers to implement multimedia technology practices into early childhood classrooms and disseminate to parents.
Through a series of collaborative workgroups, the identified DACUM standards were translated into essential technology competencies for early childhood pre-service teacher mastery, cross-referenced to the National Association for the Education of Young Children (NAEYC), framed by the Wisconsin Department of Public Instruction performance-based licensure standards, and linked to Wisconsin's Model Academic Standards. They were then integrated into each early childhood course offering along with performance-based multimedia assessment projects for application in early childhood settings and with families of young children. The completed standards and assessments will become part of the Early Childhood Curriculum Core in fall 2001. In addition to providing essential competency development for pre-service teachers, this integration will provide collaborative support to early childhood cooperating teachers interested in and/or attempting to integrate technology into their curriculum and help disseminate the standards to more early childhood classroom teachers.

GOAL 3: Educators and other professionals working with young children will be provided an opportunity to become familiar with the standards, learn or improve their knowledge and skills in using technology to enhance curriculum with young children, and apply that knowledge in their work settings.

The development of a workshop series was the planned outcome for Goal 3. The original objectives within this goal and identified for the training included (a) developing proficiency in using the equipment, (b) selecting appropriate software, (c) facilitating the active use of technology in the classroom, (d) using technology to support socialization and language, integrating technology across the classroom curriculum, and (e) designing an integrated unit that incorporates technology. These objectives aligned with what was being identified and reported in the current research on the use of technology with young children.

To further inform the development and design of the workshop series, a pilot training was offered to a local childcare center. Staff members completed a technology proficiency survey (see Table 1) and were interviewed to determine individual and group skill levels and training needs. The information gathered from the interview process identified a number of variables common to most early childhood programs that had the potential to negatively influence the application and long-term maintenance of technology knowledge and skills. Resources for equipment and training costs, for example, were limited. With most staff lacking 4-year degrees and having limited proficiency in technology, it became apparent that all workshop objectives could not be met in one workshop series. In addition, the consistent integration of technology into early childhood classrooms would be challenging, given high staff turnover and staffing crisis issues.

The development of technological literacy emerged from the surveys and interviews as the primary need of early childhood providers, and a pilot training was designed that responded to the realities and constraints of preschool settings. At the request of the director and staff, trainings were scheduled once a week in the evening for 3 hours for a period of 5 months, for a total of 20 sessions or 60 hours. The primary goal was to disengage participants from their anxiety and empower and motivate them to comfortably engage young children in technology through questioning, exploration and risk-taking. Three components were identified: technological foundations and awareness building, identification of developmentally-appropriate applications, and application and evaluation. Time and resources required the integration of these 3 components within each session. The major focus of each session was on the development of a basic foundation in technological literacy—terminology, understanding how the equipment works, and how to use the equipment. Focus areas included (a) email, (b) the internet, (c) word processing, (d) spreadsheets, (e) data entry, (f) data bases, (g) scanning, (h) desktop publishing, (i) file management, and (j) digital image acquisition, management, and manipulation. At the beginning of the first session, a ½ hour facilitated discussion on the meaning of developmentally-appropriate practice took place to provide a context for the technology knowledge and skills that were to be introduced. At the end of each session, participants were given an “application assignment” to use in their classrooms and asked to find (develop, create) additional developmentally-appropriate ways to use the skill(s) introduced that week. A “Sharing Back” took place at the beginning of all other sessions to perpetuate the

A standards-based Workshop Series is now being developed in collaboration with early childhood community professionals, UW-Green Bay faculty, and technology consultants from PK-16 schools. Data collected from the pilot training, the DACUM competencies, and the current research will all be used to design the training. Resources will not allow for 60 hours of training, as offered in the pilot, but will be more substantive than most early childhood professional development opportunities. With research reporting that less than 10 hours of inservice teacher training can have a negative effect (Ryan, 1993) and that hands-on experience and in-depth
exposure supports generalization and maintenance in the classroom (Wright, 1994), the decision has been made to have an “Opening Conference” of 6 hours followed by six 4-hour modules distributed over 3 months for a total of 30 hours of computer lab training. Program design, including module content and format, will be done collaboratively, and content modules will be selected based on the pilot results and designed to provide a basic foundation of technological literacy unique to the participants. Module formats will vary, but again include lecture/discussion, small group projects, demonstrations, and hands-on activities.

An initial cohort of 30-35 participants from early childhood programs will be recruited through the partnership to participate. Family daycare providers, center-based daycare staff, administrators, and Head Start and preschool program staff will be invited to attend together, to facilitate interaction among professionals and support a collaborative commitment to the process. Participants may register for 3 credits but they will complete an additional 15 hours of site-based application in fall 2001, culminating in a “Showcase Poster Session” in which teacher-developed units will be presented. All workshop offerings will be held in the daytime, and stipends will be available to hire substitutes for those working in childcare settings who register for the full 30-hour program.

GOAL 4: The results, both product and process, will be disseminated to a wide array of early childhood professionals to use as resources to support the further development of technology-enriched early childhood classrooms.

Project outcomes will be shared with early childhood professionals in a variety of ways at the local, state and national level to support the generalization and maintenance of the technology knowledge, skills and attitudes developed in this project. The final “Showcase Poster Session” will provide workshop participants an
opportunity to share the results of their multimedia projects with UW-Green Bay faculty and invited professionals from throughout the region, including the 62 school districts who are participants in the UW-Green Bay Institute for Teaching and Learning Partnership. Workshop participants and pre-service teachers will also be asked to share the standards with the parents of the young children they work with in ways that respond to the diverse characteristics of those families.

Dissemination to a wider audience is or has taken place through presentations at various local, state and national conferences by UW-Green Bay faculty and interested workshop participants, and the development and maintenance of a worldwide web site of project activities linked to the UW-system is in progress. The Workshop Series will be self-sustaining and continue to be offered for credit through UW-Green Outreach and Extension., the website updated on a continuing basis, and the competencies taught within the Education Program Sequence. Funding support to purchase equipment for early childhood settings continues to be sought from business organizations in the community.

Assessment

Throughout the project, both formative and summative evaluation data is being gathered. Following completion of the DACUM, a statewide survey was sent to 80-100 early childhood professionals for verification of the validity of each standard generated. Those statistics are now being analyzed to determine which standards match what is presently working for teachers in classrooms and what is of interest to and being mastered by the young children in those classrooms. A second verification will be done by the workshop participants at the completion of the series and comparisons made.

Pre and post assessment measures were administered to participants in the pilot training. Similar pre and post measures will be designed and administered to workshop participants for each workshop module and at the completion of the series. Changes in knowledge, attitude, and perceived level of competency will be identified and analyzed to determine if there are significant differences that can be attributed to the pilot training and to the workshop training. The data will also be analyzed to determine if there are significant differences in knowledge, attitude and perceived level of competency between those who received 60 hours of training (pilot training) and those who received 30-45 hours of training (workshop training). Teacher-developed performance assessments with rubrics will be used in the analysis of the Thematic Units developed by workshop participants taking the series for credit. Workshop participants will also be asked to help design an assessment tool to measure the level of technological proficiency of each of the young children in their classrooms. This assessment tool will be administered at the beginning and end of the workshop series to determine changes in level of proficiency for each technology standard for young children.

The competencies selected for inclusion in the early childhood program sequence will be validated against Wisconsin's Academic Standards in the content area of technology for the first grade. Performance-based assessments, with rubrics, will be developed for each identified competency, and measures of change in the level of proficiency for pre-service teachers, cooperating teachers, and students will be identified.

Conclusions

The completion of an initial pilot training was critical in identifying the unique needs of the population for whom this workshop series was to be designed – early childhood providers. Information gathered in the interview process identified numerous constraints specific to early childhood care and education that needed to be taken into consideration when designing the workshop series. Results from the pilot study clearly supported modifying the original workshop series goal and objectives. Initially the series was to be designed to share DACUM generated standards, improve professional's knowledge and skills in applying these technology standards to enhance curriculum with young children, and support application of that knowledge in work settings. It became clear that the overriding goal of this initial workshop series was to establish a basic foundation of technological literacy unique to each participant's personal motivation, ability level, and learning curve. Without establishing this beginning skill and comfort level, learning would not generalize in a sustained way to the work setting. Participants need to first feel confident that they understand how the equipment works, what the terminology is, and how to use it to develop “technology products.” Additionally, they need to be able
to compare, apply and evaluate their technology products within the context of developmentally-appropriate
practice.
Training in basic technology literacy needs to be repeated regularly to address issues staff turnover and
maintenance, and additional workshop trainings need to relate these newly learned skills to developmentally-
appropriate application within a curriculum framework. The designing of integrated units that incorporate
technology, the facilitation of the active use of technology in the classroom in ways that support socialization
and language development, and the adaptation of technology to meet the needs of diverse learners cannot be
presented until basic technology literacy is in place. These additional trainings will be essential if we are to
succeed in providing early childhood professionals with the knowledge, skills and attitudes needed to
successfully integrate technology into early childhood daycare and preschool settings.

Abstract: This paper explains a kindergarten project that uses multiple technologies, culminating in daily videoconferencing with another kindergarten. This project took place at a university laboratory school as a demonstration of appropriate use of technology, including videoconferencing, for preservice teachers. As the students prepared for the daily videoconferences, they were engaged in dramatic play, Internet activities, and a field trip to a television station. The project proved to be an exciting experience for the children, extending their understanding of technology and the world.

Introduction

As more and more technology is being included into early childhood program, we continue to struggle what is the most appropriate ways to use it with these young children. A simple search of the archives for the ECEOL Listserv (http://lists.maine.edu/archives/eccol-1.html) will show many conversations over the last several years about whether computers should or should not be included in early childhood classrooms. There are concerns about implementing the use of technology in classrooms that lack basic equipment and materials, is this the best use of monetary resources to benefit the children? The NAEYC position paper about technology and young children (NAEYC, 1999) talks of the balance that is necessary. The paper goes on to suggest ways that technology can be used to support children and allow them the opportunity to explore and collaborate.

Being at a university related laboratory school affords me the opportunity to look at issues and curricular options. For several years, I have looked at ways to appropriately integrate technology into the traditional kindergarten program. This paper will share a series of activities that led up to a successful videoconference partnership with a colleague in Illinois, and her kindergarten children.

Setting the Stage

In January 2000, a colleague and I began looking at ways we could use desktop videoconferencing for our children to visit. I felt strongly that our interactions needed a purpose beyond just talking with each other. After several conversations, we decided to expand on the long-standing tradition of weather reporting in kindergarten classrooms. The project was to occur during the second half of our school year and the children were doing lots of graphing. Both classrooms already graphed the weather for their area, so we decided would expand on this and exchange weather reports between the classrooms. We would encourage the children to look for patterns in the weather between the two locations. We decided to begin in April. This gave me time to prepare the children for the upcoming project.

Kindergartners have trouble understanding the concept of time, and distance. They don't understand how it can be light in our region an dark else where. Likewise, they have difficulty understanding that not everyone experiences the same weather at the same time. We felt that this project would assist with this concept. As I prepared the children for the upcoming videoconference, I located a website with live webcams listed by state (http://cirrus.sprl.umich.edu/wxnet/wxcam.html). I added a
responsibility to the classroom meteorologist's daily duties. The meteorologist was to go to the computer
before the group meeting, select a state they wanted to look at, and then locate a cam shot that they liked.
This page was left up for the children to look at first as a group, then off and on during the morning. The
children looked at a map to locate a state if they did not come with one in mind. If necessary I assisted the
child in locating the state name on the web site, then left them to explore the different links available in that
state. The kindergartners already knew how to navigate back and forth with the arrow buttons. Every day
became a new adventure. Where would we go? What would we see?

With this web cam page, we went to Florida and watched a boat skipping over the water, looked at
animals waking up in zoos, and watched many sunrises in the west. The children were fascinated with
watching dawn coming over a town. They would locate a town covered in darkness, then continually go
back an see how it was changing as our morning progressed. They began to understand that daytime in
different areas was different from ours. The children also became interested in what else a meteorologist
did.

Kindergarten on Tour

To assist with their familiarization with the responsibilities of a meteorologist, I arranged for the
children to tour the university television studio, W-IUP. We are fortunate to have a studio located in the
same building as our school, so the trip was very easy to do with the children. The university students
leading the tour focused on the parts of the studio that were important to the weather person. The children
saw the room with the television monitors and the computer mixers. Our tour guides explained how the
blue scrim screen worked. We were able to look at the two monitors, one solid blue, the other with the
image superimposed on it. We then moved into the studio.

The children explored their images on the monitors with the blue screen to their backs. Then they
looked at the monitor where the Bambi movie now played instead of a weather map. They were able to
attempt to pat Bambi or Thumper, with their backs to the screen, while looking at the monitors. The
college students explained in appropriate terms about the cameras, teleprompter, and set. The children then
were given time to explore the set and cameras. Taking turns being behind and before the cameras. The
children loved climbing on the cameras, changing the angles and focus, and watching the monitor to see
what they had done. On stage, the children were having a great time reporting the local news and weather.
While all this was happening, the digital camera was being used to document the trip. These pictures were
used to send home a note about our visit, as well as for the children to re-visit the studio.

The Re-enactment

Returning to the classroom, the dramatic play area became our own television studio. A long, low
table was the set for the meteorologist. A Kodak desktop videoconferencing camera on a tripod attached to
a computer became our version of the large cameras and production room. Two children operated the
program on the computer, one child operated the camera, and one or two children were onscreen. A
television was placed in the weather station, tuned to the weather station for the children to listen to and
watch the meteorologists. Children decided to print the Yahoo weather site to use as a "script" in their
studio. The children played for weeks taking turns being the meteorologist, the camera operator, and the
production person operating the computer and making mini-movies to share with the class.

Show Time

The time finally arrived to begin videoconferencing with the other classroom. My children were
very excited to see this new use of their camera. Because they were not familiar with how the camera
worked on a tripod, the kindergartners took turns operating the camera for the daily conferences. The
children began to immediately make connections with the other children, seeing similarities between
individual children and their names. This excited them, an proved to further involve them in the project.
The weather person from each school gave their weather report, and then we would visit. Sometimes the
children had questions, other times the teachers guided the conversation. In my room, we were doing daily graphing of a question. Several occasions we asked the other classroom to respond to our question. This gave my children a larger data source to work with. Our graphing question sometimes provoked questions in the other room that they researched later. As the school year moved on we shared many stories, answered many questions about each other, and even shared portions of special programs each class was preparing.

As the teacher, I was concerned with the time we were using to do the project. I sometimes had trouble rationalizing the time from other activities; my kindergarten is a three-hour a day program. We were videoconferencing daily for 10-20 minutes. This seemed like a large piece of my day and was it worth it? But with the questions the children asked, and the development in their understanding of the other children, I would and will do it again. On those occasions when we could not meet because of other commitments, the children always asked why we did not videoconference.

**Conclusions**

When we began videoconferencing, it was daily and continued for approximately 6 weeks. We had to overcome the dual platform issue with the cameras, by using CUSeeMe software. The project was very exciting for both the children and the teachers. While the picture was not the clearest, and the audio poor, the children were able to make discoveries about the weather and each other.

This project provided an excellent opportunity for my children to construct new understanding of weather in ways not available to them with out the technology. The children had opportunities to look at several types of technology, not just computers. What began as a simple exchange of the weather became an exciting interdisciplinary project combining math, science, social studies, literacy, and communication skills into an authentic and meaningful experience.
