Based on my experience with developing, piloting and teaching of on-line courses, there are certain issues, which I would like to concur with. The initial process of setting up such a course is tedious and requires constant revision of content for errors or simple alterations. However, the pay back is that if you ever decide to teach it again, you spend much less time in preparation of content and design, not unlike a face-to-face class. Such a class requires changes in the way you are used to doing things in the classroom, as on-line students’ needs are not all the same as those of a face-to-face class. A regular face-to-face class cannot be simply “made” into an on-line version, if you have certain desired outcomes. Sometimes our expectations and assumptions of our students’ knowledge are totally wrong, and then we become suddenly enlightened by either a test or an in-class discussion. Similarly, with an on-line class, I have been wrong in my assumptions of students’ technology experience. The pilot was a good experience for me as I did have students input as to how to better this alternate mode of delivery, which made things easier for their peers who were totally on-line. Start with an “inch”, in the classroom with your face-to-face students. The journey to the “mile” will be less tedious as your knowledge gained by the “inch” will be priceless.

Acknowledgement

This development of on-line courses was facilitated by a fellowship from the University System of Georgia granted to faculty at Georgia Perimeter College. The author being one such recipient was able
to conduct the development, pilot and teaching of these classes. All information contained in this paper is a reflection of the authors own experiences and views expressed are solely the responsibility of the author.
Real Concerns on Distance Education
When Distance is a Reality

camelpower@yahoo.com

Abstract: The study from which this report was derived explored concerns of school change facilitators (superintendents, principals, and technology coordinators) as they implemented new curricular requirements for instructional technology. This present report focused on one strand of concerns: distance education. Six informants expressed hesitation over the impending interactive video labs which were to be installed in their school districts, primarily over bad experiences from previous efforts in distance learning. Each informant expressed hope that the new systems would be useful. There appears to be the need for balance as the positive aspects of distance systems (service, teaching) are implemented against the negative aspects of distance systems (teaching changes, impersonalness).

Introduction

Distance education is a reality, continuing to be a growing factor in education, and has become the de facto focus of instructional design programs at the university level. From courses in audio visuals, to BASIC and Logo programming, to applications work, and now to teaching by means of the World Wide Web, the change in what topics need to be considered in instructional technology have morphed over my professional life, and those changes are recognized in the literature. (Becker, 1998; Cuban, 1986) In their ubiquity, distance systems are simply assumed to be the norm.

This writer has visited with many collegiate education departments, each of which believe that they are the true pioneers in distance technology, when, in fact, they are using one of a handful of commercial products which promise ease of course delivery. Noble (1997) suggests ulterior motives in promulgating distance delivery within universities and schools in their collaborations with private industry, resulting in outside control over academics in exchange for providing capital improvements.

At any rate, a cursory look at professional journals from 1998 forward reveal a preponderance of discussions over every “hot” distance topic. Notwithstanding Noble, energetic research is being conducted over instructional design for websites (Coppola & Thomas, 2000; Firdyiwek, 1999; Huang, 2000; Ingram, 2000; Maddux, 1999; Price, 1999; Smaldino, 1999), evaluation of web courses (Kubala, 1998; Kubala, 2000; Rankin, 2000), and practical and administrative concerns (Cornell, 1999; Eastmond & Lawrence, 1998; Harmon & Jones, 1999; Hawkes & Cambre, 2000; Schifter, 2000; Swartz & Biggs, 1999; Wade, 1999; Wynia, 2000; Zhang, 1999).

This writer’s earlier study explored concerns of school change facilitators during the implementation of a comprehensive statewide curriculum which included specifics on technology applications. (Wells, 1999) Concerns articulated by the study’s informants included several themes, such as student learning, finances, and power, but concerns over distance education, past and future, appeared to be dominant and strong. This present report centers and expands on the concerns over distance education that these informants expressed.

Context for the Study

This study was conducted with those designated as “change facilitators” in a seven-district technology consortium in rural Texas. Two of the districts declined to participate in this research. These districts were rural, but possessed school leaders who were committed to bring their communities up to date with technology.

In general, each of the five school districts were in Texas counties which have declined in population since 1990. The combined population of these districts is 7,306 (Texas Almanac, 1998). Each district’s economy was
based on agriculture and varying amounts of mineral wealth, resulting in substantial difference in property values.

Telephone interviews were conducted by this writer with three each of school superintendents, building principals, and district technology coordinators scattered among five of the consortium districts. Pseudonyms are given for each of these participants in this present report. Interview data was analyzed and organized to reflect patterns or "themes" which emerged from the data (Bogdan & Biklen, 1992). Bogdan and Biklen further suggest that this method of sorting piles of coded data allows the researcher to make better sense of the data and communicate the results to others.

The Salt Fork Educational Technology Consortium (the Consortium) is comprised of seven independent school districts, all of which have worked together as a special education cooperative. Six of these districts are members of Educational Service Center (ESC) Region J, while one is actually in the territory of ESC Region K. As also with special education cooperatives, a technology consortium is an "interlocal agreement" by Texas law, and has a management board comprised of district superintendents, one district designated as fiscal agent, and a chair, authorized to speak and act for the group.

The Salt Fork Telephone Company (SFTC), headquartered in Dellwood, Texas, provides telephone service for several counties in Texas. All of the school districts in these counties depend on this provider for telephone service and the possibility of Internet connectivity. In 1995, the SFTC invited school leaders from their service area to a demonstration in Dellwood to demonstrate a variety of new technologies that they were excited to announce, particularly their new capability for two-way interactive video. Because these districts had worked together before, had a common telephone carrier, and had common interests, these school leaders concluded it practical to combine together for technology improvement in their schools.

Prior to the Consortium's establishment, member districts were limited to the computers they had in the classroom. Almost all of their computers were stand-alone units. Each district also had a satellite dish for the state network materials, but were using them poorly and inefficiently.

The Consortium keeps operating funds in a bank account separate from general operating funds, administered by the business manager of the fiscal agent. To date, funding has come from grants, and from moneys generated from the two member districts designated as "property-wealthy" under Chapter 41 of the Texas Education Code. These districts recapture a certain percentage of excess property wealth normally surrendered to the State and assign those funds to the Consortium. These districts have voluntarily chosen to redistribute their funds in this manner.

Because these districts have formed this Consortium, they not only have more technology, but also more capabilities. As a whole, there is improved student performance and better trained teachers, with a rise in school accountability scores. Most importantly, these school leaders function as a group. They actively seek ways to collaborate.

A recent example of this improved outlook on technology concerns teachers' use of the Accelerated Reader (AR) program. Heretofore, it had been difficult to get teachers to travel all the way to Center City for training for AR, but with a high-quality technology center in Dellwood, closer to the other Consortium member schools, there was high and enthusiastic turnout for the training sessions.

Informant Concerns

Because the Consortium is implementing a highly sophisticated distance learning center in each of its member schools, each informant eagerly volunteered concerns over its implementation, use, and outcomes. The very concept of "distance," however, is not simply limited to "distance learning," but also to the significant distances Consortium educators have between their schools and sources of school improvement.

These informants perceived improvement for their school districts by being able to bring a greater variety of activities and services to their districts. Charlie Clark, a superintendent, jumps at the chance to use distance learning in his district. He sees benefits in distance learning to both professional and student progress, as well as it being a cost-cutting measure:
I think it's going to be extremely beneficial, especially to schools out here, like we are, that you know, we're an hour and a half away from the Service Center, or from Center City, or Tech, or anywhere like that, and it'll be extremely beneficial to our students. You know we can pick up some college classes. We can get them some dual-credit classes. I've got some people here that want to take some classes and want to work on some graduate work, and so forth, that maybe we can pick up. School board training and in-service training through the Service Center will save us lots of dollars and lots of time, because if we don't have to travel all the way to Center City to get our in-service, and even if it's a half-a-day deal, you spend a whole day by the time you drive over there and drive back.

Tim Booth, another superintendent, agrees with Charlie's concern over literal distance from school to service center. When staff have to do as much travel as do these school leaders, distance becomes a significant factor in what they can accomplish:

We're so isolated. We're a hundred miles from Center City, which is where our Service Center is... Instead of travel time, you know, because any teacher who leaves here loses a full day, even if it's an hour workshop.

Denise Stevens, a teacher/technology coordinator, echoes Tim's concerns. She experiences the pressure of the distance crunch as she budgets her time and resources:

We live a hundred miles from any kind of technical support, and we pay $100.00 an hour for somebody to come out and fix it, so you think twice before you even ask to have (a computer) looked at. Can I work around this?

Nevertheless, there is a sense of concern registered by each informant over distance learning implementation. There is also a fear of technology supplanting the teacher's role. Craig Henry sees distance learning in his professional future, but also makes this prediction:

My first instinct is to say that probably distance education is going to have effect particularly on rural America. I'm not real sure I'm ready to buy that yet. It may, but I'm not totally yet sold on distance learning as a tool for replacing the teacher in the classroom. There may come a day that that might be the only way that we can deliver some instruction to our students. If and when that day comes, I think that's going to be a shame, and I think that's going to be a step back in education.

Previous efforts with distance learning were frustrating at some informants' schools. Craig registers his experiences:

And (distance learning) wasn't that well received, either from the students or the parents. And I know that distance learning will be better than that because you'll have two-way interactive audio and video at all times. But I still have reservations, and I'll have to see it work well to change my mind on it. I probably can't stop it from coming.

Arnold Brady, having been a distance learning facilitator, also remembers problems with this teaching format for students and facilitator alike:

But it was all these schools, even as far away as Kansas that were viewing this at the same time. And it's hard to get through on the telephone line because you had all these people trying to get through to ask a question.

When asked about the net effects of all this, Arnold explained:
We had a lot of, I guess you'd say, disillusioned parents and kids because they were expecting to get, you know, they thought, "What a wonderful way to be in touch with computers," and what have you. And, you know, if we did work, we had to bundle that work up, send it to San Antonio. Well, by the time the guy got it graded, and got it back, you know, it might be a week or two. . . And at the same time, we were under "no pass no play" rules. And you had athletes that, you know, at three-week's reporting period, didn't know if they were passing or not. And then some of them would wind up failing at the end, and they didn't even really know why they were failing. And so, you know, we had a bunch of kids that were, like, ineligible.

Frustrations registered by the adult facilitators were received clearly, but students' responses to the distance experience were even worse. Arnold elaborated in detail about the "legwork" done on-site to facilitate distance learning. As is axiomatic in instructional design, inadequate feedback does not promote learning:

The kids never really knew for sure if what they were doing was what he wanted or what was acceptable, or till he had a chance to mark it, and write notes on it and what have you. And a lot of times, by the time they did get feedback on it, well, it was too late.

Denise also experienced first-hand the details of distance learning. Concerning the possibilities of interactive video, Denise questions:

I guess the biggest concern has been teachers who are afraid that they will get dumped on. How many students are you going to expect me to teach for this class that I have the same prep time that I had when I had seven kids?. . .And then all of a sudden, I'm teaching an interactive video classroom where I have kids from Woodlake, and from Dellwood, and from Beaverdam, and from Sawtooth, and all of a sudden, I have fifty kids instead of fifteen. I'm given the same amount of prep time, or maybe I'm given a second hour of prep. I still have the logistics of having to be ready for however many my school district decides to contract for. And, I have to be eminently more prepared that I ever thought about having to be prepared in a normal classroom. Because I can't go on the air and expect to freestyle it, you know?

Denise, a technology coordinator, as well as a classroom teacher, brings distance learning down to earth with her practical concerns. Contrasting with the concerns of teachers over the years, distance learning is bringing in new, heretofore unanticipated concerns and challenges. Denise relates:

You know when we just had textbooks, the worst problem you had to deal with was with the student who showed up in class without their books, or, you ran out of chalk, and you sent somebody down to the office to get chalk. But when you start using these levels of technology where the bugs are not quite as worked out, then you not only run into, you run into problems using the technology that really can crush your class time and crush your prep time.

Charlie Clark concurs adding:

It's another one of those things that, a new toy, that's going to be helpful, it's going to be beneficial, but it's going to be another one of those things that we've got to learn to USE too. We don't want just the the stuff put in, we want to be able to use it when we get it. We've got to stay on top of it. . . But if we don't stay on top of it, it won't take long to get behind.

As a superintendent, Charlie knows that he has to get the maximum "bang for the buck" as he works with his school board in defending the cost from distance education.

George Richards is adamant in his dislike for distance learning. Suggesting that distance learning might not be a good way to learn, George augments this with more mundane administrative concerns. Since George perceives
the teacher role in a traditional manner, he has concern over classroom discipline in a distance learning format:

    Well, I don't think you're going to have any kind of classroom without discipline in the class. And the only person that can do that is the one that is supposedly in charge, the one that's taking care of grades, etc. So that teacher has almost got to see her classroom.

This writer wonders whether George perceives distance education appropriately when he asserts concerning his evaluation of a distance education class:

    You know you have a facilitator. Your class can be strengthened by an excellent facilitator, but there's not any "school" going on. I guess to use the word "waste" of a certified teacher there. Sometimes, it's going to be an aide, somebody that will take care of the business, take care of mailing it off, getting everything in, and kind of keeping the students halfway quite. But it's not like anything like a good teacher would do, and because of this and because of the distance, it's a very slow pace.

Summary and Conclusions

The notion that technology could bring about needed opportunities and services to remote sites by distance learning has been discussed for some time and is now standard for evaluating a school's technology program (Becker, 1998; Texas Association of School Administrators, 1998). Nevertheless, there appears to be a need for a semblance of balance as the positive elements of distance learning (services, teaching, physical distance needs, etc.) are weighed against the pitfalls (teaching method changes, impersonal relationships) of these new technologies (Berg, Benz, Lasley, & Raisch, 1997; Dillon & Walsh, 1997). The apprehensions of Consortium change facilitators toward the impending interactive video system were quite real. They saw potential for some yet unknown distracting factor causing havoc with the learning process as a result of distance learning. At least one informant voiced active disagreement with distance as a viable means of teaching and learning.

Nevertheless, the Salt Fork administrators know that this is necessary for their students. Charlie Clark sums up the attitude of Salt Fork school leaders when he says:

    Our main goal is to make sure that when our kids leave here, they've got just as good an education as someone coming out of Central City or Riverton or Houston or wherever, and that they can just fall right in there, and get with the program, and they don't feel like they're behind in anything. . . . Let's live out in the country, but let's get out of it at the same time and make sure we're on top of the world, here, and we know what's going on.

Abstract: Distance education has come of age. Its foundations have become firmer, its applications have grown in number and variety, and its influence has become more visible and more substantive. Yet, one question is still frequently raised: “Does distance education resolve the current problems of education?” This paper aims at giving some answers to this question by investigating the benefits and challenges of distance education. What follows is a thorough discussion of the question. Finally, suggestions are made for further research in the field of distance education to improve the current educational system.

Introduction

Current trends in education reflect an expansion from on-campus education toward distance education. These trends have been evident in the exponential growth of papers published during the 1990s. As Willis (1998) mentioned, distance education, a section that did not exist prior to 1996, is now one of the largest sections in the Society for Information Technology and Teacher Education (SITE) annual conference. A review of the literature, however, found few studies directly addressing the effect of distance education with considerations of the current problems of education. If we understand which aspects of distance education resolve the current problems and which do not, we could then focus our attention to the unsolved problems in forthcoming research efforts to hasten the pace of improvement. Three main problems of current education discussed in this paper are what we regard as the root of many of the key problems facing education today. They are unequal learning opportunities, the change of demographics, and the lack of individualism.

Current Problems of Education

Unequal Learning Opportunities

People in rural or remote locations, as well as those in economically challenged districts, are often at a disadvantage educationally compared with those in well financed urban areas. Resources may be scarce, and, in the worst cases, there may not be enough teachers to reach the students. For example, a small, rural school may not be able to justify the cost of a teacher to provide advanced physics instruction or teach Japanese to a handful of students. Problems of access may be manifested in other ways as well. For example, learners who are homebound due to illness or physical disability may not be located far from an educational institution, but they are effectively isolated. Adults who wish to pursue education may lack the time needed to pursue current coursework at a local school or college. For them, home study may be the only option. Distance education can overcome many of these problems of access and provide educational opportunities (Newby, et al., 2000).
The Change of Demographics

With the disappearance of jobs the workplace is changing, workers require retraining in new jobs that require new skill sets to help revitalize businesses in a competitive marketplace. This resulted in colleges and universities in the United States being faced with tremendous challenges in the 1990s. During this time the traditional 18-21 years old students, who lived on campus while taking courses full time, shifted to students who lived away from campus, had families and jobs and either commuted to campus or looked for distance education alternatives (Hiltz, 1994). A rapidly growing population with increased workplace changes means the traditional methods of on-campus education may leave out many potential students from gaining a full educational experience.

Lack of Individualism

One aspect of education that must be considered is that all students are DIFFERENT, with different backgrounds, knowledge, interests and learning styles. Each student should be treated individually (Bork, 1997). But current modes of learning of instructor-led lecture and textbook provide little individualization. Every student tends to be provided with the same learning experiences. This cookie-cutter approach to learning works for a few students, but many learn only partially without maximizing their potential.

Benefits and Challenges of Distance Education

In order to clearly present the benefits and challenges of distance education, the benefits are classified into eight categories—access, reach, heterogeneous opinions, flexibility, convenience, comfort of learning, quality of learning, and learner focus. Conversely, the challenges are grouped into five categories—the emphasis on the hype and hoopla of technology, feelings of isolation, cost of equipment and technology, low quality of individualization, and inadequate student support systems.

Benefits of Distance Education

a) Access—Distance education addresses the problem of unequal learning opportunities in terms of the educational access. It provides service to students who are geographically isolated or who are otherwise place-bound or time-bound, such as people who have physical disabilities and/or working professionals who seek educational opportunities for reasons of career advancement. Distance learning opens up possibilities for non-traditional students who limited on-campus access due to time or distance issues.

b) Reach—The problem of unequal learning opportunities in terms of insufficient funds or resources to open the wanted course for students in a small or rural school can also be solved by distance education. As the example given above, a small, rural school may not be able to justify the cost of a teacher to provide advanced physics instruction or teach foreign languages to a handful of students. Expanding geographic reach through distance education gives an institution a wider pool of students from which to recruit. This could benefit most resident educational institutions, for some of which, this may be a useful tactic to maintain or expand general student enrollments. For others, distance education may be used to recruit students into specialized courses or programs in which a critical mass cannot be maintained on-campus (Smith, 1998).

c) Heterogeneous Opinions—Because distance education gives an institution an opportunity to recruit a wider pool of students, it is expected that students who come from different populations/areas/countries or from different disciplines could provide more heterogeneous perspectives to the topics or problems discussed in class. According to Whitworth (1999), many students felt that the educational experience was enriched by their collaboration with other students from different locations because they have learned just as much material and actually gained more ideas than they would have in a current class setting by listening to and watching the presentations of other students from so many different backgrounds.
d) **Flexibility**—Smith (1998) pointed out that for faculty, increased flexibility can allow for meeting classes from a distance while traveling, for lecture opportunities, and for maximizing time efficiency in research. For students especially with part-time or full-time jobs, distance education tactics can enhance student efficiency with time shifting within a semester and load leveling within a curriculum, allowing students to take required courses that may only be offered at a certain time of day or in a certain semester. This flexibility may decrease time to graduation and allow students time for extracurricular activities. In business, with a shrinking workforce and the rapid changes in technology, distance education can be employed as a strategy to overcome the internal "content-expert" shortages.

e) **Convenience**—With the availability of on-line interaction and content support twenty-four hours a day, convenience is another salient aspect of distance education. In today’s busy environment, highly mobile learners are requesting equally mobile and time-flexible delivery. The current emphasis on desktop conferencing and asynchronous learning are responses to this need for convenience, so that the learners may take responsibility for the pace of learning, with freedom to start and stop at any time.

According to Smith (1998), distance education technology can provide more detailed needs assessment and more frequent checks and revisions for instructional designers and/or instructors. For example, course delivery through the Web by using WebCT (http://www.webct.com)—full-featured packages for on-line courses, allows the instructor to efficiently track students’ progress throughout the course and immediately provides the instructor statistical reports of students’ performance. These results can supply the instructor useful information in redesigning his/her instruction. In addition, since much of distance education is documented in e-mails, LISTSERVs and chat rooms, it is more convenient for researchers to study the communication and instructional processes of it.

f) **Comfort of Learning**—Participating in class online allows students and instructors the ease to participate from a computer lab or the comfort of their own home. This is especially beneficial for learners who have illness or physical disability.

g) **Quality of Learning**—Distance education could maintain or improve instructional quality by providing variety and depth of course offerings within a curriculum, multi-campus graduate seminars, and seminars with industry and government research sponsors. These courses are particularly important in graduate program and can be achieved by using some common techniques, such as videoconferencing and computer communications, as well as audioconferencing.

Educational outcomes of individual courses could also be improved through distance learning. Distance education techniques can support many educational strategies for individual courses to enhance quality. It can allow team teaching with colleagues from other universities. Benchmarking—a frequent quality improvement strategy in education and business—can be facilitated through distance education. Telecommunications technology can connect students with the real world through speakers, experience, and events. These technologies and the Internet can be used to improve contact and access, as well as reduce travel, thus providing new opportunities for students. Examples include supporting interns and residents in field placements, supporting graduate students in industry research placements, and providing contact for industry researchers on campus (Smith, 1998). In addition, in order to take distance courses, students need to learn the required technology skills that will provide them with the everyday information technology skills they will need in their future study, work and life.

h) **Learner Focus**—Universities have traditionally been teacher-centered rather than learner-centered, with an emphasis on knowledge dissemination through one-way lectures and "chalk-and-talk" methods. Perhaps because teaching is less readily taken for granted when students are separated overtly by time and/or distance from the instructor, the emphasis in distance education programs has been more on the learner and on learning. Moreover, one of the advantages of classroom teaching has supposedly been the interpersonal contact between teacher and student. This has increasingly been lost, as class sizes have grown rapidly, yet there has been little adaptation to the “distance” this introduces. At least in distance education the distance is overt, perhaps necessitating more comprehensive efforts to compensate for it (Tobin, 1995).
Challenges of Distance Education

a) Hype and Hoopla of Technology—Computer technology has been used in learning environments since the late 1950s, with increasing amounts of money going in this direction. Looking nationally and internationally, it is difficult to see that this usage has improved learning performance for most students (Bork, 1997). According to many practitioners in distance learning, it is very easy to get “caught up” in the new technologies, which results in a class that is driven by the technology itself rather than by the use of technology to enhance learning performance. This might be the reason the performance of learning in some distance learning programs has not been improved as expected when technology has been used as an aid for the instruction. Educators should be careful about the “seductive allure” of gee-whiz technology and not lose sight of designing effective instruction.

Additionally, teaching instructors and students how to use equipment and software packages can often take too much time away from course content. It is recommended by Whitworth (1999) that this problem be alleviated through separate workshops and help sessions focusing solely on the technology that are supported or sponsored by the college or university.

The problems of the possibility of a technology failure are seldom mentioned. Experience has shown that the likelihood of such an occurrence diminishes with the quality of the equipment. The problems associated with the system in Whitworth’s study (1999) mainly occurred at sites that economized by purchasing less expensive microphones, monitors, and cameras. But even with quality equipment, problems can occur. Therefore, it is essential to have a back-up plan and an alternate lesson that site facilitators can deliver to students.

b) The Feelings of Isolation—In a learning situation in which the instructor is not physically present, it is easy for both the students and the instructor to feel isolated from each other. Many students feel that relying on non-personal interaction as a (sole) source is inefficient when compared to human interaction and results in the feelings of isolation. Many instructors feel that it is hard to orchestrate unity among classmates in different distance learning labs. The following entry from the instructor’s journal details her impressions after the first encounter with a real distance learning class: “I felt good about the class, but I felt removed from my students. Unless I call on a specific site there is no feedback or response. I felt so alone and the equipment makes a physical barrier between the students and me in the room. This feeling of isolation continued to be a problem for the instruction throughout the semester” (Whitworth, 1999). Therefore, creating a feeling of community to provide a social contact and increase the interactivity between the instructor and students and among students is one of the most important issues that educators should be aware of while teaching at a distance.

c) Cost of Equipment and Technology—According to a study conducted by the U.S. Department of Education in 1995, among the factors frequently reported as keeping instructors from starting or expanding their distance education courses offerings to a “major extent” were program development costs (43%), limited technological infrastructure (31%), and equipment failures and costs of maintaining equipment (23%). It is true that the economies of scale could be achieved once a certain number of students enrolled have been obtained or classes have been taught repeatedly over an extended period of time so that the high fixed cost of equipment and technology can be shared to hundreds of students or over a number of years. However, the setup cost for the required equipment and technology, such as computers, virtual libraries, central servers and networks, ongoing technical support, program development costs, and marketing, for distance learning classrooms can still be substantial. The funding has to be there!

In many institutions, there is limited technological infrastructure to support distance education (Lewis, et al., 1997). Communication systems used to support distance education can be unreliable (Hall, 1995) and equipment failures numerous (Matthews, 1999). Maintenance and repair bills for distance labs are high. Without proper maintenance, many equipment problems, such as poor reception, busy phone lines, and broken hardware, can result in downtime and canceled classes.

d) Low Quality of Individualization—Although our students are all very different, almost all the curriculum approaches we have now (books and lectures) treat them alike. Thus, it is not too surprising that existing computer learning material does the same. We need learning that is individualized to the needs of each student. The key to achieving effective learning is to use the interactive capabilities of modern computers (Bork, 1997). Unfortunately, current attempts, such as putting courses on the World Wide Web, differ only slightly from books and have not fulfilled the individualized learning that we need.
Inadequate Student Support Systems—McInnis-Rankin and Brindley (1986) described that student support services could include orientation and information, administrations and other registry services, advising and counseling, instructional support, and student advocacy. Distance education institutions, such as the Open University in the United Kingdom, have well-developed student support systems to serve the distance student (Koble and Bunker, 1997). However, distance education for Americans was almost synonymous with new technologies and their applications to learning—using computers, interactive video, and even virtual reality (Paul 1995). Paul also mentioned that when compared to the European counterparts, Americans were less interested in course design or student support, and were somewhat indifferent to the linguistic debates about the relative meanings of open learning and distance education, which received considerable attention at that time in Open Learning, the journal of the Open University in Britain. Paul's criticism can be justified by the research conducted by Koble and Bunker. In their journal—Trends in Research and Practice: An Examination of "The American Journal of Distance Education" 1987 to 1995, Koble and Bunker pointed out that only three out of the 129 major refereed articles in American Journal of Distance Education from 1987 to 1995 belonged to student administration and support issue. The dearth of articles on student administration and support is disappointing. Institutions that are now developing distance education programs and new delivery systems must also begin establishing and standardizing admission procedures and support systems to accommodate distance learners. Just as recent articles in the journal indicate an increasing awareness of the role of the instructor in distance education, we would also hope to see an increase in the number of articles addressing student support issues, such as tutoring, counseling, and advising (Koble and Bunker, 1997).

Discussion

Three important problems of the current education—unequal learning opportunities, the change of demographics, and lack of individualism have been selected for the review in this paper. Distance learning is opening doors for populations previously unreachable by current education, such as place-bound or time-bound learners. With the aid of advanced technology, it is believed that the problem of unequal learning opportunities could be resolved by distance learning in the near future. While conventional universities are geared primarily to serving younger full-time students, an emphasis on lifelong learning suggests an increasing interest in older, part-time learners, the primary target group for most distance-based programs. With its relative flexibility and convenience, distance education meets the needs for the changing demographics and, thus, can accommodate the influx of nontraditional learners, such as working professionals who have family obligations, limited free time, and career/civic responsibilities. However, the third problem of the current education—lack of individualism has not yet been achieved by distance education. Research on how to incorporate the technology to design the seamless instruction that meets the individual student needs and maximizes the potential of each student should be further conducted.

Although many of today's education problems can be overcome by distance education, it also brings up some new problems, such as higher dropout rate. The main reason for higher attrition in distance education might be caused by the inadequate student support services. This concern should be set forth and manifested in the development of a wide variety of student support services in American distance teaching institutions to assist students coping with learning difficulties in distance education. In addition, Tobin (1995) claims that, "Research with students...indicates that their successes is closely tied to the provision of these services." Moore (1996) has suggested that, "There is a direct relationship between the instructional effectiveness of a program and the time and money spent on learner support [italics removed]."

Many distance education practitioners noticed that the frenzy of activity relating to the Internet and teleconferencing technologies has produced pressure to rush into distance education without proper planning, which results in overlooking the real purpose of using technology as an aid to enhance learner performance. Thus, the performance of distant learners is not achieved as expected for some distance learning programs. Hence, rather than being "caught up" by the new the technologies, educators should focus their attention back to where it belongs—careful planning, a focused understanding of course requirements and student needs, and the awareness of the limits of distance education, such as the feelings of isolation, which might cause the problem of lacking of student persistence and lower student performance. After all, technology doesn't teach. People do! Only with proper instructional design—planning, implementing, and evaluating (Newby, et al., 2000), and the wise selection of reliable learning methods and appropriate instructional strategies specifically
tailored for distance learning to cope with the challenges of it, distance education can provide a convenient and instructionally sound method of course delivery.

Conclusion

With the help of advanced technology, such as the Internet and World Wide Web, which can do many wonderful things for distant learners, distant education provides us a promising solution to cope with the current educational problems, such as unequal learning opportunities and the changing demographics of learners. However, lack of individualism has not yet been achieved by distance education and the solution to it is waiting for us to further explore. To sum up, teaching from a distance is challenging; an effective distance education program does not happen spontaneously. Distance learning requires hard work and commitment on the part of the instructor and students who are willing to give it a chance and a support system from the institution that sponsors it. With a well-organized planning process, distance education will have its rewards—better access, better quality, more flexibility and convenience, and hopefully in the “not-so-distant” days, better individualized education to maximize student performance!

This year's overriding theme for this section is making connections through technology. Technology is connecting teachers to students from universities to public schools, urban areas to farm settings, and countries to countries. The papers demonstrate how projects come alive through technological communication. The diversity in the projects shows that man's desire to connect to others is a basic need. The papers are divided into two basic groupings: connections made by teachers and students in other lands and connections made within the United States.

The first four papers discuss connections from country to country. The writer Greenlaw of Canada at St. Francis Xavier University initiated a Canadian Chinese connection. Canadian students communicate with Chinese students about their understanding of themes, characters, and beliefs in literature selections. This cultural exchange via the Internet provides a powerful vehicle for ESL students to discuss their ideas and develop their language ability. In another experiment, Nel and Wilkinson of South Africa focus on efforts to assist first year students in a developing community with beginning computer classes. This paper focuses on the desire of a whole community to receive direct benefits of its students learning technology. The purpose of learning technology is to help them keep in touch with the rest of the world. The authors discuss the initial problems that can plague novice computer students worldwide. The next paper by Fred Wilkinson and Annette Wilkinson of South Africa discuss how solar energy can be harnessed to develop farm schools in predominately rural areas of South Africa. The project links rural farm schools to the world. Another paper comes from Norway, where Johannesen and Ogrim from Oslo University tell of six universities partnering to offer to its Norway teachers web-based network courses. This seven-year-old Co-operation Network provides seven courses to eighty students in different part of the country. Through these course offerings, teachers receive diversity through co-operation, course content, and communication methods.

The next set of papers shift to interesting research projects in the United States. Here the papers focus on many connections that are being developed from state to state or culture to culture. For example, Knecht of the University of Toledo reported a four-state connection. He discusses attempts to close the digital divide by using the Worldgate Internet School to Home program. His project involves fourth grade elementary students in a program that provides free access to the Internet for a year. Pearson and Swain demonstrate closing the gap within cultures from the University of Florida. They discuss how the computer can be used to close the gap between socioeconomic groups and how to bring equitable learning conditions between groups. The authors discuss three primary areas that influence the digital divide: the areas of frequency of use, the computer experience of students, and technology training. Another paper by McFrazier and Bailey of Prairie View and Texas A&M University identify conditions and teacher practices that have been proven effective in increasing the academic performance of African American students and students in schools with substantial minority populations. The targeted population for the research was reading and math teachers from schools whose Texas Assessment of Academic Skills performance was reported exemplary, recognized, or acceptable. Then the authors Martin and Litton from Loyola Marymount University pilot a study to explore issues surrounding computer technology and social change from the perspective of diverse learners in a university setting. They wanted to find how female students and members of different ethnic groups view the importance of technology for their families.

Cutri from Brigham Young University discusses initial insights gained from integrating technology into a required multicultural education course. She discusses how to critically analyze on-line material if the Internet is to serve as a teaching tool for diversity. Her assignments help students explore other groups from the perspective of three different areas: media, curriculum and policy. The paper by Izat, Hargrave, Brammer, and Williams from West Texas A&M reported the findings of a study conducted in
a graduate multicultural course where students send anonymous comments using a web board format. The researchers felt that the students would be more honest with their thoughts and feelings if their comments were sent on web board than a face to face environment.

Meadows from Eastern Illinois discuss the use of technology in the early childhood environment to support the development of cultural competence. The author used four objectives that directed her in identifying specific examples to aid practitioners in developing media presentations suitable for young children. She feels that using technology in a developmentally appropriate manner to facilitate cultural connections with children is a viable way in which to transform current curricula in order to fully integrate, multicultural concepts and develop an understanding of diversity that can last a child a life time. Also, Beyerbach and Russo from State University of New York at Oswego discuss using technology to support social justice in a preservice elementary program. They link foundations and methods issues in teaching social justice.

Connecting urban to suburban students is another way to close the gap. Garcia and Chen from the University of Houston-downtown discuss an online course that presents a unique opportunity for more comprehensive investigation and understanding of urban culture and schools in training future teachers. The online design was to allow students to experience urban complexities resulting from marital, ecological, economic, political, and religious or sociocultural factors. Thornthwaite from Lipscomb University discuss a study that documented the experiences of a school-university partnership in Nashville Tennessee. The students come from over 100 countries and speak more than 75 different languages. The goal was to promote community instead of isolation in this country.

Finally, evaluating the different methods of communication is important. Furr and Mcbride from Northwestern University discuss how important it is to create a feedback system that would continue to look at the problems that can plague distance learning. It discusses how to effectively incorporate faculty and student feedback into ongoing formative evaluations of distance learning programs.

These papers tell about the new connections that are being made in the 21st century. Technology within the country or abroad presents an interesting perspective.

USING TECHNOLOGY TO SUPPORT TEACHING FOR SOCIAL JUSTICE IN A PRESERVICE PROGRAM

Barbara A. Beyerbach
Pat Russo
State University of NY at Oswego
Oswego, NY 13126
beyerbac@oswego.edu, prusso1@oswego.edu

Abstract: This article describes how we have attempted to use technology to support teaching for social justice in an educational foundations and in an elementary methods course in our teacher education program. Programs, class activities, and analysis of student work will be shared and implications for practice derived.

Introduction

It is essential that as educators we continue to improve our abilities to develop multicultural, anti-bias, culturally relevant pedagogical practice. The fact that our region, state and country are becoming more culturally diverse is only one reason for this need. If we are committed as teachers, to all of our children, then it is important for us to use curriculum and teaching strategies that reflect the needs and interests of all children. Given that there is increased funding for the enhancement of Math/Science/Technology funding, are there ways this funding can be used to enhance a pedagogy of teaching for social justice?

Recently, we have had opportunity to explore this question, as co-director and participant on a Goals 2000 Preservice Teacher Technology Infusion Project. This paper describes our attempt to infuse computer technology into an undergraduate foundations and an elementary methods course and related field experiences, to support a “teaching for social justice” pedagogy. We will describe the types of learning experiences we sought to craft for preservice teachers and the children they taught, how specific computer technologies had the potential to enhance these with an aim towards teaching for social justice, and where these experiences held promise and fell short of this aim. Implications for technology infusion to support a social justice agenda will be shared.

Significance

How we use computer technology, what technologies and strategies we choose, and whom we engage with them, shapes our pedagogy as well as students' learning experiences. Foundational issues are inherent in any education course, and we have always sought to link foundations and methods issues in our teaching, with an aim towards social justice. Consistent with the Council of Learned Societies in Education’s Standards for Academic and Professional Instruction, “The objective of such study is to sharpen students’ abilities to examine, understand, and explain educational proposals, arrangements, and practices and to develop a disciplined sense of policy-oriented educational responsibility.” (CLSE, 1997, p8). This work articulates a constructivist, social justice pedagogy, describes how computer technology might support such pedagogy, and critically examines preservice teacher learning in the light of these aims. Where the learning falls short (e.g. students' tendency to see computer technology as a cure and great equalizer while at the same time choosing practices that accentuate inequities), strategies for further struggle will be described.

Defining Teaching for Social Justice
The School of Education in which we teach centers "authentic learning for all students towards the aim of social justice" in our conceptual framework. Faculty members are committed to this vision and continuously work to realize it in course and field experiences. The phrase "teaching for social justice" carries with it several key assumptions. First, that there is such a phenomenon as social justice and conversely that social injustice exists. A claim that we are teaching for social justice positions us at a point of recognizing sites of social injustice and working through our teaching toward a goal of social justice. Given society's dynamic nature and the obscure manifestations of injustice, the work toward social justice is not easily obtainable nor does it have a fixed end. Thus our goal within the School of Education is not necessarily to reach a state of social justice. Rather it is to develop in our candidates the ability to identify social injustice especially within school settings, and the desire and ability to take actions that will cause change leading toward social justice. When we talk about developing ourselves and our students as socially conscious catalysts for change, we acknowledge that we have a responsibility to play an active role in working toward social justice (DeVries & Zan, 1996; Green, 1971; Tom, 1984).

Second, the nature of injustice in our society results in school age students facing "persistent and profound barriers to educational opportunity" (Darling-Hammond, 1995, p. 465). Social injustice means that children are denied opportunities to learn and grow. When we work toward social justice we acknowledge these barriers and make a commitment to transform the educational fabric toward a more fair and inclusive educational setting. "Without acknowledgment that students experience very different educational realities, policies will continue to be based on the presumption that it is the students, not their schools or classroom circumstances, that are the sources of unequal educational attainment" (Darling-Hammond, 1995, p. 465).

According to Bell (1997) "The goal of social justice education is full and equal participation of all groups in a society that is mutually shaped to meet their needs" (P. 3). Teaching for social justice means that in addition to learning about and using "good teaching strategies," we expect our future teachers to learn to use "good" strategies within a context of working toward social justice. Our commitment to social justice has its roots in the efforts of the founder of Oswego State, Edward Austin Sheldon, who prior to establishing this college created a school for poor children in the city of Oswego in 1849, to "teach them that they may become worthy citizens as well as others" (Sheldon in Barnes, 1911, p. 76). A key goal of this school was the "intellectual and moral education and improvement of such poor and orphan children in this city..." (Sheldon in Barnes, 1911, p. 77).

How is the goal of working toward social justice manifested the School of Education? Not only is social justice an end goal of our efforts but it is also an on-going process. This work shows up in our recruitment of faculty and student, our curricula, and in many of our special programs. Given the pervasiveness of social injustice is within our society and schools, the work toward social justice must be equally pervasive in our programs.

Within our curriculum our work toward social justice spans a number of particular approaches ranging from the use of critical reflection and autobiography (Bell, 1997; Ladson-Billings, 1995; Cochran-Smith & Lytle, 1993; Schon, 1983; Noffke & Stevenson, 1995); the development of cultural diversity awareness through many, many levels of multi-cultural education (Banks & Banks, 1993; Sleeter & Grant, 1999; Darling-Hammond, 1998) and anti-bias teaching (Byrnes & Kiger, 1996; Derman Sparks, 1989); examination of issues of oppression including racism, ableism, sexism, classism, and heterosexism, field experiences in culturally diverse settings (Syracuse City Schools, Onondaga Nation Schools, New York City Schools); and requirements that units and lessons in any field experience setting be reflective of cultural diversity and consistent with a social justice framework. We develop a critical perspective within our students and an ability to take action directed toward social change. In developing an awareness and an ability to work for social justice in our students, our own pedagogy must reflect this process (Adams, 1997). Following the pedagogical frameworks described by Adams (1997), we: "balance the emotional and cognitive components of the learning process; acknowledge and support the personal (the individual student's experience) while illuminating the systemic (the interactions among social groups); attend to social relations within the classroom; use reflection and experience as tools for student-centered learning; and value awareness, personal growth, and change as outcomes of the learning process" (p. 30-43).

In the Elementary Education program, the following are some examples of activities which build upon this process and goal of teaching for social justice: In Edo 301 (Foundations of Education) students develop reaction papers where they examine their personal knowledge and attitudes about oppression (race, gender, [dis] ability, class, and sexuality); they trace the flow of forms of oppression throughout the history of education in this country; and they identify issues of gender, race, disability, class, and sexuality in
classroom settings in their field placements. In EED 394-396 (Methods of Instruction and practicum) students infuse their unit plans with evidence of anti-bias teaching strategies; they develop single child-study reports in which they collect evidence of a child’s social, cultural, intellectual, and emotional background, and develop an instruction plan which can help the child to flourish; and they critically assess their field placement around issues of social justice. We have attempted to extend these experiences through the use of technology-supported learning experiences as follows.

Using Technology to Support Teaching for Social Justice in the Foundations Course

The strategies used in the foundations course to infuse technology to support social justice pedagogy included the following:
1. E-mail discussions between faculty and students to explore social justice issues raised in class and readings.
2. Listservs on multicultural education, educational standards, and children’s literature, which students subscribe to and critique.
3. Web searches for links to social justice sites.
4. Interactive desktop videoconferencing between OSU students and students in JH56 in Manhattan, focused on foundational issues in an urban context.

Supporting Teaching for Social Justice in the Methods Course.

The strategies used in the methods course to use computer technology to support teaching for social justice included the following:
1. Helping students explore equity issues with respect to computer use in schools, and in their own learning. We encourage preservice teachers to examine who took leadership roles in what computer related tasks in their work groups as well as in the elementary classrooms in which they were placed. We examine what factors were related to this (particularly class and gender), and how activities could be structured and designed to include all learners.
2. Choosing technologies that are likely (based on the research) to support the learning of diverse students. For example, research indicates girls prefer to use computers to communicate, or accomplish a task, rather than engage in competitive games. Web sites were selected with an eye towards multicultural opportunities, (e.g. Classroom Connect, Global Schoolhouse).
3. Making Teaching for Social Justice the focus, and using computer technology as a strategy to enhance this aim. For example, learning centers on books of choice dealing with diversity issues (Paley’s The Girl with the Brown Crayon, Ladson-Billings’ The Dream Keepers, Jones and Newman’s Our America, Cora Lee Five’s Special Voices, and Victoria Purcell Gates’ Other Peoples’ Words) incorporate relevant software (KidPix, Inspiration, Hyperstudio) into reader response activities.
4. Students in the course participate in a listserv of class members, where they reflect on course readings and experiences, and link these to their readings. Particular questions are posed to the group to expand their understanding of diversity issues, to challenge injustices or narrow perspectives, and to encourage them to view situations from multiple perspectives.
5. Students conduct a group investigation on a topic relating to teaching for social justice, conducting E.R.I.C. and web searches, and share PowerPoint presentations on their learning journeys.
6. Students construct instruction mini-units on topics such as Civil Rights, Women in History etc. using resources on websites linked to the instructor’s website that incorporate anti-bias teaching materials.
7. Students have opportunities to explore multimedia authoring software such as Hyperstudio, Inspiration, and PowerPoint, which draw on multiple modalities and centered on learner-constructed knowledge.
8. Students teach technology infusion lessons in their field placements using such resources as Classroom Connect’s Galapagos Quest, which potentially expand students’ worlds.
9. Preservice teachers also participate in two-way interactive videoconferencing with a fourth grade, team-taught, elementary inclusion class, observing diverse learners and interacting with them and their teacher.
Conclusions

Technology has the potential to support a teaching through social justice pedagogy by
1. Facilitating communication among course members and with the broader educational community, unbounded by geographical distance.
2. Allowing for a shared practicum experience designed to highlight teaching for social justice pedagogy, where issues can be discussed interactively, in real time, across contexts.
3. Empowering more sophisticated research across diverse sources of knowledge via web search engines that make accessing multiple types of information more easy.
4. Positioning students as constructors of knowledge that allows for multimedia representations of that knowledge enhancing communication and learning.

Some of the perils we have noticed in attempting to use computer technology to support teaching for social justice are:
1. Students can be enamored with the glitz of computer technology into a non-critical stance in which they see technology as the great equalizer, meeting needs of students with all learning styles.
2. Students exposed to websites of low quality may take information shared there as truth.
3. Students focus on how to use the technology, diverting attention from issues of substance, for example struggling with the mechanics of signing on to a listserv or using KidPix as opposed to engaging in dialogue, or representing their understanding of scenes from a literature selection.
4. Without adequate processing, students peeking into culturally diverse classrooms may reinforce stereotypes they hold about particular contexts/groups.

Teaming as foundations and methods instructors has allowed us the opportunity to infuse foundational and methodological issues through both courses, in and effort to realize the vision articulated in our School of Education's conceptual framework. We have increasingly come to realize the importance of developing critical literacy in our students, regardless of the educational context or medium, in helping them become reflective, authentic learners who actively support teaching for social justice pedagogy.

Abstract: This paper presents initial insights gained from integrating technology into a required multicultural education course. Students were required to include sources from the Internet in an assignment where they explored how a cultural group other than their own was represented in the media, curriculum, and policy. The range of Internet sources students found included easy to locate sites such as the state department of education site to highly specialized sites focused on a particular cultural group. Students' ability to critically analyze the on-line content they found greatly varied. Some students merely summarized content. Others students applied terms and concepts from multicultural education to identify the messages conveyed through the sites and the potential impact of these messages on students and teachers. Greater attention must be devoted to teaching students how to critically analyze on-line material if the Internet is to serve as a teaching tool for diversity.

Introduction

The push to integrate technology into curriculum and pedagogy is being felt by all levels of educators—in-service teachers, pre-service teachers, and teacher educators. The majority of us are novices in this area, but many undergraduate pre-service teachers, because they are from a more computer savvy generation, actually have more experience than many teacher educators. I thus decided that the best way to respond to the challenge to integrate technology into my university course was to learn from my students. By modifying one of my existing assignments in a multicultural education course, my students became my guides into how diverse cultural groups were represented on the Internet.

This paper presents initial insights gained from integrating technology into an assignment where students explore how a cultural group other than their own is represented in the three areas of the media, curriculum, and policy. The assignment is called a "Snapshot of a Prominent Cultural Group". The students are asked to choose a cultural group other than their own and create a snapshot of that cultural group by gathering visual and narrative representations of the group from three categories: (1) media—newspapers, magazines, television, the Internet, etc; (2) curriculum—textbooks, videos, posters, chapter and picture books, school brochures, etc.; (3) policy—classroom, school, district, state, or federal guidelines or mandates related to a particular cultural group. Students were required to use the Internet to locate evidence of how a particular cultural group is represented in the area of policy. However, students also chose to use the Internet as a source for evidence in the areas of the media and curriculum.

To date, four students have included a total of 13 Internet web sites in their snapshots. In the following sections, I will discuss the range of Internet sources students located and students' varying abilities to critically analyze Internet content.

Different Levels of Digging

In preparation for the assignment, I provided students with a list of eight web resources as initial points of exploration and informally described each site. The range of Internet sources students included in their assignments greatly varied. Some students simply went to the web sites that I had provided and did not dig any deeper. Other students initially went to the web sites that I provided, and then made connections to other sites through various links. Other students used their own knowledge of exploring the Internet and found sites pertaining to their cultural group of focus that were totally unrelated to the original eight sites that I provided. The latter group of students found web pages specifically devoted to a certain
cultural group for instance Native Americans, African Americans, and Middle Easterners. These sites varied from informational resources about the specific cultural group to highly politicized commentary about the status of the cultural group within the U.S. majority culture.

The majority of my students are white, middle class females. Naturally, their cultural backgrounds serve as a lens through which they viewed the politicized material of some of the web sites they found. Many of the web sites were designed to be viewed primarily by members of the specific cultural group with like-minded political opinions. In other words, the materials were aimed at “insiders” to the cultural group rather than designed for “outsiders”. Yet, the amazingly easy access provided by the Internet makes it possible for “outsiders” to view “insider” material. Professors must prepare students for experiences such as these. Otherwise, there is a possibility that students will make rash and unfounded judgements about a cultural group based on information that was not designed to be viewed by “outsiders”. The consumption of on-line information about diverse cultural groups is influenced not only by students’ cultural backgrounds. Additionally, students’ varying abilities to critically analyze on-line information also emerged as a finding from this small study.

Analytically Consuming On-line Information

The students’ ability to identify and interpret the various messages conveyed by on-line information about diverse cultural groups was greatly impacted by their ability to critically analyze information. Critically analyzing information in my course is defined as applying terms and concepts from multicultural education and social theory to identify the potential impact on students and teachers that societal messages about diverse cultural groups can have. The purpose of such analysis is for my undergraduate students to better understand the experiences and treatment of diverse cultural groups particularly in U.S. settings. Some students, even though they found quite specialized web pages about their cultural group of interest, merely described the on-line content. Other students applied terms and concepts from multicultural education and social theory to systematically identify the messages they perceived from the on-line content. Through the analytic use of the terms and concepts from multicultural education and social theory, these students were able to place the messages that they perceived into a larger social context. This, in turn, allowed the students to do more than just glean information from an on-line source. One student commented, “It seems that there must be some level of awareness about the Native Americans for their culture to be so widely available on the Internet; however, this doesn’t seem to translate into tangible powers afforded to them in society.” The same student said, “A majority of the lesson plans that I located on the Internet were based on the “food and holidays” approach to multicultural education.” (In our course, the “food and holidays” approach to multicultural education is considered a superficial treatment of multicultural issues.) Another student said, “I found they [the Internet sites] were careful to include minority students in their photos. One picture included three white students, a white teacher, and an African American boy. Another featured an African American teacher working on a computer. As trivial as this mere inclusion may seem, it conveys some strong messages. Pictures like these tell the entire classroom that African American students are an integral part of the classroom.”

Students who critically analyzed the on-line information evidenced an emergent understanding of the social and political contexts in which information is both created and interpreted. The ability to identify the social and political contexts of information, particularly about diverse cultural groups, is crucial in the education of multicultural students. Teachers must recognize the impact of social and political factors in both the way that multicultural students are schooled and treated in the U.S.

Conclusion

On-line resources offer a great wealth of opportunity for students to learn about how diverse cultural groups are represented in the areas of the media, curriculum, and policy. However, great attention must be devoted to teaching students how to critically analyze on-line material if the Internet is to serve as a teaching tool for diversity.
Is Anybody Listening? Inherent but Typically Ignored Problems in Distance Learning

Abstract: Desktop Video Conferencing (DVC) is one of newest evolutions in delivering distance learning courses. This paper reports on findings of an ethnographic study conducted in spring 2000 at a mid-sized university that underscored the importance of formalized faculty feedback and formative evaluations in planning, implementing, and assessing distance learning programs. The study examined the experiences and perceptions of 163 participants—faculty, students, and support staff—in five DVC teacher education courses offered to undergraduate and graduate students at eight remote sites.

Introduction

During the last two decades, higher education initiatives for distance learning have been accelerating at a rapid pace. Years of research and practice have paved the way for expanding course offerings and, in some cases, degree programs to students at a distance. The dramatic growth can be attributed in part to the collegiate enterprise's ability and desire to modify and broaden its traditional mission to meet the needs of a changing clientele: older students with full-time roles as parents and providers, as adults, and as employees or employers. Colleges are also having to compete with commercial enterprises like Jones International University, which offers its courses entirely over the Internet and became in March 1999 the first such for-profit institution accredited by a regional body, the North Central Association of Colleges and Schools. The Council for Higher Education Accreditation (June 1999) reported an expected 180% increase nationally in distance education students by 2002 with more than two million students as compared to 710,000 in 1998. That figure was matched locally at the researchers' institution, where student enrollment in distance education increased 195% between fall 1998 and spring 2000.

Yet, despite Herculean efforts to implement distance learning courses and entire programs to meet burgeoning enrollments, two vital components to ensure long-term success largely have been ignored by traditional higher education institutions: formalized faculty feedback and ongoing, local, formative evaluations. The intent of this paper is not to enter the "No Significant Difference" debate over traditional classroom versus distance learning. Instead, the focus is to reassert a seemingly ignored obvious: Those who teach using technologies of the trade discover and identify the problems related to teaching students at a distance. They, and not technologists, are in a better position to observe and evaluate the process. A program's success or failure depends in large measure on their experiences while interacting with students, the content, and the technology.

Many distance education programs evolve hastily to meet an observed need or simply to compete with other institutions in a state or service area. What can result is an organizational structure designed to
disseminate information, enroll students, and proctor classes but not designed to provide an ongoing, comprehensive support system for faculty teaching at a distance. Worse yet, seldom are formalized systems in place for faculty to report and receive immediate, corrective action on problems that occur while teaching at a distance. At the semester’s end, valuable information for improving the next round of teaching is lost because no after-action reports are compiled, complete with lessons learned and solutions taken or recommended. Why? Is it that many higher education administrations consider distance learning important, but not a priority or simply that too many do not understand the complexity of teaching at a distance and the need for unique instructional design and specially trained faculty?

The Study

In this ethnographic study, designed to examine and describe incidental learning activities, the researchers employed grounded theory to study the experiences and perceptions of 163 participants—faculty, students, and support staff—in five desktop video conferencing courses offered spring 2000 by a mid-sized university in the rural South. Undergraduate and graduate students at eight rural sites were enrolled in teacher education courses delivered via a synchronous audio and video delivery service. Data were triangulated from field observations, interviews, surveys, participants’ journals, and course documents. Simple quantitative measures of participant satisfaction and content analysis of journals and course documents also were used.

Because the researcher is the primary instrument in qualitative research, it is highly personal in nature and dependent upon the skill, competence, and rigor of the researcher for its validity and data reliability (Patton, 1990; Wolcott, 1997). Bogdan and Biklen (1998) said that some characterize qualitative research as “a dialogue or interplay between researchers and their subjects” (p. 7). Bogdan and Biklen said that researchers must become critical thinkers about what they have observed, not mere recording machines (p. 161). As they stated, “The worth of a study is the degree to which it generates theory, description, or understanding” (p. 34). Patton (1990) found that the qualitative-naturalistic-formative approach is especially appropriate for developing, innovative, or changing programs where the focus is on exploring a variety of effects on participants.

Two types of evaluation are typical: formative and summative. According to Bogdan and Biklen (1998), formative evaluation is meant to “improve an ongoing program through continuous reporting of the evaluator’s findings” (p. 218). Information is shared quickly, informally, and congenially. Summative evaluations, the most common type, are more formal with feedback rarely given during the course of the research. Instead, final reports are issued to a program official. “These reports are used to make decisions concerning reorganization of the program and allocation of resources” (p. 218). Regardless of the evaluation purpose, feedback on the participants’ multiple realities they experienced in a particular setting is an essential methodological concern. With its focus on “participant perspectives,” qualitative research seeks to study “phenomena or occurrences as seen through the eyes of those experiencing them, rather than through the eyes of outside observers” (Tuckman, 1999, p. 397).

During the 16-week study, the researchers followed a grounded theory approach by spending considerable time collecting data during fieldwork and considerable time later analyzing collected data. More than 800 pages of typed field notes and data were compiled from which to render an accurate and plausible account through thick description of participants’ experiences. Data was obtained from observing 35 desktop video conferencing classes; conducting 81 interviews; organizing and studying 35 instructor and 208 student journal entries, 71 e-mail messages, and 2,520 “chat box” entries; and studying official documents related to implementing the desktop video conferencing program. Although the findings of this study can be generalized only within the settings for the particular courses observed, given the cross-section of students and four different education courses observed, administrators and faculty may be able to generalize the findings to other distance learning settings as well.

Findings

Despite a notable level of frustration expressed by faculty, student, and support staff participants with audio and video delays, insufficient technical training, and inadequate administrative support, the
majority were forgiving in their assessment of the technology and learning environment provided by
desktop video conferencing, acknowledging its newness and future potential. Many students cited the
convenience of not having to drive to campus and the opportunity to improve computer skills as the prime
motivations for current and future distance learning experiences. However, as one student said: “I believe
the glitches in the system will be worked out, but if I took another course like this and had the same
experience, it would be my last.”

Faculty noted the “hard work” associated with teaching at a distance, compounded by inadequate
training, no practice time on the system, technical support not readily available, and no curriculum design
support available to assist instructors in converting their classes to a new medium. For instructors
delivering real-time interactive courses, “the high potential for confusion, chaos or boredom” accentuates
the need for faculty to have a host of well-practiced skills (Kearsley, 1995, p.2). One of the teaching
faculty commented:

The teaching/learning situation is one where focus and concentration for extended periods is
required. Add to this the extra focus and intensity required for technology use alone, and the
result is fatigue, loss of attention and concentration. This extreme intensity is very underestimated
by most technology-oriented people because of their facility in the technology. They seldom deal
with a very demanding content-oriented course that also places high demands on learning new
technologies.

Additionally, the teaching faculty distinguished between technical training on the system and
professional development addressing the pedagogy of teaching at a distance. As one said, “Technologists
do not understand teaching and learning. They know one way to do things, and this does not always reflect
how teaching and learning take place.” One suggested that probably only 5% of the faculty should be
designated as distance education faculty. “They are like graduate faculty, and they are special. Not every
faculty person is suited to distance education. Poor people can damage the program,” the instructor said. In
faculty exit interviews, the need for faculty focus groups to share concerns, issues, and teaching strategies
and for set procedures for the administration to address faculty concerns was strongly voiced. None of
these occurred during the study nor had they since the desktop video conferencing program’s inception the
previous semester. Moreover, no formalized plans for faculty feedback were in place for future semesters.

As Conley (1993) noted, “problems are our friends” and “natural, expected phenomena. There
must be a willingness to confront and resolve problems, rather than to deny, ignore, or repress them” (p.
314). Ehrmann (1999), the director of the Flashlight Program, noted that immediate, local, formative
evaluations could help guide administrations in making sound decisions and assessing programs. Indeed,
the role of technology, evaluation of process, and support for distance education cannot be understated.
Without such local, ongoing evaluations, he noted, institutions cannot know whether good practices are on
the increase and problems are on their way to being solved. Chute, Thompson, and Hancock (1999) warned
against a one-size-fits-all approach to distance learning because each technology has different
characteristics, making it more or less appropriate for a given learning need. For this particular university,
the researchers found no documented evidence of plans or procedures for ongoing formative evaluations to
assess and improve the program.

Conclusions

If higher education administrators want a smooth transfer to “high tech” from “high touch” (the
traditional face-to-face instruction and its traditionally associated “bond” between teachers and students),
then distance learning must be more than installing the latest equipment and software and cursory faculty
training to meet growing student demands and needs. After all, people are by far the single most important
factor in bringing about any kind of change, including the adoption of a distance learning system (Chute et
al., 1999, p. 84). Effectively introducing distance learning into any organization requires understanding (1)
people’s current attitudes and behaviors, (2) desired changes, and (3) the process needed to encourage and
support such changes. To be effective, distance education must be viewed as a partnership or an enterprise
with many parts working toward a common goal (Schlosser & Anderson, 1994, p. 39), with faculty a key
component.

Distance learning is fundamentally an educational issue, not so much a technology issue. Educators
must guide and shape the process with support and direction from administrators. Those on the
"front line" need instructional design support and they need to learn from those faculty who preceded them.
The purpose of the paper was to enlighten educators who currently provide or plan to offer courses at a distance about probable inherent problems that will arise if institutions do not incorporate faculty feedback into ongoing formative evaluations of distance learning programs. Lateral discussions between faculty and program administrators, shared experiences, and documented "lessons learned" are vital to ensure the success of distance learning initiatives.

Abstract: Social Sciences-Education, SOSE 3306 Culture of the Urban School, is a prerequisite introductory course required of all students in the teacher preparation program at the Department of Urban Education (UE) at University of Houston Downtown (UHD). The course investigates urban culture as the dominant form of community life in contemporary schools. Students explore characteristics, unique properties, and problems of urban schools. The online course presents a unique opportunity for a more comprehensive investigation and understanding of urban culture and urban schools in training future teachers to facilitate the academic achievement of students from diverse racial, cultural, gender, and social-class groups. The purpose of the paper is to share the proposed instructional telecommunication (IT) format that would meet the same standards, prerequisites, and requirements of on-campus sections.

Purpose and Instructional Design

In the Spring 2000, the authors submitted a proposal “Online Course Development for SOSE 3306 Culture of the Urban School” to the CampusNet Instructional Design Collaborative (COW) of the University of Houston System. The proposal was granted and the funding allowed the authors to participate in a two-day workshop on general online course design issues using WebCT.

The primary goals of the online course are to sensitize students to the problems of urban schools, to develop greater self-awareness and increase problem-solving perspectives. The online design will allow students to experience urban complexities resulting from marital, ecological, economic, political, religious or socio-cultural factors. The online format engages students in individual, group, class projects, presentations, discussions or readings on relevant, current and emerging urban issues. Interacting with each other and schools in urban settings, the students will explore the impact of ethnicity and culture and effective teaching strategies in multicultural settings.

In Distance Education: A Systems View, Moore and Kearsley (1996) suggest that “because so many skills are needed to design a distance education course, one of the key characteristics of most successful distance education courses is that they are designed by course teams in which many specialists work together” (1996, p. 6). The Garcia-Chen team will heed this recommendation and plan the online course as a team. One author, who has extensive school-related experience and knowledge with multicultural education, will act as the subject matter expert (SME) and pilot user of the initial versions. This faculty member will contact the students taking the traditional version of SOSE 3306 the semester before officially offering online SOSE 3306. During this time, the instructor will gather comments and bring back feedback for course modification. Another author, who is teaching Educational Computing courses for the department, will provide technical support and polish the final product. Both faculty will collaborate on the...
design and development of the online course and benefit from each other’s experience. Once the online SOSE 3306 is developed, the authors will team-teach the course, provide a student orientation where they will meet face-to-face, or in real-time, with students at least once during the semester the course is offered.

The supporters of the constructive approach (Jonassen, Peck, Wilson, 1999) to teaching and learning argue:

...technology engages students in meaningful learning, where they are intentionally and actively processing information while pursuing authentic tasks together in order to construct personal and socially shared meaning for the phenomena they are exploring and manipulating. Using technologies to help them articulate and reflect on what they know is the glue that holds personally constructed knowledge together.

Instructional materials, including visual and/or audio materials, will be developed in redesigning the course for web design delivery. It is a University of Houston System decision to deliver web-based course through WebCT. WebCT is a web-based system that combines both one-way and two-way asynchronous and synchronous applications including e-mails, bulletin boards, chat rooms, web pages, calendars, and quizzes/surveys. These activities will be instrumental to students’ understanding of the course content. While choosing activities for the online course, the authors reviewed a number of researched designs to support learning communities, both within the classroom and beyond. Harris (1994, 1995) suggested a list of online activities that foster virtual learning communities:

1. Interpersonal exchange, which gives students an opportunity to interact with others from a distance. Examples include keypals, electronic appearances, impersonations, etc.
2. Information collection, which focuses on collaborative, distributed collection, analysis, organization, and presentation of ideas. Examples include information exchange, database collection, electronic publishing, etc.
3. Problem-solving projects, which focuses on individual or group problems. Examples include information searches, social action projects, etc.

The authors will incorporate activities that foster interpersonal exchange, information collection, and problem-solving projects to enhance interactions. It is the intent and hope of the authors that meaningful interaction can be achieved in all categories: learner-content, learner-learner, and learner instructor though careful planning of collaborative course activities.

Course Requirements and Course Units

The proposed course outline is organized into several instructional units. The first unit will be an Introduction to the Culture of the Urban School. The students will access the introductory forum on the course bulletin board and become acquainted with key concepts and definitions of Multicultural Education by investigating opposing views of multicultural education and visiting a variety of selected newsgroups and websites. Students are to approach assertions that are made from a skeptic’s point of view. They will critically examine the information and compare it to information found in the text used for the course, Banks, J. (2001) Cultural Diversity and Education: Foundations, Curriculum, and Teaching. They are to post to the course bulletin board an evaluation of two of the sites selected.

A second activity will involve students’ use of problem-solving skills and multiple perspectives to determine the reasonableness of goals for Multicultural Education (Banks, 2001). Students will submit a proposal for transforming total school environments from centers of stress and anxiety to centers of learning. Students will include an annotated reference list and use the mail function to interact with small groups regarding their proposals. The rationale, goals and need for an understanding of Multicultural Education will be explored. The implications of multicultural training on the human impact that educators have on students, parents, other educators, the community, the classroom, and the world will also be explored.

A second unit will be an Investigation of Culture and Human Development. The purpose of the unit is to help students develop greater self-awareness by viewing themselves and their own
group(s) from the perspective of other cultures and different mirrors (Takaki, 1993). The activities are intended to lead students to develop a more inclusive multicultural context by exploring the emerging demographic diversity in American culture: Black Voices, Hispanic Voices, Native American Voices, Asian American Voices, and White Ethnic Voices. Sites from the American Civil Liberties Union, The Equity Center, The Freedom Forum, The National Multicultural Institute, and the Smithsonian, as well as others, will be explored. Brief reports will be posted on the bulletin board for ready access to all.

*Attitudes and Values Clarification* is designed to reduce prejudice, discrimination and conflict so that future teachers are sensitive to problems and conflicts in urban schools. After an initial period of investigation of factual data collection related to racial, ethnic and cultural diversity, the students will investigate their own personal values, beliefs and attitudes. Students will be assigned a number of activities that will heighten their cultural awareness (Noel, J., 2000). The students will share information by identifying a number of positions that can be taken on an issues (e.g., affirmative action, busing to alleviate segregation, interracial dating). A personal perspective will also be attained by student responses to self-awareness surveys. One will be administered at the beginning of the semester and another one will be administered at the end of the semester so that students can ascertain whether their beliefs, values or attitudes have changed during the course of the semester. It is hoped that activities in values clarification will sensitize students to do reflective teaching and to become more aware of the problems of urban schools.

A fourth unit, *Implications for Effective Practice: Teaching and Learning* entails a team project in which students investigate and assess a selected urban school setting. On site visits and data collected from the Academic Excellence Indicator System (AEIS) reports (http://www.tea.state.tx.us/perfreport/aeis/) would be included in the project report. The students would explore a school district's website, and the Texas Education Agency (TEA) school rankings based on student performance. The AEIS reports provide a great deal of performance information about every public school and district in the state. These reports also provide extensive profile information about staff, finances, and programs. Students will determine, as much as possible, indicators of declining academic performance, increases in dropout rates, crime and conflict, or other factors that positively or negatively impact that selected school community. Group discussions through chatboards and online connections would facilitate the group project.

A final unit on *Teaching and Projects* would allow students through a process of inquiry, decision-making, and use of social action skills to suggest curriculum and teaching strategies for a transformative curriculum for empowerment (Banks, 2001) for the selected school setting. The students are required to fully integrate the human impact into this Web-based multi-culture course for teacher education. Additional resources available to the students to complete this final project would include: the reading text, chat board discussions, puzzles and suggestions made on a week-by-week calendar.

In addition to the units of study, the students will be required to complete the assignments and projects that fully integrate the human impact of the course content, discussions, and theoretical frameworks in a Web-based multicultural course for teacher education. A week-by-week calendar will inform the students of the integrated instruction using course texts, links to related sites and Internet activities.

**Technical Implementation of Online Resources**

The online course will be offered via computer modem, using e-mail, listservs, and the Internet. The course may also be supplemented by videotapes for "homeviewers."

**World Wide Web Hyperlinks**

The online version of SOSE 3306 Culture of Urban Schools will provide quality World Wide Web Hyperlinks including:

- web pages of research findings published by local researchers in the fields of sociology, anthropology, and education
- major community and historical web sites in the US
• major culture-related web sites hosted in foreign countries
• collections of culturally responsive lesson plan archives
• national cultural awareness events such as Women's Month, Black History Month etc. hosted on the White House homepage

World Wide Web hyperlinks are non-linear and thus flexible in terms of how they can be used. Students can pursue their interests by conducting research on the Internet. The content can be expanded and updated as the core fields change.

Internet Discussion

The electronic mail, chatroom, bulletin board, and listserv functions of the online model provide an environment in which both the diversity of groups and the uniqueness of individuals are recognized and celebrated. Under the instructors' moderation, students can discuss how appropriate instructional methods and resources help students compensate for differences. Students also have an opportunity to explore the implications of recent developments and issues in multicultural education on instruction by engaging in professional conversations with community leaders and experts in the field of multicultural diversity.

Chatrooms allow students to type messages in a virtual room and the message appears on other viewers' screens almost instantaneously. Chatrooms allows for open discussion and instant feedback, which makes it an ideal medium for effective interaction. However, faculty who used the chatroom feature of WebCT have had mixed responses. First of all, it requires an established time for meetings that means that schedule conflicts or equipment malfunction may cause a missed meeting. Another disadvantage is that the answers are instantaneous and may not involve in-depth thought. If the dialog is going on too fast, students can easily lose track and also lose their interest. The authors are taking this input into consideration during the design and development process.

Online Case Studies

The case study approach has been used extensively to conduct research on ethnographic issues and critical pedagogy. The quality and quantity of texts, calendars, timelines, pictures, photos, maps, manuscripts, and case study descriptions that can be scanned and posted onto the on-line version of SOSE 3306 will far surpass what can be done with textbooks, lectures, and hand-outs in the traditional approach.

Other Technologies

Other research also suggest new technologies such as Java/JavaScript, 'half-based software,' ActiveX/VBScript, and IRC to make Web pages interactive (Cafolla & Knee, 1999; Box, 1999). Yet, since it may involve more development time, and they may not be fully functional on the WebCT platform, the authors are not currently considering these options.

Summary

The proposed online version of SOSE 3306 Culture of Urban Schools is (1) non-linear and thus flexible in terms of how it can be used, (2) extensive, which means more information can be covered in a typical semester thus allowing instructors and students to select what they want to explore, and (3) expanded and automatically updated through hyperlinks to resources on the Internet that are regularly revised and updated. The authors believe that the course will create a content rich web-delivered course. However, Lai (1997) warns that the web should be more than "an electronic lecture-notes turner" or the self-paced Computer-Assisted Instruction (CAI) of the 70s. We hope that the design of the course can add the interactivity that teachers need in a learning situation.

Developing Intercultural Understanding Via the Internet:  
Canadian Student Teachers and English Students in China  
Study World Literature Together

Jim Greenlaw  
Education Department  
St. Francis Xavier University  
Canada  
jgreenla@stfx.ca

Abstract: In this project English students at a Chinese university and Secondary English Education student teachers at a Canadian University used e-mail to discuss with each other their interpretations of short stories from fifteen different countries. The purpose of this activity was to develop the participants' intercultural understanding and literary critical skills through collaborative responses to world literature. At the same time the Canadian student teachers gained valuable experience at tutoring ESL students. Through the application of postcolonial pedagogical theory, I attempt in this paper to explain what the students have learned from each other.

Introduction: Background to the Project

In 1985, I moved to China for a year to teach English to university students. It was an experience that permanently and profoundly changed the way I viewed my role as an educator and global citizen. Currently, I am an English Education professor in Canada. Some of my student teachers over the past few years have chosen to teach in Asia upon graduating with their Bachelor of Education degrees. When I am asked by aspiring English teachers what it is like to work in China, what are the best books to read and what preparations are necessary in order to cope with the living conditions and culture shock, I have not been able to provide satisfactory answers to these questions. I find conversations about teaching in China to be both exciting and frustrating: exciting because I know that teachers who are going to China will have fascinating experiences, but frustrating because I have not been able to explain to them the significance of my own encounters with Chinese students. Books devoted to preparing Canadians for work in Asia talk about the importance of cultural sensitivity and effective intercultural communication, but they rarely address the significance of how Canada's historic relations with Asian countries may impact upon our lives as teachers in contemporary Asia. Canadian teachers' Eurocentrism is just one aspect of our identities which may undergo a transition as we travel to teach in Asia. When we return home, our transformed identities can cause us to view our roles as educators in Canada with a different awareness. One way to begin to prepare English teachers to work in Asia, and to prepare them to be ESL teachers in Canada, is to introduce them to Asian students via the Internet. During the past decade I have involved Canadian high school students and student teachers in intercultural e-mail exchanges with students in Asia (Greenlaw, 1992, 1997). I have also had the pleasure of taking students on a service learning trip to China, so I realize that cultural exchanges via the Internet are certainly no substitute for actually living and working in countries such as Japan, Korea, and China. Nevertheless, e-mail communication is an important first step in preparing Canadian student teachers to communicate more effectively with Asian students. In the following pages I make use of the postcolonial notion of transnational literacy to describe the kinds of insights that Chinese students of English and Canadian student teachers have gained from each other by sharing their interpretations of short stories from around the world.

In May 1996 and June 2000, as a guest lecturer and researcher in Wuhan City on the Yangtse River in Eastern China, I worked closely with Professor Yuan Xuefen, at the English Department of the South Central University for Ethnic Communities (SCUEC). Most of the students at the SCUEC are members of China's ethnic minorities such as the Tibetans, Hui, Miao, and Tujia. There are approximately one hundred million minority people in China. As Professor Yuan and I considered how we might connect her students in Wuhan with my student teachers in Canada, we decided that a course in short stories from
around the world might prove the most effective way to encourage them to share their ideas with each other via e-mail communication about global issues. Thus we decided to provide the students with the opportunity to read together short stories from Trinidad, Japan, Botswana, Brazil, New Zealand, India, Canada, Australia, The USA, Mexico, Ghana, The Philippines, Russia, Singapore, and China. One purpose of this project was to develop the participants’ intercultural understanding and literary critical skills through their collaborative responses to the stories. Some of the topics which the students discussed included: Art and Artists, Family Relationships, The Critique of Class, Race Relations, Ethnic Identity, and Social and Cultural Criticism. Another purpose of the project was to provide the Chinese students with an opportunity to develop their writing skills as they composed written responses to world literature with the help of their Canadian partners. At the same time we hoped that the Canadian student teachers would gain useful experience at tutoring ESL students as they guided their Chinese partners through their reading and writing activities.

Transnational Literacy

One of China’s leading postcolonial theorists, Wang Ning (1997), believes that there are two views of the West which are held by the Chinese. To some people the West’s material civilization and culture are considered superior to Oriental culture, but to other Chinese people the West is perceived as the enemy. To these people, the West is in decline, its outward prosperity merely a false mask through which we can see its implied crisis; to them the twenty-first century will surely be the century of China or the Orient, and Oriental culture is superior to Western culture and is bound to dominate the world. In short, the West to these people is nothing but a hell and even an evil spirit. Obviously, the two attitudes show that if we could have dialogue with the West, this kind of dialogue is by no means equal: either Chinese culture dominates or is dominated. Will there be no other way out of these simple modes of thinking characterized by binary opposition? (p. 64)

If both Chinese and Canadian students are to overcome this tendency to see China’s relations with the West in the oppositional terms which Wang Ning has identified, then they need to develop a form of literacy that causes them to reflect quite deliberately upon the gradations of difference that exist between Canadian and Chinese perspectives on global issues. Transnational literacy, a term coined by postcolonial theorist Gayatri Spivak (1993), involves the ability both to move beyond simplistic, stereotypical misunderstandings of another person’s culture and to begin to view one’s own culture through the eyes of that person. Professor Yuan and I observed our students attempts to help each other interpret the short stories by relating the problems of the characters in various countries to similar situations in their own lives and countries. At the same time, my student teachers’ experiences as cultural border crossers caused me to consider how potential English teachers can come to know their students not simply as linguistic problems to be solved but as global citizens with complex needs and interests. This project helped them to rethink their own assumptions about global issues with the help of their Chinese friends.

We organized the students into groups of four so that a pair of Chinese students could work with a pair of Canadian students. According to Marion Crowhurst it is important to use cooperative groups when teaching ESL in heterogeneous and multicultural classrooms. “Classrooms should be organized to facilitate interaction and collaboration in the interests of language learning” (Crowhurst, 1994, p. 279). Thus the two Chinese students in each group shared their ideas with each other before they sent their weekly interpretations of stories to their partners in Canada, and the pair of Canadian students discussed with each other what they should say in reply to the Chinese students. Each week the Chinese students wrote a 300-word essay in response to a story. The stories were grouped according to themes, and the students focussed on each theme for two or three weeks. Professor Yuan and her colleagues in the English Department at SCUEC had warned me that the Chinese students were not interested in conducting detailed literary critical analyses, but that they preferred instead to carry on issues-based discussions. So the questions which my students developed to help initiate discussions were intended to identify themes and issues, and to help the Chinese students to relate the stories to their personal experiences and cultural identities.
The Magic Chalk

The story, "The Magic Chalk," by Japanese writer, Kobo Abe, is a surrealistic tale about an artist named Argon who discovers that the pictures he draws with his magic chalk literally come to life. For example, Argon draws his representation of the perfect woman and calls her Eve. When Eve steps out of the picture and begins to talk, however, it turns out that she is actually Miss Nipon, and that she has strong ideas of her own about her purpose in the world. This Eve has a realistic appreciation of her market value and has no intention of conforming to Argon's fantasies. While the Chinese students were all very perceptive in their interpretations of the relationship between Argon and his artistic creations, they were even more astute in their explanations of the artist's power to change the world. In the following paragraph, we can see how the Chinese students, Shumei and Huifang, have responded personally to a question which my students asked about what kind of world they would create if they possessed Argon's chalk.

If I had the power of Argon, I would design the world as the following. Firstly, there would be less population in the world, especially in China. Secondly, the world would be just like a carpet of green grass with no pollution and careless littering. In that case, the seas and oceans would be blue, the air would be fresh with fragrance. Lastly, I hope there would be more peace reports and no war abuses at all.

Their Canadian partners, Barb and Melanie, then replied that they particularly enjoyed these ideas of Shumei and Huifang about the world they would design if they had Argon’s power. Then they proceeded to point out that Canada, too, has problems such as pollution to confront.

Pollution is a big problem everywhere these days. Actually, there is a badly polluted area in our hometown of Sydney. Decades of steel making resulted in the pollution of a creek and pond area in which children once played. This area has come to be known as the "Tar Ponds," because the water has turned black, oily and thick.

The theme that the students were considering in this story was the role of art and artists in society, but the students soon moved beyond discussions about the utopian and dystopian imagery in Abe's story and into analyses of the role of artists in their own societies. Kobo Abe's story raises issues about the power of artistic representation. For instance, Huifang and Shumei felt very strongly that while artists and writers cannot directly improve the masses, they can still inspire people to change through various forms of artistic and literary representation.

Luxun, a famous writer in China, once studied medicine in Japan, because he thought he could make the nation stronger. But later he changed to start a literary career for the minds of the Chinese people were weak at that time. He came back to raise the fighting spirits of the whole nation in the anti-Japanese War.

The postcolonial teaching strategy which was employed in the above exchange involved decentering the classroom. Neither Canadian nor Chinese perspectives dominated the discussion. Instead, a genuine sharing of perspectives helped both sets of students to understand Abe's theme of the role the artist plays in improving society.

The Third Bank of the River

As the students read together the story, "The Third Bank of the River," by Brazil's Joao Guimaraes Rosa, they consider the theme of family relationships. This story is about a father who decides to leave his grown children and wife, and to spend the rest of his life floating in a canoe on the river. The Canadian student teachers, Neil and Wayne, were both committed to going to China with me for their final practice teaching experience, so they were particularly interested in using their communications with their Chinese partners to learn more about China's cultural context. One of the questions which they asked the Chinese students, therefore, was: "What does the symbol of the canoe mean to you? In what ways does it help you to understand the effect of Father's departure on each of his family members?" In their response, Alice and Helen in China asked a question of their own to Neil and Wayne:
Father was a serious man, and he wouldn’t show his affection easily. He just
buried it deep in his heart. His sailing, in our opinion, was to fulfill a promise or
to chase a dream. There we have a question, “Who is Noah?” It seems to us
that Noah and Father have something in common. Can you help us?

In the following answer to Alice and Helen which Neil and Wayne provided, notice how careful
they were to choose the right words to communicate what they thought their Chinese partners might want
to know about Noah. Notice, as well, that they continued to engage Alice and Helen in a dialogue in order
to learn more about Chinese culture.

Noah is one of the best known folk stories in our culture. A long time ago
people on the Earth were behaving badly and God was upset with them. He
ordered Noah to build an ark, a big boat. God flooded the earth with 40 days
and 40 nights of rain. Noah’s job was to take two of each animal on the boat to
keep each species alive. The flood was like a bath cleaning the filth from the
earth. Many cultures have similar stories. Are there any stories that are similar
to the tale of Noah in Chinese culture that you are aware of? We would be
interested to hear about them.

Another question which the Canadian students raised about the story concerned the problem of
homelessness. They explained that there are millions of people around the world who, like Father in this
story, end up living alone at the margins of society. In Brazil, for instance, where the story takes place,
millions of children live unprotected on the streets of the major cities. They pointed out that in Canada
people like Father are called homeless. It is against Canadian law to force these people to live indoors if
they do not wish to do so. So some homeless Canadians freeze to death each year on city streets in the
winter. Then the Canadian students asked, "What are some of the reasons why people become homeless?
Why do you think Father decided to leave his family in this way? What should countries such as Canada,
Brazil, and China do for homeless people such as Father?" In another group, a Chinese student proposed
the following answer.

The story happened in Brazil, but the same story takes place in every corner of
the world. The causes that make people homeless are various, such as a lack of
understanding, lack of affection, pessimism, natural disaster and wars. In China,
there is a small basic organization called the neighborhood committee whose
duty is to assist to solve the family problems. For example, if a couple is
quarreling severely, the committee members will act as a mediator to calm them
down. If the child drops out of school for poverty, the committee will appeal to
the communal residents to donate money for this child. The existence of this
organization remarkably reduces the chances of becoming homeless. I think this
is the measure that other countries should adopt.

Postcolonial theorists (Said, 1993) have argued that Western intellectuals tend to represent Asian
countries such as China in essentialist terms. So, if Europeans and North Americans are industrious and
honest, then Chinese people are considered to be the opposite, that is, lazy and deceitful. By comparing
homelessness in Brazil, with the situations in China and Canada, the Chinese and Canadian students were
able to learn more about their distant partners' societies. Such intercultural communication can help to
reduce the essentialist notions of China and Canada that these students may have held before engaging in
this sharing process. The insightful social criticisms by both the Chinese and Canadian students in the
above messages and in many other communications about the fifteen stories made it impossible for either
the Chinese or the Canadians to see their partners in one-dimensional, essentialist terms.

Dhowli

As the students read the story, “Dhowli,” by the South Asian writer, Mahasweta Devi, they
discussed the problems of class and gender discrimination in India. There are several references to castes
throughout this story. The young woman, Dhowli, is an untouchable, a member of a low caste, who must
struggle to survive after the Braham boy, Misrilal, fails to marry her when she becomes pregnant with his
child. At the beginning of the story old Parashnath questions Dhowli's intentions in wanting to marry
Misrilal: "What does she think? An untouchable, Dusad girl can make a Brahman give her home and
food?" To determine what the Chinese students thought about Dhowli's predicament the Canadian students asked them to describe the Brahman caste and compare it to Dhowli's untouchable caste. They also wanted to know: "Why do you think Dhowli's own people turn their backs on her?" and "In your opinion, how should society treat unwed mothers?" When Neil and Wayne posed these questions, Helen gave the following reply concerning the plight of unwed mothers in China:

Most of us almost hold the same opinion as Dhowli's people do. We think that if one is forced to, she is worthy of sympathy; if not, she is not. People will think that if the girl is unwilling, how can the boy have the opportunity. Thus, they always put the blame on the girl. However, the real victim is the girl. If this happens, it will be very difficult for her to face the people and the world. So we should not discard them but help them and encourage them to live a new life again. I remember that, several years ago, I watched a film that talked about unwed mothers. In the film, there was a man who set up a home for them and offered them jobs to kill the time. They lived together just like a big and warm family because they had similar experiences. Gradually, they learned from their life in the unwed mothers' family that they are useful and the society needs them and they need the society. They were encouraged to go on and finally stepped into the society again. Here, I don't mean we should imitate this. I just want to tell those who discriminate against them that they are also human and they also need attention and love as we do.

In this story, Dhowli suffers from multiple oppressions. She is discriminated against both because she is a woman and because she is a member of a lower caste. One of the goals of postcolonial pedagogy is to encourage students to critique for themselves the injustices which result from classism and sexism. Clearly, in the above excerpt from Helen's response, she demonstrates a strong awareness of the unjust treatment both of Dhowli and of unwed mothers in China.

The Loons

In this final story, "The Loons," by Canadian author, Margaret Laurence, the students had the opportunity to discuss the problems of marginalization and racial discrimination that are experienced by hybrid cultures (Bhabha, 1994) such as Canada's Metis people. "The Loons" focuses on the relationship between a Scottish-Canadian girl named Vanessa and her Metis classmate named Piquette. In this tragic tale, Vanessa is puzzled by the fact that Piquette does not enjoy associating with her when Vanessa's family takes Piquette with them to their summer cottage. Piquette suffers from tuberculosis, and Vanessa's father is the doctor who must help her to survive the disease. Vanessa's father takes Piquette with them for the summer so that he can help her to rest and heal. As she tries to coax Piquette to come with her to see the loons, Vanessa remarks: "My Dad says we should listen and try to remember how they sound because in a few years when more cottages are built at Diamond Lake and more people come in, the loons will go away." The Chinese students discussed the ways in which the Metis were suffering from the same plight as the loons. When the Canadian student teacher, Janean, who is herself a member of the Mi'kmaq aboriginal community in Nova Scotia, asked her partner, Xie Si, what she thought would have been different about the story if it had been narrated by Piquette, Xie Si had this to say about the treatment both of Piquette in particular and of minorities in general around the world:

If this story was written by Piquette, the tone must have been gloomy and full of fear. Piquette felt helpless and sad because of the discrimination and other various difficulties confronting her and she was filled with fear because she wasn't sure of her future or even reluctant to face it, which was doomed to be miserable and hopeless. Not only the Metis people in Canada but also the minority groups around the world are immersed in trouble. Their most serious problem is discrimination from society. The public view them as strange and inferior species. The society does not provide them with sufficient opportunities for the individual and collective development. Their beliefs and traditions are despised and laughed at. Their living conditions are deteriorating and they are badly educated which deprives them of all the chances of
promotion, even survival. They are isolated from the society and are not understood by people.

As this response illustrates, one final strategy of postcolonial pedagogy which proved to be significant during the students' intercultural communications, involved enabling students to perform a critique of racism. Because many of the students in the SCUEC are members of China's ethnic minorities, they possessed a strong appreciation for the plight of other ethnic minorities around the world. Given the opportunity to share their feelings about this issue with students such as Janean in Canada, they were able to express themselves powerfully. Their communications were not simply literary or linguistic exercises, but were opportunities to establish strong positions about their cultural identity.

Conclusion

It is difficult to capture in a few pages the richness of the communications which took place between the Chinese and Canadian students. From these limited examples, however, it should be clear that intercultural communication via the Internet can provide a powerful vehicle for ESL students to develop their abilities to express who they are, and for student teachers to learn more about the thoughts and feelings of English students from various cultural communities. Given the large percentage of ESL students in Canadian schools, and given the fact that many new Canadian teachers are choosing to spend their initial teaching years abroad, it seems prudent to provide student teachers with authentic learning experiences in which cultural differences and global issues can be explored.

Abstract: This paper is a report on the findings of a study conducted on a graduate level multiculturalism in education course. Data collected from a world wide web based anonymous comments submission technology were coded and analyzed simultaneously by three researchers. Findings indicate that approximately of the 97.1 percent of students enrolled in three consecutive semesters responding to a statement which sought their perceptions of current efforts toward multiculturalism in education, 56.5 percent of responses were found to be either clearly positive or positive, while 40.5 percent of responses could be considered negative or clearly negative. It is postulated that the provision of a consequence free communication facility has provided students with the opportunity to make authentic comments about sensitive multiculturally related topics.

Introduction and Review of Literature

Education students are increasingly realizing the importance of multiculturalism. In part, because the country's cultural dynamics are rapidly shifting. By the year 2035, the population is projected to be 358 million, with people of color making up about 41 percent. By mid-century the total is projected to be 394 million, with people of color about 48 percent of that total (Tomes, 1998). The resulting changes will affect the general population faster than they will the field of education. Still, there are always some changes apparent. For example, while there is disagreement over how significant an influence Black History Month has had on what students learn, most educators and experts agree it has affected school curricula (Kennedy, 1998).

In order to further test theories of exposure effects, much of the research into prejudices and ideologies have involved group decision support systems (GDSS). In essence GDSS provides a structured
process by which information/opinions are collected from the group, analyzed and fed back for final
discussion. A typical method of surveying individuals might place participants in a large room with around
40 seats. At each chair there is a microcomputer, which enables every participant to interact with the
information discussed simultaneously. After participants submit their ideas regarding the topic of
discussion, the computer sorts the ideas, and then the participants will then vote or comment on which ideas
they like or they dislike.

The anonymity of the GDSS system was thought to help shy or passive team members to voice
their opinions. It was also hoped that the anonymity would increase participants' honesty because it would
eliminate negative consequences. However, support for such benefits has proven weak. The use of the
anonymous methods of communicating biases does not assure increased honesty. When Postmer and Lea
(2000) studied the effect of anonymity, they found that in GDSSs, their meta-analytic found no advantage
to anonymous reporting. The only reliable effect of anonymity was to lead to more contributions,
especially more critical ones. Even when the role of anonymity is examined in the collection of surveys
regarding drug use, it appears that participants in the anonymous survey have none or only slightly higher
reporting rates than those taking confidential surveys (Bjarnason & Adalbarnardottir, 2000; O'Malley,
Johnston, Bachman, & Schulenberg, 2000).

It appears, as Postmes, Spears, and Martin (1999) argue, that computer-mediated groups, such as
GDSSs, while providing anonymity still involve social influence and social identity. In short, when people
are together, even when making comments that cannot be traced to themselves, they will champion ideas
common to their observed group. Stereotyping, ingroup favoritism and attachment to the group are not
eliminated by GDSSs.

The limitations of GDSSs have led authors such as Clark and Maynard (1998) to advance the use
of the Internet for sources of analyses. They believe that the Internet is underexploited for its capacity to aid
analysis, and advocate making survey data more easily available online to all potential users. Such tactics
would be especially useful when surveying sensitive information about which participants might feel
uncomfortable regarding their positions.

Method

Participants
The subjects for this study were drawn from three online graduate Multiculturalism in Education
courses taught during three consecutive semesters from the Fall, 1999 through Summer, 2000. A total of
105 students were enrolled in these three sections, of which 102 replied to the statement posed yielding a
response rate of 97.1%. Of students enrolled in Multiculturalism in Education from Fall 1999 to Summer
2000, 71.4 percent were female (average age 37 years), and 28.6 percent were male (average age 35 years).
1.9 percent of enrolled students reported their race as African American, 2.9 percent Asian American, 92.3
percent Euro-American ancestry, and 2.9 percent Hispanic American.

Data Collection
The online course presentation is organized into instructional units each of which takes as its topic
one identified culture in the educational setting (e.g. Students of Color, Gender, Sexual Orientation, etc.).
Each unit presents to the student relevant information collected from the World Wide Web, the text and the
professional literature and is organized into four web pages (Introduction, Professor's Comments,
Activities, and Wrap Up). Once each student has read the introduction and professor's comments pages,
and has visited the web sites linked to each unit, they then read and respond to the learning activities on the
activities page.

In addition to traditional assignments, students find an “Anonymous Comments Box” at the
bottom of each activities page. This box is a standard text submission box wherein students can type in
their answers to the question or questions posed in the unit. These questions have been designed to
stimulate student's thinking on the multicultural issues covered in the unit of instruction, and to extend their
reflections on the material outside their accepted “comfort zone” as concerns multiculturally related issues
in the educational environment.
Although this research only focused on the first question regarding students’ thoughts concerning the overall concept of multicultural education, the questions posed for all units and the themes of the questions corresponding instructional units are listed below in table one.

The use of the anonymous comment technology is very simple from the student perspective. All the student must do is to type their answer or answers into the text box, and click on the submit button below. The text that the student has written in the box is then sent to the server on which the online courseware is resident. The submitted text is forwarded to the instructor in the form of an email which contains only the number of the unit anonymous comment box from which the comment has been sent, and the students comment. The email message received by the instructor contains a dummy from, and reply to address. There is no information forwarded to the instructor that could identify the sender’s identity in any way.

The PHP script code that is used to submit the information from the web page form, and later send the text to email address of the instructor is included below, (see table 1).

<?
//prepare email variables
$mailTo="jizat@mail.wtamu.edu";
$mailSubject=$unit." $type;
$mailBody = "Comment: "$comment."n";
$mailHeaders= "From: student@mail.wtamu.edu";
// send the email
mail($mailTo, $mailSubject, $mailBody, $mailHeaders);
?>

<html><head><title>Response</title></head>
<body bgcolor="#ffffff">
<h2><center>Thank you, your information has been sent.</h2><br><a href="#" onclick="history.go(-1)"">Click here</a>&nbsp;to go back.
<br><br></center>
</body>
</html>

Table One: The PHP Script Used to Create the Anonymous Comment Box

During the first and all subsequent semesters in which the Multiculturalism in Education course was offered online to graduate students a general introductory meeting was held with the professor. The purpose of this meeting was to describe the mission and contents of the course. Along with the standard online course delivery technologies required for use by students (email, posting to the discussion forum, attaching documents to email, connecting to university dial up Internet access, accessing web pages etc.) Students were familiarized with the anonymous comment technology they would be using during the semester.

Due to the simplicity of use, the description of how to use the technology was brief, but time was taken to both explain to students the rationale for using the technology, and giving them assurances as to the true anonymity they could expect when submitting their answers in this manner.

Students routinely ask early each semester if copies of their anonymous comments can be sent back to them for inclusion in the portfolio of their work. These requests cannot, however, be honored as there is no way, once a comment has been submitted through the anonymous comment box, to ever identify from whom the comment was submitted.

Analysis of Data

The researchers in this study were particularly interested in the first anonymous response prompt concerning the overall idea of multicultural education and its impact of the treatment of various groups in
the classroom. The text of the first prompt was: "I am very interested in what you as an individual feel about one thing: the overall idea of multicultural education, and the changes it has made in the treatment of the many distinct cultures, races, socio-economic groups, learning abilities, sexual orientations, etc., in the classroom."

The researchers examined this question using a constant comparison method for data analysis which consists of simultaneous coding and analysis of data (Taylor & Bogdan, 1984). The data from the first question was analyzed initially by three researchers who examined the anonymous responses independently to identify themes. The three researchers met and developed five consistent themes and definitions that emerged from the responses. Three researchers then examined the anonymous responses from the three semesters independently and coded the comments using these themes and definitions. The researchers finally met to discuss the accumulated data, emerging themes, and reliability of the coding.

Findings

There were a total of 105 students enrolled in the online course, Multiculturalism in Education, over the three semesters from Fall, 1999 to Summer, 2000. Of this total, 102 anonymous responses were given to the first question regarding the impact of multicultural education in the classroom. This represents a 97.1% response rate. As students were aware that, due to the anonymity ensured by the technology used, there was no way for the instructor to know whether or not any individual student had in fact answered each comment prompt the high response rate is remarkable.

Themes and Definitions

Five themes were identified from the anonymous responses by the research team. These themes were discussed in detail and definitions were developed for each theme to aid in the coding of the data. These themes and definitions were as follows:

Applied Positive Statements. The comments reflect positive statements regarding multicultural education and demonstrate some clear experience or application of multicultural education.

Positive Statements. The comments reflect positive statements regarding multicultural education with no contrasting/negative/rebutting statements. While the comments do not reflect experience or application, they may make reference to using the benefits of multicultural education in the future.

Somewhat Negative Statements. The comments reflect some positive content concerning multicultural education, but also includes clear contrasting/negative/rebutting statements about the effect of multicultural education.

Clearly Negative Statements. The comments reflect clearly negative, blaming, or derogatory statements concerning multicultural education with no positive comments.

Neither Negative Nor Positive Statements. The comments reflect content that does not fit the criteria listed in the other definitions.

Interrater Reliability

Three researchers performed the coding of the 102 anonymous responses. Raw data representing the three raters' coding for the 34 responses during the Fall, 1999 semester showed complete agreement on 24 of the 34 ratings representing a 70.6% accuracy. In the Spring, 2000 semester, the coding of the three raters showed complete agreement on 32 of the 42 total ratings representing a 76.1% accuracy. Finally, raw data representing the coding for 26 responses during the Summer, 2000 semester showed complete agreement on 19 of the ratings representing a 73.1% accuracy. Interrater reliability for the total 102 cases was computed at .9019.
Applied Positive Statements

Approximately 17.4% of the anonymous responses were rated as Applied Positive. Statements in this category not only reflected positive content regarding multicultural education, but also suggested that the respondent had made some application of his or her multicultural knowledge or understanding. For example, one respondent said, "Multicultural education is very important because as our classrooms become increasingly diverse, we must rethink our current way of teaching. I have experienced the way that this knowledge has made a difference in my own experience in the education field." Another respondent explained, "Multicultural education has made a positive change. I speak from personal experience. After attending a multicultural workshop, myself and the two other teachers that I attended with, all changed the way we taught, disciplined, and praised."

Positive Statements

Almost 39.1% of the comments reflected Positive Statements regarding multicultural education. These statements were positive with no contrasting/negative/rebutting statements, but did not reflect experience or application. Respondents in this category concentrated on thoughts that education should recognize the importance of multicultural education. For instance, one respondent said, "I think that it is very important to have at least a basic understanding of the diversity of cultures that are present in the classroom. Multiculturalism can impact everything from success in the classroom to discipline, to how the student reacts to different situations." Others made positive statements as to how much multicultural education has already affected the classroom. "I feel that multicultural education has made a tremendous difference in education and has been beneficial to all students," one student responded.

Negative Statements

Nearly 31% of the anonymous responses were somewhat negative. Responses coded "Somewhat Negative" indicate that respondents viewed an awareness of multicultural education as important but felt that too much emphasis is being placed on making curricular changes based on multicultural awareness. Three out of every 10 students who responded made positive statements about multicultural education but presented contrasting, negative, or rebutting statements. One respondent stated, "sometimes in our efforts to address multicultural issues it creates another problem." Others made statements that included concerns with being overwhelmed by change, "it is difficult to address all issues without hindering learning in another area. Some people take advantage of multicultural education. It has taken away from the classroom by the teacher having to focus on individual needs when that time could be used to teach the whole class." The respondents indicated that an awareness of multicultural differences often negatively impacted both class-wide learning and treatment of students from different cultural groups. Many respondents felt that multicultural education had (a) been taken too far, (b) had created an environment where teachers spent more time being politically correct than meeting the needs of the whole, (c) created conflict and fear, (d) been used as an excuse to obtain advantages by minorities.

Clearly Negative Statements

Approximately 11% of the anonymous responses were found to be clearly negative. One out of every 10 students who responded made negative, blaming, or derogatory statements about the effect of multicultural education in the classroom. Examples of such statements include, "Multiculturalism has gone beyond reason. We go above and beyond to make everyone equal. Let's face it, no one is equal. It has lowered the education standards, and "It seems like minorities get all the breaks and help with their education. How can this be fair to the middle class white people?, and finally, "Minority rights have superceded the rights of the majority. It seems that the majority must make sure that the minority is not offended. When we worry more about who may be offended rather than the good of the whole, we are missing the boat."
Conclusions

It has been observed by the researchers that the most significant difference between teaching a multicultural course in the traditional classroom and in the online World Wide Web environment is communication in the form of class discussions. Due to the sensitive nature of many of the multiculturalism in education related issues being discussed rarely are more than ten to twenty percent of students willing to make their thoughts and feelings know in an open, face-to-face environment.

This reticence may have two main negative effects upon the learning environment. Students who do not feel free to comment in an open forum course will not be as integrated into the learning experience as they might be. Also, the lack of input on the part of the students will have a negative effect upon the instructor's ability to structure teaching to meet the perceived needs of the particular students in each class taught.

The anonymous comment technology provides a facility for meeting both the needs of students to communicate their thoughts and feelings on difficult issues in a safe communication space, and to allow for these comments to be used by the instructor in tailoring the courses evolution to the needs of the class members as perceived by the instructor through these comments.

leikny.ogrim@lu.hio.no

Abstract. This paper describes some Norwegian experiences from the Co-operation Network project in teacher education. Through the network, students in the study programme "ICT for Teachers", are offered a diversity of web based optional subjects from several university colleges. Different forms of collaboration are applied in the network, and Tony Bates' three categories of inter-organisational co-operation are used to discuss the alternative forms. An organisational and economic model of co-operation is presented and discussed according to diversity.

INTRODUCTION

In accordance with the National Curriculum in "ICT for Teachers", one fifth of the study programme is offered as optional subjects. In Norway, the university colleges are rather small, and the classes for in-service teacher education in ICT typically have 15-30 students. Naturally, optional subjects are thus too expensive for a single college. Instead, six university colleges co-operate on offering a pool of optional subjects to their joint group of students.

Through a web-based network, each participating college provides one or several subjects. Each college is then able to offer their own students a real choice between subjects. Most students are ordinary on-campus students, and all courses are delivered through the web. Each institution is responsible for the content and the quality of the course they offer. When attending a course through the Co-operation Network the student is guaranteed the right quality and level, and that the subject fits into the study programme.

The Co-operation Network provides the basis for open and flexible learning. The project includes co-operation on the development of technology-based distributed learning among public and private university colleges. Both teacher education and computer science departments from several colleges participate as partners, developing electives. In addition, the network has established and formally agreed of a model on running management regarding both administrative and maintenance issues.

The Co-operation Network has been running for a year and a half; six colleges provide 7 courses to approximately 80 students. Systematic evaluation data were collected on the first year of the experiment. The data have been collected through interviews with all participating teachers, evaluation forms from the students, and systematic logging of student activity and final marks, as well as minutes from meetings in the project group, analyses of ideas, solutions and practical experiences from the co-operation (Rekkedal & Johannesen 2000).

The Co-operation Network can be said to be the realisation of the vision of "Technology-based Distributed Learning", as described in (Bates 1995); ICT-based flexible learning both for on-campus and off-campus students. This form of learning – and teaching – is more and more organised independent of time and space. In order to realise flexibility in time and space, information technology is used for communication. The co-operating colleges enrol both ordinary on-campus students, following the fixed progression of a study, and off-campus students starting and ending their studies according to their individual schedule. More students are also in-service students, following the courses beside their paid work and family duties, and are somewhere between on- and off-campus students. Open and flexible studies are thus practical, wanted and necessary.

In the further presentation, we will emphasise how the Co-operation Network leads to diversity in content and thus better quality for the students.

ON CO-OPERATION
Universities try to maintain their own autonomy. Why should they co-operate? In the present
economic situation, the universities are not able on their own to fulfill the needs and wishes of their students. The
possibilities to gain better quality and fulfill the students' needs are especially mentioned by (Neil 1981) as
important motives for co-operation.

The Co-operation Network is an active working partnership both on academic and administrative
issues. One private and five public university colleges are co-operating on development and delivery of credit
courses, based on flexible solutions. In (Fig. 1), the large circles placed around the network centre, denote the
university colleges. The arrows between the colleges and the network centre denote, from an academic point of
view, that each college provides students and courses for the network, at the same time as their local students
attend courses delivered by other partners in the network. From the administrative perspective, the arrows denote
the information flow of students and courses. And from an economic point of view, the arrows can be said to
denote the stream of money between the network partners. The small circles, marked with S, denote typical in-
service students, attending separate courses through the same network. The acceptance of individual students in
addition to the college on-campus students contributes to the flexibility of the offer, and also to a larger diversity
of perspectives between the students on every course.

The Co-operation Network is built on practical co-operation between academics on the development
of courses and negotiations and testing of agreements. Also, the colleges co-operate on the development and
delivery of exams. All parties deliver and use the same kind of services through the Internet, however related to
their different fields of interest. The commitment of every institution is established through formal acceptance of
the co-operation model defined by the project group. This kind of co-operation, between private and public
university colleges, has never been fulfilled in Norway before.

In his recent book, Tony Bates presents three forms of co-operation between colleges (Bates 2000).
He denotes the forms as franchise, transfer of course and credit and joint course production. In the franchise
model, the course is owned by an institution. The owner institution develops the course and the exam, and may
deliver the course in (parts of) the market. The course may be delivered by one or more of the partners in
cooperation. This is the traditional distance education model. The distance education company buys courses
from authors, and then engages teachers. Maintenance and further development is the responsibility of the
distance education institution. This model is used only to a small extent in the Co-operation Network. The
project aims to test some more dynamic and flexible forms of co-operation.

Co-operation built on transfer of course and credit, puts mutual co-operation on development and
delivery of courses as the crucial point. Each partner "owns" courses and may sell and buy them mutually. This
model is the most frequently used in the Co-operation Network, and is stated as the default model in the network
contract. The advantage of this model is that the owner institution holds the responsibility of maintenance and
further development of the courses, and is committed to the entire lifecycle of the course. This commitment is
also regulated in the economic agreement – the owner institution gets paid from every student attending the
course. If the owner institution for some reason is not able to deliver the course, then some other institution in the network may perform the delivery. Still the owner institution is responsible for maintenance, and the student fee is divided between the two.

The last one, joint course production may be seen as the most challenging. The partners will develop and own courses together, and find ways of organising the co-operation of delivery. This form of co-operation is however not central in the project, and such agreements are established as bilateral agreements. The Co-operation Network includes elements of all three forms of co-operation, even if the main idea falls in the category of transfer of course and credit. When the developers deliver a course, they will feel a strong commitment to the course - the course will be a part of the ordinary educational infrastructure, and not an add-on. Teachers will catch the needs for change while teaching.

**INDIVIDUALLY COSTED SERVICES**

There is a need for a clear understanding of the connection between costs and benefits, regarding both development and delivery of teaching. The development and negotiation of an organisational and economic contract for the co-operation have been crucial in the project. The project has developed a value chain for the project.

![Figure 2 Value chain for a student in the Co-operation Network (Johannesen & Øgrim 2000)](image)

The basic idea is to divide the costs related to the education of each student into logical pieces. This is illustrated in the value chain shown in (Fig. 2). The model is inspired by Porter's well-known value chain (Porter 1985), and is the basis for the division of costs and benefits between the participants in the network. Standard costs are divided into teaching costs: development, delivery and exam (76%) and administrative costs: subscription, class administration, exam, and accreditation (24%).

![Figure 3 Economic settlement for 1999/2000](image)

The co-operation model and distance education model easily allow us to scale costs and benefits in relation to the actual student mass. This is expressed in the first year economic settlement, summarised in (Fig. 3). The course costs for the optional topics of the 18 students at Oslo University College (HiO) were only a fraction of the costs of corresponding on-campus courses. The result is more students at each subject, and more offers for the students, that is a broader market.

**DIVERSITY**

In this section, experiences from the Co-operation Network are presented. We will focus on how the co-operation model has led to diversity in topics offered and pedagogical solutions. To the students, the model...
means flexibility, access to lifelong learning and more courses. To the institutional partners, the model means cost effective offers, the possibility to fulfil local needs and the needs of special groups of students. Also, they give the basis for customized study programmes (see also Brindley & Paul 1993).

**DISTANCE EDUCATION AS A MEANS FOR DIVERSITY**

Distance education is a precondition for the whole project. Most students are enrolled as on-campus students in one of the participating university colleges. They make use of the local infrastructure and co-operate with their local fellow students, at the same time as they make use of the distance education facilities of the Co-operation Network. Even if the students generally express scepticism with respect to distance education they are satisfied when the result is more optional subjects. An evaluation of academic and pedagogical aspects of the project is documented in (Rekkedal & Johannesen 2000). Other similar studies may be found in (Rekkedal 1998, Rekkedal 1999, Keegan & Rekkedal 1999).

This form of teaching can also be said to describe modern technology based on-campus education: partly independent of time and space and with information technology as a means of communication – technology based distributed learning/e-learning. Using distance education technology as a part of a study programme at universities and colleges is also in line with official educational politics all over the Western World.

Not only do the students choose among different course content, but also among different forms of communication and different forms of technical and pedagogical solutions. In content, they choose among for instance programming, technical issues of local networks, data modelling, and gender issues in ICT. Regarding communication, all courses are web based, and apply asynchronous one-to-many and one-to-one communication (see Paulsen 1998, Fjuk 1998). Other forms of communication, including many-to-many synchronous and asynchronous communication are applied to various degrees. Some of the partners have chosen to purchase communication solutions. With respect to technical solutions, there are also differences. The network has agreed on not to standardize neither the technical solutions nor the web design. The reason for this is the idea of courses owned by their developers and that technical- and interface-design is included in the ownership.

Also with respect to pedagogical solutions there are differences. Two in principle different teaching models are used. The first one is a flexible model with an individual starting point and progression. The other one has a fixed starting point and group-based progression. There is a tendency that the students who normally study in free progression prefer that model, and those who are attending on-campus studies prefer the other. Group-based progression is often preferred because this model fits best with other courses in their total curriculum. Co-operation with and help from other students are also arguments in favour of group-based progression. The arguments in favour of free progression are mainly based on the need for individual freedom, adapting to working hours, and family duties.

Modern ideas of teaching and learning, including theme organisation, problem-based learning, seminars and project pedagogy are challenging for distance educators (see Fjuk 1998, Fjuk & Øgrim 1997a, Fjuk & Øgrim 1997b). So far, the Co-operation Network project has not dealt with these challenges collectively. Some of the partners, however, have experimented with co-operational pedagogical ideas. Here we will only indicate two examples. One course is based on seminar pedagogy, combined with problem based learning. In this course the communication technology, especially for synchronous communication, is crucial. Another course gives practical training in running a local network – taught via Internet and one week of practical laboratory work.

**QUALITY THROUGH DIVERSITY**

The potential customers for the Co-operation Network are teachers with a basic knowledge of ICT. This market is relatively small in Norway. By co-ordinating the offer of optional subjects, each course may achieve a critical mass of students and it is profitable to invest the necessary development resources (Moran & Mugridge 1993a). Without co-operation each college will in practice make the choice itself, and the result may be one single offer to the students. (Moran & Mugridge 1993b) describe related problems in their survey of international studies on co-operation in distance education.

Co-operation makes it possible to specialise because each college does not have to develop and deliver all subjects in the National Curriculum. This specialisation makes it possible for each college in the network to concentrate their professional resources on the optional subject they offer, and thus strengthen the academic competence in this field. In the economic model the Co-operation Network differentiates between development and delivery of courses with the following consequences: 1) Both the developing institution and the delivering institution benefit from students attending the course owing to the fact that student fees are divided between these services. 2) The developing institution has the continuous responsibility for course maintenance,
expressed by the parts of the student fee that are always related to the development- and maintenance-services.

3) Course delivery may easily be distributed within the network, because the model expresses delivery services as distinguished from the development. The economic model prepares easily for diversity even in co-operation arrangements between the partners.

**STUDENTS' EVALUATION: DO THE STUDENTS EXPERIENCE DIVERSITY?**

The students’ evaluation was collected through a web based questionnaire. The students are mostly positive and express that net based studies can give satisfactory learning results. Most of them can see themselves attending net based studies again, and will recommend such studies to others (Rekkedal & Johannesen 2000). The most important property of the Co-operation Network from the students’ point of view is the possibility of choosing among several courses. An other advantage is the possibility to study at a distance and the flexibility of this form of teaching, including gaining experience with information technology. Except from these qualities, their experiences differ. This is expected due to the network idea of diversity.

The students’ general experiences, both on the Co-operation Network’s web site (Samarbeidsnettverket 2000) and administrative issues, are mostly positive. Negative comments seem trifling. Some of the courses are still characterised by lack of interaction. The poor contact between the teacher and fellow students is mentioned as a disadvantage in distance education. These are obviously conditions that should be improved in the future. The lack of communication is also among the students’ proposals for improvement. Both the form (quality) and the amount (quantity) need to be enhanced. The teaching material can be made richer through the use of for instance sound and video. Some more participants in the network would also be desirable in order to offer more optional subjects.

**CONCLUSION**

The project has through negotiations around practical solutions, the work with the value chain and practical experience managed to establish agreements on economic and administrative relations. The agreements have so far been tested and evaluated for one year of study. They have been renewed, and extended to larger parts of the study programme. The principles from the Co-operation Network, as expressed in the formal agreements, are accepted as the organisational basis of two new projects at Oslo University College; The development of a Master Programme in ICT and learning, and the development of an open and flexible specialisation programme in the combined pre-service and in-service teacher education.

A close relation between the development, delivery and maintenance of the learning environment and course material, also on the Internet, is of importance. Commitment and organisational anchoring is the result from an economic point of view, development is thus not seen as a one time cost before course delivery, but as a running cost of continuous development and maintenance closely related to the delivery of the course. The student fees will in the first placed hopefully cover the investments of first time course development, and then continuously cover the costs of maintenance.

Many colleges and universities wish to deliver open and flexible courses, most of them by themselves. In this project we have experienced that co-operation on the development and delivery of courses is beneficial to all partners. The partners have gained economic advantages along with better and more offers to their students. The result is diversity through co-operation, diversity in course content, combined with structure of the study programme, diversity in communication methods, in technical solutions and in pedagogical approaches.

"WorldGate:" An Attempt to Close the Digital Divide

Richard J. Knecht
Department of Communication
The University of Toledo
United States
rknecht@utnet.utoledo.edu

Abstract: WorldGate offers the consumer a low-cost, simple-to-use means of connecting to the Internet, and sending and receiving email, without a PC or telephone line. All that WorldGate requires is a TV set, wireless keyboard, and a set-top box connected to a cable TV system.

This fall, fourth grade students from elementary schools in Connecticut, Illinois, Louisiana and Ohio will be among the first to participate in the WorldGate Internet School To Home (WISH TV) Program. WISH TV is a public service initiative provided by WorldGate, local cable operators and participating set-top manufacturers. The program provides participating elementary school children a full school year of free in-home Internet access.

The WISH TV Program ensures that children from all economic levels will have the opportunity to ride the technology tidal wave and not be left behind.

Through WISH TV, students and teachers will be able to integrate the Internet into the curriculum. The program expands existing school curriculum by linking students and parents directly to teachers. Students' Internet access to questionable Web sites will be restricted through current filtering technology. Home Internet access will enable them to do research on their homework, and gain access to school calendars, schedules and class information and extra curricular activities.

Introduction

Invariably, on a day-to-day basis, we hear of the importance or role that the Internet plays and how it has the potential to improve the quality of our lives in the workplace, in our personal setting, and finally, in a global capacity. Much of what the Internet had promised has already been accomplished and is taken for granted in disseminating information to the masses who can afford, have the capability and the knowledge to utilize this technology. However, there are a group of individuals who would be categorized as the "have-nots." It is these citizens who must be encouraged to advance and be given the opportunity to do this. One segment of the population deserving of help are the children who have been ignored. In order to close the gap, which is frequently referred to as the digital divide, "WorldGate" is pioneering a project in Fall, 2000. Its objective is to provide students on all economic levels the ability to gain access to the Internet - from school and from home - via cable TV.

The Study

Through WISHTV, "WorldGate" Internet School-To-Home will be working with local cable operators and school systems to provide a full school year of free - in-home and in-school - Internet access by providing a set-top converter to be placed on a standard television set to all of the students in a single grade. The program provides participating elementary school children a full school year of the free in-home Internet access. Home Internet access will enable them to do research on their homework, and gain access to school calendars, schedules and classroom information, and extra curricular activities. The program expands existing school curriculum by linking students and parents directly to teachers. Students' Internet access to questionable Websites will be restricted through
current filtering technology. For Fall, 2000, it is the fourth grade in certain elementary schools in Connecticut, Illinois, Louisiana, Missouri and Ohio. In this pilot project, students who participate will be evaluated by using standardized exams and compared to the control group who are not able to take advantage of the experiment. "WorldGate" has promised to assist school administrators in utilizing national standardized tests and other reputable measures to determine the effectiveness of the program. The plan is that in the program’s second year, the number of schools participating would be increased to over one hundred. Although this may seem ambitious, it does have its rewards for both the user and the industry as a whole. As already mentioned, students taking advantage of the system would improve their scores on standardized exams and the manufacturer of the hardware, who receives positive strokes from the campaign, will ultimately have an increase in sales of their product.

Through the combined efforts of Motorola Broadband and Communications and Scientific Atlanta, Inc., have pledged to provide free equipment. This includes the donation of keyboards and set-top boxes in specific markets, which include the eleven schools in the five states already mentioned. The cable operators participating in this launch include Charter Communications, Buckeye CableSystem and Massillon Cable TV. Each of them has promised to provide free connections to those students in the program.

Proposed Findings

The goals of this ambitious project include the following:

1) Provide students with a capability and their own email accounts. This technological service will permit students to collaborate on projects, receive homework assignments, chat with penpals, here and abroad, open lines of communication between parents and teachers, and allow for students to communicate with their teachers and fellow classmates.

2) An enhancement of the school curriculum will enable students to access the Internet in order to complete school assignments. Assignments may be sent home directly, even though they be absent from class, so that they may keep up with their schoolwork.

3) Students would be able to gain the opportunity to become involved interactively and explore new ways of learning directly from home. WISHTV actually extends the school day. It gives homework a whole new meaning.
Conclusion

Unfortunately, due to circumstances beyond the control of the participants, cable companies, WorldGate and the schools involved in the project hit a major obstacle, which meant postponing the launch until the week after Thanksgiving. This would mean it would begin at or about November 27, 2000. According to Theresa Durso, Senior Marketing Representative for WorldGate, the required testing of the system took more time than was expected. To say that WorldGate was apologetic for the delay would be an understatement. There is little consolation to those who were so actively involved in the project up to this point. However, what might be garnered from this is the knowledge that the industry and teaching professionals are dedicated to improving the learning curve on a grand scale. What can be salvaged from the remaining academic year is anyone’s guess. Perhaps what can be accomplished is the laying of groundwork, which can be continued next school year. The funds, which were dedicated to this, have not been spent and should be reserved for the future. Ms. Durso feels that the schools that were involved could seek additional funding from some philanthropic source. As educators, we can hope that the WISHTV project is able to make the dreams of those involved a reality.

The proposed presentation, to be given March 5-10, 2001, in Orlando, Florida, will monitor the progress of the project up to the time of the conference and include those results.
Technology and Social Change: 
Perceptions of Culturally Diverse University Students

Abstract: This paper is a report on the findings of a pilot study addressing the perceptions of culturally diverse university students and computer technology. A survey instrument was generated to assess differences in attitudes, background and usage of computer technology. Specifically, the study addressed three questions: How do female students and members of different ethnic groups view the importance of computer technology for themselves and for their families? What role do cultural traditions have in creating interest in using computer technology? How do female students and members of ethnic minority groups use computer technology? Results indicate the affects of gender bias in computer technology, and some differences between ethnic minority groups and European American students. Questions for further research on this topic are discussed.

Introduction

Technology has been viewed by society as a powerful tool for social change. As a result of the belief in the power of technology, computers are increasingly being used in educational settings. However, despite all the attention that computer technology is receiving, researchers and educational leaders are realizing that computer technology has done very little to change the lives of people who are female, an ethnic minority, or people who are poor. Thus, there is a growing gap between those who have access to computer technology and those who do not. Students who are female, ethnic minorities or members of low-income groups tend to have less access to computer technology. Members of these groups who do have access to computer technology tend to use it for less cognitively demanding tasks. Societal issues such as poverty, gender and ethnic discrimination have also played a part in determining who has access to computer technology. The gap between those who are able to participate in the technology revolution and those who are not is often referred to as the digital divide (Bracey, 2000).

A parallel concern to the question of computer technology access is the issue of who is setting the agenda for the use of computer technology in schools and whose voices are being heard in the discussions. Similar to the academic curriculum, in most institutions in the United States educational technology is controlled by the dominant, European American middle class perspective. This lack of engagement can result in disillusionment and disassociation with technology. If this trend continues, ethnic minorities, women or people who are poor may never be able to reap the benefits of computer technology since members of these groups may feel that computer technology may not be addressing their needs.

The purpose of this pilot study is to explore the issues surrounding computer technology and social change from the perspective of diverse learners in a university setting. In this paper, diverse learners refer to students who are either female, identify themselves a member of an ethnic minority group, or someone who grew up in an economically poor neighborhood. This paper will specifically explore the following questions:
Background

The digital divide is a matter of great importance to educators and policy makers. While computers are being used more frequently in the lives of most people, there is a growing concern that some members of society are not able to participate in the technology revolution. One concern is the lack of access to computer equipment, especially access to computers in the home (McAdoo, 2000). Another concern in discussions on the digital divide also centers on how the equipment is used in communities that have computers. Students in wealthy areas tend to use computers for higher order thinking skills while students in low socioeconomic neighborhoods tend to use computers for drill and practice. There is also a difference in the computer usage of male and female students. Further, the digital divide exists between people who are ethnic minorities and those who are not.

Female students are less likely to see the importance of computers in their lives than male students. Gender inequity in education is nothing new. Sadker and Sadker (1995) showed how schools perpetuate the underachievement of female students, especially in Mathematics and Science. Golnick and Chinn (1997) explain that the underachievement of females in school is a product of a system that perpetuates the belief that female students are not as academically capable as male students. Teachers expect less of their female students. It is therefore not surprising that female students are less interested in computer technology. Kelly (2000) states, “one of the first indicators of this gender disparity may be the Advanced Placement exam in computer science. Girls accounted for only 17 percent of the test takers on the A exam and 9 percent on the more difficult AB exam” (p. 155). Huber and Schofield (1998) studied the attitudes of male and female elementary school students in Costa Rica. Their study revealed that female students have a less positive attitude towards computers than the male students due to a number of factors: male biased software, the stress on competition in most computer classes, the stereotypical view of computer use as a male activity (even by female computer teachers), less teacher assistance for female students, and less computer use by female students outside of the classroom. As a result of these school experiences, women are less likely to seek a career in the computer industry and are not able to enjoy the same economic prosperity as their male counterparts.

Economics also plays a role in how computers are used in teaching and learning. Access to computers is a major factor that prohibits all students from learning through computers. The high cost of computers continues to prevent many schools from making computers available to students. Schools in affluent neighborhoods are also more likely to have a full-time technology coordinator, and teachers in less affluent districts have less access to technological professional development (McAdoo, 2000). Furthermore, students in poorer communities use computers for drill-and-practice types of activities while students in affluent communities use computers for inquiry-based lessons and collaborative learning (Kleiman, 2000). Thus, in poor communities, the computer leads the student. In more privileged communities the students control the computer for their own purposes. In order to bridge the digital divide, researchers and educators need to come up with ways to make computer usage meaningful for people who are poor.

There is belief that the digital divide will fade due to “market pressures, with decreasing hardware and connectivity costs inevitably leveling the digital playing field” (Carvin, 2000, p. 3). However, some researchers have been able to show that members of ethnic minority communities may not see computer technology as important to their lives even if they have the money to purchase computers. Holmes (1997) notes that many African Americans do not see the Internet as a relevant part of their lives. Hoffman and Novak (1999) show that the absence of relevant multicultural content on the Internet makes surfing the World Wide Web less interesting to ethnic minority communities.
Methodology

As university teachers, we are anecdotally aware that the concerns mentioned in the previous section are true for many of our students, at least in a general way. Because we were not completely sure of what specific research questions to ask, however, we conceived of this study as a pilot study whose purpose would be to help us understand how we need to formulate further research in this area. Our hope was that the tentative results of this study would lead to refining our research questions and methods for a future study.

This study was conducted during the Spring 2000 semester with students attending courses in our university. After an initial review of the literature, we formulated a survey instrument and pre-tested it on three students similar to our target population. One hundred sixty eight students participated in the survey, including 122 female (66.7%) and 50 male (29.8%). Since we wanted to understand the experience of diverse students, we selected university courses in which these students were more likely to enroll and asked professors in these courses to administer the survey and return it to us. Approximately 30 course sections were identified, in the areas of African American Studies, Chicano/a Studies, Asian American Studies, American Cultures and multicultural education courses. We received completed surveys from 12 course sections, a 40% return rate.

The student population included 53 graduate students (31.5%), 34 seniors (20.2%), 40 juniors (23.8%), 24 sophomores (14.3%) and 15 first year students (8.9%). The majority of students self identified as European American (n=68, 40.5%), and the rest self identified as Asian/Asian American (n=38, 22.6%), Latino/Hispanic/Chicano (n=24, 14.3%), African American/Black (n=12, 7.1%) and Pacific Islander/Hawaiian (n=8, 4.8%). We used the Survey Pro software package to create the survey, enter and verify data, and analyze the data using descriptive statistics and cross tabulations.

Findings and Discussion

The findings indicated that the vast majority of students (n=156, 92.9%) owned computers. However, 100% (n=15) of first year students reported owning a computer compared to 85.3% (n=29) of seniors. This could suggest that computer ownership is increasing among newer students. In other survey results there were more commonalities than differences among ethnic groups, with a few exceptions, and differences between gender groups.

In terms of ethnic groups, 41.7% (n=10) of Latinos and 58.3% (n=7) of African American respondents strongly agreed that using computers has improved their lives, compared with 38.2% (n=26) of European American, 34% (n=13) of Asian American and 12.5% (n=1) Pacific Islander/Hawaiian. Students of color respondents were more apt to describe their interest in computer technology as high or very high than European American students. While 48.5% (n=33) of European American students so described their computer interest, 66.7% (n=16) of Latinos, 65.8% (n=25) of Asian Americans, 58.4% (n=7) of African Americans, and 50% (n=4) of Pacific Islander/Hawaiians described their interest as high or very high. The results were reversed, however, when students were asked if their home and/or cultural traditions encouraged them to use computers on a regular basis. Twenty-five percent (n=17) of European Americans strongly agreed with this statement compared to 23.7% (n=9) Asian Americans, 16.7% (n=2) African Americans, 8.3% (n=2) Latinos and no Pacific Islander/Hawaiians.

It was somewhat surprising to us that ethnic minority students indicated higher interest than European American students concerning computers and whether using computers had improved their lives. We were not surprised that ethnic minority students reported less encouragement from their home and/or cultural traditions to use computers on a regular basis. Taken together, these data can be understood by the fact that the majority of students of color at Loyola Marymount University are first generation college students.
students. This could suggest they might have less experience of computer technology at home and are more interested in it as college students.

In terms of gender, the results of this study support literature that suggest women are less inclined toward technology than men. Close to half of the male students (44.0%, n=22) strongly agreed that using computers has improved their lives compared to 34.8% (n=39) of female student respondents. Male respondents were more than twice as likely than female respondents to describe their interest in computer technology as very high, 38% (n=19) compared to 15.2% (n=17). Likewise, male students were more than twice as likely as female students to strongly agree that their home and/or cultural traditions encourage them to use computers on a regular basis, 32% (n=16) compared to 14.3% (n=16).

The above findings support research (Huber & Schofield, 1998) that indicates differences in attitudes concerning computers between female and male students. It is not completely clear as to why these gender difference in technology are present, although the research of Sadker and Sadker (1995) would suggest that this phenomenon is an extension of the gender bias that already exists in schools.

Conclusion

As previously mentioned, this study was conceived as a pilot study. In reviewing the data, we conclude that our sample of university students is not representative of ethnic minority communities in general. Because we want to understand how these communities relate to technology, we need a broader sample that controls for level of education. Further, our data did not allow us to answer our question about socioeconomic status, because there was not enough socioeconomic variance in our sample.

In thinking about new questions that we want to ask in a future study, we are interested in finding out how respondents became interested in computer technology and at what point in their lives did they have access to it. We are also interested in examining the question of gender differences in more detail to understand the source of these differences.

A larger sample size will allow us to analyze variance in socioeconomic status concerning computer technology. We are interested in examining how poor people get access to computers and how they use them. Our overall goal is to understand how the digital divide can be bridged for the various groups that are left out of the technology agenda.

Abstract: Reading, Writing and Arithmetic: finding ways to make them stick! The focus of this research was to identify those conditions and teacher practices that have been proven effective in increasing the academic performance of African-American students and students in schools with substantial minority populations. The targeted population for this research was reading and math teachers from schools whose Texas Assessment of Academic Skills (TAAS) performance was reportedly Exemplary, Recognized or Acceptable. Research participants must have been teaching in classrooms with at least a 50% minority population. They also must have had at least 70% of their students passing the TAAS exam. Research results indicated that over 90% of the respondents Always exhibited the following strategies in their classrooms in Reading and Mathematics: Believing in their own self efficacy; Projecting a vision of excellence; Believing students can reach their potential; Encouraging students to ask questions; and Teaching students critical thinking strategies for solving math problems.

Introduction

Our nation is becoming ethnically and racially diverse. Several studies indicate that by the year 2005 about 30% of the U.S. population will be racial-ethnic minorities. Moreover, this percentage is projected to increase to 50% by the year 2050 (Reed, 1998). By the turn of the century only 15% of the new entrants into the workforce were native-born white males, compared to 47% in 1987 (Johnston, 1987). Even though the workforce will be more dependent than ever before on women and people of color, a disproportionate number of these individuals are not gaining the skills and knowledge needed to successfully function in the labor force (Johnston, 1987).

Currently about 30% of school-age children are minorities, and this number will increase to about 36% by the year 2005. It is predicted that Hispanic American school children will increase from 12.5% to 22.6%, African Americans from 14.7% to 17.7% and Asian Americans from 3% to 9% (Larger, 1995). Florida, Mississippi, New Mexico, California, and Texas already have more than 30% children of color (Allen, Hutchinson, and Johnson, 1995). According to various national and state assessments, minority students, specifically African American students, are in the last or lowest tier of academic achievement (Journal of Negro Education, 1993). Whereas there is no reported emotional, psychological or intellectual reason that fully explains the low academic performance of many minority students, this phenomenon has baffled educators. Signham (1998) states in the article The canary in the mine: the achievement gap between Black and White students, "The educational achievement gap is real and has serious social, economic, and political consequences; however, the situation is by no means hopeless, if we start looking at the problem in new ways and avoid simplistic one-shot solutions." Many minority students are poor, neglected, abused, under housed and/or undernourished. Further exploration
of this issue often finds schools that have large minority student populations characterized by discipline
problems, heightened security, high absenteeism, dropouts, and few intellectually challenging courses. Also,
pervasive in this environment is the attitude that the school's problems are a direct result of the students, their
families, and their neighborhoods. Educators must realize that the children themselves, their parents, and the
communities from which they come are not solely to blame. The blame for the low achievement of any group of
students in an academic institution does not rest solely upon any one entity. It is, however, the responsibility of
all (i.e. teachers administrators, community members, parents). Bloomington (1993) suggests that schools, in
order to be successful in our rapidly changing society, must cross barriers of language, values and culture. To
enhance the academic performance of minority students, we must investigate the conditions and instructional
practices that are occurring in our schools and classrooms. We must also analyze the climate of the school as
well as the attitudes of teachers. No longer can we point the finger of blame! We must accept responsibility
and work to meet the needs of our increasingly diverse student population.

Research Focus

The main focus of this research was to identify those conditions and teacher practices that have been proven
effective toward increasing the academic performance of African-American students and students in schools
with substantial minority population. Clearly, students from poor and/or challenging family situations can
perform as successfully as children from high-income families. According to Singham (1998), there is little
evidence for the belief that minority, more specifically African American, students are somehow genetically
inferior to whites and that the barriers impeding their academic achievement are insurmountable. Minority
students, again and again, have consistently beaten the odds and demonstrated successful performance in schools
across the nation. This research sought to identify the techniques and strategies that have proven effective in
increasing the math and reading achievement of African American students and students in schools with
substantial minority student populations.

Research Questions

The purpose of this research study was to contribute to the knowledge base information that would help in the
development of practices to facilitate the academic success of African-American and other minority populations
in the areas of Reading and Mathematics. In order to gain a deeper understanding of this issue the following
questions were addressed: 1) What characteristics (clear vision, teacher attitude, strong leadership, knowledge of
curriculum, etc.) do teacher view as important to student success? 2) What strategies do teacher who work
successfully with minority students (as measured by the Texas Assessment of Academic Skills (TAAS) test
scores) in the areas of Reading and Math employ in their classrooms? 3) Are there differences in the strategies
teachers believe are successful in working with minority and at-risk students and in those that teachers actually
use? 4) Are their certain building practices or conditions that contribute to the success of African-American or
minority students? If so what are they? To what extent do successful teachers use these strategies? 5) Which
strategies are most successful in helping African-American and minority students improve their performance in
Reading and Mathematics on the TAAS test? 6) What can be done to help teachers and schools better meet needs
of the minority and low income at risk population? 7) Are teachers using culturally specific pedagogy? If so,
what pedagogical strategies are best used and where have teachers received the training for these instructional
practices?

Review of the Literature

A review of literature has highlighted numerous factors, which have influenced the success of minority students
in schools. Daisy Reed believes that because there is a shortage of minority teachers, whereas Anglos make up
86% of the teaching population, there is a need to educate teachers on teaching minorities (Reed, 1998). Many
times teachers, of all races, have extremely different backgrounds, from the student population, and therefore
need assistance in understanding the pupils’ lifestyles. Some identified aspects that would be helpful in
educating minority children were: Have knowledge of the student’s background; Have first hand experience
working with minority youth; Understand the child’s community; Promote desirable learning; Have classroom organization for effective discipline and control; Allow children to see and develop a relationship of similarities with the teacher (Reed, 1998). Educating teachers to teach minorities may not change the student’s living conditions, but it can provide a better learning environment (Stephen, 1993). Claudia Steele, of Stanford University, says that the low performance of African-Americans on standardized tests, as compared to the Anglo population, is due to a stereotypical “threat”. This threat subconsciously demeans their test scores because of the historical fear that is instilled that African-Americans are inferior to Anglos, and especially exhibits this inferiority when their scores will be compared for achievement. The explanation for the low scores could be contributed to the fact that African Americans feel that they will not be the successor of the two groups (Steele, 1995). Researcher John Ogbu says that if the African-American community does not begin to see a reward for their effort given, then visible improvement on their academic performance will be minimized (1991). He suggests that the African-American community does not see a relationship between giving effort and receiving a reward, due to former denials and rebuke of employment and educational opportunities. History has shown that no matter the effort exhibited the rewards did not prevail among the community (Ogbu, 1991). Therefore, self-encouragement for academic achievement, for the youth of today, is minimal. Studies of the achievement related beliefs of African-Americans have focused on the premise that African-American children often do poorly because of their low expectations, lack of interest or giving up in the face of potential failure (Cose, 1998). Children’s beliefs about their achievement outcomes are determinants of their behavior and performance in school. Students who perform poorly often feel they do not possess the ability to do well in school and as a result often do not attribute their success to their own efforts. According to research results reported by Dweck (1975), gains in the achievement of African-American students were attributed to intervention procedures that were designed to raise the self-confidence of these students.

Writer Barbara Lerner says the key factors to gaining minority success in school are increased self-esteem of the student and having minimum standards set that enables the student to obtain a high school diploma. In addition, she mentions that the educator must make the student knowledgeable of the student’s failure. She says that the acknowledgement of failure is very beneficial to the child’s drive to success (Lerner, 1995).

In order to meet the minimum competencies for high school graduation, the candidate must pass the state’s objectives in Reading and Math. Teachers advise that the success of minority students can be granted, if the educator learns the culture of the students. She mentions how integrating literature, will inspire enjoyment for the class to discuss different books and stories (Diller, 1999). She mentions that selected literature must not only reflect the role of the educator, but the world of the student. Other key factors mentioned that can assist with educating minority youth are: To have dialogue with the students; To have dialogue with the children; To listen to the children; To have dialogue with the parents; To continue the dialogue (Diller, 1999).

Patty Shafer says that low scores in Math could be in part due to out of date curriculum and curriculum not being aligned with the state’s objectives. Therefore, she said in order to gain improvement, schools must: Teach the objectives to be mastered; Use manipulative; Teach problem solving skills; Spend more than 1.5 hours on teaching Math. Over the years several characteristics of “effective schools” have been identified. “Effective schools” are those schools that have been successful in producing high academic performance among minority and/or low-income students. The identified characteristics include: A productive school climate and culture; Focus on student acquisition of central learning skills; Appropriate monitoring of student progress; Practice-oriented staff development; Outstanding leadership; Effective instructional arrangements of low achievers; Active and engaged learning; Salient parental involvement; High operationalized expectations and requirements for students; Multicultural sensitivity (Levine & Lezotte, 1990).

The Center for the Development and Study of Effective Pedagogy for African-American learners (CPAL) took the Holmes Group characteristics of effective schools and ran a Delphi technique with the principals of ten schools, ranking the Holmes Group characteristics of effective schools as related to Holmes fifteen characteristics of effective schools. Their goal was to determine the most important characteristics as: Clear vision; Knowledge of curriculum; High mutually determined; Demonstrative professionalism; Performance expectations; Teacher attitude; Parent and community involvement; Administrator attitude; Change implementation; School climate and morale; Innovative programs and Technology strategies; Staff development and training. These items were prioritized by effective schools and identified as extremely important and extremely relevant items (CPAL, 1996).
Methodology

Population

The targeted population for this research was teachers from schools whose TAAS performance was reportedly Exemplary, Recognized or Acceptable. These teachers must have been teaching in classrooms with at least a 50% minority population. They also must have had at least 70% of their students passing the TAAS test. These teachers worked in a variety of school districts in the state of Texas.

Procedures

The initial phase of this project was devoted to a review of the literature to determine what strategies and practices have contributed to the increased academic performance of minority students in the areas of math and reading. The Holmes Partnership, research from Haberman, Lewis, Edmonds, Levine and the Charles A. Dana Center provided valuable insight and helped to identify some common characteristics important to student success. These characteristics (e.g. clear vision, teacher’s credentials, strong leadership, school climate, etc.) were used to construct the survey instrument. The survey instrument was drafted after much thought over wording and the type of question best suited for this instrument. The respondents were asked to indicate the extent to which factors influenced student success in the areas of reading and math by making choices in categories of Always, Some of the time and Never. Respondents were also asked to provide information about their age, ethnicity, educational background, years of experience, and to indicate the percentage of minority students in their classrooms. The initial instrument was tested for validity. Students enrolled in ADMN 5073 School Curriculum Leadership were administered the survey instrument as asked to make recommendations as to its readability and clarity. From the recommendations several revision were made resulting in an instrument that adequately addressed demographic information, teacher expectations, classroom strategies and practices.

TAAS performance was the primary determinant in identifying schools for this research. We requested a listing (i.e. name, location, enrollment, etc.) from the Texas Education Agency’s Customer Assistance and Training Department of all school districts within the State that have a 50% minority population and have made significant gains, 70% or above pass rate, on the TAAS. This request yielded 14 districts that fit the criteria of our study. Additional, we requested Academic Excellence Indicator System (AEIS) reports for the 14 districts previously identified. The AEIS reports allowed us to identify specific schools within the 14 districts to solicit research participants. The survey instrument was administered to teachers from a variety of school districts and schools. Over 150 useable instruments were returned.

Results

Respondents

The majority of the respondents were female (79.9%) between the ages of 26-55, most falling within the 36-45 year old range. 64.9% of these teachers were African American, 24.3% were White and the remainder were Hispanic or Asian. The respondents represented 33 schools in the state of Texas. The majority of these teachers had 1-5 years experience as teachers with 57.3% coming from elementary schools and 40.6% coming from Middle or High Schools. In order to determine the practices and strategies that contribute to the increased probability of academic success for African American and other identified minority students, a survey instrument was distributed to teachers asking them to respond to the research questions.

Question: To what extent are certain characteristics important to student success? Teachers were asked to evaluate the extent to which fifteen factors were important to student success by rating them as Always, Sometimes or Never important. Over 90% of the respondents felt that the following characteristics or strategies were Always important to student success: Teacher Attitude (97.9%); School Climate and Morale (93.6%); Clear Vision (90.8%); Strong Leadership (90.1%). Question: To what extent do you exhibit the following characteristics or strategies in your classroom in reading? Over 90% of the respondents stated that they Always exhibited the following strategies in their classrooms in Reading subjects: Believing students can reach their potential (94.3%); Encouraging students to ask questions (93.9%); Encouraging students to take initiative (93.3%); Projecting a vision of excellence (90.4%); Believing in your own efficacy (90.3%). Question: To what extent do you exhibit the following characteristics or strategies in your classroom in mathematics? Over 90% of the respondents stated that they Always exhibited the following strategies in their classrooms in Mathematics: Encouraging students to ask questions (96%); Believing in your own efficacy (94.7%); Projecting a vision of excellence (93.7%); Believing students can reach their potential (93.5%); Teaching students strategies
for solving math problems (93%); Teaching problem solving (92.6%). Respondents were also asked to list their responses to four (4) open-ended questions. The following are consistent responses to all questions form teachers who taught Reading, Math, both Reading and Math and other related subjects. These responses were not tailored to fit the researcher’s purpose and are in the words of the respondents. **Reading Question:** Do you find certain strategies more successful than other when working with minority students? Some of the responses included: Strategies that promote independent thinking; One on one teaching; Small groups; Classroom relaxation w/music and snacks; Speaking to Hispanic students w/Spanish phrases raises the level of trust; Relating trends/styles to lesson; Knowing the different “in” topics; Being able to relate to students; Real life material; Hands on manipulatives; Role playing; Scenarios; ESL strategies; Multisensory instruction; Reading aloud at home; More parental assistance/involvement. Please list any specific Reading/Math programs you have found to be successful in working with minority students. Some of the responses included: SRA Reading; Direct Instruction; Montessori Instruction; Hooked on Phonics; Oarton-Gililigham.

**Math Question:** Do you find certain strategies more successful than other when working with minority students? Some of the responses included: One on one help; Hands on activities; Parent involvement; Convincing them that they can do the work; Teaching each other; Team competitions; Individualizing instruction based on weaknesses; Drill and practice; Repetition; One on one; Serve as role model; Give frequent assessments. Please list any Math programs you have found to be successful in working with minority students. Some of the responses included: TAAS Classes; Host Math Program; Block Scheduling; Problem Solving Software; Basic Math videos; Hooked on Math; Mountain Math; SRA Math; Computer Assisted Instruction. Are you using and culturally specific pedagogical strategies? If so, please list these strategies? Where did you receive training? Some responses included: English as Second Language – School In-Services; Differentiating In Curriculum - Rice University; Gifted and Talented – School In-Services: “Bridging the Gap” Cultural Conversations through Literacy – Rice University.

**Implications and Recommendations**

The results of this survey suggest that the strategies that have the most significant influence on the performance of minority students are: Teacher Attitude; School Climate and Morale; Clear Vision; Strong Leadership; Student Expectations; Historical Achievement Related Beliefs; Cultural Awareness. The teachers stressed the importance of encouraging students to ask questions, believing in their own efficacy, projecting a vision of excellence and believing that students can reach their potential. Learning must be student centered and teachers must understand the needs of their students. Teachers indicated that students must be accountable for their own learning. Students must be taught strategies that will assist them in successful school performance and skill that facilitate academic achievement. Although the literature review strongly encourages Ahands-on® activities, having students monitor their own reading and performance behavior, and making them aware of their own unproductive reading and math problem solving styles, teachers to a large degree do not utilize these strategies in their classrooms. Experts also recommend having students read a large number of books, yet these teachers do not utilize this classroom strategy. In Math it has been strongly suggested that strategies such as memorizing, drill and practice should be de-emphasized, yet the teachers surveyed do not de-emphasize this approach.

This research identifies teaching practices used by 150 extraordinary teachers that have proven effective when teaching minority students. The results of this study suggest that effective teachers employ sound research based strategies that facilitates the academic success of minority populations.

Abstract: This application-oriented paper describes the use of technology in the early childhood environment to support the development of cultural competence. Four objectives are identified and specific examples are described to aid practitioners in developing media presentations that serve to reinforce multicultural theory through the integration of technology in a manner that is suitable for young children. All of this information is shared with an eye toward methods of developmentally appropriate practice and the incorporation of technology as deemed valuable in regard to the licensure, certification, and accreditation standards of early childhood professionals.

Introduction

Society is changing. In order to survive and thrive in a new, diverse nation, individuals must adapt. The children who will guide the future must be equipped with skills to navigate on uncharted waters. As stated in the National Association for the Education of Young Children's publication, The Children of 2010 (Washington & Andrews 1998), "In a nation where no single race or culture will ultimately be in the majority, the next generation will be called upon to work together - to move beyond the injustice, intolerance, resentment, and anger that has been such weighty baggage in United States history." (p. 14). Children can't achieve this hope alone. They need help cultivating the interpersonal skills that will allow them to accept and appreciate both the commonalties and the differences that exist all around them.

Drawing on the work of James A. Banks (1996) and Stacey York (1991) the following objectives are identified to support developmentally appropriate work with young children in the area of multiculturalism and diversity.

The children will:

- form an awareness of self and explore individuality in relation to their place in the larger group;
- gain knowledge of the traditions, rituals, and practices that combine to form an individual's cultural heritage;
- build a sense of identification with others through the recognition of commonalties and move toward an appreciation of differences; and
- recognize unfair characterizations and begin to understand their roles as agents of change.

Frequently commercial curriculum materials, play props, literature, games and activities are not the most appropriate when attempting to construct an environment for children that will support the growth of cultural competence. Commercially produced materials often contain stereotypical images of costumed children in various geographical regions; the use of the English language is almost exclusive; and alternative family styles, gender roles, ability levels and mixed-age relationships are not often seen. Fortunately, the developmentally appropriate use of technology in early childhood environments is now viable (Haugland 1999) and can aid early childhood professionals in the development of methods and materials that are made in the classroom with a focus on strengthening critical cultural connections for each child.

True multicultural education involves the integration of diversity concepts into every aspect of the curriculum (Banks 1996). Often educators fall into the "tourist" trap and treat multiculturalism as a thematic unit or a specific lesson that must be covered. A month spent studying Mexico, for example, is added to the early childhood curriculum. During the Mexico unit children dine on traditional Mexican foods, listen to Mexican music, wear sombreros and serapes, and learn about Cinco de Mayo celebrations. This practice is called the tourism approach and involves the children looking at groups of people or geographic areas as if they were touring a strange and exotic place. The tourist approach serves to highlight differences, which is not the purpose of multicultural education (Banks 1996). Unfortunately, the media permeating children's lives generally follows the tourism approach as well, often going so far as to exaggerate differences as a comedic device. When children see artwork of adult Mexican males napping against a cactus, watch Speedy Gonzalez cartoons, and see Mexican children photographed exclusively in traditional costume, a patronizing caricature of an individual from Mexico begins to form.

All children are harmed by this practice. Those from Mexico or of Mexican decent are clearly marginalized by these images, but other children also are impoverished. Children should not be exposed to material that trivializes others and does...
not deal with their real, day-to-day living. Children can easily develop a false base of security founded on perceived superiority over others. Unfortunately, they may begin to form pre-bias prejudices if they are not given the opportunity to learn alternative methods of thinking and behaving (Derman-Sparks & A.B.C Task Force 1989).

Instead of resorting to the tourist approach to multiculturalism, educators should highlight commonalities among people and integrate diversity issues into every aspect of daily activity with children. Since commercial materials may not be suitable, technology offers educators the opportunity to integrate multiculturalism in a appropriate manner by developing material specific to the needs of the program.

Objective One: The children will form an awareness of self and explore individuality in relation to their place in the larger group.

From a child's earliest sense of awareness until approximately the age of two the major developmental task in which they engage is identifying themselves as a person separate from others. Young children must gain a clear sense of who they are and where they fit into their family, the community, and their peer group before they can begin to understand others (Derman-Sparks & A.B.C. Task Force 1989). Teachers of very young children set up an environment that is rich in opportunities for the exploration of both the familiar and the unfamiliar. They are primarily in the role of a facilitator of knowledge (Gonzalez-Mena & Eyer 1993).

Activities that label and observe facial features, skin color, and hair color and texture are suitable first steps into the world of diversity. Taking photographs of each child, both individually and within a group helps them examine their own features, compare themselves to one another, and discuss the physical characteristics that make them who they are. Children are capable of all of these tasks. They are not oblivious to differences, but generally have not yet learned to place the value judgements on them that adults often do. An open, honest atmosphere in which to explore is crucial to multicultural education in the early years.

Digital cameras are immediate and therefore are extremely useful in documenting occurrences as they happen. When the need to wait on the developing of film is eliminated children can view high-quality photographs of activities immediately after they take part in them. This immediacy is especially important for young children who are visual learners and are often not yet able to think symbolically.

Group photographs posted in the facility can easily take the place of commercially prepared posters and displays and have the added benefit of allowing the children to build up an appropriate context in which to understand and accept individuality and differences. Commercially produced media generally feature caricatures of ethnic children dressed in native costume while digital or scanned photographs of each child represent the real world and provide fertile ground for the growth of cultural competence.

Photographs of daily activities or special visitors can also be displayed at the end of the day in order to give parents or others who transport a child from school or day care facilities a peek into the day’s events. Instead of the generic “What did you do today?”, parents can be encouraged to ask specific questions of their children, such as “I see that you talked about hair today. On the way home we are visiting Aunt Regina. What color is her hair? Is it the same color as mine? She is my sister.” Families can play a greater role in their child’s learning when they reinforce and build on multicultural ideas learned at school.

Teachers can expand the use of digital photographs in the classroom. Flashcards can be made by printing the photographs and laminating two cards, one with the child's eyes and the other with a view of the full face. The children use the cards to identify the eyes and faces of each child. This activity would be appropriate for use with children of toddler age. Digital or scanned photographs can be inserted into a Microsoft PowerPoint presentation or a Hyperstudio stack to allow for its continued use in many different capacities. The presentation can document a day in the facility and record each child's arrival, playtime, snacks or meals, and departure time. The presentation can then be used to replace commercial children's software, which may not be considered a viable representation of diversity for use in the early childhood classroom.

Objective Two: The children will gain knowledge of the traditions, rituals, and practices that combine to form an individual's cultural heritage.

It is crucial for early childhood professionals to help young children gain awareness of and appreciation for their own culture. By putting forth every effort to gain a familiarity with each child's family of origin, teachers or caregivers help children through this stage of multicultural education. Families are embedded in their native culture to varying degrees, assumptions about cultural and ethnic association cannot be made (Lane & Signer 1996). One way to find out about a child's family and its unique aspects is through the use of electronic family portfolios. An electronic family portfolio contains
Johnson 1993). When children see a visual representation of themselves involved in activities and hear sound files replicating others eat their rice plain. Rice can be served in small, shallow bowls or on wide, flat plates and can be eaten with forks, are both options. Some people mix their rice with fish, pork, or vegetables. Some people eat butter and sugar on their rice. different multicultural concepts. Many families eat rice, but they can get the rice for their meal in different ways. Some

Conferencing is also a technique that teachers and caregivers use to build relationships with families. Individual technological portfolios can be constructed for each child in order to facilitate positive connections with parents during conference visits. Photographs, artwork, and documentation of each child's development can be displayed on a computer screen. Sound files add an extra dimension to the portfolio and electronic voice recordings would allow the child to narrate sections of the presentation. Personal electronic portfolios can give a visual representation of a child that paper and pencil files cannot. A great deal more data can be incorporated into an electronic portfolio, allowing areas of interest or concern to be easily highlighted. Moreover, the portfolio can easily be updated, daily if necessary. An electronic portfolio can open dialogue in a unique manner in order to support and maintain the open and honest exchange that is an important aspect of a positive association between parents and caregivers or teachers (Newman 1998).

The community in which a child lives also plays a part in shaping individual cultural constructs. It is important that early childhood educators integrate activities that authenticate significant community connections and allow children access to people and events outside of the facility. Customized technological activities can bring the community into the classroom or care facility. Actual photographs of community helpers such as police officers, health care professionals, firefighters, grocers, and postal workers can be matched with photographs of the equipment or supplies that they use in their work. A "virtual field trip" can be conducted by the teacher that tours the community taking photographs of buildings, vehicles, and other points of interest. Presentations, games, and activities that utilize community resources help reinforce relationships already formed between children and their community as well as introduce them to new concepts. An early childhood professional that makes his or her own materials can do so with an eye toward the integration of specific multicultural concepts. Through the use of professionals of both genders, such as a female police officer, or a male nurse or including those of mixed age groups, races, and ability levels children's concepts of what is "normal" can be greatly expanded.

Objective Three: The children will build a sense of identification with others through the recognition of commonalities and move toward an appreciation of differences.

In order to gain an understanding of others, children must first identify with them in some manner. Activities that stress characteristics that groups of children have in common are the first step toward this objective. An activity involving transportation is an example of an activity that builds a sense of unity among children. Every child travels to school; they all might not arrive in the same way, but they all use some type of transportation. A discussion in regard to the various types of transportation used by the children on a daily basis can broaden to incorporate the idea that children in some parts of the world travel to school by bicycle, some travel by boat, some use a bus, and some walk. Photographs of each child arriving at school can be used to graph a chart of various types of transportation. The Internet or a technological encyclopedia can yield photographs of children around the world traveling through the use of various modes of transportation. In addition, presentations can easily be supplemented with high-quality children's literature. Ann Morris' book On the Go explores the diversity of transportation with photographs by Ken Heyman and simple text. As children begin to isolate events that are common to all and events that are unique to various cultures or geographic regions, they can develop a deeper understanding of multiculturalism.

Cooking activities are also appropriate to support this objective. Everyone eats, but people eat different types of food, prepare the food in different ways, and use different utensils. Preparing rice for a snack or meal can expose children to many different multicultural concepts. Many families eat rice, but they can get the rice for their meal in different ways. Some families go to the grocery store and buy a bag of rice. Some families grow rice, and still others purchase their rice already cooked. Rice can be prepared and served in many different ways; boiling rice in a pot over a flame or frying rice in a wide wok are both options. Some people mix their rice with fish, pork, or vegetables. Some people eat butter and sugar on their rice. Others eat their rice plain. Rice can be served in small, shallow bowls or on wide, flat plates and can be eaten with forks, spoons, chopsticks, or the fingers. Technology compiled during a rice activity can be used to construct either classroom or individual books, games can be made, and posters or collages can be put together. For example, photographs can be printed and laminated so that children can work on sequencing as they put each step of the process in chronological order.

These activities support the young child's development by making learning relevant to their daily lives (Roopnarine & Johnson 1993). When children see a visual representation of themselves involved in activities and hear sound files replicating information and artifacts that are of import to the child and his or her family members (Dodd & Lilly 1997). A digital camera or scanner and a presentation software package are used to put together this document for each child.

Family portfolios can empower children as decision-makers by enabling them to choose what will be included in their program. Furthermore, as children help select materials for their portfolios, family history and special traditions can be discussed that may never have been addressed with the children in the past. In addition, family members can visit the classroom or facility in order to construct portfolio materials. Family members can also help the child present their finished product to the rest of the group in order to facilitate diversity exploration among peers. Each of these practices aid in cementing the important bond between the child, their family, and the school or care environment.

the events, their ability to remember the occurrence is heightened. As an adult helps guide children through the experience of using the media, their sense of reliving the event can be richly enhanced. Each time children are exposed to a situation they integrate it more fully into existing paradigms and real learning takes place (Roopnarine & Johnson 1993).

Objective Four: The children will recognize unfair characterizations and begin to understand their roles as agents of change.

Young children are capable of empathy, which is the trait that is needed to explore how marginalized groups feel when they are treated with prejudice by majority groups. The Thanksgiving tradition in the United States is an area in which young children can consider unfair representatives of American Indians. Throughout the month of November, children in the United States are constantly exposed to caricatures of Indians involved in the first Thanksgiving dinner. Black-clad pilgrims and near-naked Indians gather together to eat turkey and corn with a complacent contented demeanor. These images are piled on top of other images of American Indians in children's media.

The Disney cartoon "Pocahontas" falsifies the life of a real American Indian woman for entertainment purposes. The stereotypical picture of an American Indian who communes with nature and can talk to the animals is also reinforced by the cartoon. Classic "Looney Tunes" and other media portray American Indians as savages who scalp and raid with a bow and arrow. In addition, many programs use the "red" man who speaks in monosyllables as a comic foil. When the cumulative effect of these negative images is considered, it is no wonder that children develop unrealistic paradigms in regard to Native Americans.

Technology can help a teacher gather cartoons of American Indians and allow children to compare and contrast those images with both historical and contemporary photographs of American Indians as they live, work, and raise families. A picture of a stereotypical Indian teepee will elicit immediate recognition in children who may not realize that American Indians may live in frame houses, in brick condominiums, and in city apartment buildings at this point in time. It is appropriate to counter the negative media images that permeate a child's life with positive, realistic, and contemporary images that depict American Indians both as they really were in the past and as they are now. Children can consider why it might hurt an American Indian's feelings to be portrayed in cartoons as a savage. They can even begin to make decisions about hanging Thanksgiving decorations on the wall that show American Indians in a negative light, and watching cartoons that are discriminatory in nature. To see children take control of an unfair situation and work to make positive changes is what multicultural education is all about.

Conclusion

Clearly the family is the child's first teacher, but the community in which the child lives and the media to which the child is exposed can be strong determinants of values and beliefs (Hildebrand, Phenice, Gray & Hines 2000). Children generally are not required to learn cultural competence in their homes since the skills are not needed in that environment (Clark, DeWolf & Clark 1992). The preschool classroom or child care setting is often the child's first exposure to diversity and, therefore, is a natural starting point for multicultural awareness (Swick, Bowle & Van Scoy 1994). Therefore, teachers or caregivers are given an excellent opportunity to integrate the various images that children are exposed to into a workable model of non-bias behaviors and beliefs. Using technology in a developmentally appropriate manner to facilitate cultural connections with children is a viable way in which to transform current curricula in order to fully integrate multicultural concepts and develop an understanding of diversity that can last a child a lifetime.

Where is the “Any Key”, Sir? Experiences of an African Teacher-To-Be

Guillaume Nel & Liezel Wilkinson

liezel@tofs.ac.za

Abstract: This presentation focuses on efforts to assist first-year students from developing communities in beginning computer classes at the Technikon Free State (TFS) in South Africa. The research is based on the experiences of Thabo, a student teacher from a rural area who was willing to live in the poorest conditions just to be able to attend a tertiary institution. The compulsory computer literacy classes posed a major problem because he had never touched a computer in his life. On his first day the class mocked him when he indicated that he could not find the “any key”! The pace was just too fast and he also did not have a computer of his own. He ultimately failed the course. After researching the nature of students’ problems, lecturers at the TFS drew up a seven-point action plan that might serve to alleviate the initial stress experienced by students like Thabo.

Thabo’s Story

Second-year student Thabo Mbokweni lives in a temporary structure (often called a “schaack”) in the Mandela squatters’ camp in the Bloemfontein-Mangaung area, a typical South African settlement with rows and rows of corrugated iron dwellings - the only shelter of many against the harshness of the elements.

Thabo came from a rural area to prepare himself to become a technical teacher. His family is poor, but he fared well at school and they decided that they were willing to sacrifice everything for a good education for their son. Thabo’s father is a municipal worker in a small village, while his mother is a domestic worker. They succeeded in saving enough for the fees. The problem, however, was that they could not afford hostel accommodation as well. Thabo then decided to share a shack with a cousin working in the city.

The two young men’s dwelling is surrounded by hundreds of shacks – not two similar in construction or size. The only water is available from the tap in the street, but they have an electricity supply where a prepaid card system is used. One electric light, a two-plate stove, a radio and a small television set make up their earthly wealth.

Thabo is an intelligent boy. He has always dreamt of being a teacher and creating a better life for himself and his parents. There was only one major problem – he had never in his life touched a computer and computer literacy is a compulsory subject for student teachers at his institution. His first day in class was a disaster. The whole class burst into laughter and mocked him when he told the lecturer that he could not find the “any key” – not the least the young man from an advantaged community where computer literacy is as commonplace as the traditional biltong and braaivleis.

The pace was just too fast for Thabo, resulting in the fact that he became completely lost somewhere between double click and pull-down menus. Furthermore, because he did not have a computer of his own, he could not get any other practice than during the formal class periods. He ultimately failed the course. He would have to repeat it during his second year. He was not happy, because the fees were high and he did not want to disappoint his family and place an extra burden on them.

Thabo is now in his second year. He is one of the brighter students in the computer literacy class and spends most of the practical classes helping those who cannot find their “any keys”. But was it necessary for Thabo to have gone through all the initial trauma? Could other teaching methods and approaches not have given him the opportunity to adapt to the unfamiliar situation more easily?
What Does Our Research Tell?

Accommodation and Transport

In surveys undertaken at the Technikon Free State, it was found that, in some of the classes, up to 40% of the students from rural areas live in less than appropriate conditions in the townships surrounding Bloemfontein. Although some students were not willing to discuss their accommodation problems in detail, it was estimated that 10% of these students live in temporary structures, similar to those of Thabo, as described above. Another 30% rent small, unfurnished rooms in the township. In most cases they share these rooms with at least one other person. Thus it can be understood why the surveys indicated that fewer than 40% of all the students from the developing communities have their own rooms for study purposes. Students also complained about noisy and unsafe conditions. A few remarks on problems experienced in this regard are the following:

- It was my first time in Bloemfontein and it was difficult for me to go through all the township sections to look for accommodation. Now I don't have money to come to school every day.
- I share a room with family members. Each room in the house is rented out. Some of the people are not students, creating an environment not suitable to study.
- I rent a room and share it with a friend. It's very noisy. I cannot study well, so I am forced to stay in the library until late in the evening.
- There is no table and no chair in my room. A friend I am staying with makes a lot of noise with his radio and TV.
- The place where I stay is not safe, and taxis only operate until 19:00 in this area.
- I do not have electricity in my room.

Daily transport poses another major problem to the students. Some live in the Botshabelo and Thaba Nchu areas (about 70 and 90 kilometers respectively from Bloemfontein) because they cannot find or afford accommodation in the city. Almost two hours a day is spent on buses and students complained about exhaustion and not enough time to study or attend extra computer classes ("I have to travel by bus from Thaba Nchu every day, which makes me very tired, so I cannot study when I arrive home"). Others who live in the Mangaung township or surrounding informal settlements said they simply could not afford the daily taxi fare of R6 ($0.75) for travelling to and from the Technikon ("I can't afford R6 a day, so I have to be a pedestrian"). A few students admitted that they walked to the TFS every day ("I travel on foot to school each morning and back, for one hour. Sometimes when it is raining I don't come to classes").

Financial Problems

It seems as if many students make use of loans in order to be able to study at the TFS. The natural and almost casual way in which many treat their financial problems is amazing. They suffer, but they succeed in "coping" and "managing", and that is the most important thing to them, because, in the end, they will have earned a better future for themselves:

- My parents have to borrow money to see to it that I pay for everything.
- I really don't know how I manage, but I do.
- If I do not have enough money for transport, I am forced not to eat lunch.
- I try to find temporary jobs over weekends.
- I'm coping. Try to find bursaries. Money for food is sometimes a problem.

Possession of Technology

A group of 150 first-year students in a Computer Literacy class in the Faculty of Management at the TFS (many of them teacher education students) was requested to indicate their access to technology at their dwelling places, including computers and related equipment. The findings are represented in Tab. 1. The most promising factor is that more than 93% have access to an electricity supply. Very high percentages also have access to radios and television sets - although it may not always belong to themselves. The possession or access to telephones lies at 55%. The alarming fact, however, is that only 7% of these students have a computer at their disposal after hours - not to mention Internet connections and E-mail. This means that they must be able
to fit in time to work in the computer laboratories during scheduled times (which is not always easy, because many of the labs are used throughout the day for lecturing and practical sessions).

Table 1: % availability of technology to a group of students at the Technikon Free State

The survey was extended to a group of 47 second-year Computer Science students. Very similar results as for the other group were obtained, except for a higher possession of computers (38%), printers (31%), E-mail (10%) and Internet (7%). This is, however, still far from the ideal situation for Computer Science students. The students were also requested to indicate possible solutions to their problem of access to computers. The overall indication was that students need more and longer access to the computer labs. Several asked for 24-hour accessibility and a card system by means of which computers can be operated. There were requests for more student assistants and also for the implementation of a Help Desk in the IT department.

Initial Problems in Computer Classes

The above-mentioned group of first-year students was also asked to indicate their initial problems in the compulsory Computer Literacy course. (The survey was conducted about two months after the classes had commenced). A fairly clear pattern of problems was revealed: Fear of the computer (“Everything was difficult and I was nervous because it was my first time”), uncertainty (“The first time I was just confused at what’s going on with this TV-like instrument”), keyboard problems (“First of all I didn’t know how to use a keyboard” and “I did not know how to operate and communicate with it”), using the mouse and clicking (“I tried but could not get the whole thing right”), SAVE, OPEN and CLOSE (“I didn’t know how to get back the information I had because it didn’t show up the next time”), and impatient assistants and lecturers who do not understand that students had never used a computer before (“Lecturers and assistants were not people-oriented. They started as if everyone in the room knew how to use a computer. The way they lecture us is difficult”); difficulties in following instructions in the practical books, etc. The following comments from students on their initial experiences may further reveal the nature and extent of some of these problems:

- Everything was difficult except pressing the computer, which is what everybody can do.
- I did no know how a turn on the computer and type it.
- Everything was new for me and I encountered a lot of problems, e.g. why do we use UNDO?
- Firstly, the assistant was horrible, unfriendly and acted as if we were supposed to know everything about computers.
- The time was not enough to do the practical work.
- I did not understand all the multiple-choice questions in the test.
- Assistants don’t show us what to do. They do it for us.
- We were kept in a pool of darkness with nobody to help us.

For every prospective computer user, the major obstacle is clearly to achieve a basic level of computer literacy. According to Pearn and Down (as cited by Garavan & Mc Cracken 1993 p. 8), a learner has to overcome the following in order to reach this basic level:

- Emotional resistance.
- The lack of availability of tools.
Limits on the time taken to become computer literate.
Lack of assistance.
Fear of interacting with a computer.
Fear of not being able to cope.
A desire to hang on to the familiar ways of doing things.

The comments of TFS students show a remarkable resemblance to the above list. Many of the students reported that, after some time, they started to cope and even enjoy the classes. After two months of lecturing, however, about 50% of the respondents were still uneasy about many aspects of the computer lessons. (Fortunately not many students felt as negative about computers as one of the respondents who wrote after two months: “I didn’t know a thing about computers and still I don’t know”.)

In a study undertaken by Callaghan and Smit (2000), also in the South African context, it was found that most students in their investigations took at least one month just to overcome the initial barriers on the road to computer literacy. The authors also mention that only a few of the students had balanced ideas of what they expect of the computer. In accordance with the views of these authors, we also argue that we cannot ignore these facts and should address them in our computer classes.

The following remark also serves to place the problems of TFS students in their South African social context: “When I went to the class of an African lecturer who explained in my mother tongue, I understood much better”. It must be understood that almost all the respondents were African students with English as their second language. Their lecturers were mostly Afrikaans-speaking persons teaching through the medium of either English or Afrikaans. (At the TFS a dual medium of instruction is used, Afrikaans and English, two of the eleven official languages in the country.) This fact may have contributed to students’ problems with the multiple-choice tests, for example.

Suggestions on the handling of Computer Literacy Classes

Students were asked to explain how they managed to cope with their problems, and also to make suggestions on ways of improving the teaching and learning in beginning computer classes. The following comments more or less summarize the overall trend in the responses:

- I kept on for asking assistance and going through the work all by myself.
- I just concentrated and worked harder.
- I started to ask questions where I didn’t understand.
- Getting help from my classmates.
- Tried to learn at my own and ask people who are familiar with the course.
- By attending extra classes.
- I just attended the open-lab times.
- Practice is the solution.
- I learnt to teach myself following instructions in the book.

In considering the above comments, clear signs of growth in students can be recognized. Students started to take responsibility for their own learning on the one hand and, on the other hand, they started to realize the value of seeking for assistance from peers and other knowledgeable individuals. These are important directives when deciding on a more effective approach to use in lecturing.

What about a co-operative learning method?

Some of the suggestions of the students in the previous paragraph show resemblances with co-operative learning methods as well as with self-instruction methods. A literature search gave indications that not many institutions over the world experience problems quite identical to those of our TFS students. It became obvious, however, that much research has gone into researching the effectiveness of specific teaching methods in Computer Science courses. The discussions on co-operative learning methods in particular proved to be very valuable. The notes of Henry Walker (1995) on collaborative learning in computer classes provide a number of very applicable guidelines:
All students MUST work in groups for the first two weeks of class; thereafter, individual work is allowed but groups still encouraged.
Groups of not more than two or three students are recommended.
Formal lectures rarely extend beyond 15 minutes per class.
Labs at the beginning must be very clear concerning what is to be done and turned in.
During group work the instructor circulates, regularly asking if there are questions.
The faculty member needs individual contact with every group every day.
When common problems arise, the class convenes as a whole to discuss the difficulties.
While labs are collaborative exercises, programs and tests are to be individual efforts.
Walker feels that by means of the above approach, active learning by students is promoted and a variety of learning styles can be accommodated. Furthermore, oral and written communication skills are developed, the reading of the text is required, and the responsibility for learning is explicitly placed with the students (p. 1).
A jigsaw technique may also be tried out in the computer classroom. Each student in a group of four or five students is assigned a specific task. The groups then break up and all those with identical assignments group together to work on their specific task. When accomplished, each person goes back to his/her original group with the responsibility to teach the other members what has been learnt in the single-task group (see Aronson 2000). Group members now have to work together as a team to reach a common goal and each member depends on all the others. The jigsaw process encourages listening, engagement and empathy by giving each one in the group a very essential part to play in the activity. (In the South African context, the language problem may also be addressed if group members are sharing the same mother tongue.)

A Seven-Point Plan for Thabo and His Friends

In considering our research and other views referred to in this discussion, we suggest the following seven-point plan to be implemented and further investigated in the Computer Literacy classes (and other beginning Computer Science classes) at the TFS in 2001:

1. Awareness: All IT lecturers must (again) be made aware of the nature and extent of the social, economical and cultural problems many students from developing communities are experiencing, problems that may have a profound influence on their performance in computer science courses as well as their personal well-being. They must also take notice of students’ specific problems in the beginning phase of a computer science course, in particular those who have never before worked on a computer. A survey by means of which the prior computer knowledge of students is determined, may prove to be very valuable. If possible, students without any prior computer experience should be grouped together. The careful compilation of student profiles may also help to better understand students and their personal circumstances (and, hopefully, their “any key” problems!). Students may also be encouraged to keep reflective journals in which their specific fears and frustrations can be pinned down.

2. Orientation: In the beginning enough time should be spent during a long enough orientation period to acquaint students with the basic elements of a computer keyboard and provide them with basic hands-on experience, in particular in using the mouse and doing the “double-clicking”. They should also be shown what the computer can and cannot do. Their fears and expectations need to be discussed in an informal way (see Callaghan & Smit 2000).
3. **Teaching methods:** The possibility of the use of alternative teaching methods such as co-operative learning in theoretical as well as practical classes should be thoroughly investigated and exploited.

4. **Language:** The possible language problems of students need to be acknowledged and addressed, also when referred to instructions in practical guides or manuals. The language used in test and examination questions needs to be considered very carefully. More attention needs to be given to computer terminology in general.

5. **Access:** The effect of the fact that a very large percentage of students do not have computers of their own should be considered in coherence with possible accommodation, transport and financial problems. Appropriate and sufficient open-lab times need to be discussed and negotiated with students.

6. **Assessment:** Assessment techniques need to be revisited; it should be of a continuous nature, with tests in line with what has been done in classes. A co-assessment technique where peer assessment as well as teacher assessment is used, may be considered (to fall in line with co-operative learning methods), as well as the possible introduction of portfolio assessment

7. **Feedback:** Lecturers (and lab assistants) must be willing to listen to their students and not be afraid to ask for feedback on lessons or specific teaching methods.

**Conclusion**

The researchers are of the opinion that the implementation of the above seven-point plan could bring about a marked difference in the ability of students to cope with problems in beginning computer classes. It is important that the effects of the implementation of such a plan would be carefully monitored and alternative plans developed where necessary. Ultimately, the institution as a whole could benefit from a successful implementation of a plan in which "any key" problems are to be foreseen and avoided.

The Digital Divide in Schools: We Can Make a Difference

Colleen Swain
University of Florida
United States
cswain@coe.ufl.edu

Abstract: Overcoming the issues surrounding the Digital Divide often appears to be insurmountable. However, in our recent examination of 28 research studies and reports we found the emphasis to frequently be on matters of access and not equity in the learning environment. The studies dealing primarily with access suggest the gap between socioeconomic groups is declining. Yet, access to computers does not provide equitable learning environments. Findings from the literature we examined indicated three primary areas that influence the digital divide in the school system. These areas are frequency of use, the computer experience of students, and technology training for teachers. The encouraging aspect of our review of the literature is that teacher educators can have a positive influence on these areas. We can make a difference in the digital divide in the school systems.

Introduction

The digital divide has been the subject of numerous documentaries, books, and articles (Bolt 1999; Bolt & Crawford, 2000; Harrell, 1998; Schon, Sanyal, & Mitchell, 1999) and continues to gain more attention through the plethora of materials documenting the technological access opportunities for students in U.S. public and private schools. Because the focus of the digital divide is so vast, statements coming from these materials range from "the digital divide is not as serious a problem as it first appeared" (United States Internet Council & ITTA, Inc., 2000, p. 20) to "One can't get around the statistics. There is a 'digital divide' in this country" (Rosenthal, 2000, p. 10). For this article we will define the digital divide as the difference in use of technology by schools based on ethnicity and socioeconomic status. Although strides are being made in giving poor and minority students more access to technology, the ways technology is used with these groups is often left unexplored. There are some exemplary studies (Attewell & Battle, 1999; Coley, Cradler, & Engel, 1998; Wenglinsky, 1998) investigating how digital divide issues and the use of technology influence the academic success of school-aged children, but overall there is scant literature available with strong methodology sections or data that can be generalized beyond the scope of the study. Nevertheless, the studies available do provide valuable insight into the use of computers and the digital divide. This article will examine the digital divide from the perspective of school technology integration for children in the United States using twenty-eight research studies and reports as a foundation.

Background Information

The Effectiveness of Technology on Student Achievement

No matter how one defines it, studying the impact of technology use on student achievement is just beginning. Examining student achievement data with respect to technology is a difficult task because research reports either define student achievement in a variety of ways, or do not define it at all. For example, in Mann, Skaeshaft, Becker, and Kottkamp's study (1999), scores on the Stanford 9 were used to measure the effectiveness of technology use on student achievement. In contrast, in a University of
Michigan study students were assessed using both a standardized test and a performance based biology test (Huebel-Drake, Mouradian, Stern, & Finkel, 1995). Dr. Martha Stone is quoted in The Impact of Education Technology on Student Achievement (Schacter, 1999) as saying “one of the enduring difficulties about technology and education is that a lot of people think about the technology first and the education later” (p. 10). It is critical that more studies focus on how educational technologies can enhance the learning process for students.

Higher-order thinking and critical thinking is one area where research of this type has already begun. Reports (Thurrow, 1999; U.S. Department of Commerce, 1999; U.S. Department of Labor, 1991) state that workers of tomorrow must be able to think critically and use higher order thinking skills and strategies in a variety of ways. The term “higher order thinking skills” refers to Bloom’s Taxonomy of Thinking Skills, which begins with the lowest level, knowledge, progresses to comprehension, application, analysis, and synthesis and concludes with the highest level, evaluation. In today’s classrooms, students are often assessed at the knowledge and comprehension level, because assessment is relatively easy to write and grade. However, many items at the lower levels of Bloom’s taxonomy (knowledge, comprehension, and application) do not develop and foster the critical thinking strategies in students. By forcing students to dissect and organize information in new ways (analysis), make new connections with existing knowledge (synthesis), and critique the usefulness of many types of information (evaluation), students can gain experience in critical thinking as well as develop a richer and fuller understanding of the content.

Several studies (Berson, 1996; Chessler, Rockman & Walker, 1998; Harel, 1990, 1991; Pogrow, 1996; Scardamalia & Bereiter, 1996; Wenglinsky, 1998) document that students demonstrate stronger higher order thinking skills and problem-solving techniques with computers as compared to students who did not use computers for higher order thinking skills and problem-solving. Findings from other studies suggest that the use of technology can enhance student achievement scores (Cognition and Technology Group at Vanderbilt University, 1994; Coley, Cradler, & Engel, 1998; Kulik, 1994; Mann, et al., 1999; Svin-Kachala, 1998; Wenglinsky, 1998). Studies such as these imply that student use of educational technologies, specifically computers, can enhance their learning environment. Nevertheless, there are many areas where researchers and educators can work together to improve the educational experience of students through the use of technology. Knowing how technology is used in the schools, in curricular programs, and with various groups of students is a critical component of this issue.

Technology Access in the School

Many states and school districts are making progress toward putting computers into public school classrooms. Computers and Classrooms: The Status of Technology in U.S. Schools, a policy information report by Coley, Cradler, & Engel (1998), states that 98% of all schools own a computer with the typical number of computers per school being between 25 and 50 (Coley, et al., 1998, p. 11). This has caused the average ratio of computers to students to drop from 19.2 students to one computer in 1992 to a current ratio of 5.7 students to one computer (Coley, et al. 1998) with Florida and Wyoming having the lowest student to computer ratio (5.9 to 1) and Louisiana having the highest (16 to 1). A 1999(b) report, Student Computer Use, from the U.S. Department of Education, expands on these findings showing that there have been dramatic increases in the frequency of computer use by students between 1984 and 1996. In the 4th grade, the percentage of students who stated they used a computer at school once a week rose from 15.5% in 1984 to 36.0% in 1996. It is important to note that schools with a high percentage of minority and Title I students have above average computer to student ratios (Coley et al., 1998, p. 13). Schools containing 90% or more minority students have an average ratio of 17.4 students to one computer, and as the percentage of Title I students increase, so does the ratio of students to computers (Coley, et al., 1998, p.13).

One must also take into consideration that even though most schools have computers, many of those computers are not connected to the Internet. As stated previously, 98% of all schools have computers, however, current statistics (Education Week on the Web, 1999; U.S. Department of Education, 1999a) show that only 89% of schools have Internet access making the average ratio of students to computers 13.6 to one. The disparities that exist in computer access continue regarding Internet access and are actually more pronounced. Schools that have less than 11% of their students receiving free or reduced lunch have a seven to one student to computer ratio (U.S. Department of Education 2000a, p. 2). This increases as the number of disadvantaged students increases peaking at 16 to one in schools where 71% or more of the students receive free or reduced lunch (U.S. Department of Education 2000a, p. 2).
percentage of minority students in a school has disparaging statistics as well, going from 57% of instructional rooms having Internet access in schools that have fewer than 6% minority population, to 37% in schools that have 50% or more minority students (U.S. Department of Education 1999a, p. 1).

These research findings regarding technology access at school provides researchers, educators, and other stakeholders with an abundance of statistics. Yet, these statistics prompt even more questions. For instance, are schools counting all computers in the school (broken ones in storage closets, the administrator’s offices, etc.) or are they counting equipment that students have easy access to during the typical school day (classrooms, libraries, and computer labs)? Nevertheless, these statistics provide all stakeholders in the educational system with a starting point. By making connections between technology penetration and the various uses of technology in schools one can begin to explore how this separation can influence students' success in school and in the future.

Making the Connections

Digital divide studies often measure access to the technology; yet, access alone does not ensure equity. Merely counting computers and the number of times a student can use a school computer will not eliminate the digital divide problem in the school systems. There are complex issues associated with the digital divide in the schools. In order to gain insight into these issues we conducted an analysis of twenty-eight studies and looked for areas that dovetailed when examining the use of educational technologies in the schools. We found three areas that appear to impact the digital divide in schools: frequency of use, the differences in students’ experiences with respect to computer use, and technology professional development for teachers.

Frequency of Use

Many times the idea is presented that if we equalize the time students can use computers at school this will diminish or completely eliminate the digital divide. If one views the digital divide simply as an issue of access this would be true. However, the frequency of computer use does not necessarily lead to academic gains. In Teacher Use of Computers and the Internet in Public Schools (U.S. Department of Education, 2000b) and Does it Compute? (Wenglinsky, 1996), the authors state that students in Title I programs and minority groups report more frequent use of computers than those not receiving special services. However, this frequency of use did not lead to gain in achievement because the computer was used primarily for low-level thinking activities like drill and practice. This does not mean that drill and practice computer experiences are never appropriate; however, using drill and practice as the only computer experience appears to negatively impact student achievement. Wenglinsky's significant research study presents the idea that it is the quality of technology use that can positively impact the achievement of all students—not the frequency of use.

Differing Computer Experiences

The opportunities students have regarding computer use varies widely. Teacher Use of Computers and the Internet in Public Schools (U.S. Department of Education, 2000b) is one such report that provides evidence for this idea. Students in high poverty schools (with 71 percent or more of students eligible for free or reduced-price school lunch) used computers for drill and practice 35% of the time as opposed to students in low poverty schools (with a free or reduced lunch population of less than 11 percent) who used computers for drill as practice 26% of the time (U.S. Department of Education 2000b, p. 2). This is in contrast to students in schools with the lowest number living in poverty who were more likely to assign students work involving computers applications, research using CD-ROMs, and research using the Internet than teachers in the highest poverty schools. Minority, poor, and urban students were more likely to use computers for lower-order thinking skills than their white, non-poor, and suburban counterparts.

Wenglinsky's (1998) Does it Compute? report provides striking statistics on how computers are being used for students in 4th and 8th grade. In the 4th grade, data was obtained measuring the percentage of students using computers primarily for learning games and activities that involved higher order thinking.
skills. Asian, Hispanic, and White students used learning games more than 55% of the time as opposed to Black students who used learning games 48% of the time (Wenglinsky, 1998, p. 13). Black students in the 4th grade used the computer primarily for drill and practice activities (Wenglinsky, 1998, p. 13).

The results for 8th graders are even more dramatic. Teachers reported that Asian students used simulations and other higher-order thinking applications for their primary computer use 43% of the time while only 14% of Black students used simulations and higher-order thinking applications as their primary use (Wenglinsky, 1998, p. 13). Whites and Hispanic students used the computer primarily for simulations and higher-order thinking applications 31% and 25% of the time. These findings suggest that students are receiving different learning experiences with computers and these differences can be categorized according to ethnic groups. The reasons for this disparity among computer experiences provided for students needs to be explored. One area that does influence the digital divide in schools is the training provided for educators to use technology in their classrooms.

Teacher Training

Data describing the importance of professional development involving technology for all teachers can be found in digital divide studies examining schools. One of the primary reasons given by several studies (Coley, et al., 1998; U.S. Department of Education, 2000b; Wenglinsky, 1998) of why teachers use technology differently with certain types of students was technology training. For example, Wenglinsky (1998) noted that for 4th and 8th graders in his study, students in urban and rural schools were less likely to have mathematics teachers who had been trained in technology over the past five years than suburban students. He went on to state, "Teacher's professional development in technology and the use of computers to teach higher-order thinking skills were both positively related to academic achievement in mathematics." (Wenglinsky, 1998, p. 4). These findings suggest it is critical for teachers to have ongoing and exemplary professional development with respect to technology use in the classroom. This involves not only learning how to use technology but also how to integrate it into the daily learning environment.

Therefore, in order for teachers to feel comfortable using technology in their classrooms, training must take place in such a way that makes them feel confident in their abilities. In a CEO Forum (2000) report on assessment of technology training, the authors stated, "To achieve sustained technology use, teachers need hands-on learning, time to experiment, easy access to equipment, and ready access to support personnel who can help them understand how to use technology well in their teaching practices" (p. 129). However, many schools do not have this type of technology training and support for their teachers. A 1992 survey of district coordinators found that on average, only 15% of the computer budget is spent on training (CEO Forum 2000, p. 136). This is supported by the study Technology Support: Its Depth, Breadth and Impact in America's Schools (Ronkvist, Dexter, & Anderson 2000) which reported that although 87% of schools have a technology coordinator only 19% of them are full-time (p. 6). The professional development of teachers impacts not only themselves but also their students' potential achievement.

Implications and Suggestions for Future Research

The data on the digital divide available to researchers, educators, and other stakeholders in the educational system strongly indicates students from certain minority groups and economic groups do have different experiences than their White, high-income counterparts. What is encouraging is that teachers and teacher educators can affect and change these experiences. Educators at various levels can improve the preparedness of teachers to effectively use educational technology in their daily teaching. District-level professional development and teacher education programs must get teachers comfortable with using technology and equip them with ideas and strategies to use technology in engaging and meaningful learning environments. Providing all students with challenging computing opportunities is critical. Allowing all students to obtain, organize, and evaluate information, conduct research and other higher-order thinking skills will assist in closing the digital divide in the schools.

There are numerous areas where researchers can document the status of the digital divide in the educational system and lead educators in the direction of improvement. Researchers can examine in detail how computers are used in the schools. This type of study can prompt teachers to closely examine their habits when using computers. It is also important that we examine whether certain academic curricular
programs (local, state, and federal) that use computers are enhancing or hindering student achievement. Curricular programs that appeared to be successful in the past may no longer be appropriate for today's students, and may be adversely affecting them. We need to shift from merely examining the number of computers in a classroom or lab to focusing on how the technology is being used to enhance the learning environment. This investigation needs to include the examination of data from various ethnic groups, academic levels, and learning styles.

In summary, there are significant digital divide issues that need to be overcome in the school system. Issues such as frequency of use, students' computer experiences, and professional development using technology for teachers are within the control of stakeholders in the educational system. Only with the assistance of researchers and stakeholders can teachers and administrators make a difference in striving to provide an equitable learning experience with computers for all students.

Abstract: This study documents the experiences of a school-university partnership initiated in January, 1998, between Lipscomb University and Glencliff High School, both of Nashville, TN. The partnership was established with a focus on the preservice training of university students and the professional development of inservice personnel, with a particular focus on technology. The partnership strove to follow guidelines for professional development schools (PDS) as established in research. Unique characteristics of this PDS developed as a result of the facts that Lipscomb is a small, private university with limited diversity and Glencliff is an inner-city school with tremendous diversity. Annual studies have been conducted using qualitative research methodologies. Although the research indicates success in several areas, the valuing of diversity and community has evolved as the outstanding hallmark of this partnership.

Introduction

The changing nature of schools today often leaves administrators and teachers struggling to adjust to dramatic changes that occur often over short periods of time. In 1988, I began to teach at Glencliff High School, a large urban, public school, located in Nashville, TN. Over a twelve year span to the year 2000, the school as well as the entire school district experienced remarkable change, particularly in two areas: diversity and technology. Although those two areas may appear to be mutually exclusive, the establishment of a Technology Professional Development School at Glencliff has shown that the availability of technology can do much to alleviate the growing pains that result from the remarkable changes in diversity. The purpose of this presentation will be to share the results of research conducted in the spring of 1999, as well as discuss on-going programs.

Concerning the Changes in Diversity & Technology

Today, the Nashville population of over 600,000 residents includes approximately 89,500 immigrants and refugees. These new residents have come to this country from over 100 countries and speak more than 75 different languages. The school age children of those families often know little English and, therefore, must be placed in English as a Second Language (ESL) classrooms. In 1988, Metro school system enrolled 739 ESL students. That number has grown to 4504 students at the beginning of the 2000-2001 school year. In 1995, Glencliff High School became one of two designated ESL high
schools in the city. At the time, Glencliff enrolled approximately only 50 ESL students. Today, however, 25% of the student population (approximately 400 students) live in homes where English is not the language of choice. One ESL counselor and eight full-time ESL teachers currently work at Glencliff. The curriculum for the ESL classes was developed to assist the students in acquiring sufficient language skills to be able enroll in the regular classrooms. Unfortunately, since the ESL students are generally separated from the rest of the student population, they often fail to feel a part of the normal school culture. Other students rarely associate with them, primarily because of the language barrier. The ESL students experience a sense of isolation.

In 1988, computers were just beginning to appear on the educational horizon. Very few of the Glencliff teachers showed much interest. Many teachers considered them merely a diversion from the classroom routine. Teachers who accepted computers often only used them to allow students to play computer games when they were finished with their work. Only a few teachers considered that those early computers could be valuable tools for both teachers and their learners. Through the efforts of the administration, Glencliff currently has four computer labs in addition to areas for computers in both the media center and the counseling area. School literature (September, 1999) reports a computer/student ratio of one to six. Despite those numbers, however, most of the faculty fails to use computers as an instructional tool in their classrooms. In fact, only 25% of the teachers have one or more computers in their classrooms. Many teachers now acknowledge the instructional value of computers, but they lack the training to effectively use them.

Role of Technology Professional Development School

In February 1998, Glencliff High School and Lipscomb University agreed to form a Technology Professional Development School (TPDS). Initially the primary purpose of this alliance was to enhance the training of preservice teachers and to facilitate the professional development of inservice teachers with a special focus on technology (Thornthwaite, 1999). Consistent with those goals, the professors at Lipscomb conducted free technology workshops for the Glencliff teachers and would follow-up with individual assistance as needed. The inservice personnel at Glencliff began to mentor the university students who enrolled in the university’s secondary methods course.

As part of this symbiotic relationship, the professors and teachers would collaborate on the best approach to address specific needs. One project grew out of the university’s concern that their students had limited experience in working with diverse cultures. This project requires that each student in the university’s secondary methods course collaborates with a group of ESL students from a single country. Each group is challenged to develop a multimedia presentation about the homeland of the ESL students. The university and high school students meet together on both the high school campus and the college campus to plan and create their presentations. Each semester, the collaborators show their finished product to an audience of high school students in the school auditorium.

Certainly, literature abounds with writings that document a myriad of programs designed to reform educational systems though the activities of Professional Development Schools (Abdal-Haqq, 1998; Clark, 1997; Darling-Hammond, 1994; Demsey, 1997; Hoffman, Reed & Rosenbluth, 1997; Levine & Trachtman, 1997; et al.).
Some PDS research addresses the importance of the empowerment of teachers (Duffy, 1994; Zeichner & Miller, 1997). Indeed, Book (1997) writes, “empowerment is part of the goal to be accomplished” (p. 198). Initial research concerning the accomplishments of the Glencliff-Lipscomb PDS showed that the collaboration was indeed providing a more realistic preservice training for the university students (Thornthwaite, 1999).

Additionally the PDS was beginning to provide empowerment for the inservice teachers. To the delight of both the university and the high school, a serendipitous benefit derived from the ESL project. Dr. Lydon, Glencliff’s ESL counselor, first recognized that the project was empowering the ESL students simply because they were being given an opportunity to share information about their homeland. This opportunity allowed them to be the expert and helped to break down their sense of isolation. Additionally, Dr. Lydon maintains that the project has increased the learning skills of her students through the aid of technology. The ESL students are thrilled by the availability of information about their homelands that can be found on the Internet.

With the approach of the third anniversary of the Glencliff-Lipscomb TPDS, plans are underway to continue on-going research. This research has made it apparent that the Glencliff-Lipscomb TPDS has helped both Glencliff and Lipscomb to adjust more smoothly to the dramatic changes in diversity and technology. As a result of this partnership, computers at the high school are being used on a more regular basis and the ESL students are finally breaking down their sense of isolation.

Abstract: This paper highlights the initiatives to develop farm schools in a predominantly rural area in South Africa. Of the 2500 schools in the Free State province, 63% are farm schools. The remoteness of these schools, as well as the absence of basic facilities is stumbling blocks in the delivery of sound education to communities. The lack of infrastructure is also responsible for attracting teachers with low qualifications, resulting in the offering of low quality education. The Gelukwaarts Farm School took the initiative to emerge from the typical farm school set-up by utilizing modern communication technology driven by solar power to get their computers connected to the World-Wide Web. New communication channels have opened, and teachers and learners are no longer confined to the radio and out-of-date newspapers. By utilizing lots of sunshine the school emerged from a half-forgotten farm school to a school with informed teachers, learners and parents.

Orientation

The Free State (FS) province, the third largest province in the Republic of South Africa (RSA), covers 129,480 square km or 10.6% of the land. Although it is relatively large, it accommodates only 2.6 million people or 6.5% of the total population (Statistics South Africa 1998). The economic activities in the Free State mainly center around agriculture with some mining in the north/north-western areas. A recent study (Statistics South Africa 2000) indicates that the Free State is the province with the highest proportion of households in the lowest expenditure category. Thirty-nine percent of all households spend R600 ($80) or less per month on goods and services. Almost a third (31%) of the population live in the rural areas in small villages and on farms where the infrastructure is not conducive to education. Nevertheless, the Free State has the largest number of farm schools in the RSA.

The existence of farm schools is a very unique characteristic of the African school system. It originated in the 1950s when Government promulgated the so-called Bantu Education Act. This led to the introduction of the category state-aided schools, which were created mainly to accommodate the children of farm workers. The establishment of such schools largely depended on the willingness of the farmer to make land available for the erection of a school building. Farmers had two options in erecting school buildings: they could either carry the entire cost or opt for a state subsidy covering 50% of the cost with the obligation to make the facilities available for nine years and eleven months for education purposes. The state in turn provided furniture, learner support materials and the salaries of educators. In 1993 the subsidy structure was revised by extending the subsidy amount to 100% of the cost and the period to 20 years. The regulations also allowed for the level of education to be extended to include standard Grade 12 classes. The Department of Education (DoE) also extended the curriculum to include agricultural, hotel keeping and catering subjects in some of the larger farm schools.

Several factors have had a negative impact on the efficiency of the farm school system. Among the problems faced by farm schools are the following:
The learners at farm schools are mostly the children of the farm laborers and farmers will often expect them to be available for additional labor, resulting in the disruption of the education process. Parents’ literacy levels are often low, which affect their participation in their children’s education. Lack of supervision in small schools leads to a lack of educator accountability. Educators often have to teach five to six grades per class. Many schools only offer tuition from Grade 1 - 6, all in one classroom. Transport problems lead to frequent absenteeism; some learners cover long distances to and from schools (15 km one way on foot in some extreme cases). A lack of hostel facilities in nearby towns and villages as well as the low income of parents prevent many learners from furthering their education after Grade 6. District officials often neglect farm schools in their planning and visits to schools. Change of farm ownership and worker evictions make farm schools vulnerable. Furthermore, the number of learners in farm schools is still declining due to the migration of farm workers to urban areas. Drought, the strive towards owning land of their own, as well as the attractions of urban life are the main driving forces behind migration. Since 1995 the farm school population in the Free State declined from 105 000 to a mere 60 000 in 2000 (FS DoE 2000). In this process more than 400 farm schools had to be closed. Similar tendencies occur in other provinces. For example, in the Eastern Cape province the existence of 700 farm schools are threatened, as the DoE cannot make an additional R14 million ($1,87 M) available to meet its contractual obligations to these schools dating back to 1997 (Teacher 2000a).

The Conditions at Free State Farm Schools

Infrastructure

In Tab. 1 the infrastructural shortages at farm schools in the province are indicated (FS DoE 2000). It is obvious that the infrastructure and support structures are not conducive to quality education.

Table 1: Infrastructural shortages at farm schools in the Free State, 2000

Few schools have access to printed media other than textbooks. The educational TV programmes broadcast by the South African Broadcasting Company (SABC) are not accessible due to lack of electricity and equipment. Some schools utilize the School Radio Service. Periodicals and newspapers are not available in most cases, not even a classroom collection of books. Some farm owners pass on old copies to schools. An investigation by Khulisa Management Services (1998 p.17) revealed a low literacy assessment which is partially ascribed to insufficient learning materials.

Educators

Unfortunately the remoteness of the schools and the lack of infrastructure (including dwellings for teachers) only attracted teachers with low qualifications to farm schools. Even in 2000 a significant number of educators are still regarded as underqualified. As these teachers are deployed at farm schools it implies that their learners cannot reap the full benefit of education. A total of 6142 educators (24.4%) out of 25128 in the Free State fall in this category (FS DoE 2000). Most of these teachers are attached to farm schools. The recent
report on Education for All (EFA) for South Africa (DoE 1999) highlights several discrepancies in the education system. It states, among others, that capacity-building of educators and low morale amongst educators and principals need to be addressed. The report specifically stresses the point that excellence in teaching and learning cannot be realized where educators and school managers suffer from low morale and have negative attitudes toward the profession (p.42).

Initiatives to Improve the Quality of Farm School Education

Status of Farm schools

The national DoE has taken the initiative to negotiate with farmers to sign agreements with the provincial departments in order to change the status of farms schools to that of public schools on private property. This would enable the various departments of education to fund education in these schools on the same basis as for ordinary public schools. The agreement also protects the rights of farm owners. The owner must approve matters like school hours, access routes, developments on the school site as well visitors to the school. The National Minister, Professor Kader Asmal, called on all role-players to ensure the speedy signing of agreements as “agreements are entered into for the sake of our children, who deserve the best” (DoE 2000a p.1).

A national conference on farm schools was held on 13 May 2000 at Midrand near Johannesburg to address the needs pertaining to farm school education. In his opening address Prof. Asmal called upon all stakeholders to put aside political considerations and rather put heads together to identify blockages and to seek ways to remedy the blockages (DoE 2000b).

Several provincial departments organized workshops to interact with stakeholders in an attempt to get agreements signed and to pave the way for quality education in farm schools. In the Northern Province special attention is paid to improve learning and teaching in multi-grade farm schools. The Member of the Executive Committee (MEC) for Education, Edgar Mushwana, expressed his appreciation towards farmers who are donating land for the education of rural children (African Eye News Service 27 September 2000 p.1).

The Free State Department of Education organized a strategic planning workshop with regard to farm schools on 29 September 2000. The main emphasis was on the following:

- The signing of agreements.
- Learning and teaching effectiveness.
- Physical facilities and resources.
- Role of school governing bodies.

The MEC for Education in the Province, Papi Kganare, announced in the Legislature that schools where no agreement was signed before the end of 2000 will most likely be closed, as they cannot exist outside the framework of the new agreement. However, the department would determine beforehand what the impact would be in terms of learners in those schools (Volksblad 14 October 2000). The MEC also announced that schools where agreements had been signed would be eligible to apply for support in the order in which the agreements had been signed (p.1).

Technology-enhanced Education

The outcomes-based model, Curriculum 2005, is in the process of being implemented in South African schools. The ideal is to move away from the stereo-typed teaching methods and passive learning to a learner-centered approach in which the learner is actively engaged in constructing his/her own knowledge and comprehension. The model lends itself toward a resource-based or technology-enhanced approach. A ministerial investigation into technology-enhanced learning (Technology Enhanced Learning Investigation, TELI) has been undertaken parallel to the introduction of Curriculum 2005 since 1995. TELI regards its role against the background, and in complete harmony with the objectives, values and principles of Curriculum 2005. Several reports have already been published and both national and provincial workshops presented.

The private sector as well as non-governmental organizations have also taken the initiative to create education-related Web sites. The Teacher (online version of The Mail and Guardian print publication) and Naspers SkoolNet Sunday Times Education Online Siyafunda, sponsored by the First National Bank (FNB), are examples. These sites typically provide online visibility for existing educational involvement (for example Naspers’s Koerante in die Klaskamer program) or media coverage of education (Sunday Times Top 100 Schools Survey). Cyberschool Africa as well as The Learning Channel provides excellent on-line access for
learners and educations. The Dial-a-Teacher concept, which was introduced in March 2000, literally bring any learner in direct contact with an experienced teacher to solve specific problems. Unfortunately access to these fascinating developments is limited to those who are connected.

The introduction of technology-enhanced learning creates as many problems as it is trying to solve, and may even serve to widen the gap between advantaged and disadvantaged communities even further. The lack of infrastructure and skills in poorer communities; maintenance of equipment in remote areas; as well as lack of funds to acquire hardware and software, are some of the major stumbling-blocks preventing the implementation of technology-enhanced learning on a large scale. In addition to the lack of infrastructure mentioned, the introduction of modern technology in the farm school environment is more than just an ordinary challenge. Therefore alternative ways and means to implement these concepts properly should be looked into. And it is here where the possibility of solar energy has to be looked into.

The utilization of solar power in schools is not a new concept. Several projects are currently running in developed countries, usually driven by environmentalists, where the emphasis is on the beauty of clean renewable solar power as an alternative to electricity generated in the conventional way (see www.ITcorp.com). However, in the rural South Africa, solar power may often be the only way of getting a rural school connected to the outside world. One of the best-known examples of the utilization of solar energy in the country’s school system is Myeka High School in the Kwazulu Natal Midlands. This school got solar panels for lighting purposes in 1995, but soon realized that the use of the solar energy should be optimized to bring learners in contact with computer technology as well. This ideal was achieved when twenty computers were donated to the school and three of the educators trained to teach computer skills at the school.

It is against this background, as outlined in the first part of the paper, that the story of Gelukwaarts should be told.

The Gelukwaarts Story of Success
Born out of Sorrow

The Gelukwaarts Agricultural and Hotel School was established in June 1997 when three small farm schools in the South Eastern Free State in the district Vanstadensrus magisterial district amalgamated. The name is derived from the Afrikaans name of the farm on which the school is situated and literally means “towards luck or happiness”. As remarked by the present headmaster, Daniel Wilken, the school was born out of sorrow after the cold-blooded murder on the owner of Gelukwaarts, Neels Wilken, and a fellow farmer, Hennie Bekker, on Christmas Eve 1993. The farmers in the particular area, referred to as the “Moot”, afterwards had an in-depth discussion with all the role-players in order to stabilize again and to establish the needs of the farming community as far as education was concerned. Eventually it was clear there was a great need for education, especially secondary education in that remote corner of the province.

Although the three amalgamated schools function as a single school, the three educators and learners were still accommodated on three sites as none of the schools could accommodate all the learners. The first step was to negotiate with the Department of Education for the provision of additional classrooms to accommodate everybody on one site. Two new educators were appointed when two storerooms were made available on one of the farms.

But even in 2000 the five educators are still teaching 160 learners in ten grades in just four classrooms. As from 2001 two more posts will be provided by the department, which will alleviate the pressure to some extent.

Developments

During October 2000 all the learners and educators moved to the present site. A donation by the National Union of Mineworkers enabled the school to erect three classrooms while the community added a bookstore to the complex. The bookstore is currently utilized as a classroom. The department erected a fence and will shortly start with the erection of two more classrooms. Although still not ideal, the school will be able to perform most of its functions under one roof as from 2001, except for the practical work in Farm Mechanics, Hotel Keeping and Catering which are carried out in the workshops and kitchens of adjacent farms. Extramural activities take place on two afternoons after school while two more afternoons are used for practical work. The land next to the school site is already ploughed and a vegetable garden will soon be established.

Facilities for sports are almost non-existent, however. During a visit to Gelukwaarts, Danie remarked, “We don’t have anything, just an incredibly lively spirit”. He showed me the athletics track, a dirt road leading to an adjacent farm. The soccer and netball fields are part of a paddock. A patch of well-known Wepener sand
(for building purposes) serves as the pit for long jump practice. Despite the meager facilities, the school recently set five athletics records during a competition for farm schools held at Wepener. The local farmers will transport athletes who qualified for the regional competition.

A unique school fee system was also introduced. The monthly school fee is based on what the parents expect from the school. Once a budget has been drawn up to cover the expectations, the parents must indicate how much they can contribute towards the expenses. During the negotiations the staff then would also make a pledge to provide the outstanding amount by means of fund-raising. Thus far the scheme worked very well and school fees are paid regularly. Danie is also negotiating with the Department of Agriculture in the province to secure funds to start pig farming on the school premises. Every grade eight learner will be provided with two pigs and sufficient funds to buy food. When the pigs are sold, one-third of the profit will go to the school fund, one-third to a savings account for the learner and the remainder will be used to pay the school fees of the learner.

Travelling long distances on foot to school was also a problem until Danie solved it by obtaining second-hand bicycles from the Far East. These bicycles are rented at a nominal fee to learners. At the end of each year a competition is held to identify three learners who looked after their bicycles very well. These learners will get their bicycles for free for the following year.

Linking Up

In spite of all his efforts to upgrade and expand the infrastructure and extramural activities at the school, Danie realized that his school was still tucked away in a remote corner of the province. Learners and parents continued their lives in isolation from the rest of the world. Occasional visits to the town of Wepener, some 35 km away, was the farthest trip that could be undertaken by most of them. Much more needed to be done in order to make an impact on the lives of these people. Danie wrote dozens of letters, made presentations and paid visits to a number of institutions and organizations. Ultimately his dedication, perseverance and extraordinary patience were rewarded when some sponsors decided that his school was not an ordinary farm school and should be given the opportunity to cross the Rubicon. A computer company provided a satellite dish, solar panels and a cell phone, while an insurance company donated six computers.

The utilization of modern technology is the greatest achievement of all that happened since 1997 at Gelukwaarts. Contact has not only been established with the Department of Education to receive circulars and survey forms, but learners and their parents now have regular access to the latest news by accessing Web sites like News24.com. The headlines are printed and pinned to notice boards where learners can look at it on a daily basis. There is no further need to collect old newspapers when the information can be obtained directly from the Net!

Teaching and learning are enhanced further by utilizing the excellent material from The Learning Channel and CyberSchool Africa. On-line access to the distance education programs of several institutions is also no longer a dream but a reality. Since the installation of the satellite dish, the school established a wide network of interested parties and supporters of the school by exchanging E-mail messages (gelukwaartslhs@mweb.co.za).

Another exciting development is the utilization of the classrooms for the Adult Basic Education Programme (ABET). In the evenings two of the teachers teach 80 adults basic literacy and numeracy skills. It is envisaged that these learners will eventually also be taught basic computer skills.

Recognition

The success story of a farm school, fired by the enthusiasm and dedication of one man and his wife, made the headlines. All of a sudden the once-forgotten school was in the limelight. Perhaps the greatest honour bestowed upon the school thus far, was Danie being one of 40 educators nationwide who received a National Teacher Award on 26 October from the National Minister, Kader Asmal, in Pretoria (Teacher 2000b). This achievement is best described in Danie's own words: "It was a fascinating experience to be one of forty dedicated teachers who have one thing in common - a vision for their schools and their learners spotting a challenge in every problem". In his opening address at the awards ceremony, the Minister highlighted the qualities of the ideal teacher as follows: "The teacher who is able to transport the learners beyond the boundaries of today and into the possibilities of the future is the one we have been looking for in the teacher awards process. The passion, the identification with the learners, and the vision to see beyond the often-
depressing realities of daily life, are the qualities we seek. For as we are, so the learners will learn" (DoE 2000c p.3).

The Future

According to Danie, the success story of Gelukwaarts is not the end but just the beginning of a new era for the provision of education to farm schools in the province. He is in continuous discussion with all role-players like the Government, the Agricultural Union, Tswelopele (a non-governmental organization aimed at the upliftment of farm schools), as well as the private sector. As a result of his deliberations many more farm schools will benefit from a grant of R12 M ($1.6 M) by the National Lottery Trust. Three companies will provide satellite dishes, cell phones, solar panels and computer literacy training to schools and the community in order to promote computer literacy and access to information on the Internet. Even farmers will benefit from these developments, not only to increase communication between the farmer and the school, but also to provide farmers with the latest information regarding prices of their products, as well as information on agricultural matters in general. Danie sees this as a way to acknowledge the willingness and positive attitude of those farmers who have made contributions towards the education of learners on their farms.

The educational computing course takes many shapes and forms in the different colleges and universities around the United States and the world, but its basic purpose is universal - prepare the teacher to effectively use and integrate technology in the classroom. This purpose now has more of a structure being imposed upon it with the introduction of the National Educational Technology Standards (NETS) (http://cnets.iste.org) that encourage learning opportunities that will produce technology-capable students. In order for this to happen, the teachers must be prepared. In the National Educational Technology Standards for Teachers (NETS-T) the teacher is called the key individual and teacher preparation is called critical. This document goes on to say, “Being prepared to use technology and knowing how that technology can support student learning must become integral skills in every teacher’s professional repertoire. Schools and classrooms, both real and virtual, must have teachers who are equipped with technology resources and skills and who can effectively teach the necessary subject matter content while incorporating technology concepts and skills.” All of this preparation does not occur in the educational computing course alone, but it is an important piece of the total process.

The papers for this year reflect these changes, some more than others and some in very different ways. One common strategy for preparing the teacher was a much more extensive use of the World Wide Web. The paper by Bump describes the use of WebQuests with all the instruction presented within them. Murray advocates the use of constructivist, web-based projects for the pre-service teachers that help the teachers think about how they learn as they construct their knowledge and their web pages throughout the semester. Pan presents a working model based on a three-level Delta learning theory that includes self-defined goals, hands-on computer experiences, real-world projects and collaboration.

Another strategy for preparing the teacher was changing the structure of the educational computing course. Chen describes the efforts by her college to change the course from a one-hour to a three-hour course that would conform to the new standards and frameworks. Bump proposes a flexible structure for the course so that the inexperienced students would receive more in-class help and personal interaction than the experienced users who were quite comfortable with more online activities. Another part of the flexibility would be some class days for group work and some for individual work time, if needed. Byrum details varying ways to structure the classes within the course to work with the diversity of skill levels in the students. He includes both individual, as well as group, strategies.

The last strategy for preparing the teacher was apparent in many of the papers. This was the need to make a concerted effort to align the objectives of the classes to the national standards and to integrate technology in all the teacher preparation classes. Nonis discusses her college’s efforts to change the learning experienced by their pre-service teachers. She says that teacher education students have a better chance to achieve the NETS if effective uses of technology are implemented and expected to be demonstrated throughout all phases of a teacher education program. Espinoza highlights the experiences of three faculty members as they integrate the standards and the technology-rich activities into the teacher preparation sequence.

Wren Bump is a clinical assistant professor in the Instructional Technology Program at the University of Houston. This is her seventh year to teach the educational computing course at UH and before then she taught the same course at Texas A&M University. Her other educational experience is in elementary education and special education. She can be reached at wbump@bayou.uh.edu or 713-743-4959.
Using a Flexible Format to Create a Constructivist Learning Environment in the Educational Computing Course

Wren M. Bump
Instructional Technology Program
University of Houston
United States
wbump@bayou.uh.edu

Abstract: This paper describes the restructuring of the Educational Computing Course CUIN 6320 Technology in the Classroom, a graduate class at the University of Houston. The purpose of the restructuring was to model to the students appropriate, constructivist teaching methods and activities used in the integration of technology for instructional purposes. By experiencing a constructivist approach, the students were able to make their own connections between technology and its use in the classroom and reflectively evaluate their progress and growth. It is hoped, since there was much growth and improvement in their knowledge of technology and its applications, that they will use these strategies and activities in their own classrooms.

Introduction

How do you teach a teacher to teach differently? How can you get students totally involved with their own learning? How do you introduce the new technology standards to pre-service teachers? The answer to all three questions is simple – model it for them. The Educational Computing Class was restructured so that teachers and pre-service teachers could participate in a constructivist learning environment. The class was set up with a flexible format that had four features: 1. Web Quests to introduce new concepts and topics and provide practice with several technologies, 2. Collaborative work, 3. Web page creation by each individual student as a means for turning in assignments and learning to upload files, and 4. Discussion lists to discuss topics and readings and respond to class members' responses.

The Need to Restructure

The International Society for Technology in Education (ISTE) in the new National Educational Technology Standards for Teachers (NETS-T) stresses that teaching must be different. “Today's classroom teachers must be prepared to provide technology-supported learning opportunities for their students. Being prepared to use technology and knowing how that technology can support student learning must become integral skills in every teacher's professional repertoire” (ISTE, 2000b, p. 2). Over the last ten years the demands on what teachers should know and what skills they should possess have changed dramatically. It is no longer what they know and what they can do technically – it is what they can apply and integrate into their teaching practices, as well as a complete change in how they teach. If teachers are trained in the traditional, lecture style with the professor dispensing all the knowledge, then it is more likely that they will continue to teach this way. But if the professor will model for them a collaborative, constructivist, interactive environment, then teachers will begin to see the exciting possibilities that exist for them and their students. March (1999) says, “... don't look for the online equivalent of your textbook or handouts (though they may exist), look for the sparks that create insights, the contrasts that promote problem-solving, the bells and whistles that motivate, and the passion that inspires”. This change needs to be modeled so that the teachers can experience and understand what will be expected of them as they enter the teaching field.

The Major Components of the Restructured Class

WebQuests
"A WebQuest is an inquiry-oriented activity in which most or all of the information used by learners is drawn from the Web. WebQuests are designed to use learners' time well, to focus on using information rather than looking for it, and to support learners' thinking at the levels of analysis, synthesis and evaluation. The model was developed in early 1995 at San Diego State University by Bernie Dodge with Tom March, and was outlined then in Some Thoughts About WebQuests" (Dodge and March 1995) (http://edweb.sdsu.edu/webquest/overview.htm). WebQuests are designed to utilize the student's time efficiently and to provide a clear purpose for the activity. In order to achieve both clarity and efficiency, WebQuests should include an "introduction that sets the stage and provides some background information, a task that is doable and interesting, a set of information sources needed to complete the task", resources that point to information on the World Wide Web, a "description of the process the learners should go through in accomplishing the task, the process broken out into clearly described steps, and a conclusion that brings closure to the quest, reminds the learners about what they've learned, and perhaps encourages them to extend the experience into other domains."

In the Educational Computing Class, five WebQuests were developed and used throughout the semester to introduce new topics and technologies. Students were able to work through the WebQuests at their own pace and with as much time as was needed. All the WebQuests were online (http://www.tocities.com/cuin6320/) and could be accessed at anytime and from anywhere. Any supplemental material was also available online and could be printed.

These WebQuests introduced an overall topic to the students and the assigned task involved the use of a selection of technologies that would best accomplish the task. In WebQuest 1 the students worked with e-mail and discussion lists since these would be critical for communication throughout the semester. WebQuest 2 introduced the efficient use of the web in both teaching and learning. WebQuest 3 illustrated the use of graphic elements and organizers and the importance of their use in the classroom. In WebQuest 4 the students actually worked through an ISTE learning activity from the new National Educational Technology Standards for Students (NET-S) - Connecting Curriculum and Technology (ISTE 2000a) that explored the practical use of spreadsheets and presentation tools. WebQuest 5 introduced primary sources on the web and combined them with desktop publishing.

An important part of any online work is the evaluation of that work and all its components. The students participated in a “WebQuest about WebQuests" (Dodge 2000) (http://edweb.sdsu.edu/webquest/materials.htm) that helped them to see the differences in the quality (or lack of quality) in several WebQuests that were already online. These WebQuests were on several different grade levels, so each group could evaluate WebQuests that would be appropriate for their particular grade level. After WebQuests 1 and 2, the students evaluated the professor-made WebQuests with the evaluation form created by Dodge (1998) (http://edweb.sdsu.edu/webquest/webquestrubric.html). The students were told that their WebQuest, which they would create with their group, would be evaluated with this same form. Hopefully, being familiar with the evaluation form and actually having to apply it would help the students understand the necessary components of any WebQuest and would help them use this knowledge as they developed their own WebQuests.

Collaborative Work

Students worked in groups as they completed the WebQuests. By doing this, they had a support system to help them and to be another resource besides the teacher. The group also provided help that the teacher might not be able to provide because of differences in learning styles, time conflicts, etc. Each of the five WebQuests included a collaborative piece so that the students could get an idea of how valuable collaborative work could be in their own classrooms one day.

As the semester progressed, the groups met during some of the class periods to begin to develop a group WebQuest. These WebQuests included all the above pieces and students were free to structure their group tasks as necessary. For example, some groups divided the tasks by job descriptions, such as resource gatherer, web page designer, editor, etc, while other groups divided the tasks by the pieces of the WebQuest
itself, such as introduction, task, process, resources, and assessment. Near the end of the semester, the groups exchanged URL's, worked through another group's WebQuest and then used the evaluation form to critique their WebQuest. The professor did the same so that the groups would receive multiple and hopefully very useful feedback. The final class day was used to present the updated WebQuests and to provide their URL's.

Online Interaction and Manipulation

Another aspect of the flexible format was the way that students turned in their work that was due. Instead of them having to hand in a disk or a printout, the students would upload their assignments to their own webspace. This webspace was created and maintained by each student and gave them practice with another form of computer-mediated communication. By creating their own website the students experienced many of the possibilities they could offer in their own classroom and in their own students' learning experiences.

Computer-Mediated Communication

The last aspect of the flexible format was the use of computer-mediated communication. One such communication method was use of the discussion list (hypergroup) to discuss topics and readings and respond to class members' responses (http://www.coe.uh.edu/hypergroups/courses/). Every other week there were 2 questions posted on the list to which the students had to respond thoughtfully. Each student also had to read fellow students' responses and then respond to one classmate for each question. Students liked the flexibility of the time involved with the hypergroup since they could read the assigned readings at a convenient time for them and then respond to class members at a different time. If they preferred, both could be done at the same time – post their response to the question and also reply to a fellow class member's response.

Another communication method was the use of e-mail. It was mandatory that students set up an e-mail account and actually use it throughout the entire semester in order to interact with group members and the professor. In prior semesters, the requirement of the use of e-mail was limited since most students were very happy to use e-mail in most of their interactions and no more encouragement was needed from the teacher. But each semester there was always a handful of students who resisted e-mail and were able to complete the course without a thorough, personal knowledge of e-mail's use and advantages.

The Results of the Restructuring

At the beginning of the semester, students evaluated their computer use and knowledge of technology integration using the instrument developed by ISTE, ISTE Recommended Foundations in Technology for All Teachers (http://www.coe.uh.edu/~wrn/cuin6320/ISTEsefl.doc). This instrument has 18 areas in which the students rate themselves with a scale of 0 to 3. If they have never heard of the application, they give themselves a zero. If they are aware of it, they receive a 1. If they use the application, they get a 2 and if they could integrate the application into instructional practices, they receive a 3. With the highest score possible being a 54, the beginning scores ranged from 5 to 47. At the end of the semester, the students re-evaluated themselves using the same instrument. On the average, students gained 22 points with the lowest-scoring students making the most significant improvements. A reflective essay, written by each of the students and posted on their personal website, described their growth and experiences throughout the semester.

Here are a few excerpts from their reflective essays: "I discovered that there are many possibilities for the use of basic productivity software to enhance instruction in new and creative ways. I was constantly exposed to valuable resources and encouraged to share my discoveries in the context of classroom activities. From developing a website to creating a PowerPoint presentation to collaborating with others on the creation of a WebQuest, I continually developed skills and applied concepts." "The course has opened my eyes to the possibility of teaching technology skills within the context of real-world problems. Students will benefit from my experience as they learn the skills that I have recently learned and as they strengthen the connections of the skills learned in class with the world outside the classroom. This is timely because I had previously been
teaching these skills in isolation and I was looking for strategies to 'break the mold.' "I was continually challenged to think critically about the use of technology in the classroom and to apply the principles of instruction to the acquisition of technology-related skills." "When we began to create the web-based lesson, I had my first opportunity to see how I could use my newfound ability to create web pages for instructional purposes. While doing this, everything came together—the different aspects of using technology in the classroom that had been covered in previous WebQuests and the whole idea of the instructional power of WebQuests." "I have developed a WebQuest that two of my fellow teachers will actually be using next semester!"

The students also wrote a paper about their group experience and their own contributions to the group WebQuest. All of the papers in each group were compared and a part of the students' grades were based upon their ability to work with their group. It was very interesting to see the differences in what the students perceived about their own contributions as compared to how their group members saw their contribution. In most groups the different perspectives corroborated the others, but in a few cases it was very easy to tell who had slacked off in the group work and participation.

Here are a few of the students' comments about working with their group: "There were no problems with our group's ability to engage in the task, work cooperatively, or with the group's dynamics. Our group was comprised of a very diverse collection of individuals with a range of academic skills. Our diversity helped to make our interactions rich, although there were times that we did have some difficulty in reaching consensus on how to proceed. The group's members were mature enough to overcome individual differences in order to produce desirable results. I truly enjoyed working with this group of individuals and I feel fortunate to have been a part of such a dynamic and intelligent group." "One of our group members was going to drop the course. We are the ones who urged her to stay in the course as we needed her help. As a group, we really had to stick together and use each other's individual expertise in order to ensure quality work." "(one student said, in referring to another group member) She was a great asset because she served as a point of reference for me when I felt swamped. She always was encouraging and very helpful when I was lost in the course."

The last result of restructuring that needs to be discussed is the use of the WebQuest in structuring the class periods, as well as the students' intentions to develop and use WebQuests in their own classrooms. Once the students got used to the concept of WebQuests, they were excited about their use and availability online. They enjoyed the variety of activities, as well as the introduction and application of new technologies. But most of all, many of the students could actually see themselves constructing their own knowledge as the semester progressed and developed an ownership of the concepts presented throughout the course. They saw WebQuests as an efficient way to create similar learning experiences for their students. One student observed that the initial time investment by the teacher would be countered by the time saved in class by having all the necessary materials ready for the students to begin working and also to work at their own pace. Another student observed that WebQuests could be revised, after the students completed them, in order to include needed elements, exclude unsuccessful elements and make other changes based upon feedback by the students, thus minimizing preparation time for the next year.

Conclusion

Modeling the use of the four components made a significant difference in the total course and produced the many desirable outcomes illustrated above. Many insights were gained from the students as the professor solicited much feedback and necessary revisions as the semester progressed. Some of the suggestions were incorporated into the present semester while others will be implemented the next semester. Overall, the students were pleased with themselves for their mastery of so many forms of computer-mediated communication and were surprised that they were able to do so many things with technology in an instructional setting. They appreciated the flexibility of the class and the activities, and were glad to be able to construct their own knowledge from this unique experience.

Technological Diversity: Managing Differing Technology Skills in the Edtech Course

David C. Byrum
Department of Curriculum and Instruction
Southwest Texas State University
United States
Db15@swt.edu

Abstract: Students are coming to Educational Technology courses with extremely diverse technology skills. This presentation/paper will discuss varying ways to structure classes or instruction to work with these varying groups. The author will detail several of the strategies used in past classes, the results, and other methods the instructor may wish to consider depending on the situation.

Introduction

Students as never before are coming to Educational Technology with extremely diverse technology skills. Once, when teaching technology skills, you could assume that all students were starting from the same point. Today, however, you must assume all students will be coming to you with a completely different set of skills. In many of our graduate classes, the students often range from the level of computer novice to the student who works in the Austin high-tech corridor and wishes to become certified to teach. The difficult task for any instructor is to find ways to deal with these differing skills in Educational Technology classes and make the class meaningful to all students regardless of prior skills.

This presentation/paper will discuss varying ways to structure classes or instruction to work with these varying groups. The author will detail several of the strategies used in past classes, the results, and other methods the instructor may wish to consider depending on the situation. This paper/presentation will discuss individual strategies and group strategies.

Individual Strategies

Student as Expert Assistant

One method is using the student with superior skills to assist the instructor in classes, often assisting those persons needing extra help with projects. The expert/assistant also learns through one-to-one interactions how to deliver instruction. Overall, I have had much success with this strategy.

*Advantages: The instructor receives much needed help in large lab classes by letting the expert/assistant answer some of the general questions and to help those struggling to keep up. The assistant feels he/she is playing an important part in the class and tends to stay engaged.
*Disadvantages: Some students tend to resent the fact that the expert/assistant is allowed to help and not required to complete the project.

Student as Teacher

Many advanced students find that they only really know the intricacies of a software program when they are given an opportunity to teach it to the class and see the results. When students begin working on projects the student/teacher comes to a greater realization of the many ways instructions can be interpreted.
Advantages: Practice in developing instruction for training, a chance to work with learners and a deeper understanding of the software.
Disadvantages: The instructor must closely monitor the instruction being prepared for quality and be ready to step in when things go wrong or are confusing to students. The instruction process could prove to be overwhelming for those with little or no experience in teaching.

Testing out

Testing out allows for students to show work or display skills that prove the class is not needed. Great care must be taken if this option is made available and documentation should be extensive. A portfolio of technology work can allow the instructor to give credit for past work, such as basic word processing, spreadsheets, etc. Portfolios can be used to demonstrate basic competencies as well as show the integration of technology in lesson planning and curriculum.

Advantages: Students do not need to attend a class in which they already have extensive skills. Student can go on to next level.
Disadvantages: Often students can pass the technical portion but have no knowledge of educational application of these skills. Testing and documentation can be tricky to determine in project-based courses.

Independent study

An independent study may often be a last resort for a student with superior skills and needing a real challenge. I feel independent studies should only be used in extreme cases, those in which you are sure the student easily meets all prerequisite skills for passing the normal class.

Advantages: Customized to meet student's needs can provide a real challenge, and projects may benefit the instructor.
Disadvantages: Students can not make up for time in class interacting with peers and discussing issues and trends. Hard to determine if the student is lacking knowledge in certain areas.

Group Strategies

Multiple path instruction

Multiple path instruction gives the learners varying paths to follow in completing class work. This approach takes students "as they are" and helps them improve skills. For example, the instructor may set up a beginner, intermediate, and advanced path for students to take in completing the course, each level with its own expectations and rigor.

Advantages: Students can progress at their own pace on their own skill level and is challenging to all students.
Disadvantages: Students may be working on different projects and end the course with varying skill levels which tends to lead to confusion. Often students will misplace themselves in the beginner, intermediate, and advanced levels and may need to change to a different level.

Differentiating assignments

Somewhat like multiple-path instruction except that all students are on same level and allowed to pick and choose from topics and skills in which they feel help is needed. The instructor may require that certain projects be mandatory and leave student choice to many minor projects. The instructor also needs to set minimum competencies for all students. One danger is many students often overrate themselves in their competencies and skip projects actually needed.

Advantages: Students are allowed to pick and choose areas they feel they need help or in which they are weak. Students like the feeling of setting their own goals and projects.
Disadvantages: Students sometimes choose what they perceive as the easier projects and stick with things they know.
Contextual Experiences: The Revision and Implementation Process of an Information Technology Course for Master Teachers

Wanda I. Carrasquillo-Gomez
Westminster College, School of Education,

d-stokes@wcslc.edu

This paper explores the revision of curriculum within a technology course; the curriculum implementation and outcomes. In similar vein, it explores my reflections of the process, with suggestions of pertinent issues, recommendations, pitfalls, and successes.

Although technology skills are certainly important for teachers to learn, few graduate programs in the State of Utah prime teachers for these demands. The Master of Education Program at Westminster College, a small liberal arts college in Salt Lake City, is one of the few programs in the state that offers the technology specialization, for teachers at a graduate level. As a student in this program, I realized that the present instructional approach lacked the latest instructional tools and resources that would enable teachers to effectively transfer and apply technology skills to classroom situations. From this beginning emerged my effort in a curricular revision of the Information Technology (IT) course; one of three courses offered and required to obtain the technology specialization. My thought was to focus more on a hands-on approach, recent instructional technology tools and resources available for teachers, and their classroom application.

Rationale

The impact of technology in the classroom is promoting changes in the role of teachers. Teacher's roles have shifted from dispensers of knowledge to one of facilitators of the learning process with the attendant need to know how to integrate technology effectively to improve student learning. "Teachers must take time out from an already full schedule to learn new techniques and then incorporate them into daily activities" (Hale & Kieffer, 1995).

This technology trend is sending a clear and widespread message noticeable among people in the education field; teachers should be proficient computer users. "Teachers, administrators, and parents are finding that using technology requires more than adding Internet access or placing computers in a classroom" (Norum, Grabinger, and Duffield, 1999). However, Cradler, and Bridgforth (1999) said, "Many educational leaders have little understanding of or experience in using and managing advanced technologies." This situation implies the need for better technology programs at all educational levels.

Although technology skills are certainly important for teachers to learn, few graduate programs in the State of Utah prime teachers for these demands. The Master of Education program in which I was enrolled, through its technology specialization, attended to this need, but not to my satisfaction. My plan was to persuade students to integrate technology applications in their own teaching practice. By using a hands-on approach, I planned to model teaching strategies from instruction to construction as described by Cradler and Bridgforth (1999),

It [Technology] can shift instruction from Teacher didactic to learner-centered and interactive, from fact telling to teacher-student collaboration, from memorization to inquiry and invention, from the accumulation of facts to the transformation of facts, and from the use of standardized tests to relevant portfolio and performance-based assessments (http://www.fwl.org/techpolicy/techrefom.html).

This approach held much appeal.
The Curriculum Design Process

As a framework to commence the curriculum revision process, I raised the following questions:

- What subject content and topics do I need to include in the curriculum to support the course’s objectives and goals?
- What learning activities do I need to include in the curriculum to support the content and topics?
- What resources or materials do I need to use to support the instruction and learning activities?
- What are the learners’ interests and characteristics?

To obtain answers to these questions, I compared the previous curriculum with my personal rationale for the course. Ideas acquired through a literature search, prior teaching with technology encounters, and what I believed to be effective educational practice. In addition, I appraised the content and objectives of other IT courses at the graduate level tendered in the state of Utah. I wanted to ensure the topics I sought to include were suitable and comparative with other IT courses.

The new curriculum was developed using the same learning objectives as the previous course, but included topics to elevate discussions applicable to teaching theory and computer knowledge. In addition changes included a shift in focus to a variety of hands-on activities designed to expose students to the classroom application and uses of the most recent instructional technology tools and resources available for teachers.

As a neophyte in the area of curriculum design, I attempted to grasp a constructivist approach, where “…most knowledge is constructed in an active, effortful way by learners who are engaged in experiences that promote an opportunity for reflection and assimilation/accommodation to existing knowledge” (Smith and Ragan, 1999, p. 15). Furthermore, the new curriculum reflected my understanding of how to put into practice Dewey’s belief that the purpose of education is to prepare children to live in the world; students would opt to utilize the technology tools and resources learned in their own teaching practice.

Method

My mentor professor examined and endorsed the curriculum before implementation. The class convened on thirteen occasions from January to April of 2000. The participants in this inquiry were graduate students seeking the Technology Area of Specialization in their graduate studies at Westminster College. All but one of the students who enrolled in the class had teaching experience in K-12 or post secondary education levels. Students ranged in age from 22-54 years, three men and six women. Their technology experience and skills ranged from emergent to proficient.

In the majority of classes, the professor conducted the reading discussion from the text. As the curriculum designer I sought out and chose this text. I wanted a text that would be able to provide a link from computer knowledge to teaching practice. Following a review of available texts, I chose Computers as Tutors: Solving the Crisis in Education by Frederick Bennett, Ph.D. (1999) The professor also conducted the final project assignment. I conducted the demonstrations and hands-on activities which followed the topics stated in the syllabus for each week. The following table displays the topics and activities comprised in my curriculum proposal week by week.
**mini-projects**

As the course unfolded, students were encouraged to submit weekly comments or reflections for each topic. Additionally, I kept a journal of personal insights from my teaching experience. The professor and I met regularly to discuss student progress, curriculum adaptation strategies, possibilities, and concerns. At completion of the course students shared their comments about the course.

**Reflections**

The following are brief transcripts of sample journal notes that highlight the progress of the course and my thoughts as curriculum designer.

**Week 1: Course Overview**

The class did not go as well as I had hoped. Soon after I began to teach, I had more topics to cover than time. I started to rush through the material. I panicked, looking at the clock, and suddenly nothing was working for me. When I tried to explain one of the options for the final project, developing this course online using WebCT, it didn’t succeed the way I had planned. “I am not very familiar with the product, but I practiced before class and created a small course; however, in class it did not work! I could not login and I looked, and felt, foolish.” In the middle of all the commotion, I forgot to mention the second option for the final project [select one of the tools learned in class to create a lesson]. Even as I near completion of the class instruction, the anguish of that moment is still with me. I decided, “Next time I will try not to cover so much material.” However, I was confused about how to do this. The syllabus was set; so how could I make profound changes this early?

**Week 2: Planning for Media use and Instruction**

A technician from the information technology department at Westminster came to pull a computer apart to show how they work. Students’ feedback suggested that the majority of them appreciated learning about the parts and functions of the computers. One said, “I enjoyed the hands-on approach. It helped me by actually seeing the computers and the slots and how they went together.” Unfortunately, the technician did not bring enough computers to allow all the
students to use a hands-on approach and monkey around in the guts of the computers. This was a major drawback. Overall, I am not sure what we really gained with this demonstration, other than a general overview of the computer parts. Can the students use this application to actually troubleshoot their classroom computers?

Week 5: Integrating Computers into the Curriculum

One student conveyed, “I think we are extremely involved and so concerned about defining what we are going to do for our final project, that we are distracted from other activities [Integrating Curriculum demonstration].” Students sent a consistent message, however, that while the primary concern of an IT course is to learn educational tools for integration, the time needed to prepare each project and assignment brings stress and frustration.

Throughout the curriculum revision process, it never occurred to me that the intensive amount of topics would provide an avenue for students to disengage from the topics and lose focus on other projects due to the lack of time.

Week 8: EDNET

Today we delivered the class via EDNET, which is the Utah Education Network’s interactive system that electronically brings a teacher from one classroom to another. To me this was the biggest event of all because the students had the opportunity to participate in a real life distance learning experience. In education, many courses, degrees, and programs are delivered at a distance. Perhaps ten, fifteen, or twenty years from now, the majority of instruction will be conducted from an EDNET site or another distance learning medium. To facilitate this activity, I encountered many hours of preparation, including training on the system. In addition, some technical difficulties occurred during the event, but that did not diminish the experience.

Although I am in favor of using this type of system as an alternative medium of instruction, it can be a disadvantage. Perhaps it is just a matter of tweaking the way of teaching. The disadvantage comes from the boundaries set by the camera and TV screen. While delivering the instruction, “I felt tight: I could not move, use my hands, or show excitement.” My professor could not restrain himself from looking at the monitor to catch a glimpse of the class. The students also felt intimidated by the camera and the microphones. However, the class setting created a meaningful environment that prepared the professor and I to model the use of technology and its practices in a real situation. One student said, “Although I am not entirely sold on EDNET, the chance to participate and learn about it was great!” What does she mean by saying, “entirely sold”? Did she mean that distance learning is not effective for teaching and learning? Did the other students feel the same way? What did we gain today?

Week 11: Web Page Editor

I was absent for this class and the professor was going to cover the topic. However, the whole class decided to spend the time to work on the final project. According to the professor, the class was thankful. I do not know how to express my feelings when I found out what happened. As a developer of the curriculum, I would have preferred to follow the plan. Does this make me a behaviorist? On the other hand, as an instructor, I am sure I would have made an adaptation to meet the students’ needs allowing them to work on the final project, instead. Does this make me a constructivist? I know that in my personal practice I tend to be flexible and like to negotiate learning and instruction with my students. As an instructor or developer, do I need to stand firm on one or the other approach? Can I mix both: behaviorist and constructivist? Perhaps I need to examine both approaches more closely.

Outcomes

At first, what I tried to do while revising and implementing the Information Technology curriculum was to expose students to the most recent instructional technology tools and resources available for teachers; tools that would be effectively use in a classroom situation. When I asked a student to give me suggestions for a future IT course, the response was, “If the purpose is to offer lots of information about technology, then probably none...[but] I would like the opportunity to become more proficient in some of it [technology tools]. I will have to do that [practice] on my own.” Considering this comment and many other issues that arose through the implementation of this curriculum, it is apparent to me that the approach I took to expose the students to a—wide variety—of resources was not effective for some.

This was not an easy personal journey. I began confident in my abilities to envision what an effective Information Technology course should be. I was at time shaken by peers’ criticisms and by my professor’s concerns
about the plethora of topics each week. Many of those emotions are captured through my weekly reflections and
questions.

As a novice curriculum designer, I emerge from this challenging situation with an understanding that
curriculum development means much more than creating a syllabus of neat ideas. I agree with Kemp, Morrison, and
Ross (1996) when they said, "The design process includes the activities of analysis, strategy development, evaluation,
and revision" (p. 11), I have learned this first-hand.

Recommendations

From my experience the fledgling curriculum designer would be wise to consider the following
recommendations before beginning the design process:

- Plan each step of the curriculum development with special consideration on the time entailed to
  accomplish each assignment or task.
- Ensure that all the technology components work appropriately before the launch of the course.
- Be prepared to absorb great quantities of frustrations before and during the implementation of the
  curriculum.
- Use outside resources when needed.
- Prepare assignments, projects, objectives, and rubrics beforehand. Participants need to have specific
  guidelines.
- Carefully revise references, books, and other resources used in the class.
  Do not limit the revision to the content, rather examine the validity of the document to avoid unwanted
  controversies.
- Provide handout material and visuals to reach each individual.
- Allow more computer time to work on projects and assignments.
- Teach fewer topics to allow more in-depth exploration and technology skills development.
- Combine related topics or assignments (e.g. non-projected and projected projects)
- Do not spend too much time on a subject if the students are comfortable with the topic.
- Teach applications that reinforce basic computer skills early in the course (e.g. graphics) to allow students
  to build their knowledge according to the difficulty of the concept.
- Spend more time on technology integration strategies and applications.
- Consider the possibilities of working in small groups rather than a large group. This will allow each
  student to become more familiar with different technology applications.
- Be prepared to make adaptations to the topics and activities as the course develops.
- Be available when the students need help.
- Make each activity as close to real world context as possible.
  When choosing the topics and assignments for a course, ask yourself the
  following questions: How will these topics fit into the scope of the program? What technology skills will
  the students need to make sense of the topics sufficiently to ensure transfer to their practices?
- Above all, be flexible.

Comparison of Face-to-Face, Semi-Online, and Fully Online Approaches for Introduction to Educational Technology Courses for Educators

Cathy Cavanaugh, Curriculum and Instruction, College of Education and Human Resources, University of North Florida, Jacksonville, FL USA. ccavanau@unf.edu

Terence Cavanaugh, Curriculum and Instruction, College of Education and Human Resources, University of North Florida, Jacksonville, FL USA. tcavanau@unf.edu

Zella Boulware, Curriculum and Instruction, College of Education and Human Resources, University of North Florida, Jacksonville, FL USA. zboulwar@unf.edu

Abstract: An important experience for educators is learning to use computer technology for teaching and learning. In Florida, a course for undergraduates and a graduate class offer that experience. The courses topics include educational hardware, software, multimedia, Internet, and ethical and legal issues. Both courses share primary goals: building technology skills, and helping students to become integrators of technology into teaching. This year, six simultaneous sections of the courses were offered using a range of approaches. Two sections were taught fully face-to-face. Three sections were taught with students meeting in person for 50% of the time, and working in a web-based environment half of the time. One section met only online. Surveys of all students were conducted at the beginning and the end of the course, and student performance on class activities and assessments was tracked. Comparisons were made on student attitudes and self-reported technology abilities, as well as course grades.

Reports from businesses, standards documents from ISTE, and educational accreditation policies from NCATE underscore the importance of technology as a teaching and learning tool. Studies indicate that there are new and veteran educators who do not have the skills for using technology in the teaching and learning process (Barron & Roblyer 1993; Market Data Retrieval 1999; Southeast and Islands Regional Technology Consortium, SERVE, Inc. 1998). An important experience for both preservice and inservice educators is learning to use computer technology effectively as a teaching and learning tool. Higher education programs that prepare professional educators address the need for technology experience in several ways. Educational technology courses may be required, or technology may be integrated throughout other required courses.

In Florida's state university system, students in education programs leading to initial teaching certification take a required educational technology course. Undergraduate programs include the sophomore level Introduction to Educational Technology. Graduate programs include Computers in Education. Both courses have twin goals: building student skills as technology users, and providing background for students to become integrators of technology into teaching. The beginning course in educational technology, mandated by the state of Florida in 1996, is critical in the education of preservice teachers because it is the only required technology course. Web sites and conference presentations confirm that there are multiple approaches to teaching this course.

The courses cover the following topics: educational hardware, application software, multimedia, Internet, and ethical and legal issues. Each course is a three-semester hour class. Traditionally the course has been offered fully face-to-face in a classroom. The class has been web-enhanced with online assignments. This year a group of faculty taught the course using a continuum of approaches ranging from fully classroom-based to fully online. The purposes of employing the continuum of approaches was to determine whether there is a balance of classroom and online learning that is most appropriate for the students in the courses. Six simultaneous sections of the courses were offered: two sections were taught fully face-to-face, three sections were taught with students meeting in person for 50% of the time and working in a web-based environment the rest of the time, while one section met only online. Three instructors were involved with the six sections, teaching a total of 115 students.

In order to evaluate the success of the approaches, several measures were used. At the beginning of the Fall 2000 semester, all students in the courses took online surveys. The surveys and survey methods were identical. The surveys captured baseline information about the students regarding their views of their technology experience, attitudes and skills. The survey items are described in the appendix. The surveys were repeated at the end of the semester. During the course, students participated in similar learning experiences to receive course grades. Students also completed university course evaluation forms at the completion of the course.
Using the surveys, course grades, and course evaluations, results were compared to answer the following questions:

- Do students who opt for an online course initially differ from those who choose a classroom course in their skills and attitudes toward instructional technology?
- Do graduate students initially differ from undergraduate students in their skills and attitudes toward instructional technology?
- Do students experience a positive change in their skills and attitudes toward instructional technology as a result of participation in a course, and if so, does that change relate to the teaching approach of the course?
- Are changes in skills and attitudes toward instructional technology related to the student's graduate or undergraduate standing?
- Is student class performance related to the teaching approach of the course?
- Is student course evaluation related to the teaching approach of the course?

The results of the comparisons will be used to determine the most effective teaching approach, and to incorporate that knowledge into planning for future semesters. The survey completed at the beginning of the semester provided a baseline of student status, and a comparison of technology experience and attitudes among classes. At the start of the term, the undergraduate students rated their computer skills and experience at a significantly higher level than the graduates students did (p value of 0.001867). Using the 5-point scale, the undergraduates gave themselves a score of 2.15, averaged over the experience questions for all students in the undergraduate classes. The graduate students rated themselves at 1.75 on average. When comparing the students according to the teaching method, the graduate students who chose to take the fully online course rated their skills at a significantly higher level (2.34) than students in both the fully classroom-based (1.67), and hybrid classes (1.63) (p value 0.019356). The skill ratings of undergraduate students in the fully classroom-based classes (2.32) did not differ significantly from those in the hybrid classes (2.06) (p value 0.152215).

Market Data Retrieval. (1999). New teachers and technology: Examining perceptions, habits, and professional development experiences. Shelton, CT:

Appendix of Survey Questions

The first set of questions asks students to choose from among a set of options to: Identify your course instructor, your gender, your class standing at the university, your age range, and whether you are taking this class as a requirement. The set of questions related to computer experience ask students to rate their level of experience on a scale from 1 indicating no experience to 5 indicating extensive experience. Students rate their experience using operating systems (Unix, Linux, Windows, Macintosh OS), web publishing software, presentation software, digital video, word processing, web browsing, email, animation, search engines, databases, spreadsheets, digital audio, digital graphics, gradebook software, FTP. The set of questions related to computer attitudes ask students to rate their level of agreement with statements on a scale from strongly agree to strongly disagree. The questions relate to students' comfort or anxiety with computer applications, and feelings about the importance and usefulness of computers. Questions ask about student's confidence with email, word processing, and databases.
Redesigning an Educational Computing Course to Meet New National and State Technology Initiatives

Linlin "Irene" Chen
Department of Urban Education
University of Houston Downtown
United States
cheni@zeus.dt.uh.edu

Abstract: The Department of Urban Education (UE) at University of Houston Downtown first began in the fall semester of 1995. It has just started along the technology trail to learn from other institutions that have already addressed some of the issues and found some answers. The shared goal of the faculty in the department is to offer an educational computing course that falls on the end of "teaching with technology across the curriculum". The one credit hour educational computing class CS1105 is in the process of being redesigned by the UE faculty as a 3 credit hours class ETC 3301. The brand new ETC 3301 is proposed to open to all entering pre-service teachers starting spring 2001. Texas Education Agency, State Board for Educator Certification, and several other governing institutes of teacher education programs in Texas are raising standards for computer literacy for new teachers. It was suggested to all computer literacy courses to conform to the current versions of the national and state frameworks and guidelines. On the survey, the students were asked to evaluate their skill levels on using programs such as spreadsheet, database, and philosophy of using technology. This paper will also analyze results from students' self-reports completed on the first day of class for three semesters. The students' input will be implemented into the redesign of the CS1105 to ETC 3301. The paper will discuss the processes of redesigning the educational computing course to meet new state technology application initiatives.

Introduction

In the state of Texas, Texas Education Agency, State Board for Educator Certification (SBEC), and several other governing institutes of teacher education programs in Texas are raising standards for computer literacy for new teachers. For example, it is projected that in 2002-3, the on-line version of the ExCET, the state mandated teacher certification exam, will be piloted, and technology related questions will be embedded across the question sets in the professional development exams for all levels. To meet new state technology application standards, the paper plans to discuss the processes of redesigning the educational computing course ETC3301 at the teacher preparation program at University of Houston Downtown to better prepare the future teachers for the higher expectation on using technology in classrooms. Educational technology in preservice and in-service teacher training organization is a new field that has attracted researchers attention during the last decade of the 20th century. The research findings of the proposed research will also contribute to the study of educational technology and teacher education worldwide.

The Need to Change

The Department of Urban Education (UE) at UHD first began in the fall semester of 1995. It has just started along the technology trail to learn from other institutions that have already addressed some of the issues and found some answers. The teacher education programs across the country may be placed along a continuum in their integration of technology: on one end is teaching about technology while on the other end is teaching with technology across the curriculum (Office of Technology Assessment, 1995). The shared goal of the faculty in the department is to offer an educational computing course that falls on the end of "teaching with technology across the curriculum".

The one credit hour educational computing class CS1105 is in the process of being redesigned by the UE faculty as a 3 credit hours class ETC 3301. The brand new ETC 3301 is proposed to open to all entering pre-service teachers starting Spring 2001. Following several governing agencies' suggestions, the new educational computing
class ETC 3301 plans to conform to the most current versions of the following national and state frameworks and guidelines for technology education for beginning teachers:

- StaR CHART from the CEO Forum (http://www.ceoforum.org/)
- SBEC standard (http://www.sbec.state.tx.us/certstand/certstand.htm)
- ISTE NETS*T (National Education Technology Standards for Teachers, ISTE) (http://www.iste.org/standards/index.html)

The purpose of the redesign of ETC 3301 is three-fold: (1) the new course will conform to the national and state frameworks and guidelines for technology education for beginning teachers; (2) to help the students have a better chance of passing the state mandated certification exam ExCET, which, as stated in previous section, in the near future is going to embed more technology related questions across the question sets in the professional development exams for all levels; (3) to help our students to become better teachers for the 21st century.

The Process

Understanding Students' backgrounds

Research has shown that a pre-service teacher's initial attitude toward technology may impact their future use of educational technology in the classroom (Rodriguez, 1996). Instructors should be knowledgeable of the factors that could cause students to exhibit behavioral characteristics.

In order to gain initial knowledge of students' background, since 1999 when first started teaching the computer literacy course, the author has requested students taking CS1105, the predecessor of ETC 3301, to fill out a paper-and-pencil questionnaire when the students take their first professional development course, asking them to answer computer/technology related questions. The author has analyzed results from students' self-reports completed on the first day of class for three semesters. The questionnaire is then followed by e-mail-based homework answering questions such as their teaching strategy, their teaching philosophy, their position in integrating technology into teaching, etc.

On the survey given out during the first class of the computer literacy course, 94% of the population indicated that they were at least fairly competent with word processing and 76% of the population indicated that they were at least fairly competent with Internet. All students agreed that integrating technology into instruction is very important. Yet only 12% of the population indicated that they were at least fairly competent with spreadsheet, 4% of the population indicated that they were at least fairly competent with database, and 15% of the population indicated that they were at least fairly familiar with educational software. The results suggested that database, spreadsheet, and educational software are the areas that need more enrichment activities.

Many researches have been done and many instruments have been developed to investigate prospective teachers' attitudes toward computers in relation to gender, age and academic major (Collis, 1996; Hadley & Sheingold, 1993). However, this is the first time this type of research has been done on the students seeking teaching certification at UHD. It was hoped that the students' inputs could be implemented into the redesign of the CS1105 to ETC 3301.

After teaching CS 1105 for many semesters, the initial impressions of the author were: the students are positive in their attitudes toward using computers; database is one of the weakest areas for the students; many students stated that they are not familiar with Macintosh computers although Macintosh computers have been used widely in K-12 schools; more than half of the students have access to computers at home, office, or the classrooms where they are doing their student teaching.

The variables of the research include: familiarity with Windows computers, familiarity with Macintosh computers, familiarity with word processing, data bases, spread sheet, e-mail, World Wide Web, CD-Rom technology, educational software packages, and anxiety level using technology, computer ownership, access to computer from office/classroom, access to the Internet, philosophy of using technology to enhance learning, opinion about using technology to facilitate teaching, opinion about computers being necessary educational tools, etc.

The author has collected information from approximately 200 subjects from the student pools of Spring 1999, Summer 1999, and Fall 1999. The returned responses are in the formats of paper-based questionnaire and Microsoft Exchange e-mails, and Microsoft Word document. Under the support of the Organized Research Committee fund at UHD, the author has conducted a project “Instructional Implications of UHD Teacher Education Students' Basic Skills, Attitudes, and Anxiety Towards Using Computer Technology” in Fall 2000. The author has conduct analysis to find the reliability coefficients, multiple regression, etc of the variables. This project has reported
findings on the archived data of a survey of students in the professional computer literacy course for educators and has related some implications these findings have for teacher educators. The findings of the proposed research will help to identify the weakness of students' computer skills, attitudes, and the anxiety levels of the students in the UHD teacher education program. Based on the findings of the research on students' computer background, special redesigning can therefore be made for the whole class or a special group of students.

Maintaining Student Motivation

To further incorporate the motivational design into lesson planning, a search for a better instrument to assess course motivation has been conducted. The author is considering using John Keller Course Interest Survey, Personal Background Information, and the Instructional Materials Motivation Survey (IMMS). In his online article “How to Integrate Learner Motivation Planning into Lesson Planning: The ARCS Model Approach”, John Keller of Florida State University discusses applying the ARCS Model to meet the challenge of stimulating and sustaining learner motivation and the difficulty of finding reliable and valid methods for motivating learners (http://www.netg.com/research/kellerwp.htm). According to Keller, the ARCS model of motivation (Keller, 1999a) provides guidance for analyzing the motivational characteristics of a group of learners and designing motivational strategies based on this analysis. The ARCS model is based on a synthesis of motivational concepts and characteristics into the four categories of attention (A), relevance (R), confidence (C), and satisfaction (S) (Keller, 1999b). These four categories represent sets of conditions that are necessary for a person to be fully motivated (http://www.netg.com/research/kellerwp.htm). If the learners are attentive, interested in the content, and moderately challenged, then they will be motivated to learn. But during the course planning process and when the course is ongoing, the satisfaction criteria will also be constantly monitored to sustain this motivation.

Alignment Analysis

Detailed analysis has been conducted to ensure complete alignment of the curriculum with the standards. The author who is scheduled to teach ETC 3301 has downloaded the national and state frameworks and guidelines from the Internet, formatted them into rubrics, and undergone an item-by-item analysis of the standards with the planned classroom activities. Take the curriculum alignment with the SBEC standard for Technology Application for example, there are eleven Standards in total which provide the general guidelines. Within each Standard there are a section for “Teacher Knowledge: What Teachers Know and Understand” and a section for “Application: What Teachers Can Do” which provide detailed interpretations of the specific Standard.

There are three columns on the rubric used as a template for the faculty in the Department: (1) detailed description of “Teacher Knowledge: What Teachers Know and Understand” and “Application: What Teachers Can Do”, followed by (2) textbook chapters that correlate with the knowledge and application, and (3) finally the activities that can be conducted during class. If unmet standards were identified, either original activity could be modified or new activities could be added around the unmet standards. The alignment analysis has been turned in for the departmental curriculum alignment committee to review. A copy of the alignment analysis is kept in an open area for the faculty member to add more ideas and facilitate information sharing with each other.

Textbook Selection

In addition, as the second step, from a pool of 5 pre-selected potential textbooks on the topic, one new textbook has been singled out for adoption for Spring 2000 by a departmental curriculum committee made up of faculty members teaching a variety of subjects within the Department, including but not limited to science education, bilingual education, language arts and social studies.

Conclusion

In the initial planning stage, the topics chosen are as follows: Operating System, Desktop publishing, Database, Spreadsheet, E-mail, Web search, Multimedia/hypermedia, and Software evaluation. Depending on individual needs, students will be allowed to pick up a few subjects from the above list and complete small projects assigned by the instructors. The students will also have the flexibility to do work for different subject content and grade levels. Throughout the whole semester, students are required to conduct at least two mini-lessons or micro-teaching which demonstrate their proficiency in integrating technology into curriculum. Mini-lessons or micro-teaching also offer a chance for students to observe and learn from each other. In general, student-centered teaching and learning approach will be encouraged.

Abstract: What technology should be included in teacher preparation programs, and where should it be taught and/or practiced? As states (and other entities) establish technology standards to be addressed in teacher education, programs are looking for the best way to integrate these standards into existing (or new) courses. Three faculty members share their recent experiences, from their examination of the Texas Technology Applications Standards, to a determination of where each is addressed in the professional development sequence of courses as well as in the technology courses, to the development of activities to assure that all students address all of the proficiencies that are included in the standards. Included are the standards, the procedures used to determine and/or add needed technologies, and student activities.

Technology and Teacher Education -- two items that are becoming increasingly intertwined. Much money and talk have been devoted to the duo, with a growing awareness that just putting the technology out in the schools is not enough. Teachers must be trained to use that technology to enhance student learning, and a natural place to start is with preservice teacher preparation programs. This comes at a time when universities are evaluating and expanding or otherwise enhancing technologies (and related infrastructures), some of which are to be used for alternate methods of course delivery (Internet based, videoconferencing, etc.) by faculty members who may or may not have had any training in such techniques. Even 'traditional' classes are changing, as instructors (and/or their students) expect to have computers, projectors, and Internet connections in the classroom for use as an integral part of instruction and presentations. Teacher education faculty are hearing how important it is to learn the technology, to model its use for their students (future teachers), and to help those students learn to integrate it into their (the students') teaching fields. So how did we get to this point, and how are we addressing the issue?

Technology and Teacher Education

Teacher education programs have been charged with preparing teachers for the classrooms of today and tomorrow. Many of these k-12 classrooms are changing, and some have changed drastically from the days when the current teacher education faculty were students in elementary and secondary schools. Some of the students in these programs, especially the growing numbers of non-traditional students entering the teaching field, may also find that the classrooms in which they will teach are not like the ones in which they received their education. The challenge is to prepare both faculty and students to work with students in these new environments.

One of the most visible changes in the classroom and school of today is the presence of computers and related technologies. Although technology has come to be recognized as an essential component of education, much
of that recognition in both k-12 and higher education has been demonstrated by the acquisition of computer hardware and software. This technology was often under-used because the teachers either did not have the appropriate software to use with their students, did not have access to enough computers for all class members, or just didn't have the time. A basic reason, though, was a lack of knowledge about how to use the computers and what those computers could help them and their students. Teachers needed to learn how to use the computers, but they also needed to learn to integrate computers and computer-related technologies into classroom activities and to develop a vision of the role of technology in education.

Technology Standards and Teacher Education

The importance of technology in education, and the need to prepare teachers to use it as an educational tool, is highlighted by the prominence of technology goals and standards for education and educators. At the national level, four goals (Educational Technology Goals, 2000) have provided a general framework addressing technology in the classroom in terms of accessibility, connectivity, integration, and teacher preparation. More detailed are the ISTE/NCATE National Standards for Technology in Teacher Preparation (ISTE, 1998), which have been used by many institutions to guide the integration of technology into their teacher education programs. As part of their National Educational Technology Standards (NETS) for Teachers (ISTE, 2000) ISTE has revised and expanded the earlier standards, to accompany the standards that they had developed for students. Many states also have been developing technology standards. Texas has just approved a set of Technology Applications Standards (SBEC, 2000) for which all educators will be accountable – and education programs are currently working on ways to assure their graduates will have the prescribed knowledge and skills to enable them to pass certification exams which will cover these standards. (Although there are eleven standards, only the first five are for all teachers. The others are for teachers of the high school computer science and technology applications courses such as web mastering, desktop publishing, etc.)

While standards suggest what skills and knowledge must be acquired, there is still the question of how and where. And that brings us to the often debated issue of the best way to teach technology in teacher education programs. This on-going debate has two (often opposing) forces – those who believe a separate technology course is essential, and those who consider it better to integrate technology throughout the curriculum. There are advantages and disadvantages to each. The integration approach will require coordination of content in different courses and different disciplines, to assure that all students received appropriate (and required?) technology experiences. On the other hand, a student taking a technology course may not consider using the technology skills and knowledge outside that class. A third option is to combine these two approaches, having students take a technology class, but also having technology integrated throughout the other courses in the teacher education program.

The Dual Approach

At Texas A&M University-Commerce, students in the preservice secondary education program complete introductory education courses and all or most of their out-of-education courses before their final two semesters, when they will have a year-long field experience. The first semester they will be interns, and then during the second, they will be residents – with increasing responsibilities for classroom activities ending with full student-teaching. One of the program goals is that the students use technology in their teaching (and other school-related) activities in a way that enhances student learning. Shortly after we instituted the intern/resident year, we introduced a technology integration course into the final semester, feeling that this would give students an opportunity to apply what they were learning in their university class when they were in their k-12 classrooms. We quickly found, though, that this was not adequate. Currently we use a dual approach, as described below.

Before entering the secondary education program, students must take an introductory computer course (ETEC 224) to provide them with basic computer skills to prepare them for the computer integration course as well as for computer-related activities in their other classes. Then, before their internship and residency semesters, they take ETEC 424 (Integrating Technology into Curriculum). Meanwhile, in their professional development sequence courses, technology experiences are integrated into the various courses. Although originally (as mentioned above) ETEC 424 was taught during the residency semester, it was determined that the students needed these technology skills in place before they began their classroom activities. Now, they acquire and practice skills and knowledge in ETEC 424, and then are expected to use these in their classrooms during semesters after they complete the course.

Key to the integration of technology throughout the program is the involvement of faculty, and we have
used the May, 2000 release of the Texas Technology Applications for all teachers (SBEC, 2000) as a way to find out what technologies are being used what students are expected to know before getting to specific courses, and what training faculty want and need.

Technology Skills

As we began our integration and alignment efforts in terms of technology in all courses, faculty members from the technology classes and the secondary professional development courses each reviewed the Texas Technology Applications Standards and indicated which they addressed in their classes and how. This provided us with a base, from which we could be sure that prerequisite skills were included in the appropriate computer course, and that all of the standards, including the 17 knowledge and the 66 applications statements, were addressed in one or more courses. Then, to get a better idea of what skills students came in with, and what they left with, we interviewed the faculty members who taught the first and last secondary professional development courses that students took. Information from those interviews is presented below, and is followed by a discussion of the technology classes and how the Technology Applications standards fit in with all of this.

The First Semester

The first professional development course students take is SHED 300 - a basic introduction to the teaching profession, which includes a field-based component where students go into the schools for 30-hours. Before taking this course, students must have completed a basic introductory computer course (either ETEC 224 or a similar course in another college). Therefore we looked at this course to see what technology experiences these students had in class, and whether all prerequisite skills were included in ETEC 224. The SHED 300 instructor submitted the following information.

Students entering the teacher education program possess a wide range of computer skills from computer programmers and repair technicians to the computer challenged. Some students have completed the required educational technology courses, others are simultaneously enrolled in the introductory teacher education preparation course and the educational technology courses, while others are planning on taking the educational technology courses in a future semester. This wide range of knowledge and abilities poses a challenge for the college instructors.

On the first day of class in SHED 300, students are required to submit their Early Field Experience applications to the Certification office by using a newly-developed on-line system. Using this application method within the first week of the semester greatly reduces the time to place students in the schools where they will be observing. It also gives them an initial experience in the use and value of technology.

Other uses of technology in the teacher education program include PowerPoint for class presentations, sending and receiving e-mail, submitting assignments over the Internet using attachments, searching web sites for lesson plans and other teacher topics, downloading TEKS (Texas Essential Knowledge and Skills - curriculum information) and ExCET (Texas certification examinations) information, and word processing programs.

The Last Semester

During the final semester of their certification courses, students are in the schools everyday, but come back to class for seminars several times throughout the semesters. University supervisors visit them in their classrooms each week, observing and conferencing with them. The instructor for the seminars, who also visited some of the students as supervisor, provided the following the technology uses in her classes, and in the students’ teaching activities in the schools:

When students come into the second half of student teaching they must know how to use the computer. They do extensive online searches for lesson plans at different sites to improve their lessons; they write journals each week about classroom experiences and send these to me via e-mail; they use WebBoard (posting messages and chatting) as an electronic forum to communicate with each other and their peers; and they practice testing skills online at state and university web sites.

They are expected to integrate technology into their lessons, providing interactive learning activities for their students. For example, one student used the computer to allow students to trace the steps to the Presidency. Students gathered information on the candidates as well as looked at the issues, as they progressed through the sites suggested by their teacher. Immediate vocabulary assistance was available – a student who did not know the
meaning of a word needed only to click on the word for an explanation. Student had fun while gaining information, and various learning levels were addressed.

In another unit a math student created a PowerPoint presentation on Scuba Diving to use with his students. First, though, he had his students create and present to the class their own PowerPoint presentations about famous mathematicians and other math related topics. This activity helped prepare these students for their instructor's presentation about how to use a profile in scuba diving.

Another math teacher used PowerPoint to show students how to take notes on math theorems. The students would later collect these, make note cards, and have a small math book of their own at the end of the year.

An ongoing use of technology for the residents is posting on WebBoard, where their comments can be read throughout the semester. This is a closed environment, open only to class members, so it is basically their online classroom, where they feel free to discuss issues openly with each other. At the start of the semester, each student's first posting includes answers to the following:

- Who are you?
- What district are you teaching in?
- What was your first lesson?
- Why do you want to teach?
- Discuss one thing that has surprised you most about teaching.

This helps students get to know each other, and also provides a place where the information may be found later when it is needed. Students also post reflections—over assigned topics or as 'free-writing.' This interaction helps student to overcome the isolation that some of them feel. One teacher said that it gave him a chance to know what his peers do in their classes—since his classroom was on the other side of the school. Away from most of the other classrooms, he felt alone. Students were also asked to share information about what they were doing in their classes, especially examples of how they were using technology. As they posted and read, they began to use each other's ideas, and when they came to the university for seminars they discussed what they had learned from their WebBoard exchanges. They were learning from each other, and it was not restricted to time in class. Technology (WebBoard) was enabling them to have this on-going forum that they could access from anywhere (provided they had Internet access) at anytime.

The Technology Courses

In the secondary teacher preparation program, students major in other areas, and only come to us for their professional development courses. When they come to us as juniors, they have already completed an introductory computer course—this is what some people refer to as 'basic computer literacy.' Course content includes how to operate a computer and to use basic computer applications—and includes all of the skills that students will need to perform the SHED 300 activities, described above. Because of the wide variety of skills possessed by the students, activities are often personalized—to encourage all students to go beyond their comfort level.

Before students enter their internship and residency year, they take ETEC 424, the technology integration course. There, they build upon the skills from their introductory course, with an emphasis on the relationship between learning and technology, and on ways to integrate technology into the curriculum. These are the skills that lead to the classroom activities observed by the instructor during students' resident semester. WebBoard, which was introduced briefly in the previous course, is used more extensively here, and the chat mode is introduced. The classroom/lab environment provides students with the opportunity to share and to learn from each other. Many students take this at the same time that they are taking SHED 300, and the observation hours for the SHED class prove helpful here, too, as they look specifically for technology use in the classroom (which is one of the required SHED observation topics).

The Standards

So how and where do the Texas Technology Applications Standards fit in? The activities listed by the instructors of the first and last SHED classes fall under several of the five standards that are for all beginning teachers. Those five basic Technology Applications Standards (SBEC, 2000) are:

Standard 1. All teachers use technology-related terms, concepts, data input strategies, and ethical practices to make informed decisions about current technologies and their applications.
Standard II. All teachers identify task requirements, apply search strategies, and use current technology to efficiently acquire, analyze, and evaluate a variety of electronic information.

Standard III. All teachers use task-appropriate tools to synthesize knowledge, create and modify solutions, and evaluate results in a way that supports the work of individuals and groups in problem-solving situations.

Standard IV. All teachers communicate information in different formats and for diverse audiences.

Standard V. All teachers know how to plan, organize, deliver, and evaluate instruction for all students that incorporates the effective use of current technology for teaching and integrating the Technology Applications Texas Essential Knowledge and Skills (TEKS) into the curriculum.

Under each Standard there are 3-5 knowledge statements, and 8-18 applications statements, for a total of 83 proficiencies. The challenge to our program is to provide every student with experiences related to each. Some of the content areas do a good job of integrating technology into their classes, but others do not, so we are addressing all of the standards (and their components) in the ETEC and/or SHED courses. To determine where we stand, a form listing the proficiencies and asking faculty to indicate which they addressed and how they did so was distributed. Input from those forms has been reviewed, and ETEC courses have been modified so that all students will have the skills needed for SHED classroom activities. Examples of the proficiencies and responses, demonstrating the differences between the two technology classes include:

1.3 Select and use software for a defined task according to quality, appropriateness, effectiveness, and efficiency.
   ETEC 224: Students will work in groups to evaluate basic categories of computer applications programs (word processor, spreadsheet, database, etc.); and to analyze advantages and disadvantages of each.
   ETEC 424: Students make software selections based on appropriateness/effectiveness for the task. They choose between word processing, database, presentation, scanning, and spreadsheet software.

2.6 Determine and employ methods to evaluate electronic information for accuracy and validity.
   ETEC 224: Provide students with real life problems to research and have them work in groups to evaluate the accuracy, relevance, appropriateness, comprehensiveness, and bias of their accumulated information, and to prepare a report of their findings.
   ETEC 424: Students learn to evaluate the information they retrieve from the Internet and electronic database for accuracy and validity. They learn basic rules to follow and to use with their students when they are teaching.

3.2 Plan, create, and edit spreadsheet documents using all data types, formulas, functions, and chart information.
   ETEC 224: Have students create a budget spreadsheet that would reflect their individual yearly, monthly, and daily real-life expenditures.
   ETEC 424: Spreadsheet – create a gradebook including intermediate formulas, charting, and data comparison.

4.8 Use telecommunication tools, such as Internet browsers, video conferencing, and distance learning, for publishing learning.
   ETEC 424: Students develop a web portfolio that is published on the Internet and also present their PowerPoint presentations via distance learning system on campus.

5.6 Identify and use resources to keep current with technology information.
   ETEC 224: Discuss as a group the sources of current information on new technology concepts and devices, and have students explore for and show examples to the class.
   ETEC 424: Students develop a list of resources to use as links on their web portfolio.

5.7 Create project-based teaming activities that integrate Technology Applications TEKS into the curriculum and meet the Technology Applications TEKS benchmarks.
   ETEC 424: Students locate the discipline-appropriate TEKS on the Internet and incorporate them into their collaborative WebQuest assignment.

The Future
Our initial examination of the standards and how they are addressed in our program, indicates that we are already addressing most of the standards and proficiencies in one way or another. Questions arise about what we need to add, and what we need to reinforce. Of utmost importance is the determination of what benefits students are deriving (and retaining) from these experiences. Classroom observations, as described above provide documentation that some students are taking what they learn and implementing those ideas.

An added bonus resulting from the Technology Applications Standards is that they may have a tendency to help encourage non-technology faculty to learn and then model use of technology in their classes. The more people use computers, the more comfortable they become, and the more comfortable they are, the more they learn, and the more they learn, the more they will undoubtedly want to use computers. The next question will be whether we can eliminate the computer literacy class, because people are coming in with such greater knowledge and skills in the computer arena. With the nature of technology, though, we may want to keep the course and update its content!

Conclusion

Technology is helping us to improve some things we have done in the past, but it is also helping us do things we never dreamed of. The various technology standards at all levels provide guidance for us in the ways that technology can be used to enhance instruction. This is definitely an exciting time to be teaching.

The Anatomy of an Educational Technology Seminar

Sebastian Foti
School of Teaching and Learning
College of Education
University of Florida
Gainesville, Florida U.S.A.
e-mail: sfoti@coe.ufl.edu

Abstract: In this case study, a group of advanced educational technology students “invent” methods that infuse technology into a dry, research-based history course. In the process, the students develop several products and create educational software for other students to use.

Recent research we have been conducting at the University of Florida suggests that educational technology courses have a high degree of cross-grade similarity from the elementary grades through graduate school. Educational Technology instructors seem to focus on what is hot (everyone is making web pages), rather than clarifying a vision of the discipline. One could make the case that the field changes so rapidly that instructors are simply trying to “keep up”, or that in times of rapid change practice precedes theory, but most current educational technology programs, including ours, have serious deficiencies.

Our students, for example, have very little knowledge of historical figures in education, and in educational technology. Although our program includes the study of innovation diffusion and change theory, students have an extreme lack of interest in historical change agents. As a response to this state of affairs, I recently decided to offer an Educational Technology seminar to investigate historical figures in education. I intended to make the course a pure research course, and foresaw no need to schedule computer lab time. My students, however, had other ideas. What follows is a description of how a group of self-actualized students can integrate technology into a course in meaningful ways, apply collaborative methods, and develop sophisticated, content-specific media for a larger learning community.

In the summer of 2000, at the first meeting of my seminar, I distributed a list of seventy-two famous educators, including about 25 contemporary educators to my class of eight students. I gave each student two weeks to write a one-page biography of each educator, meaning that each student would produce 72 pages of biographical information during the first two weeks of class. During the second session, we discussed some of the radical thinkers involved with education, and the passion of their beliefs. After a lively discussion, one student asked, “What are we going to do with all of our research?” Since the students in the seminar were all Masters and doctoral students that had been with me for a few semesters, they were comfortable with computers. “Let’s synthesize our individual pages into a biography for each educator and create a book for every member of the class”, said one student. Another said “No, let’s put it online so other students can study these people.” “Let’s do both!” said another. So they set up committees, divided up the list, and met to synthesize the pages and pages of information they had gathered.

At the next session, a student suggested that we create a database and enter the data about each person into this “Master” file so that we could generate web pages and the book from the same file, thus optimizing our error correction work. Another suggested putting the database online so that the class editors could work on the database from home. Then, someone had an idea. It started with “Hey, you know what would be really neat?” “What if we could make a game, kind of like the Millionaire game, and put it on the web, so that all the students could learn who these people are...” Another student said “Yeah, and people could use the game to study for their quals...”

During the weeks that followed, the students set up an online database for questions, answers, and hints, entered about 150 questions, designed the game (and redesigned it several times), programmed the game, posted it to the web, and continued to work on the other projects they had initiated. The fact that the magnitude of the
project was so great that it would take longer than the seminar lasted didn’t seem to matter. They would keep working on it until they finished it.

The class finished some projects before the class ended; others took until October (the seminar lasted until August). Seminar time was filled with discussions, watching videos about history, and making decisions about the products... hundreds of decisions about every aspect of the game, the databases, the web site for reference - and everyone was involved.

What is the goal of an educational technology class? How do 21st Century learners differ from their predecessors? How is it that educational technology students are often more interested in problem solving than in “how to get an A”?

I have come to believe that educational technology leaders need to have gumption. Once they decide not to give up, they have to become problem solvers. In order to do that they have to be able to make decisions...many, many decisions related to human-computer interaction, instructional design, screen design, and pedagogy. They must realize that a response or solution to a problem may be extremely complex and involve many layers of decision making. They must always have an eye on community - is there a way my work can benefit others - we are smarter and more prolific collectively than we are individually. Somehow, they must develop vision, and must be able to communicate that vision. It is cause for celebration that somehow, often in spite of us, our students seem to be doing these things, and learning these truths.

I couldn’t have designed a course that achieved the standards the seminar students set and achieved for themselves, but I believe that as we develop curricula, we must be concerned about more than topics. We must be concerned with developing leaders with vision and decision making ability, with gumption and a sense of community. It seems to be less about learning rules and more about enjoying a good, ill-structured challenge. Can we teach students to have fun being perplexed?

Come play the game: “So you want to be an Edugator?”

Technology education and integration: A position paper on attitude, perspective and commitment

Jerry P. Galloway
Indiana University Northwest
http://www.iun.edu/~galloway/
ian@jerrygalloway.com

Abstract: You cannot get a generation of non-computer-users to integrate classroom technology for children. Instead, enable teachers to become technology-users and classroom implementation will follow. This author suggests a relational link between (a) teachers' educational expectations, (b) computer educators' notions of how teachers learn computing, (c) what administrators believe teachers need, and (d) teachers' personal commitments to computing. It is suggested that this relationship accounts for the 25 year failure of technology integration.

The full expanded version of this paper is available on-line at: http://jerrygalloway.com/papers.htm

Based on a recent survey of parents and children (National School Boards Foundation, 2000) by the time children are teenagers, nearly three out of four are online using the internet. Our society is clearly becoming a nation online, a technological world, especially among children. While computers have been in our schools for more than a generation (since before the middle 70's), educators are still concerned with how to integrate technology into instruction. Why has this issue or goal not been successfully addressed among educators over the past 25 years?

Teachers in our society are expected to lead rather than follow children to mastery of the world in which they must live and work. If teachers are not leading, then children will inevitably learn on their own. As the rock-n-roll generation grew to adulthood, whose music was originally considered renegade, subversive or rebellious, that same music is now integrated into established adult society. Even elevators today play themes originally found on the 45 rpm records of adolescents. Young people from generations past, without guiding classroom leadership, brought with them elements of a culture exclusively their own and simply by virtue of growing to adulthood replaced established society with their own. The same is becoming true of the computer generation. Young people, learning technology without significant leadership from educators, are learning on their own. They have grown - are growing - to adulthood to establish a new cyber-society as a new standard. Unfortunately, educators are following instead of leading.

For a full generation educators have presumably been about the business of integrating technology. The tech-limitation of the novice teacher is as important today as 25 years ago. Being a total beginner to computing today is the same as 25 years ago. Certainly there is a kind of societal "tech-awareness" that is different today but not knowing is not knowing. Beginners are beginners. Society's cyber-development does little to provide an education for interested teachers who know nothing of technology. And, contrary to the mission of today's teacher trainers, you cannot get a generation of non-computer-users to integrate classroom technology for children. Instead, enable teachers to be technology-users and classroom implementation will follow.

However, teachers' perspectives skew their expectations and attitudes about computing experiences and limit if not preclude the achievement and acquisition of computing knowledge and problem solving skills. This author suggests a relational link between (a) teachers' educational expectations, (b) computer educators' notions of how teachers learn computing, (c) what administrators believe teachers need, and (d) teachers' personal commitments to computing. It is suggested that this relationship accounts for the 25 year failure of technology integration.

Quite common today, teachers expect recipes for using technology. Simply stated, they want to be shown how to do something with computers without actually learning to use them. Teachers invariably seek to be given procedures to follow, packaged lesson plans to implement, imaginative and representative applications of technology that they can carry back to the classroom and put into practice in teaching. This is a popular notion among many teacher and technology educators and seems on the surface to make sense. This idea as a goal for empowering teachers with technology for the benefit of school children seems quite appropriate at first glance and is thought to withstand any criticism as noble and obviously beneficial for the target group.
The problem of course is simply that this does not constitute learning anything. That is, the teacher (the technology user) never actually learns to be a competent user. This misconception about what it takes to successfully bring technology into teaching precludes experiencing concept-building and other valuable competence-building activities. That is, teachers resist those experiences that have no obvious classroom applications.

The intuition, problem-solving and critical thinking abilities consistent with learning and mastery are not commonly recognized as vital for classroom integration of technology. Such elements of education require one to change. To risk over dramatizing, becoming a competent user of technology involves a transformation as one acquires an education—a mastery. Teachers don’t want to change and prefer instead to merely pickup copies of their recipes and thus their mindset precludes being educated at all.

**Empower Teachers: A Prerequisite to Integration**

Leading the call for a focus on computer integration is a recent study that accounts for the current status of teacher technology-training programs across the United States (Moursund & Bielefeldt, 1999). Available equipment and beginner-level courses are thought to be sufficient for the purpose they serve but teachers still need more. The report recommends that computing instruction for teachers be integrated throughout the curriculum rather than isolated classes.

Educators should emphasize the importance of a personal commitment from teachers who are learning to use computers or who intend to use computers in teaching. Integration has failed to the extent that teachers have failed to personally adopt the computer in their personal and professional lives. This must change for integration to succeed.

Most commonly today, efforts at integration focus on helping teachers to use computers with and for classroom children. This might be fine for non-beginners and teachers well established in using technology but does not work for limited users or beginners. Empower teachers with technical skills, computing knowledge and intuition, and critical thinking skills in using computer technology. This is a prerequisite to focusing on technology integration into classroom teaching.

**Summary**

The goal is integration. The ultimate end is of course providing a state-of-the-art technological presence (instruction, resources, guidance, support, etc.) for school children. That’s the purpose of education and why teachers exist. There are funds available for staff development, equipment, education or training programs. In any event, those resources are typically directed to using computers with or for classroom children to the detriment of the teachers. This approach has failed for over 25 years. The point is simply that you cannot get a generation of non-computer-users to integrate classroom technology for children. Instead, enable teachers to become technology-users and classroom implementation will follow.

Training and education are not the same thing. Other disciplines find a more appropriate balance of skills, knowledge, understanding, and intuition. Science, for example, clearly involves training and skill development in order to successfully conduct experiments of various sorts. Yet, in Science such skills and training are clearly a means to a different end. Such skills are not the end in themselves. They support and make possible the development of a conceptual understanding, critical thinking and problem-solving skills. This must be true in educational computing and instructional technology as well if teachers are to continue to adapt to the quickly changing world.

Abstract: The goal of the Traeger Technology Target project is to provide the opportunity for pre-service educators, K-12 faculty, and university faculty to form a learning community. The project facilitates the following objectives: university undergraduates will begin to bridge theory and practice through the authentic learning experiences afforded only through classroom practice; K-12 faculty will share their expertise in the areas of curriculum development, instructional strategies, and classroom management with pre-service teachers; and, university faculty will facilitate the interactions between the pre-service and in-service educators while providing appropriate technology skills in a just-in-time setting for both groups. The theoretical framework for this project is profoundly constructivist and supports the notion of service learning.

Introduction

The traditional instructional technology course of many preservice teachers' experience is undergoing a fundamental change. Just as K-12 educators have come to reconsider the traditional placement of computer technology in central lab facilities, so also are colleges of education beginning to question the wisdom of isolating digital technology as if it were a separate subject area rather than a rich tool for facilitating student learning. Current NCATE standards focus on the need for university faculty to model the use of technology throughout the undergraduate education student's coursework. However, many university faculty are in much the same position as their secondary counterparts. Faculty at both the secondary and higher education levels face both intrinsic and extrinsic barriers to implementing the use of technology in their classrooms. Brickner (Ertmer & Hruskocy 1999) proposes that extrinsic barriers include lack of access to computers and software, insufficient time to plan instruction, and inadequate technical and administrative support while intrinsic barriers may include beliefs about teaching, beliefs about computers, established classroom practices and unwillingness to change.

While university faculty struggle to learn technology skills as well as the means for integrating curriculum with technology, the stand-alone course, properly conceived, may continue to serve as a vital area of focus on the application of technology to curriculum. The challenge for the instructor of that course then becomes to consider how linkages can be created between the university students, the course concepts, robust content, and the K-12 classroom. This experience can be significantly enriched when genuine efforts are made at creating a learning community consisting of university undergraduates, university faculty, K-12 faculty and their students. University undergraduates can assist K-12 teachers in the design of instructional materials, student instruction, and web resources while the K-12 teachers assist the undergraduate students in creating units of study that include logical use of available technology resources and real-world application of technology skills.

The Traeger Technology Target (TTT) project engages a University of Wisconsin Oshkosh instructional technology class of 24 undergraduate students in a collaborative project with four educators teaching multiage fourth-fifth grade classrooms at Carl Traeger Elementary School. The project spans two semesters - fall 2000 and spring 2001 - and thus two different groups of undergraduate students. The project provides an authentic opportunity for university students to apply technology knowledge and skills acquired during their university class in an environment that fosters the connection of theory and practice. In turn, the practicing educators at the elementary school develop an increased awareness of the technology resources available at the site, their application, and have the time to consider how to integrate that technology with their curriculum. Elementary students benefit from the continual assistance of the undergraduate students in their
portfolio development, literature circles, and the use of the World Wide Web as a learning tool. University faculty remain available to all Traeger teachers in the consideration of curriculum-technology integration. A balance is sought whereby undergraduate scholars, university scholars, and teacher scholars may begin to truly address the four components of scholarship at all levels: teaching, discovery, integration and application (Boyer 1990).

This collaboration benefits all participating groups in a manner consistent with the notion of service learning whose relevance at all levels of education has been affirmed (Lynton 1995). The literature on service learning supports the view that educational institutions from elementary school through higher education must develop formal relationships with one another that mutually benefit all concerned. It is envisioned that this project may serve as consideration by other instructional technology courses as it seeks to build a learning community with the shared purpose of improving education for all students.

Additionally, the ISTE National Educational Technology Standards for preservice teachers repeatedly stress the critical need to provide the opportunity to link theory with concrete field experiences. Specifically, this is found in the essential conditions of the document within the shared vision, skilled educators, professional development, student-centered teaching, and community support areas.

Background

The University Instructional Technology Course

The junior-level, three-credit instructional technology course in the College of Education at the University of Wisconsin Oshkosh has been in a state of transformation over the last five years consistent with the prevalent view of technology as a powerful learning tool for students. Originally conceived as a stand alone, skills acquisition course, it has been afforded the opportunity to evolve into a course focusing on the integration of curriculum and technology. This change in focus has been made possible (and necessary) because of the implementation of a prerequisite requirement to the course that focuses entirely on computer skills, by the increasing sophistication of the undergraduate students themselves, and by the needs expressed by surrounding school districts. Various strategies have been implemented with one of the most successful being the linking of one section of instructional technology course with a corresponding secondary level methods course (i.e. social studies, science, math, etc.). Students are co-enrolled in both course sections, usually in back-to-back time periods which affords ample opportunities for interaction between both the methods and technology course objectives and professors. However, such a structure for the elementary pre-service teachers has not been found to be suitable given the parameters of the program structure.

The instructional technology section that participated in this project during the fall 2000 semester consisted of 24 junior level students. Fifteen of these students were pursuing elementary licensure exclusively, 5 were pursuing dual licensure in special education and elementary education, while the remaining four represented combined elementary and secondary licensure in music, physical education and Spanish or ESL. Students were not notified of the intensive off-campus component of this course section prior to enrollment and were given the option of transferring to other sections after the first class meeting. Of the original 27 students enrolled, three transferred with the remaining 24 students enthusiastically opting to stay with the project. They were cautioned that this project represented an untried formula for both the college and the elementary teachers and that the design would be evaluated at iterations by all parties and modified based on most current feedback.

Carl Traeger Elementary School

Carl Traeger Elementary opened in 1997 and serves almost 600 students in kindergarten through fifth grades. It was originally designated as a technology-intensive school and has a large computer lab as well as small minilabs located in each of the learning pods throughout the school. The principal is very supportive of technology as one of the many hands-on experiences afforded students. Teachers at the school are acknowledged within the district as innovative and creative and are proud of their use of a variety of instructional strategies aimed at encouraging student excellence according to individual abilities. The elementary school is physically attached to Carl Traeger Middle School and benefits from both enhanced facilities and placement opportunities for students. Unique to the school is the availability of both multi-age and grade level classroom configurations.
Four teachers at Carl Traeger elected to participate in the TTT project. These teachers team-teach in pairs; each pair has 48 fourth and fifth grade students in a classroom consisting of two large instructional spaces joined by a common student area and a common teacher office. Thus the entire project dealt with four teachers and 96 fourth and fifth grade students.

**Project Design**

The impetus for the Traeger Technology Target project came from the Preparing Tomorrow’s Teachers to Use Technology Capacity Building Grant received in 1999 by the College of Education and Human Services. Part of that grant specified the need to design means for undergraduate students to observe and practice curriculum-technology integration throughout their years at the university. Thus funding was available to pay stipends to the teacher participants and to support transportation between the two sites. Cooperating teachers were recruited through another grant initiative, Wisconsin Regional Instructional Technology Support, that affords districts the opportunity to provide constructivist technology workshops given by outstanding area teachers.

University faculty and Traeger faculty met at intervals during the summer to discuss the direction of the collaborative effort. Central to these discussions was the expression of the needs of the various project constituents. University faculty desired an authentic context for the work done by their undergraduate students with content that was directly from the field and applicable to a real classroom setting. Traeger faculty wanted assistance in designing published background materials for parents of their students, ideas on how the World Wide Web could assist their own teaching and their students’ learning, and assistance on instructing students on various software applications. They also expressed the need for planning time to develop units of practice that made use of technology tools and a curiosity about electronic student portfolios. As these needs emerged the context and content evolved for the university undergraduates.

Based on stated needs, an ambitious project was developed with the full understanding of all faculty involved, and eventually undergraduate students in both the fall and spring semesters, that various components would be distributed over the two semesters. That is, the second semester would build upon the experiences of the first, independent of the fact that the university class composition would significantly change.

The university undergraduate students were initially divided into four production teams. Each team was assigned to one of the four mentor teachers. This facilitated e-mail communication while providing the structure that enabled development of brochures, literature circle journal partners, and a unit of practice. At various times throughout the semester, the students were rearranged into pairs to develop webpages and HyperStudio stacks. Students also worked one-on-one with 4/5 students in development of PowerPoint student portfolios.

To be respectful of the travel time required between the university and the elementary school, every effort was made to keep elementary site visits confined within the time period of the university course. While the instructional technology course meets twice weekly for an hour and a half, there are twenty-minute breaks on either side of the course. Most students found this to be ample time to get to the elementary school. Teams were not scheduled to visit the school all at the same time; that is, work teams one and two might be working at the elementary school while teams three and four remained at the university working in the lab. This minimized the confusion and influx of numbers at Carl Traeger School. The only time that all teams visited the elementary school at the same time was on the last day of class in the university semester that served as a time for community sharing and celebration.

**Project Components**

The following tables outline the artifacts originally proposed for the collaboration, the process involved in those projects, and correlates the product with both the university class need and the 4/5 classroom need.

**Discussion**

As of the submission of this paper for publication, the first semester of the Traeger Technology Target is just two weeks away. Six out of the seven artifacts detailed above were accomplished during the semester. Given lab size constraints at the university, it was decided to implement the PowerPoint electronic portfolio during the first semester with 48 of the elementary students and to implement the HyperStudio project in the spring semester with the remaining elementary students.

Feedback obtained throughout the semester from the undergraduate participants has been overwhelmingly positive. One student, when reflecting upon the opportunity to work with the elementary students in the college computer lab, said, "This is the first time I've ever seen kids in this building. This is the way it should always be...we can learn so much from them - more than they could ever learn from us!" Another stated, "I was so scared because I wasn't that sure of myself with PowerPoint...but my student and the kid next to him were both familiar with it so they taught me some things. I can see from this that technology is an area that I must be willing to become the learner in, which is all right. Since I didn't have to teach them to do the program, I could spend lots of time talking with them about their accomplishments during the nine week period." One young woman summed up her experience, "My students did not know how to do anything with the program [PowerPoint] but they did come with their portfolio information up-to-date and their experiment photos on disk. It was difficult for me to keep my hands off of the keyboard - to allow them to make their own mistakes and learn on their own. Ultimately, however, this was for the best because they learned from one
another rapidly and we could spend a lot of time sharing what they had learned from the experiences they chose
to illustrate in their portfolio."

The elementary aged students were proud to have been associated with the university undergraduates
and were particularly thrilled with the opportunity to "come to school with the big kids". In viewing one of the
web pages created as a resource for Jean Craighead George's book My Side of the Mountain one elementary
student remarked, "This website is really easy to read...it has some ideas that I think I'll use for my final
project." One student, while presenting her portfolio to her undergraduate partner, stated, "I would never have
been able to finish this without your help....My dad was so impressed and didn't really believe that I knew how
to do all that stuff until I sat down at home and showed him!" Another added, "I haven't shown my parents yet
but I'm glad I'll get the chance to practice here - it's fun to see all the stuff I've done this year in one place - the
year's just beginning and I already have a whole lot!"

The teachers at Carl Traeger Elementary are pleased with what has been accomplished this semester
with their fourth and fifth grade students. They feel the collaboration has been beneficial to them as well. One
educator enthusiastically endorsed the project saying, "As a new teacher, I remember desperately wishing that
I'd had more opportunities to work with students while I was an undergraduate. I think that we have a
responsibility to mentor these students and provide for them the experiences so necessary prior to entering a
classroom." Another noted that undergraduate students have so little experience on which to apply theory and
mused that perhaps an apprenticeship approach would better serve the profession rather than the traditional
student teaching model.

**Conclusion**

It would hardly be possible to offer an informed conclusion to this project as only twelve weeks of the
expected twenty-eight week project life have been completed. However, at this juncture, the project has been
successful in engaging undergraduate students with authentic content and experiences within four elementary
multiage classrooms. The fourth and fifth grade students in those classrooms have benefited from the presence
of the undergraduate preservice teachers. The faculty participants at Carl Traeger Elementary are pleased with
the informational materials published by the students, the provision of an authentic context for World Wide
Web and telecommunication usage by their students in their literature circle discussions, the affordance of
instruction in software programs by the undergraduate students, and the opportunity to share their expertise and
experiences with the next generation of teachers. Preservice undergraduate students, university faculty,
practicing educators, parents, and students: the Traeger Technology Target is beginning to foster a learning
community.

Abstract: This paper is intended to provide educators with a basic understanding of the creation, development, and implementation phases of on-line exams. The content includes an overview of on-line exams to explain the specific features and the advantages and limitations of this medium. Design and development are also presented to explain the different test development tools. The implementation phase covers areas of administration and distribution based upon personal experiences.

As the impact of Internet grows in education, more educators have turned toward computers as an instructional vehicle for delivering courses and course materials. There are three categories concerning the use of Internet in teaching and learning: (1) utilizing specific attributes of the Internet in creating supplemental on-line materials, (2) developing inclusive courses in which students take on-line, and (3) offering complete degree programs on-line. Regardless of the category in which these educators fall under, the Internet will be a major factor for delivering instructional materials to learners.

The use of computers in teaching and assessment already has a considerable history within education and training. However, the rise of the Internet presents new opportunities for many aspects of education, particularly assessment. With the Web technology, it is possible to construct on-line tests that are: (a) available beyond the walls of the classroom, (b) independent of paper or other physical resources (apart from a computer and access to the Web), (c) immediately graded with assurance of objectivity, and (d) used for formative or summative purposes (Dalziel & Gazzard, 1998).

The purpose of this paper is to provide educators with basic information and resources concerning the development and implementation of on-line exams. The paper is organized into five areas of discussion. First, an overview of on-line exams will be provided to assist readers in understanding what it can provide and the features pertinent to on-line exams. Second, a review of advantages and limitations of on-line testing will be given. Design issues such as layout, flow, and planning will be the third area. The fourth area touches upon the development phase that includes a discussion of related software and on-line course authoring tools. Finally, the implementation phase will cover areas of administration and distribution based upon the authors' personal experiences.

Introduction

Interactivity on the Internet is one component that educators have been drawn to recently. On-line assessment has been growing in popularity and educators have been exploring different ways in which exams could be delivered to students on-line.

On-line exams are simply defined as a mode of delivering tests, quizzes, and surveys via computer in a synchronous or asynchronous mode. An example of a synchronous environment would consist of students taking the on-line exam during class time where the teacher can monitor students' behavior. An asynchronous environment is where students are taking the exam at their own chosen time and at their own pace either in a monitored (e.g., testing center, library, school computer lab) or unmonitored (e.g., home, work) situation.
Web-based assessment provides a way to administer, grade, and record a test via the Internet. Students can easily take the test by accessing the Web site. They enter their names and other information like an ID number and password. They are then presented with the test. When students have completed the test, they click on a “submit” button. Immediately, the test is graded and the results are shown. Questions answered incorrectly are shown with the option to reveal the correct answer in company with a brief explanation supporting the correct answer.

The types of on-line exam questions vary and are dependent upon the purpose of the exam itself. Most commonly used types are the true-false, multiple-choice, and fill-in question objects. Most on-line test development tools provide educators with a way to create questions and assign answers with individual scores. These question types can be graded automatically. Another question type is the short-essay. Short-essay questions cannot be graded by the computer, and thus, requires the instructor to grade the question individually. However, scores obtained from the short-essays can be added automatically to the scores from the computer-graded exam questions. Thus, writing for an exam to be delivered on-line do not vary much from the paper tests except that now the student and teacher both need access to a computer with Internet connection.

**Strengths and Weaknesses**

On-line testing has several advantages. For one, on-line testing is not restricted to time and place. On-line testing has the ability to deliver tests efficiently and effectively in asynchronous mode. Thus, timeliness is an advantage that educators have been drawn to as a result of on-line testing. Convenience and access are added benefits to non-traditional students.

Immediate feedback is an area of importance for many educators who have adopted the Internet as an assessment vehicle (Kibby, 1999). Allowing students to view how well they performed on exams is an excellent way to reinforce learning, a feature found with most on-line assessment tools. Once students complete the on-line exam they can immediately examine their performance by viewing their overall score and discern which questions they answered wrong and find what answers were correct. In addition, instructors can add personal feedback to on-line questions to help the learning process. For instance, if instructors not only want their students to view the correct answer but explain why that answer is the right one, on-line assessment tools can provide that extended, immediate feedback. This way, students will remember the question more if the feedback occurs directly after completing the exam as compared to reviewing the exam a week later (Jonassen, 1988).

Interactive multimedia is another advantage of on-line testing. The primary strength of on-line testing in this area is to allow educators to create test items that incorporate other types of media besides text. On-line exams can incorporate visual, aural and interactive components. Multimedia elements such as charts, graphs, photos, animation, audio, and video can all be incorporated into the on-line exam.

Student tracking is a feature of on-line exams that can be of an asset to teachers (Juchnowski & Atkins, 1999). For teachers, on-line student tracking can provide them with information such as date and time in which students accessed the test site. It can also tell teachers whether students have made several attempts at taking the exam. Finally, student tracking provides teachers with information such as the length in which the students took the test. This could be beneficial in assessing whether an extended time-length could be a result of the student not understanding the material, especially when other students completed the exam in half the time.

On-line testing also provides statistical analysis that has been traditionally done by hand or calculator. Many test development tools provide instructors with the option to calculate the test scores for each student and provide an electronic grade book for all the students. On-line testing programs also provide instructors with other statistical analyses such as means, modes, medians, standard deviations, and item analysis on each test item.

In short, on-line testing can provide students and teachers with timeliness and convenience, the opportunity to increase retention through feedback, provide interactive multimedia to maintain interest, track and manage test scores, and obtain computerized statistical analyses. For these reasons, the use of on-line testing has experienced a significant increase and will continue to flourish in years to come.

On-line testing does have several limitations worth mentioning. Time is a major factor in developing on-line exams. It requires a large pool of test items to be effective. Not only do instructors have to learn the test development tool, but they also have to develop the exams and upload them to the Internet. Network and server complications can cause a student to end the test prematurely and the
educator can lose all of the student's scores. This can double-up the management responsibilities of the instructor, and thus, take time away from the workday. However, once the exams are placed on-line, developing and implementing the exams are no longer a concern because the instructor can always modify the exam later.

On-line exams can also be impersonal (Juchnowski & Atkins, 1999). Often times, students take the on-line exams alone. If students are in a monitored situation (e.g., a librarian monitoring the exam period) with other students, the feeling of isolation will not be as overwhelming. In addition, students often do not get the chance to ask for clarification on puzzling questions as they would in a classroom environment. This can lead to student isolation and disenchantment that will hinder the student's academic performance and success.

Student integrity and cheating are other concerns for on-line testing (Juchnowski & Atkins, 1999). The common question that educators ask with on-line testing is, "How do I know whether the student sitting behind the computer is who she/he says they are?" The bottom line is that you will not know. Cheating is something that cannot be resolved either in an on-line environment or in a classroom. Although no one can guarantee that students taking on-line exams are not cheating, this should not sway educators away from using the medium because of the other advantages that on-line exams do provide.

Overall, although on-line assessment tools do have its limitations such as time consumption, remoteness, and student dishonesty, on-line assessment tools should not be disregarded. Depending upon the instructional situation, on-line exams can increase teacher productivity with better accuracy. For students, convenience and interactivity are major factors toward academic success.

Design

Creating and designing on-line exams are quite simple. In the past, educators had to know programming to create on-line exams. However, with the proliferation of the Web, there are many tools available to assist educators with various degrees of technical abilities to create on-line exams. Traditional instructional design models work well in terms of designing and developing on-line exams. The ADDIE and ASSURE (Heinich, Molenda, & Russell, 1993) models are the most popular and are similar in the way they present the steps toward designing and developing instructional materials, lesson plans, and in this case, on-line exams. In short, the steps toward designing on-line exams should include (a) assessing the learner, task, and learning environment, (b) generating objectives and goal, (c) designing the on-line exam and how it should be presented and delivered, (d) creating the actual on-line exam by writing test questions and developing the testing program, (e) implementing and delivering the on-line exam, and finally, (f) assessing the effectiveness of the on-line exam.

In the design phase, things such as layout, flow, and feedback should be considered. Depending upon the tool being used to develop the exam, the educator can have either some or an abundant amount of freedom in how he/she wants the on-line exam to look like, the types of questions to be included, and how the program will respond to students' answers. The following are design guidelines for those who are designing on-line exams:

- Keep the background design consistent for the entire exam and use a background that is not too busy such as textured patterns and those having more than two colors.
- If different types of questions (e.g., multiple choice) are used, keep the types grouped together and reserve the fill-in's and short answers toward the end.
- If feedback is provided to the student (e.g., telling students which is the correct answer and explaining why), the feedback should be presented at the end of the exam to prevent disruption.
- Use uniform placement of questions and answer choices (e.g., if answers are given on the right side of the first slide, then answers should always be presented on the right side).
- When working with fonts, keep the font style and typeface consistent, avoid double emphasis such as simultaneously bolding and underlining a word, keep colors to a minimum, and use the largest size of font for readability considerations.

These are considerations that one must observe when designing on-line exams. A few others are worth mentioning such as limiting the number of questions to be asked at one time to avoid student fatigue and writing questions that are succinct and to the point. The later point is important because students who take on-line exams do not have the luxury of asking for clarification on confusing questions or unknown
terms. Hence, the design of on-line exams is critical to the success of the student, and thus, need to be taken seriously.

Development

Though there has been a growing array of software tools being developed for creating computer-based tests, many tools have been developed recently to facilitate the teachers in authoring, delivering, grading, and analyzing the tests on the Web. The selection of the software determines the placement of the question and answers, how the feedback will be provided, whether the score is shown to the student, the type of background design used, the style of fonts, and whether any multimedia or graphics is used. In general, there are five categories of tools that can assist with the development and delivery of on-line exams: (1) CGI (Common Gateway Interface) programs, (2) JavaScripts, (3) commercial testing programs, (4) authoring software, and (5) on-line course authoring tools.

CGI is a server-based method that can be used to implement on-line testing. There are a great number of CGI programs available on the Web and many of them are free. Exam Mail [www.oyston.com/ExamMail/home.html], Simple On-line Interactive Test-generator (SOIT) [www.cals.ncsu.edu:8050/soit/], Web Test [ftp.uwaterloo.ca/WEBTEST/], and Web Exam [www.admin.northpark.edu/imartin/WWWAssign/] are some examples of the CGI programs for creating on-line exams. The advantages of CGI programs are: (a) the scripts will work with virtually any browser, (b) permit interactivity between a client and a host operating system through the Web, and (c) the scripts allow the creation of a test report or a follow-up messages to the learner. The primary disadvantage of CGI scripts is that the teacher must be more knowledgeable about computers and be able to edit the CGI scripts to get them to work. Often, some technical assistance will be needed to identify sever paths, etc. or install the scripts to the server. Some institutions also have strict rules for installing CGI scripts for security reasons. In addition, CGI programs are well suited only for presenting basic types of tests. More advanced and interactive types of tests (e.g., tests which involve drag-and-drop activities) cannot be implemented with CGI programs (Brusilovsky & Miller, 1999).

JavaScript is an interpreted scripting language that is embedded with HTML code to develop interactive Web pages. JavaScript processes information on the client side and works with all browsers. Most of the processing such as checking the correct answers takes place on the users' browser. It is most suitable for creating tests with multiple-choice, fill-in-the-blank, and true-false type questions. The main advantage of JavaScript is that form validation can be built into provide immediate feedback to the students. However, the major disadvantage is that the source code cannot be hidden (Hazari, 1998). A learner can easily find answers from viewing the source code of the page. In addition, there is no way for recording the test results. Thus, the JavaScript-based exams are more appropriate for self-assessment than for assessments used in grading (Brusilovsky & Miller, 1999). There are many pre-designed JavaScripts that are made freely available for educators to use and customize. Examples of these include CASTLE [www.le.ac.uk/castle], Hot Potatoes Web Authoring Tools [web.uvic.ca/hrd/halfbaked/], Quiz Maker [www.attotron.com/pub/QuizMaker.html], and On-line Exercises System [math.uc.edu/onex/demo.html].

Besides using CGI and JavaScript, commercial testing programs are also used to create and deliver on-line exams. These software are designed specifically for developing on-line exams. Generally, they are user-friendly and provide manuals and technical support. Some examples of commercial testing programs are Question Mark [www.questionmark.com], Interactive Test [www.interactivetest.com], Quiz Factory [www.learningware.com/quizfactory/], and Quiz Maker [www.mrtc.org/~twright/quizzes/quizcenter/].

A few authoring software that have the capability of providing on-line exams are ToolBook [www.click2learn.com] and Authorware [www.macromedia.com]. There are others, but ToolBook will be discussed in more detail because of our personal experiences with this. Advantages of using ToolBook include easy uploading of files to the server and the freedom to personalize the exam. Though the software is mainly intended for creating training modules or lessons, computer-based exams can be created and uploaded to the server, and thus, become on-line exams.

When creating exams in ToolBook, educators have the choice to select (a) the types of questions to use, (b) how the exam will be graded (e.g., point over a percentage value, grade each question individually as the student progress or wait to tabulate scores at the end), (c) how many points will be allocated to correct responses or subtracted for wrong answers, (d) whether feedback is given at all, and (e) randomization of questions so a student will not see the same order of questions more than once.
Uploading of the exam to the Web server is quite simple. ToolBook has its own Distribution Wizard that allows an educator with three choices: save as an .exe program, convert files to HTML and DHTML pages on the hard drive, and upload all pages directly to the server. ToolBook has a lot of dynamic HTML options in its program and has made it easy for the educator to upload files by automatically converting the files and including extension programs that are required for DHTML to work properly on the server. However, authoring software like ToolBook is expensive and requires a steep learning curve.

Examples of on-line course authoring tools include WebCT [www.webct.com] and Blackboard [www.blackboard.com]. These tools are provided on-line and educators have to be connected to the Internet to gain access to these sites. WebCT and Blackboard have their own design layout and instructors do have the options to change certain features such as the style of buttons and what buttons provide. However, the layout is consistent for all course sites. One major advantage of using these tools is the template. The on-line course tools contain primarily of templates that educators fill in with either typing the test items or uploading documents and files from the hard drive. No HTML programming is necessary. It is merely just filling in the blanks.

The only drawback of using on-line course authoring tools to create exams is inflexibility. The layout of the on-line exams is the same. Multiple-choice, true-false, fill-in, and short answer questions can all be used, but the appearance will be the same no matter which course Web site you are accessing. Feedback is possible, but it can only be given at the end of the exam. In addition, students have to scroll down to answer questions that may not appear in the window. This can be distracting and cumbersome. Thus, limiting the amount of questions for each exam needs to be done. Nonetheless, ease of use and economic convenience are reasons why educators should investigate on-line course authoring tools as an option for developing and delivering on-line exams.

Implementation

Administration and distribution are critical for successful implementation of on-line exams. Certain factors need to be addressed ahead of time before making the final leap to offer exams on-line. Based upon personal experiences, these are just a few of the areas that need to be investigated before deciding to deliver exams on-line.

Network capability is the first area of consideration. There are several aspects that instructors must examine. First, one must find out whether the server he/she is uploading the files to is software-friendly. In other words, will the server be compatible with the chosen test development tool. For instance, many school servers have strict firewalls that do not allow certain scripts or Applets to be used because of security reasons. Second, one must consider the computers that the students will be using. Assessing whether students have access to the proper equipment, and even the proper browser and plug-ins, is important. If students cannot gain access to the on-line exam, then the whole purpose of offering on-line exams in the first place is defeated.

Staffing is another important issue concerning the implementation of on-line exams. The instructor may not be the only one responsible for administering and delivering on-line exams. Others may include teaching assistants, administrative assistants, and test monitors (e.g., testing coordinator, librarians) who need to be trained. If students are required to attend a facility in which their exams are to be monitored, then the other individuals will come into play. In short, when on-line exams become a heavy part of the curriculum, others will eventually become involved.

Support is vital toward the success of delivering and administering on-line exams. When situations arise that require troubleshooting, a supportive and competent technical staff is important. Often the companies that provide the software or on-line course authoring tool provide support, but that support is not always immediate or even effective. Thus, instructors need someplace else to turn for assistance. In addition, not only do instructors need assistance, but students. If students are taking the exam in a monitored situation, it is important that the test facilitator or librarian knows how to use the program (Kibby, 1999). Problems will arise if the monitor does not know anything about the program students are using. No matter who is the monitor, students will consider that person as the instructor and expect the same. Therefore, the support structure must be considered before implementing on-line exams.

Student integrity is the final area of consideration. Issues surrounding cheating and plagiarism exists with on-line exams as they do for in-class exams (Juchnowski & Atkins, 1999). No one will ever circumvent cheating, and thus, should not be used as an excuse to denounce on-line exams overall.
However, student integrity is an issue and needs to be approached carefully. One suggestion is to develop the on-line exam with the intention that it will be offered as an open-book or take-home test. Although the exam may not be open-book, one must consider the fact that students will be taking these exams on their own, even in a monitored situation, and will have the opportunity to cheat. Thus, one might even consider on-line exams as take-home tests, thus eliminating instructor’s concern of deception. In short, if the assessment requires strictly controlled conditions and requires a high degree of security, then delivering exams on-line should not be performed (Kibby, 1999).

There are many more issues that involve the implementation of on-line exams. However, network capacity, staffing, technical assistance, and student honesty are major concerns that have been brought up repeatedly. For these reasons, educators must have a contingency plan to deal with unforeseen technical difficulties such as the server being down and for handling disciplinary issues. As long as the educator is aware of these problem areas and anticipates such obstacles ahead of time, then the implementation process will be much more successful.

**Conclusion**

Testing has always been an important part of the instructional process for traditional classroom courses as well as Web-based courses. The goal of testing is to determine if learning objectives have been accomplished by providing feedback to the instructor of what students are understanding and the areas that need further explanation or clarification (Hazari, 1998). Assessment is also a powerful motivator of student learning. With the rise of the Internet, Web-based assessment has also grown considerably in education. Appropriate use of Web-based assessment can play an important role in student learning while at the same time reducing teacher workload. Many authoring tools are now available to facilitate educators in authoring, delivering, grading, and analyzing tests on the Web. Web-based assessment has demonstrated its ability to deliver exams efficiently and effectively at anytime and anywhere. Thus, on-line assessment will continue to grow in years to come.

Abstract: Twenty-two preservice teachers involved in a cohort group were enrolled in both an educational computing class and a curriculum development class in the same academic quarter. The instructors for both courses collaborated their teaching efforts whereby the preservice teachers used the educational computing class to research, record, and document their experiences in the curriculum development course. The theme of the curriculum class was therefore used as an anchor for the educational computing class. This paper describes how the technology instructor structured the educational computing class around this anchor. It also describes the lessons learned from this collaborative experience. The paper includes some reflections from the preservice teachers that highlight some advantages of this collaborative process from the preservice teachers' perspective. The paper concludes with suggestions for implementation of similar teaching designs to allow other technology instructors to take advantage of the benefits of anchored instruction in teaching technology to preservice teachers.

Introduction

The infusion of information technology into the teaching and learning process is challenging to preservice teacher preparation programs. Yet these programs are viewed as the most direct and cost-effective way to prepare the approximately 2 million new teachers who will be teaching in the next decade (National Council for Accreditation of Teacher Education [NCATE], 1997).

Although institutions of higher education vary in their specific responses to this challenge, most institutions require at least one educational computing course as a core component of their teacher preparation programs (Leh, 1998). Such courses play a critical role in introducing preservice teachers to fundamental information technology components and skills (Kim and Peterson, 1992).

In a recent study, Leh (1998) studied design and structure of educational computing courses in teacher preparation programs. The study indicated that each university has its own way of preparing their students for the use of information technology in educational settings. The structure and content of the courses also vary from one university to another. One approach to the design of such course involves using a theme or anchor around which various learning activities take place. This approach has been referred to as "anchored instruction" (Bransford, Sherwood, Hasselbring, Kinzer, & Williams, 1990). This model provides learners with a "situated, authentic and social learning environment" which encourages problem solving (Shih, 1997).

Anchored instruction has been suggested as a model of instruction that "can be used to show preservice teachers how to integrate appropriate technologies in their teaching..." (Bauer, 1998). This paper describes the experiences of a cohort group of preservice teachers who used their curriculum development course activities as an anchor in their educational computing class.
Using Coal Project as an Anchor

Twenty-two preservice teachers involved in a cohort group were enrolled in an educational computing class and a curriculum development class in the same academic quarter. In the curriculum development class the preservice teachers worked with a class of eighth graders in a local Junior high school. The eighth graders were involved in an expeditionary research project in the local community. In the project the Junior high school students, together with their teacher, researched the question of whether a local controversial coal mine should have been reopened. The students gathered different perspectives from the local community. One way was by visiting and interviewing different groups of individuals in the community. In the end the students presented a readers theater depicting the different voices represented in the coal mining controversy.

The preservice teachers accompanied the eighth graders in this coal project expedition to learn along, and from, the experiences of the eighth graders. They worked together with the eighth graders (as learning teachers) to plan the field trips involved, prepare interview scripts, and to prepare scripts for the readers theater. In the educational computing class the preservice teachers were involved in hands-on sessions where they learned how to use various technology applications for personal and professional use as teachers. These applications included Word processing, KidPix, PowerPoint, Database, Spreadsheets, and Hyper Studio.

The technology course and the curriculum course instructors collaborated their teaching efforts whereby the preservice teachers used the educational computing class to research, record, and document their experiences in the expeditionary learning process. The theme of the curriculum class was therefore used as an anchor for the educational computing class. This paper describes how the technology instructor structured the educational computing class around this anchor. It also records the lessons learned from this collaborative experience. The paper includes some reflections from the preservice teachers that highlight some advantages of this collaborative process from the preservice teachers' perspective. The paper concludes with suggestions that other technology instructors can draw from to implement similar teaching designs that would allow them to take advantage of the benefits of anchored instruction in teaching technology to preservice teachers.

The two instructors involved in this teaching experience conducted a study of their collaborative teaching activity for the purpose of improving instruction in their respective areas. A qualitative inquiry was used to gather data. The instructors kept daily journals of their experiences. At the end of the quarter, each preservice teacher wrote a reflection paper based on the collaborative learning experience. The journal and the reflective papers were the main sources of data.

Structuring the Technology Course Around the Anchor

The goals of the educational computing were based on the ISTE standards which aim at preparing teachers to use technology for acquisition of basic computer/technology operations and concepts, personal and professional use of technology, and integration of technology in instruction. The preservice teachers spent some time learning the skills involved in using various applications. This was followed by activities that gave them opportunities to practice the use of these application within the setting of the anchor. The following is a description of how the activities around each technology application emerged from the theme, content, and activities of the curriculum development course.

Word Processing. On the first meeting of the educational computing class, each preservice teacher used word processing to write an introductory story to the eighth grade partner that he or she would be working with. They also used a digital camera to take personal pictures. They inserted these pictures in their stories. The preservice teachers later shared these stories with the eighth graders.

Web searching. The first meeting of the curriculum class involved a brainstorming lesson around the questions “what do we know about coal mining, and what do we want to know?” After listing down several questions, the next task at hand was “how are we going to find out what we do not know.” This became an opportune time to introduce web searching. In the following educational computing class the preservice teachers used different search engines to search the Internet for information about the topic of coal and coal
mining. The preservice teachers created annotated bookmarks of resourceful sites, and saved them on floppy disks. They shared this bookmarked resources with the eighth grader on the next meeting.

**PowerPoint.** One curriculum class involved a discussion of the principles of expeditionary learning. The next technology class involved reviewing the expeditionary learning web site (ELOB) for further information. The preservice teachers then created a PowerPoint presentation around the topic of expeditionary learning based on materials covered in the curriculum development class and information gathered from the web.

**Spreadsheet.** The eighth grade class and the preservice teachers spent one session planning a field trip to the coal mining area in question. In this session the eighth grade teacher involved the students in an activity aimed at figuring out what they needed for the trip, how much money they would need, and how to raise the funds. In the next educational computing class spreadsheets were introduced to spreadsheet as a possible trip planning application.

**HyperStudio.** The eighth graders and the preservice teachers engaged in several research-oriented activities aimed at providing information around the questions on coal mining. These activities involved interviewing different players, visiting coal-mining areas, and searching materials and information from the library. The preservice teachers used HyperStudio to document this entire experience. During the fieldtrips digital cameras were used to capture different scenes. These graphics were woven into the HyperStudio multimedia presentations.

**Database.** To help them keep track of the different components of the learning experience, the preservice teachers used a database. Some preservice teachers were able to use the screen capture option of Macintosh computers to use these weekly database presentations as part of their HyperStudio stacks.

**Inspiration.** One session of the curriculum class involved concept mapping. The eighth grade class mapped out, on a chalkboard the different aspects of coal mining that they would explore in the expedition. This became an opportune moment to introduce inspiration as a concept mapping application. The preservice teachers later used these maps as part of their multimedia stacks.

**KidPix.** In the culminating project in the curriculum class, the eighth graders worked with the preservice teachers to set up a readers theater. KidPix was introduced as a possible readers theater presentation application. Some of the preservice teachers used KidPix slide shows depicting some of the perspectives represented in the readers theater.

**Reflections and Discussions**

**Flexibility.** In this study, the content for the anchor was open-ended and evolutionary in nature in the sense that no one could determine ahead of time either what the eighth grade class was going to find out during the expedition or the sequence of activities they would need to take to complete their task. As the learners (eighth graders) explored the task ahead of them, they identified their own questions and these questions became the basis for formulating goals and designing the activities that would lead to the realization of these goals. One of the goals of immersing the preservice teachers in this collaborative teaching/learning experience was to emphasize relevance of technology in teaching and learning by allowing the preservice teachers to use technology in a real life setting. To achieve this goal, it was important for the activities of the technology class to relate closely to those of the anchor.

One of the challenges of anchored instruction is for the instructor to know “how and where to fit anchored instruction into the existing curricula ...” (Baumbach, Brewer & Bird, 1995). The existing curriculum in this case was for the preservice teachers to learn the use and application of various technology applications for teaching/learning environments. Relating the activities of the technology class to the anchor, and fitting these activities within the curriculum of the technology course necessitated planning the technology activities as the content of the curriculum class evolved. It therefore became necessary for the technology instructor to attend the curriculum course class sessions. This created a great demand on her time, but as she reflected, “this was the only way I could make the assignments and class activities meaningful. I had to know what they are doing in the other class in order for me to create corresponding and complementary activities for them.” This suggests the need for flexibility on the part of the instructors involved in anchored instruction and confirms the suggestion by Baumbach, Brewer & Bird, (1995), that “with anchored instruction, the teacher can no longer follow a fully scripted lesson plan.”
Providing on-demand learning. “On-demand learning allows the individual to learn the topics they need when they need” (Duke, 2000). It has been suggested that “people learn best when they can learn exactly what they need at exactly the moment they need it…” (Skillsoft, 2000). In this study the technology instructor provided on-demand learning on several occasions. An example was in the case of Inspirations as described above. At the beginning of the course, the technology instructor had not planned to use the Inspiration software. Upon attending the curriculum class sessions and watching the concept mapping session (using a chalkboard), she quickly recognized this as a very timely opportunity to introduce Inspiration as a concept mapping software. The preservice teachers then used inspiration to create an electronic version of the concept map which they had tried to create on the chalkboard earlier on in that day. Inspiration became the exact topic they needed to learn at this particular moment. Providing this on-demand learning helped the preservice teachers appreciate the use of Inspiration. As the ease of forming concept maps using Inspiration unfolded to them, the class was full of “aahhs” and “ooohs” in appreciation.

One of the advantages of providing individuals with on-demand learning is that it allows “them to immediately apply their newly gained knowledge… Immediate application cements the knowledge gain and makes it far more likely that the knowledge will be retained and used in future” (Skillsoft, 2000). A number of preservice teachers in this study reported that they started using some of the applications such as Inspiration, PowerPoint, and KidPix for other courses as well.

Recognizing teachable moments. Closely related to the concept of providing on-demand learning is the need for instructors to recognize and seize teachable moments. Teachable moments refer to a time when individuals are ready to learn. In using this approach “the teacher may appropriately decide that the current discussion or situation may offer a prime opportunity to meet current or anticipated learning goals better than the planned instructional activities” (MentorNet domain, 2000). In this study, some time the technology instructor had to change a planned course of action in order to seize a teachable moment. The case of Inspiration above was one example. The prior plan for that particular class session was for the preservice teachers to work on completing previous assignments. The introduction of spreadsheet as a possible trip planning software, as described earlier, was another example. “Suitable recognition and capitalization of teachable moments can increase instructional efficiency, despite deviation from planned activities” (MentorNet domain, 2000).

Cohort group. Cohort instructional programs, where students are required to take all or nearly all courses together toward a degree, have been associated with some benefits. An example of these benefits includes higher levels of cohesiveness and group interaction among the students (Reynolds, 1993). These interactions in turn result in, enhanced professional confidence and life long learning relationships. This study reveals an additional advantage of cohort instructional programs, namely that cohort instructional programs present an excellent setting for educators to implement anchored instruction. The collaborative teaching experience in this study was made possible by the fact that the preservice teachers were involved in a cohort instructional program based on a partnership between the university and the local Junior high school.
Motivation. One major difference between this class and other similar classes that the technology instructor had taught before (based on same technological applications) was the level of enthusiasm and motivation in the preservice teachers. As she indicated "on average, for example, I spend considerable time just trying to get the students to think of a topic of interest to use when practicing web searching. In contrast, it seemed like this class could hardly wait to lay their hands on the WWW, because they were very eager to see how much information about coal and coal mining was available on the web".

The preservice teachers' perspective. At the end of the technology class the preservice teachers shared some of their reflections on the anchored instruction experience. These reflections highlight some of the benefits of this anchored instruction in their learning experience including: increased motivation to work on and complete tasks, a sense of pride and accomplishment, understanding of integration of technology in the curriculum, and developing a vision for integrating technology in their own classrooms. Some of these benefits are captured in the following excerpts from the students' reflection papers.

"It was because I was involved in this unique integrated curriculum that makes it easy or me to envision technology in my own classroom."

"This integrated experience has made learning to use technology effectively all the more meaningful."

"I found myself practically bragging to other technology student [not involved in the anchored instruction partnership] throughout the quarter about how our class made so much more sense because we were connecting our classes together."

"The integration of these two classes really helped me to be a reflective educator."

Summary, conclusions and suggestions

A cohort group of preservice teachers was immersed in a hand-on experience where the preservice teachers learned the use of technology applications within a real life setting. The theme, content, and activities of a curriculum development class were used as an anchor for the preservice teachers to learn the use and integration of technology applications in teaching and learning. Planning the activities around the anchor in such a way as to fit the activities within the curriculum called for flexibility in the part of the instructor. By recognizing and seizing teachable moments the instructor provided on demand learning which led to transfer of skills to other areas. Anchored instruction was found to be an effective way of training preservice teachers to develop a vision for integrating technology in the curriculum. It also resulted in increased motivation to work on and complete tasks, a sense of pride and accomplishment, and understanding of integration of technology in the curriculum.

One of the unique situations that made this collaborative partnership possible was the fact that the preservice teachers were in a cohort group. Cohort groups of preservice teachers therefore present an excellent opportunity for implementing anchored instruction. Where cohort groups of preservice teachers can be organized, technology instructors should take advantage of such a setting and create collaborative partnerships that would allow the activities of an educational computing course to be anchored around the theme, content, and activities of another course.

Challenges to Currency in the Educational Computing Course

Kathy A. Sisk
Department of Mathematics and Computer Science
North Georgia College & State University
United States
ksisk@ngcsu.edu

Abstract: This short paper is an initial report on the challenges facing the instructor of the educational computing course as colleges and universities strive to prepare technology-capable teachers who in turn can produce technology-capable students. These challenges include the changes in entry-level computing skills for preservice teachers, along with the many new innovations in hardware, software, and course delivery tools. These dramatic changes pose wonderful opportunities and demanding challenges for the instructor of the educational computing course and for teacher education programs.

Introduction

A major goal of teacher education is to prepare teachers to play a vital role in preparing students to function in a technology-rich environment. The International Society for Technology in Education document, National Educational Technology Standards for Teachers, states that "Our educational system must produce technology-capable kids." Colleges and universities have the responsibility for producing technology-capable teachers. A major challenge to the instructor of the educational computing course and to teacher education programs is maintaining currency, and even innovation, in a course that must constantly change. This is not an easy challenge. Pre-service teachers' entry-level computing skills have improved substantially over the past few years, hardware as well as software is being updated and replaced at a rapid rate, instructional delivery tools are constantly being developed and modified, and the expected skill-level for teachers is approaching higher standards. These dramatic changes pose wonderful opportunities and demanding challenges for the educational computing course and for teacher education programs.

Entry-Level Computing Skills

Information collected from a survey of students entering an educational computing class in 1995, and a comparable survey in 2000, demonstrates the change in skills of incoming students. Less than five years ago, most students entered college with few computing skills. These skills were mostly restricted to the use of word-processing or spreadsheet applications. Today's students arrive in the college classroom with an array of computing skills and some savvy experience in using technology. These same students usually carry cellular phones, must have an e-mail fix every few hours, and have access to a computer outside of the university lab or classroom. Before students arrive on campus, many have listened to music via the web, played with an array of interactive game software, downloaded plug-ins, and participated in chat-rooms. These students also bring an expectation to the computing classroom for more than a sampling of presentation software, database applications, and web development. As teacher educators, we must continually assess the skill-level and knowledge of our incoming students and strive to update course curriculum and activities to meet the needs of our pre-service teachers and the students whom they will teach. With computers in most homes and students arriving at college with more experience in computer use (Digest of Educational Statistics, 1999), it is vital that the educational computing course take into account these significant improvements in students' entry-level skills. As a result, the instructor of the educational computing course must continually examine the curriculum, throw out the obsolete and replace it with new applications and skills. These skills must be blended with the appropriate focus on activities
which will allow pre-service teachers to gain the design and delivery experiences needed for classrooms which will produce "technology-capable kids."

Changes in Hardware and Software

In early 1995 there was no need to assess student skills in using the web or to teach students about web design. Although the Internet was in existence in the late 1960's (Shelly, Cashman, & Gunter), prolific creation of web sites and use of the web for education have only exploded during the past few years. Today's entry-level students are adept at searching for information on the web and are beginning to be much more experienced in creating web pages. Yesterday's web creation lessons for the educational computing class, which included some basic activities using HTML or Netscape Composer, are not sufficient for today's students. Students can now expect to use a variety of packages, such as Macromedia's Dreamweaver 3.0 or Microsoft's FrontPage 2000, to develop professional web sites and web pages. It is a major challenge for an instructor to maintain currency in the various web-development and graphics-applications packages and provide appropriate learning experiences for our students. Presentation software has also moved from simple screen designs with text and clip art to complex learning kiosks with interactive buttons, digital video and audio, and complex designs that allow the user to view only certain portions of the materials and not just a sequential show. It is no longer a question of which button to add but rather how does one design an on-line learning module which encourages higher-order thinking skills. The teacher educator must possess skills in using digital cameras, digital video cameras, scanners, and know how to use appropriate software to capture and edit the products of these peripherals into viable electronic objects for learning. Computers must constantly be replaced with those having faster processors, more memory, and special cards for all of these powerful new tools. The average life expectancy of a computer in a college lab or in a public school classroom is less than two years and the average life expectancy of a course syllabus for the instructional computing course is barely one semester. Curricular revision, combined with changes in hardware and software, adds to the challenges facing the instructor of the educational computing course and these are not the only elements of change. Perhaps the greatest element of change comes from the challenges placed on new methods of course delivery.

Changing Delivery Methods

Classroom face-to-face interaction is sometimes being replaced, or at least challenged, by courses which are totally or partially on-line. Pre-service teachers may be experiencing these new learning environments in classes as well as studying appropriate ways for using these new tools. The instructor of the educational computing course must learn this new technology and also learn how to use this new technology to create dynamic learning environments that are very different from the four walls and blackboards used a few years ago. By the time an instructor masters the basic skills of a new package, such as WEBCT or Blackboard, the instructor finds that there is an updated version on the market--one that has more bells and whistles and holds the promise of a more effective learning environment with a shorter learning curve.

Future

How does the instructor of the educational computing course address these challenges posed by new entry-level computing skills of students, modifications of hardware and software, and new delivery techniques? The instructor of the educational computing course is also a learner. Consequently this learner heads back to the classroom in whatever form that classroom currently exists, either face-to-face, on-line, or wireless, to learn new applications or upgrades that will hopefully make the classroom of the future a better place to learn and the teacher a more effective facilitator of learning. If a major goal of education is to produce lifelong learners, then the instructor in the educational computing course makes an excellent model. This instructor probably learns something new regarding educational technology every day and enjoys almost every challenging minute of the experience.

Abstract: Cooperation is one of the most important human activities. Several researchers over the world showed that cooperation enhances learning. Cooperative learning is very important because it produces greater student achievement. In this paper, we present the architecture of an environment-based hypermedia that supports cooperation between learners. We also present its implementation.

1. Introduction:

The application of cooperation principles in hypermedia environment is not a new idea. Many researchers have proved that providing cooperation opportunities to learners can reduce the problems of hypermedia, i.e., the lost in the hyperespace and the cognitive overloading. In this paper, we present an architecture of an hypermedia that offers cooperation opportunities to learners.

2. Architecture of the system:

This hypermedia is composed of a set of human-machine interfaces, a tutor, and some other modules.

2.1. Student interface:

It is through this interface that the learner navigates, requests advice from the tutor or cooperate with their peers. Learners can exchange ideas, some points of view, suggestions, ... a.s.o. A dialogue model is under construction in order to facilitate the negotiation between learners.

2.2. Author interface:

The author creates the hypermedia (nodes, links, ...). The material to be learned is divided into a set of educational objectives. So, the hypermedia contain a set of educational objectives related by «prerequisite» relation. Each educational objective is represented by a set of nodes, so, two objectives can have the same node. For each objective, the author creates:

- the nodes of this objective,
- the « prerequisite » objectives,
- the difficulty level.

For evaluating the student's knowledge, the author creates exercises with their solutions and the score to add or subtract.

2.3. Tutor:

It is used in order to propose an educational objective to the learner following the student's knowledge state. It can give advice to learners or information about the cooperation opportunities (Lafifi &
Bensebaa 2000). It uses a set of pedagogic strategies which are constituted by a set of pedagogic rules. Theses rules have the shape of a production rule:

\[ \text{If Condition Then Action.} \]

3. Implementation and conclusion:

For implementing this architecture, we had used a Server/Client architecture. In the Server slide, we have the hypermedia, the tutor and the author interface. In other hand, in the client side, we have a student interface, the student model of each student and its historic. For accessing in each interface, a passoword is used.

We presented the main features of the architecture of an hypermedia system that can offer cooperation possibilities to learners. Now, we try to implement this architecture in the Web.

Freeing the Monkeys:
Making the EdTech Course More than Learning to Push Buttons

Daniel Laughlin
American University
United States
dlaugh@american.edu

Sarah Irvine-Belson
American University
United States
sirvine@american.edu

Abstract: Since 1995, the School of Education at American University has offered a course called Educational Uses of Technology. The aim of the class has been to teach the metaskills necessary to empower students to become self-directed learners capable of mastering new computer skills on their own. The course attempts to accomplish this through the use of tutorials and limited group projects. This study solicited feedback from former students who successfully completed the course. Most of the respondents reported that they had become more comfortable with learning new computer applications as a result of taking the course. The authors feel these results provide support for the teaching methods used.

Introduction

Several years ago I got a hair cut at one of the big franchised haircutting establishments. When I went to pay, the stylist had a problem with the computer that served as a register. The screen locked up, and she did not know what to do. After watching her stare timidly at the screen for several minutes, I offered to help. A quick reboot later I was able to pay for my haircut. The very next day I was buying a cup of coffee in a college cafeteria when the same sort of computer problem confronted the woman working the register. Instead of staring helplessly at her machine, this woman prodded a number of keys before shrugging and rebooting the computer. The moral of this tale is not that I could have gotten out of paying for a haircut if I had just kept my mouth shut. What really struck me was the difference between the ways these two women dealt with their computers. The first woman was clearly apprehensive about the machine and too nervous to try anything when it stopped working. The second woman was much more comfortable with her machine and thought nothing of doing a little experimenting to get it to work.

Semester after semester we see students in educational technology classes who approach computers with the same trepidation as the hair stylist in this story (Kay, 1989). If we are really going to give them what they need out of an educational technology course, we need to be able to help them become more like the second woman in the story. They have to be willing and able to try things for themselves.

If you stand outside any software training class and listen, you are most likely to hear the instructor walking students step-by-step through the procedure of some operation of whatever application is being taught. “Click the File Menu. Scroll down to Page Setup and click it. Choose the Paper Size tab. Click the Landscape option in the Orientation section.” Voila! You have instructed the printer to print down the length instead of across the width of the page. But did anyone learn anything from the process? In today’s climate of appreciation for learning by doing and degradation of simple memorization, this type of rote drill is to be discouraged (Bird, 1993).

In 1991, I had a job travelling around the country teaching seminars on how to repair and upgrade computers. One day the own of the company really lost his patience with me because I complained that I did not understand some aspects of the new course well enough to teach them after sitting in on the course twice. In a fit of anger he yelled, “a trained monkey could have learned it by now.” Needless to say, I was not working for the same company the next day. But the expression stuck with me and it has come to be...
the way I think of courses that focus on memorizing which buttons to push. If our educational technology
courses are not doing more than teaching which buttons to push, we might just as well be working with
trained monkeys. We believe that would both waste our time and annoy the monkeys. So we are trying to
free the monkeys and make our educational technology courses more than just button pushing seminar.

A major element of our approach has been the use of tutorials. Instead of walking students
through a new application step by step, we encourage them to read and follow a tutorial. This guides
students away from passive learning and toward self-paced, active learning (Zemelman and Daniels, 1998).
When they encounter trouble, we help them get back on track, but mostly the instructor serves as
reassurance. Students with problems are gently urged to try to solve their own problems while the
instructor guides their problem solving effort. This is a form of Piaget's (1995) scaffolding. The student
without enough experience to come up with the solution immediately is helped to reach a solution they can
call their own. The sense of personal accomplishment in this system is much higher than in a system based
on pushing buttons on cue. So is the level of frustration along the way. Instructors must be prepared to
deal with that frustration and hold on to the belief that student satisfaction with their own accomplishments
will be all the higher for it.

The Study

What we have been seeking to do is foster the metaskills necessary to empower our students to
become independent, self-guided learners in the area of educational technology. While we use a variety of
active learning techniques to foster this in our education technology classes, we have had little feedback
concerning the success of our efforts. To change that, we assembled a database of all of the students who
have completed the Educational Uses of Technology course offered by American University's School of
Education since 1995. Because the course is offered both to undergraduate and graduate students, many of
those who completed it in its early history have left the university. We were not able to contact all of the
former students. Of the 312 students who have completed the course, we were only able to successfully
contact 205. Most of this group was recruited to participate in an email survey for this study. Twenty-one
others were contacted and agreed to participate either through conventional mail, telephone or (in two
cases) personal interviews. Of the 205 students agreeing to participate, only 93 had actually responded by
the writing of this paper.

All participants were asked to respond to a questionnaire containing ten queries. Because we have
a number of records giving individuals self-reported attitudes and experiences concerning educational uses
of technology from their time in class, we chose not to make this an anonymous process. We also asked
the participants to report in which semester and with which instructor they took the course so that we might
compare responses to the questionnaire to past student evaluations.

The questions addressed to the participants fell into two main categories. Four questions solicited
the former students' impressions of the usefulness of the material they learned while taking the Educational
Uses of Technology course. Four questions asked about the former students' experiences with computers
since completing the course. The remaining two questions asked for recommendations to improve the
quality of the course. All of the questions were open-ended, and participants were encouraged to make
their responses as detailed and lengthy as they wished.

Findings

Of those who responded, 85 said they felt that the Educational Uses of Technology course had
been beneficial. Seven of the remaining eight respondents said they did not learn anything new in the class
while the eighth felt "the class was a stupid waste of time." This former student went on to say that he
thought, "the class shouldn't be required for people who already know how to use computers." Of those
with more positive assessments, many mentioned that the course helped them feel "more comfortable about
using computers."

Twenty-three percent of respondents reported learning to use new software or peripheral devices
since taking the course. Of those who were more explicit in their answers, twelve wrote that they had
learned to use at least one new software application. Four participants said they had used more than one
new package. Two reported learning to use a scanner on their own (as opposed to with the assistance of a
lab assistant while taking the course). One excited former student was the proud owner of a new web cam and wrote that it was “really cool.”

Most (86%) of the participants reported that they had used specific skills that had been taught in the Educational Uses of Technology class since completing the course. Forty-two said they had created or presented power point presentations. Twenty respondents wrote that they had created web pages for themselves or for groups or projects with which they were associated. Eighteen said they had used specific skills learned in class but failed to mention which skills those were. No respondents reported designing their own learning labs since completing the final class project. Two students volunteered that the course helped them make decisions when buying a new computer.

Interestingly, only 38% of respondents reported remembering having felt any anxiety related to computers before they took the course. Yet on average, slightly more than half of the students who take the Educational Uses of Technology course report some level of anxiety about using computers in the beginning of the class. Of those who reported remembering having felt anxiety, all said that the course lessened the level of tension they felt when dealing with computers. Most seemed to indicate that they now felt little or no apprehension, but twelve (13%) reported that they still felt some such anxiety. It was unclear from the responses how many meant they constantly felt apprehensive as opposed to periodically experiencing tension. One respondent wrote, “I usually am okay with the computer now. But some days everything seems to go wrong and I get so I just want to throw it out the window.” Since this student responded to the survey via email, we assume she has not yet given into that urge.

When asked about confidence in their ability to use skills specifically learned in class, 84% of participants said they could currently use or relearn those skills on their own. Several respondents made comments similar to one former student who wrote, “I guess I could make a web page on my own if I had to, but it would be easier if you were there. I’d be more confident just knowing I could ask for help if I had to.”

When asked about confidence in their ability to learn new computer based skills on their own, 61% of respondents reported that they either had done so or thought they could do so. It is worth noting that of the 57 participants, who answered in the affirmative, nearly half went on to mention having someone they could turn to for help or advice. We are divided on the issue of whether or not this counts as being able to learn new software “on your own.”

Eighteen participants said they felt more courses on the educational uses of technology ought to be required or at least available though American University’s School of Education. One student specifically stated that the current course should not be required of education majors and graduate students.

A disappointingly small number of former students are currently teaching using any form of computer technology. Of the twenty-eight respondents who are currently teaching, only twelve reported having working computers available to them in school. Of those twelve, none reported having more than a handful of computers in their classrooms. One particularly passionate student wrote, “It’s not fair. I learned how to do all this neat stuff getting my degree, but I can’t use any of it. I only have four computers in my classroom and they are so old they won’t run anything I can buy today. If they were even working.” Two respondents did report having class web pages where they posted scanned copies of students’ work for parents to see online. Several participants reported using email to communicate with parents. By and large, however, most did not seem to have access to the computing resources the course prepared them to use.

Conclusions

There is a natural tension between the desires of students to develop specific and explicit skills in a class such as Educational Uses of Technology and the instructional goal of helping students develop the metaskills discussed above. The majority of students taking such a class are pre-service teachers. According to Fullers (1974) Teacher Concerns Model they are primarily focused on developing basic skills. As the dreaded “will this be on the test” question indicates, many students feel they only have time to master skills and knowledge on which they will be graded. The metaskills for independent mastery of new computer skills are not easily tested for in a single semester. It is natural, therefore, for students to want to be taught new computing skills in the traditional rote button-pressing manner that we have called monkey work. Despite that urge, almost two-thirds of our former students indirectly reported having developed the ability to teach themselves new computer applications. Given that more than half of all
students starting the course indicate that they would have difficulty doing so, we find reason to believe that we have been at least partially successful in our goal of fostering the desired metaskills.

Lewis (1988) made a number of recommendations for easing anxieties about computers in education classes. Among them were relating personal experiences as a beginning computer user to relax students and make them more comfortable in the early stages of their technical skill development. We recommend creating a classroom environment that is relaxed, comfortable and informal. For many students there will be considerable tension when trying to do new things on a computer. The instructor needs to do everything possible to minimize other sources of tension. Ideally students need to develop a sort of fearless willingness to try new things. They need to know that it is okay to fail and make mistakes when learning new skills. Piaget (1995) suggested that each time humans try to learn a new set of skills that are essentially going through the stages of mental development on a micro scale. To individuals used to working in familiar areas this can be a very daunting experience. A number of participants remarked that the casual classroom atmosphere of the Educational Uses of Technology course made the experience much more pleasant.

To help minimize frustration, Konar, Kraut and Wong (1986) recommended starting with simple tasks early and working up to more difficult tasks later in the semester. This may seem obvious when it is mentioned, but many instructors do not seem to take it into consideration when laying out educational technology courses. We start off at the simplest level of sending email, web browsing and using a search engine. Mastery of these simple tasks helps to build confidence and starts students with a foundation of success. By the end of the semester, students are able to plan and design their own computer based learning labs complete with promotional web pages and explanatory power point presentations.

We cannot emphasize enough the need for this type of class to be a hands-on, active learning environment. It is not enough just to have students sitting at computers. The monkey work approach does that. Students need to be active participants in the learning process. We foster this with the use of tutorials and several group projects. The instructor needs to step back to a support role and resist the urge to explain every step in detail. A good overview of what needs to be done and how the tutorial will guide the process is enough. After that, answering individual questions while everyone is working is the best approach. The instructor should encourage exploration and problem solving by the students. Giving a prompt answer to every question may be tempting, but students will get more out of the process if they are encouraged to work through difficulties.

This study was originally intended as a way to get feedback from former students beyond the traditional end of semester student evaluation. Overall, most of our former students seemed pleased with both the content and the structure of the course. A few suggestions were made about changing the order or assignments and a couple of students even suggested adding more assignments. We will be experiment with these ideas in coming semesters. We find support for our pedagogical approach in the survey responses. We intend to continue soliciting feedback from students from current and future classes. We also intend to carry on freeing the monkeys.

"Surfing Safely with Social Navigation"

Bruce Lewis
School of Education
Freed-Hardeman University
Henderson, TN

This proposal relates to the use of instructional technology in undergraduate and graduate teacher education. It fits the topics of: The Educational Computing Course; Graduate & Inservice Education; Instructional Design; Preservice Teacher Education; Technology Diffusion; and Telecommunications.

Many parents and teachers are concerned about the growing proliferation of published material on the World Wide Web, some of it being unfit for small children's eyes and minds. Thousands of new websites are being added every month to the Internet with a wide range of HTML styles and structures. Navigating this vast sea of information safely becomes a nightmarish adventure for the uninformed and/or uninitiated.

Dieberger (1997) proposes that when Internet users help each other with this navigational task, they are using "Social Navigation." Often users will e-mail each other URLs with descriptions of the websites and recommendations. Or they might create a webpage with pointers to their favorite and/or most helpful sites. When the recipients and readers use these resources, whether via e-mail or the webpage, they are engaging in a social activity while surfing the web.

Dieberger (1997) recommends direct social navigation where a group of individuals with common interests agree to share ideas, resources, and evaluations. These recommendations become a point of discussion as others view the selected Internet resource, evaluate the site for themselves, and compare and contrast their own evaluations of the site.

Undergraduate and graduate education students at the author's current university have been involved in Social Navigation for the past few semesters in an organized manner. This has lead to more and varied integration of educational technology into the School of Education's courses and into the actual teaching of the courses by the established faculty. It has also encouraged the faculty to experiment with new technology and explore the multiplicity of offerings on the WWW.

For example, Education Strategies students, under the direction of their instructors, are now required to do web-based research on available on-line resources for their discipline as part of a lesson plan. With the technical guidance and instruction of the author, each student researches a minimum of four websites and composes an HTML document containing the name of each site, its URL, and an annotation of the webpage. The web-based lesson plan is then edited, as necessary, by the webmaster and uploaded onto the School of Education's server for viewing through the World Wide Web at http://teach.fhu.edu/technology/.

Other undergraduate and graduate courses are also involved in web research and webpage design, although to a lesser extent than the Education Strategies classes. For example, some of the introductory Special Education classes have created webpages featuring specific learning disabilities and handicapping conditions. These are hosted on the School of Education's website, as well.

The author's graduate students in EDU 506, Computer Applications in Education, have not only created webpages with Internet resources, but have also been involved in e-mailing their instructor and fellow class members. They are providing thoroughly reviewed and evaluated, hand-picked lists of URLs to other websites of interest to K-12 teachers. Dieberger (1997) argues that the locations of social navigation are important and therefore our class provides a supportive atmosphere to both explore the web and share found resources in a collaborative environment. Creating e-mail discussions that represent different interpretations reinforces an advanced state of cognitive functioning.
Collaborative Communities Think About Technology in Education: a Web-based Constructivist Course Model for Pre-service Teachers.

Sharon Murray
Education Department
St. Thomas University
Canada
murray@stthomasu.ca

Abstract: A need exists for beginning teachers to be aware of ways in which technology can be integrated into classroom instruction. This paper is a reflection on a course model that was developed to address this need. The course is available to students in a one-year post-degree education program. It focuses on the use of technology in education and is designed in a manner that encourages reflection and engagement. The students collaborate in theoretical and practical readings, field experiences and instructional design. Students in the course actively engage in the construction of their knowledge as part of a community of learners.

Introduction

That all pre-service teachers acknowledge and become familiar with the use of technology in public school classrooms is widely accepted. Acknowledging this need, pre-service teachers in our university's intensive one-year post degree program are required to take an introduction to technology and instructional design course in the first term. In the second term they may also take an optional course, Technology in Education. The model for this course has evolved over the past few years. It focuses on the process of technology use in education. This focus on process requires of the pre-service teachers theoretical investigation and the sharing of thoughts on readings, experiences, and on the rationales that have been generated for the use of technology in schools as well as in the broader community.

The course model is one structured around collaborative investigation and constructivist pedagogy. Most of the course time is spent reading in the library, working on collaborative projects, conducting field investigations and discussing and reacting to what is being read, experienced, observed and/or discovered. The pre-service teachers are active group participants in helping to shape each other’s understandings of technology. They also are members of focused discussion and research groups. As part of a learning community they collaborate by sharing thoughts and engaging in a dialogue through written texts and oral communication. This dialogue of engagement both oral and textual is often at a level of sophistication and deep understanding that I have not experienced through a more traditional course structure. The course consists of a study of three distinct areas: theory and practice surrounding technology use, learning from and through experience, and the design of a web-based project that could be used in the public school system.

Course Structure

The course structure requires the pre-service teacher to have a series of linked web pages on which they share what they have come to believe about technology use in education and to which class members react and respond. Students read about issues that are related to visions and rationales for the use of technology in education and respond to these readings on web-based Read Log pages. Students in the course are involved at the same time in reacting to their classmates writing and responding on the Read Log pages. This external dialogue enables shared understandings of the place of technology in public school education.

The second phase of the course is allocated for the actual process of learning about technology use in
schools. The pre-service teachers spend one-third of the course in a school based technology setting. This engages students in a process that, like all learning, involves doing as well as getting. The objective of this component of the course is to use a community or public service experience to enhance and impact the learning of traditional course content. This component of the course provides an opportunity to test or demonstrate abstract theory in the real world. The pre-service teachers share the knowledge they have gained from their visits to schools through a reflective web page.

The development of a web-based design for instruction is the final component of the course. The instructional design reflects the pre-service teacher's previous course work giving them a sense of the theoretical as well as the practical implications for the use of technology. The creation of the instructional design is completed as part of a team. The team often focuses on a topic within a discipline but in some cases the designs are interdisciplinary in approach. The instructional design topic is most often developed around particular areas of interest and has ranged from a study of environmental biology to the study of fairy tales in elementary language arts. Teams of pre-service teachers collaborate on the web-based instructional design package by working together—teaching and learning together.

Findings

In the first phase of the course model discussions around theoretical and practical readings are not instructor focused or directed. The opportunity exists for all students to express their views through their web pages. In traditional fifty-minute classes discussion usually occurs among a small group of vocal students; others are reluctant to enter the debate/discussion and they often remain silent. Through interactive web pages all class members have the opportunity to express their views and when the class meets as a whole everyone is familiar with each other's perspective and a more focused dialogue occurs.

The degree of engagement in a textual dialogue are sampled here in some responses from a Read Log page, "I am very interested in examining this article in full, ... I am uncertain of the direction K—[female] is aiming for in her response? Is she suggesting that the role of the public school teachers should move in the direction of caretaker, not educator? ... Granted widespread computer use will help in sharing of knowledge as well as accessing knowledge, but who will be there to filter this new knowledge?" Responding to this, “E—[male]: You have some valid questions, ... First of all I do advocate the use of computers in the schools. I see technology 'know how' as a marketable skill in the workforce and feel those who do not have any ultimately reduce their options.” The opportunities for students to share their views in a public forum enhances the understandings of the class as a whole and serves to extend the dialogue beyond the privacy of student essays and teacher responses.

Field placement experiences occur in public schools that have been identified as exemplary users of technology. The pre-service teachers are encouraged to think of themselves as active participants who may be called upon to share their knowledge. They were often impressed by what they saw, “It's amazing to think that grade five and six students were producing this work!” while others were positively reinforced by the teaching experience, “They asked lots of questions that I knew the answers to and that made me feel important.” Coming to an understanding of theoretical views and then experiencing the practical realities of the public school classrooms serves as vital information and experience for the final stage of the course which is the design of a web-based instructional learning package.

Conclusion

This course model focuses on helping pre-service teachers think about how they learn and how they can improve learning as well as how they can learn from one another. The course tasks have a real educational purpose and are not usually done for the sake of completing an assignment. Students construct activities or representations of their understanding; particularly in their electronic course web pages, which reflect their experiences and thought developments as well as a finished product. The course design supports a constructivist model of instruction, which creates an environment that has learners construct understandings of the use of technology in public education.
Revising an educational computing course to meet the National Educational Technology Standards: A process of reflective teaching.

Abstract: In our attempt to address National Educational Technology Standards (NETS) set forth by the International Society for Technology in Education (ISTE), we have faced issues impacting the conditions of learning experienced by our students. As reflective practitioners, we have revisited the curriculum to make improvements based on our experiences and our students' experiences in the required educational computing course in our college of education. Our reflections have included conversations about the scope and sequence of the curriculum, pedagogical knowledge, instructional strategies, and procedures for assessment. This paper will highlight key points of our discussions and describe interventions and their resulting consequences for our preservice teachers.

Introduction

Teacher preparation is a key factor to consider when determining beginning teachers' use of technology for instructional purposes. Most colleges of education offer a required educational computing course for all preservice teachers. This introductory course generally covers basic skills and computer operations, and attempts to provide students with familiarity with a range of technological applications such as word processing, databases, spreadsheets, telecommunications, multimedia/hypermedia and content related software. Until appropriate uses of technology are fully integrated throughout the entire teacher preparation program, a separate instructional technology course will continue to be a necessary core requirement.

At the College of Education at the University of Tennessee (UT), ITCE 486: Introduction to Instructional Computing fulfills this basic computer requirement for all teacher education students. Admission to the teacher education program is the only requirement, although this has not been strictly enforced in past semesters. Eighty students enrolled in one of six sections during the Fall '00 semester. Three Instructional Technology (IT) faculty members taught four of the sections while the remaining sections were taught by graduate teaching associates. While two of the IT faculty members were beginning their first semester at UT, both had previously taught similar courses at other universities.

Dewey's contributions to reflective teaching have provided an avenue for thinking about and discussing revisions to create a positive impact on students' learning about and with technology. According to Dewey, "the process of reflection for teachers begins when they experience a difficulty, troublesome event, or experience that cannot be immediately resolved" (Zeichner & Liston, 1996). Throughout the course of the semester, while we experienced success stories in various sections, we also faced numerous challenges encouraging us to engage in this process of reflection. We (course instructors) met on a regular basis during the semester to discuss issues, concerns, instructional strategies, and plans for future improvements. These conversations enhanced understanding of how the history and purpose of the course had an impact on the current situation. Using information gathered from the
The overall situation, reflective practitioners construct the problem and use their knowledge of experiences to make changes grounded in a contextual understanding of the problem. Our attempts to act as reflective practitioners and were carried beyond formal meetings as we continued to discuss course related issues and the larger role of technology in the College of Education in numerous informal meetings throughout the semester.

Using this framework as a guide, we have reflected on our experiences and the experiences of our students with an educational computing course, and revisited the curriculum to make improvements based on what we have learned. Our reflections have included conversations about the scope and sequence of the curriculum, pedagogical knowledge, instructional strategies, and procedures for assessment.

Areas for Consideration

Scope and Sequence of the Curriculum

One of our major course changes focused on aligning our course goals to the National Educational Technology Standards (NETS). The International Society for Technology in Education (ISTE) NETS for Teachers Project has put together a series of Performance Profiles for teacher preparation, describing what teachers should know about and be able to do with technology. The Performance Profiles address four phases that a typical teacher education student might experience: General Preparation, Professional Preparation, Student Teaching/Internship, and First-Year Teaching (ISTE, 2000). Based on our class composition, we focused on the profile targeting the professional preparation experience. To further support our emphasis on these standards, we adopted a resource book from the NETS project1 which provided students with examples and lessons based on the standards.

Our biggest challenge in this area was the sheer number of topics we felt compelled to introduce, given the fact that this course served as the only exposure to instructional technology for the majority of students. The curriculum included topics from a variety of general areas including word processing, databases, spreadsheets, telecommunications, multimedia/hypermedia and content related software. At the beginning of the semester, course instructors agreed on basic areas, but depth of coverage, timing of topics, and required assignments varied from section to section. While consistency in major course topics was necessary, we maintained the need for flexibility in implementation. This provided instructors with opportunities to target instruction based on their teaching styles and the needs of their unique sections. For example, although all sections were to learn to create instructional Web pages, one section might have created WebQuests while another section might have been asked to create online portfolios. The differences in skills and assignments were enough to warrant a lengthy discussion about the need for greater consistency within topics. We wanted to bring about some level of consistency and accountability among sections so that all students learn a common body of knowledge regardless of the section in which they are enrolled. Dividing up core topics, each instructor compiled a list of basic and advanced competencies that were modified by the group until consensus was reached. These competencies will be included in future student course packets. With this in place, other courses in the teacher preparation program can build on the foundation this course provides.

Pedagogical Knowledge

Most of the course instructors shared the philosophy that technology should not be taught in isolation, but should be tied into the curriculum. Since the majority of our students were just entering the teacher preparation program and had not taken any methods courses, they were unfamiliar with the profession of teaching aside from their own personal experiences from their perspective as a student in a K-12 classroom. As a group, we made a decision to introduce them to the state content standards—the Tennessee Curriculum Frameworks—and the national educational technology standards. We also felt it necessary to introduce the components of a basic lesson plan so students could begin to make connections in planning and designing an instructionally sound, technology-rich lesson or series of lessons. We sacrificed the time consumed by these activities that would otherwise have been spent on regular course topics, but we felt it provided students with a critical foundation to help them focus on technology as a tool to support teaching and learning in a K-12 classroom. Students were expected to connect the competencies they were learning to a curricular area and grade level of their choice.

Students' lack of pedagogical knowledge at this point of their program was evident in the initial lessons produced. Many struggled with trying to learn a new technology skill as well as address issues such as assessment,

---

1 National Educational Technology Standards for Students: Connecting Curriculum and Technology. Published by the International Society for Technology in Education, 2000
lesson planning, unit organization, and creating developmentally appropriate classroom activities. Midway into the semester, a faculty member created a structured, yet simplified electronic lesson plan for students to use as an initial template. This provided an important level of scaffolding as it helped students focus on the basic components of a lesson plan and articulate their thoughts in an organized and concise manner. We plan to provide students with this electronic template at the beginning of the semester along with examples of clearly written lesson plans that include meaningful uses of technology. Due to the time constraints, we have found it necessary to reduce the number of formal lesson plans needed for each technology competency area so students can concentrate on the quality and not the quantity of their written assignments.

Instructional Strategies

The strong emphasis on curriculum connections created special challenges in finding examples that were relevant to students within each section. Overall, 43% of the students were majoring in elementary education, 29% in secondary education (history, English, math, science, foreign language, agricultural education), 10% in special education, 10% in music education, and the remaining 8% came from deaf education, early childhood, and recreation studies. Each section was comprised of students from different areas, making it difficult to find examples of content-based technology applications relevant to all students. Similarly, all students used the same software, regardless of whether or not it was most appropriate for their grade level or subject area. For example, Kid Pix would have been a better choice for demonstrating how one might use slideshows with very young children, yet PowerPoint was selected as we felt that this tool would be relevant to the majority of the students. While our course packet consisted of practical articles that described uses of technology, it would have been costly to include examples representative of every grade level and content area. To address this need, we plan to build an organized resource file from which individual instructors can pull out articles based on specific student interests in addition to linking to online lesson databases or activities. These resources will provide students with opportunities to examine models in order to get ideas for adapting existing activities or developing their own ideas.

Archives of student projects provide another rich source for learning about applying technology to achieve sound instructional objectives. Students' course packets include an authorization form they can voluntarily complete if they would like course instructors to share their work with a wider audience. We feel that student examples provide a realistic picture of what others, who share similar experiences, are able to accomplish. By showing a variety of well-executed projects created by novice to advanced users, students get a sense of what can be done without feeling overwhelmed by perceptions of unrealistic expectations. By combining and organizing student projects among sections, we plan to build a growing archive containing projects and lesson plans demonstrating technology applications across a wide range of areas.

Another major area for improvement focuses on modeling instructional strategies that effective teachers themselves may use in a classroom. While the basic format of each class consists of direct instruction, demonstrations and hands-on lab time for project development, we feel that various models of teaching need to be implemented and articulated so that students begin to recognize, understand, and therefore use these strategies in their own classrooms. For example, instead of lecturing about Copyright and Fair Use Guidelines, we can embed case scenarios for analysis by small groups, thereby modeling the use of teaching cases and the need to make connections to real world events. Time, once again, hinders our ambition to accomplish everything in one class, but much can be done to change the manner in which we model effective and varied teaching strategies with our students.

Procedures for Assessment

The fourth standard in the NETS document addresses the ability for teachers to "apply technology to facilitate a variety of effective assessment and evaluation strategies" (ISTE, 2000). Since many students were just beginning their teacher preparation program, they had not taken any assessment classes. As a result, many were unfamiliar with this area and struggled to identify appropriate assessment strategies. In many cases, preservice teachers were asked to create samples of K-12 student products as an example of how their students might demonstrate knowledge about a subject. The projects had to tie in to instructional objectives as specified in their lesson plans. As a result of this project-based approach, we introduced the notion of using rubrics as a performance-based assessment to our students.
We modeled the use of rubrics by assessing most of our students' projects with various rubrics that we had
designed. In the beginning, different section instructors created their own rubrics. This became a topic of discussion
among the course instructors and an important decision was made to use a standards set of rubrics. One point of
discussion about the initial rubric was the concern that students might have a tendency to use the guide as a checklist
for quality. If the rubric was too vague though, then students might not apply all of the necessary project elements. If
the rubric was too specific, however, we realized that students might be fulfill all of the individual areas, yet not
achieve a quality project as a whole. Eventually, we found a way to combine elements of both the checklist and the
holistic evaluation, allowing us to evaluate the entire project in a way that allowed us flexibility and provided
students with adequate feedback about specific parts of the project that were well done or that needed improvement.

We are aware of the “law of the hammer” and are wary that students may use rubrics as an assessment tool
for all tasks without considering alternatives that may be more appropriate. One of our goals for the future is to
embed various types of assessment options at different points throughout the semester so students develop an
awareness for connecting a task to an appropriate assessment strategy.

Currently, we require students to complete a paper-based technology portfolio of instructional applications
of educational technologies based on the competencies completed as part of the course. An important part of the
portfolio process is to document the development of skills and knowledge through a process of self-reflection. We
are considering the possibility of offering an option to develop an online electronic portfolio and we are currently
piloting this activity in one section to evaluate the feasibility of this option for the wider group.

Conclusions

While the separate introductory course model for preservice teachers is widespread, numerous problems are
inherent with the structure of this type of course, especially when it serves as the only exposure to the use of
technology as a learning and teaching tool in a teacher preparation program. Oftentimes, more than a year might
pass between the introductory course offering and a student's field placement. Unless preservice teachers have a
reason to use and practice technology related skills throughout their program, many will not feel comfortable using
technology in their classrooms. Teacher education students have a better chance to achieve the National Educational
Technology Standards if effective uses of technology are implemented and expected to be demonstrated throughout
all phases of a teacher education program.

The possibilities are encouraging. One student, who concurrently enrolled in the introductory course during
his internship year, reported that he was applying what he was learning and using the projects he developed in his
middle school classroom placement. While he reported that it was not the ideal time for such an experience as he
struggled to learn new technologies, complete class projects, and teach, his experiences demonstrate that timing and
exposure are essential considerations. We believe that the introductory course can serve to provide a solid
foundation addressing the National Educational Technology Standards, but these efforts will need to be supported
by a collaborative and integrated teacher education program.

ENHANCING EDUCATORS' COMPUTER LEARNING WITH THE EMERGING TECHNOLOGY

Dr. Alex C. Pan
The College of New Jersey
E-mail: pan@tcnj.edu

Abstract:
With the emerging technology highlighting hypermedia and the Internet, educators are finding ways to modify the traditional ways of teaching and learning. The need of infusing the Web in education is evident in two surveys of our college students and faculty members as well as a result of a national survey of teachers. To fully maximize the power of the Web to enhance instruction, this paper presents a working model detailing related issues and experiences in a few computer courses, based on a three-level Delta learning theory, containing: (a) technology used as originally intended; (b) technology applied in new ways; and (c) technology as a necessary component of any application. This paper also discusses the various ways in which technology can contribute to better instruction, inspiring students to learn through working cooperatively and collaboratively.

Introduction

Currently, the emerging computer technology which includes hypermedia and the Internet, is drastically changing education. Hypermedia is the combination of both hypertext and multimedia which have a great potential to offer education (e.g., Boyle, 1997; Bagui, 1998; Stoney & Oliver, 1998). Abstract concepts may be presented with concrete examples. The hypertext-based, multimedia applications, or the so-called hypermedia applications, can be made highly interactive in the formats of tutorial, drills and practice, simulations, and entertainment games. Students can explore the hypermedia-based virtual reality as presented in the multimedia software and learn to take control over their own learning and construct new knowledge through such exploratory experiences. High quality course contents may be organized, developed, and disseminated in cost-effective manner for either formal instruction, distance learning, or remedial training purposes.

Hypermedia and the Internet have become an indispensable means to realize such a mission. Hypermedia-based applications can provide a highly interactive learning environment where students build up their own knowledge. With exciting audio and visual elements in the programs, students can master abstract concepts with concrete examples and illustrations. The introduction of the Web has resulted in teaching methods, and teaching and learning styles being changed from the traditional lecture-discussion modality to that of the student-centered learning (Roblyer, Edwards, & Harviluk, 1997). The teachers' and professors' role has also been changed from that of a traditional figure, dispensing knowledge and information to that of a facilitator of learning. As the popularity of the Web increases, so does the number of potential uses in higher education. With both faculty and students, the Web is becoming a very significant component in education at all levels. As Powell (1998) pointed out, the Internet can support lifelong learning because its usefulness does not terminate with graduation.

By its nature of inter-connectivity and huge amount of resources, the Internet and the Web can promote research. Pan (1999) indicated that technology-based research has a great potential to improve the quality of teachers' performance and suggested that higher education teacher preparation programs should engage preservice and inservice teachers in action research with the new technology. Ackermann and Hartman (1998) indicated that the Web has profound effects on the way we find information and conduct...
research. Using the Web for better education has become an ultimate mission and for this reason, a Web-enhanced instructional model is highlighted in this paper.

Technology, especially the Web-based application with the advantage of hypermedia and the Internet, is not just for science and business anymore; it is for our everyday life. The Web has, in reality, become a new fashion in education. With widely available resources, students, teachers, and college professors are learning how to use it and explore ways to maximize the learning outcome with the Web-based activities. Technology integration is deemed as an ultimate goal in most education reform plans. Morton (1996) suggested that technology should be integrated when it is used in a seamless manner to support and extend curriculum objectives and to engage student in meaningful learning.

The Reality of Computer Use in Education

To address the needs of school computer use and to prepare new teachers to know how to integrate computers in their work, it is important to know the reality of how computers are being used at various levels. In a recent survey of all the faculty members in the School of Education at our institution, the results showed that most of those who responded to the survey were aware of the importance of the emerging computer technology in education and they were interested in integrating computers in their curricula. These respondents also indicated that the computer lab resources were inadequate for their instructional needs that are very high. Also, more and easier access from anywhere and anytime was requested. Hypermedia-enhanced materials and the Web has definitely become the more desirable resource to meet their instructional needs.

In another survey of 60 preservice teachers in the School of Education, the results showed that 90% of these teachers had easy access to a computer and the Internet. Nearly everyone, 97%, has used one of the word processing programs to prepare written documents, knew how to send e-mail messages, and had some experience using the Web to surf or to search for resources. However, even if they used the Internet and the Web everyday, most did not know how to find material that is relevant to the lesson they are teaching or how to use the materials wisely for instruction or administrative tasks. These students expressed their interest in learning how to integrate the Web into teaching and to engage their future students in tasks that will help them master the content and further their accomplishments. Currently, many studies and reports show that the utilization of the Web has become a major force in teacher preparation programs. (Robin & Miller, 1998; Ivers & Barron, 1998).

In the schools, teachers are adopting the Web for their instruction and finding it an essential tool. In the Education Week’s 1999 National Survey of Teachers’ Use of Digital Content (Fatemi, 1999), the results showed that 9% of teachers surveyed use Web sites as their primary resources for instruction; 88% use it as a supplementary resource; and 3% use it as a “quiet time” or “bonus time” activities for students. These studies indicate that the use of the Web for instruction is expected to grow continuously in the near future. Likewise, the hypermedia-enhanced applications, very often the equivalent component to the Web, have gained significant importance in education.

The Potential of the Emerging Technology for Better Teaching and Learning

- It presents a new way of learning via inquiry and exploration. Students with all sorts of learning styles can benefit from using it. It promotes student-centered learning activities in which students take control of their own learning and build their own skills and knowledge with meaningful processes and tasks.
- It offers a new partnership between teachers and students in exploring the learning tasks together.
- It provides access to a vast volume of information anywhere and at anytime it may become available.
- It help teachers as well as students to stay current with the newest resources.
• Communication all over the world has made possible learning from people with different cultural backgrounds.
• It allows and encourages cooperation and collaboration between students.
• It makes available hyper links, a major part of the Web, so those teachers may easily direct their students to explore and learn.

Concerns and Issues

The following issues are the primary concerns when developing an effective model for teaching and learning with the emerging technology.
• How much should they learn?
• How can we help students get started and engage them in dynamic learning?
• What should we do to maximize the power of the Web and hypermedia for instruction?

Although the emerging technology provides a great potential for education, it contains many critical issues concerning its usefulness and effectiveness for education. Zehr (1999) indicated that educators have a lot of digital content to choose from, but not all is worth using in the classroom. Simply having students use the Web or hypermedia-based applications for resources does not guarantee successful learning. How to motivate students and how to guide them to explore the huge realm of resources and make sense out of the information becomes a more critical task.

There are a few misconceptions and inadequate practices in using emerging computer technology in education. Often, students are spending too much time on technical aspects of learning about computers, instead of concentrating on the content. Technology should be a tool to enhance learning, not its goal. Sometimes, we find that some students try to learn about computer tasks by memorizing facts and non-essential information in order to pass a quiz. In fact, the most important aspect of learning with and about computers is to learn how to learn in order that they will be able to adapt in the future as new technologies emerge.

Throughout many years of experience, we found that the best way to integrate computers into curriculum is to support learning with relevant materials and to engage students in active hands-on experience. We also found that students tend to accomplish more when they are inspired to pursue their self-defined learning goals and when they are supported by each other through working or connecting with real people and real projects.

To make a profound impact on education with computer technology, a Web-enhanced instructional model was developed based on Schwartz and Beichner's (1999) Delta Principle, which contains three levels: (a) technology used as originally intended; (b) technology applied in new ways; and (c) technology as a necessary component of any application. The Delta principle actually advocates an implementing approach, with which technology will become an integral part of education, and both teachers and students will unconsciously depend on the power and convenience that technology can provide. Teachers especially will find great value in technology and consequently change their way of working.

This model was implemented in several computer courses, including Computer Literacy, Computer Applications for Educators, and Computer Applications for Administrators. These courses have the potential to play a more significant role in our teacher education program. These courses can also provide an authentic context for both preservice and inservice educators to examine instructional practice and reflect on their learning as they acquire new skills and content. Course activities are designed with a scenario, and within this scenario, teachers will utilize the given technology in an exemplary manner, thus providing a positive model for their students and other teachers. The characteristics of this model include the following features.
• A new partnership between faculty and students
• Setting up a learning goal.
Conducting a meaningful study based on individual experiences and goals.

Presenting and contributing to the entire group learning accomplishment.

A new student-leadership through collaboration and cooperation

In this model, students started developing basic experiences with the Web as in a Delta Level I and II where they developed good strategies of searching and using the Web. They then gradually developed concerns about how to bring this technology into their work and teaching in helpful ways. With increased communication among themselves, they relied upon the Web even more than before and used the Web as an essential part of their work.

Prior to taking the courses, most students had limited computer experience. Additional experience that stresses Internet related applications can assist them in the mastering of the skills necessary to meet the challenges of a Web-enhanced learning environment. After learning the required general applications, students were asked to apply their knowledge and skills to some integrative tasks. Appropriate examples might be a written report on information found on the Web, creating a desktop publishing document or generating an on-line presentation.

Students started the course with a great diversity in terms of their computer backgrounds, personal experiences, and individual interests. It is impossible to provide one definite course outline to meet the needs of every one. Therefore, an innovative approach is offered to provide a comprehensive and flexible course outline to address individual students’ needs. As shown in Table 1, both the general computer literacy skills and the Web-enhanced learning tasks were emphasized simultaneously to go along with the three levels of the Delta principals. This approach engages everyone in the class in activities that they will be able to grow with and to better contribute to the dynamic learning experience. Access and platform preferences are also a vital issue that affects their learning. Students tend to accomplish more if they can have easy access to computers and preferably if they can do work on a computer platform that’s compatible with those used in the class. The Web can help with all of these issues.

Students are taking full advantage of the Internet for their own studies. They find resources, seek answers, and develop connections and communication with others. They are amazed by the rapidity of answers to questions. They are also encouraged by other students contributing to their learning through sharing a great variety of resources, ideas, and experiences. They particularly recognized the role of the Internet in the formulation of new learning strategies and practices. The most evident result was enhanced student collaboration and the interpersonal exchange of knowledge.

<td>Students develop the Web-based activities as the further applications to realize the Level III tasks.</td>
</tr>
</tbody>
</table>

Table 1: Technology-enhanced learning skills and computer literacy tasks

Courses based upon this model also entail the following exercises:

- Students reflect their own learning process as enhanced by the Web.
- Students can associate teaching and learning practice with learning theories.
- Students are engaged in serious research efforts.
- Students learn from each other by critiquing and discussing the teaching and learning-based experience.
- Students make adequate and reasonable modifications about their learning goals or administrative plans for implementation or reform.
Students can acquire authentic experience by working with real people for projects or conducting interviews with the personnel in the school.

Educational Implications of the Web

The Web which best represents the emerging technology has made a tremendous impact on today's education on several counts.

Firstly, the Web presents information in the hypermedia format using the combination of the hypertext and multimedia. The hypertext allows the information being accessed through a non-linear sequence so that users may click a button or a hot word to go to a different page/screen on a computer or can retrieve a piece of information or an image. The multimedia can enhance the information display dynamically with sounds, graphics, animation, audio clips, and video clips.

Secondly, the Web can reach students far and near. With an access to the Internet from home or work, students can easily gather information and resources and participate in discussion and communications. In the past, our student had to go to libraries to check out information or had to visit the campus computer lab to work on specific assignments. Presently, they can get on-line from home and conduct even more sophisticated projects than ever.

Thirdly, the Web provides a wide array of information and topics to suit individual needs. The Web allows a great variety of activities where students can browse, search, research, ask and discuss questions or issues, and contribute to the building of new information via Web page construction.

Lastly, the Web promotes communication between people. Students tend to learn more from each other or from real people in the field through cooperation and collaboration.

Examples of Assignments and Exercises

- To identify and discuss how computer technology and the Internet affects the culture of the school and the relationships among administrators, teachers, students and parents.
- To list and describe some of the many programs located on the Internet that are available and valuable to administrators, teachers and students.
- After learning how to develop Web pages, databases and spreadsheets through available tutorials on the Web, develop real or hypothetical applications that could increase financial support and improve teaching and learning in a school or school district.
- Interview school administrators, teachers and other appropriate individuals and determine the criteria, process and the rationale used in the school or district to select computer hardware and software, to initiate a staff development and support program
- Develop a power point presentation such as "Harnessing the Power of the Internet" and present the same to classes and/or other appropriate groups.
- Develop a "School Internet Use Policy" based upon legal and ethical principles, as well as the wealth of experience gained in the recent past.
- Explore how electronic communication and collaboration with other individuals, groups and institutions such as libraries, museums and schools can result in sharing knowledge, skills, values and cultures.

Minimize the Obstacles and Maximize the Learning Outcomes
Differentiate surfing from searching and researching. Students may start with some Web surfing and experience. They should be encouraged to conduct more significant research tasks and develop powerful search skills using electronic tools.

Increase efficiency with proper management of time and stay focused with the intended topics.

To avoid being overwhelmed by too much irrelevant information, help students develop strategies to screen information. For security purposes, teachers should go through most of the possible Web sites before they send students to do it.

Address important issues, such as ethics, copyright, and plagiarism.

Maximizing the Web by making the Web more interactive by adding components such as Web-based discussion, e-mailing, and so on.

When creating on-line publication on the Web, keep users in mind. Avoid loading too many big graphics or multimedia elements.

Summary

The emerging technology has provided a tremendous potential to enhance instruction. In order to integrate hypermedia-enhanced applications and the Web technology into instruction, an instructional model was developed. When implementing this model in various computer courses, students improved their computer literacy skills while they learn how to maximize the power of hypermedia and the Web for better instructional needs. This model can be characterized by various elements, including self-defined goals, hands-on computer experiences, real-world projects, and sharing through cooperation and collaboration. As indicated in the Delta principles, students made progress as they gradually acquired their computer skills and contributed to the Web-based information development. They learned strategies through the completion of various projects and eventually used the computer and the Web as an essential part of their life.

A Collaborative Course Portfolio:
The Core Curriculum of a Core Course

Catherine C. Schifter, Ph.D.; Curriculum, Instruction and Technology in Education, College of Education, Temple University, Philadelphia, Pennsylvania, USA

Abstract: Core courses are those which are deemed to be essential to a major, whether in Teacher Education, History or English. Typically there are several sections of core courses, not all taught by the same persons. How do we engage faculty in the process of ensuring equality across faculty and sections of core courses? Indeed, how do we ensure equality across sections of core courses? This paper presents a model to ensure coherence and continuity across sections of a core course on the infusion of technology in education through a case study of one technology course at one large urban university.

Core courses are essential to any major. Typically there are many sections taught by many people, including full time faculty, graduate assistants, and adjunct faculty. With the diversity of people teaching these courses, how do we ensure equity across sections? Clearly teaching styles vary across faculty, but core courses are by nature intended to teach basic knowledge for the discipline, upon which higher level courses expand. This means that core courses cannot vary in basic information taught or learned, but must have common basic outcomes across sections. However, how do we ensure this?

This paper presents a case study of an ongoing project for faculty teaching a newly revised core course on technology in education. A teaching circle was formed where faculty discuss, collaborate and compare across sections, with the end product to be a Collaborative Course Portfolio. The faculty participating in this teaching circle include 3 full time faculty, 4 adjunct faculty, and 1 graduate student, out of the total of 11 faculty teaching the course during the fall 2000 semester. The other 3 instructors were unable to participate due to work schedules. This process will continue during the spring 2001 semester, with a core of 2 full time and 3 adjunct participating. While it would be nice to have continuity in all faculty teaching core courses, scheduling does not always permit this outcome.

This group met bi-weekly since mid-August 2000 to discuss issues of lesson sequencing, selecting a textbook that better fits the revised curriculum, and assuring each section meets the four themes of the undergraduate teacher education curriculum. These four themes are: inclusion and diversity of students, authenticity of learning experiences, reflective learning, and infusion of technology. Clearly, this course addresses the last theme by virtue of the nature of the course itself; however, the other three themes are not as easy to ensure. To help in keeping track of the activities of the teaching circle, a graduate assistant took notes and began the process of developing the collaborative course portfolio.

It should be pointed out that the teaching circle developed this year is the outcome of two processes. During the 1999-2000 academic year, four of the eight teaching circle faculty met bi-weekly to develop a mutually acceptable set of core course guidelines, which provided a common set of learning objectives and student projects for all sections of the course. This group collaboration provided the foundation for the discussions this year. Secondly, this author applied for and was awarded a Carnegie Scholarship, which focuses on the process of developing the teaching circle, expanding that circle to include faculty who teach specific subject matter, and developing an overall course portfolio to chronicle the collaborative efforts of the group and provide guidance to faculty who teach this course in the future.

One challenge to the teaching circle has been to avoid focusing on technical issues rather than on substantive issues of the course. Given the fact that we teach a course that is about technology, it is quite easy to discuss the technology issues (e.g., problems with lab equipment, student problems with equipment, scheduling) rather share experiences and materials. This group has on occasion fallen into this trap, but the group facilitator has managed to bring the discussion back to issues of substance for the course by relating the technology issues back to the course. Students can learn from technology glitches they may face in their own classrooms, and how we as faculty handle these problems within the course.
In addition to the faculty who teach the technology course, faculty who teach specific subjects that education majors take were invited to participate in the teaching circle. The reason for this expansion of the teaching circle is that the technology course is a core course; therefore, the teaching methods courses should expand upon what is taught and learned. However, if the teaching methods faculty are unaware of what is taught and learned in the technology course, how can they make use of the skills and knowledge in their courses? Likewise, if the faculty who teach the technology course are unaware of technology skills required in the teaching methods courses, they cannot ensure the students are prepared appropriately. Hence, the discussions have begun with someone from Math Education and Social Studies Education. This discussion has been quite fruitful for many reasons. One example is that the revised course focuses on infusing technology into teaching through lesson plans, not merely learning how to use educational software. This is not the course responsible for teaching students how to write lesson plans, but it should not contradict those courses that do. In sharing course outcomes and materials with the faculty member from Math Education, we discovered we were indeed supporting the process taught through their courses. At the same time, the faculty in Math Education discovered that the students are expected to write lesson plans in the technology course specifically focusing on the infusion of technology into the teaching and learning enterprise, rather than on specific knowledge.

The Collaborative Course Portfolio follows one model discussed by Lee Shulman (1998). This model is one of chronicling the process of the course teaching circle, with an analysis of the outcome after the end of the semester. The analysis is a reflective analysis looking back at the discussion and contribution by members of the teaching circle. This information will be shared back to the group the next semester to help determine the direction of discussion. The course portfolio will be available through this author's web site: http://nimbus.temple.edu/~schifter

How can this process be applied to other subject areas or disciplines? The concept would be the same in developing a teaching circle. Getting core faculty to get together on a regular basis to discuss substantive issues common to their courses begins the processes. Chronicling these discussions so they provide guidance to future teachers of the core course is key to making these discussions truly fruitful. The course portfolio provides an opportunity to discuss publicly the similarities and differences across and between sections, and to invite comment and critique from colleagues. The collaborative course portfolio contributes to knowledge about engaging faculty in new teaching practices that highlight the scholarship of teaching and collaboration of colleagues.

Twenty-four articles in this section are summarized according to the following topics: (a) Utilizing Technology for Curriculum Management, (b) Utilizing Technology Resources for Leadership Development, and (c) Research and Recommendations for Improving the Utilization of Technology. Summaries are provided in alphabetical order within each topic.

**Utilizing Technology for Curriculum Management**

This section focuses on efforts of school districts to incorporate technology in tracking accountability progress. These selections would be excellent articles for K-12 curriculum coordinators and administrators as they consider efforts to improve instruction and assessment.

Anderson and Anderson, National Louis University, provide a chronology of transferring a school district's paper-based curriculum notebook to electronic form. Filemaker Pro database was utilized to manage the curriculum, assessment procedures, and reporting systems. Descriptions of other software are provided to assist teachers with lesson planning and grading.

Cafolle and Schoon, Florida Atlantic University, assisted Palm Beach County, Florida, with the implementation of the Instructional Management System to align the state's required standards to the curriculum, instruction, and assessment. The IMS Series provides teachers with data to measure the students' progress towards achieving state benchmarks and standards.

Cassidy, Adelphi University, questions administrative control over the use of technology by teachers. Effective leadership requires principals to have additional responsibilities as they make decisions in the use of school computers. Pitfalls and recommendations are provided by the author.

Floyd, Moore, Bailey, and Reed provide an interesting blend of perspectives from the state, district, university and corporate worlds in the use of technology to meet accountability requirements. South Dakota provided the technology infrastructure to districts, mandated accountability standards, and provided 2-way audio-video systems to deliver certain subjects on-line. Meanwhile, districts outlined steps in their initiatives to provide electronic tools to aid in curricular planning and student assessment. Ball State University prepares its education majors to use the state adopted software prior to graduation. The corporate perspective encourages teachers, schools, and districts to solicit private funding to implement technology rich accountability software.

Lang promotes software agents as the next evolution following the infosphere of internet, intranet, and the world wide web. Specifically, Lang asserts that the thoughtful application of pedagogical agents can support teachers with the application of pedagogical theory. Adele, an animated pedagogical agent developed at USC, has been used in medical education in the areas of family medicine and geriatric dentistry. This type of technology can address institutional goals using a minimum of resources.

Piper and Yan, Indiana University of Pennsylvania, presents the results of a study of 160 teachers and their use of technology in the classroom. Factor analysis was used for data reduction. Teacher behaviors for predicting the amount of computer use are presented.

Swiderski, Education Service Center Region XI, Texas, presents an innovative approach to staff development. "Move to the top of the class" is a series of on-campus and on-line mini-courses to provide technology skills to teachers. The program description, methods of interaction, methods of instruction, methods of evaluation and implementation are described.

Generally speaking, the **Utilizing Technology Resources for Leadership Development** section would be of particular interest to any higher education instructor or administrator that utilizes or wishes to use technology to improve skills of future school administrators.

Kaufman, Indiana University of Pennsylvania, directs a Principal Certification Program that utilizes individual web pages for students to document internship experiences matching the program objectives. Student experiences in six performance areas are posted on web pages and follow a common template. Web pages are accessible to other students, and provide opportunities for collaborative learning, technology competences, and cohort support.
Kim, California State University, Los Angeles, creates webfolios in the first preparation class for the prospective educational leaders. Portfolios used in this project are authentic assessments of leadership skills. The webfolios document school leader training throughout the program. Students and faculty become active partners in the teaching and learning process. Kim summarizes the results of the project and provides recommendations.

Sain and Weber, Florida Atlantic University, report the use of a variety of multimedia produced, simulation modules in their leadership training program. Developed with Authorware, content is delivered via interactive simulations in an educational organization course dealing with administrative theory.

Shoffner, Georgia State University, presents the results from an exploratory national survey on the presence of instructional technology professionals in school settings. State licensure requirements for instructional technology certification are explored with explicit licensure rules the focus of the study. Pros and cons of licensure are also provided.

Sobehart, Tomei, and Armstrong, Duquesne University, founded the Leadership Institute and Interdisciplinary Doctoral Program, to train future superintendents and other school executives. Cohorts of 30 students are admitted every three years. Each student is assigned a practitioner mentor. Systematic use of technology skills, electronic portfolios, distance learning, and electronic curricula are cornerstones of the program.

Walker, University of the West of England, UK, portrays the leadership role in higher education institutions as an "entrepreneurial activity" linked to the e-learning revolution. Lessons learned and issues still to be resolved are stated.

Waterhouse, Embry-Riddle Aeronautic University, profiles needed careers in instructional technology. Also presented are new principal duties and responsibilities to facilitate instructional technology.

The final section groups articles with a common theme of Research and Recommendations for Improving the Utilization of Technology. These articles would appeal to those in higher education as well K-12 education interested in the future technology initiatives.

Bork, University of California-Irvine, provides a critique of the failure of teacher inservice efforts and makes two recommendations for alternatives to inservice education.

Braswell, Auburn University-Montgomery, and Childress, Emporia State University, present findings from a study of technology use by university administrators. The perceived use and support of technology at these universities were also provided.

Carlsen, Mathies, Hawley, and Veres, Wright State University, evaluate the development of an on-line course delivered through the WebCT, WebBoard, and Tegrity while both synchronous and asynchronous methods of delivery were used. Social and cultural needs of students were considered in this development.

Chandra-Handa, Knox Grammar School, Australia, suggests a 2-level paradigm shift for leading academic change. One level is in learning and the second is in educational leadership. Learner-centered education for both students and teachers are recommended.

Gibson and McLaughlin, National Interagency Civil-Military Institute, and others provide in an interactive panel discussion addressing the needs for further development of SITE's web sites. Session goals are provided.

Gibson, Wichita State University, examines the role of administrators as instructional leaders in their integration of technology into the learning environment. The author used focus groups to collect qualitative data on the importance of administrative support in utilization of technology.

Kavanagh, University of Queensland, Australia, challenges instructors in universities using internet delivery for courses. The author describes a learning model "reflective of the needs of its learning community." The author touts flexible teaching and learning systems, shifts in university policy relative to the development and delivery of courses, and the process to bring on-line such courses.

Davis, Project Story Teller, and Engelhart and Korth, DIAL Corporation, support inquiry through the co-delivery of ideas by design teams and models the process. WebMaster Institute teams build technical skill, and other design teams combine content and technology into course modules. The program outcome is longevity and sustainability of technology.

Nelson, University of Wisconsin, focuses on the planning effort of the University of Wisconsin System to integrate technology within their teacher preparation programs. Change strategies are explained within the context of the University organization.

Szabo, University of Alberta, presents a set of guidelines to prepare educators for the Instructional Technology revolution. Recommendations are based on a review of current technological and sociological developments with an eye towards the future.

John R. Tollett, EdD is Dean of the College of Education at Northwestern State University of Louisiana. His research and teaching interests include public school finance and school administrator/leadership development. He serves as a facilitator for the La. State Department of Education's Aspiring Leaders Academy and Project LEAD for first year Assistant Principals. He also directs the Leadership Internship Program on-line. His address is College of Education, Northwestern State University, Natchitoches, LA. E-mail: Tollett@nsula.edu
Electronic Curriculum Development and Assessment

Kevin M. Anderson, Ed.D.
Director of Instruction
Kenosha Unified School District No. 1

Abstract: This poster demonstration by Kenosha (WI) Schools will show screen shots from a Filemaker Pro curriculum database representing the official academic curriculum of the district, provide samples of grade reporting formats using Easy Grade Pro, and demonstrate hands-on use of the programs through the use of two laptop computers. Visitors will be able to examine the formats and offer suggestions about future improvements to the system. The intent of this session is to provide K-12 schools and teacher education institutions with a look at how one public school district is developing electronic methods for developing curricula, assessing student performance, and reporting out on standards to parents and the community.

The Kenosha (WI) Unified School District has been working for the past several years to develop a paper-based curriculum notebook for use by teachers in all subject areas. These notebooks contain the standards and benchmarks that are the basis for instruction in the district, a 20,000 student school system about 30 miles south of Milwaukee, Wisconsin. In addition, the notebooks contain lifelong learning standards, examples of exemplary units, and other supplemental information. These notebooks have now become the official curriculum guides for the district and are available in each classroom and school library for teacher, student, and parent use.

Due to recent advances in the availability of technology for all teachers, over 6,000 computers are now in use by over 1,700 teachers and 20,000 students in the district. The majority of these computers are now connected to the web through T-1 lines, enabling easy and fast access to networked programs and Internet sites. Because of this new accessibility, efforts are underway to produce electronic versions of the curriculum notebook, including assessment procedures and reporting systems to check on progress toward meeting student academic standards. This poster demonstration presents the current work on these electronic curriculum development and reporting programs.

The Kenosha Schools have contracted with the TIES company of Roseville, Minnesota to produce an electronic curriculum notebook using the Filemaker Pro database. While the design of the notebook is not completely finished, the potential of using such an electronic curriculum notebook is readily visible. Current plans call for producing both a web-based version of the notebook and a CD-ROM version. These two versions will allow teachers to access the database in their classrooms either on-line or without an Internet hookup. As they design lessons and units, teachers will be able to quickly search for benchmarks, activities, vocabulary words, sample assessments, and suggestions for teaching about the particular skill. They, they will be able to "drag and drop" information from the database into a lesson plan template and create their own customized plans. It is planned to include scanned pictures of required lesson materials, audio clips, and QuickTime movies for use by teachers in their lessons.
Figures 1 and 2 below show a screenshot of a standard page and a benchmark page in the curriculum database. It should be noted that the vocabulary and content specific notes sections are still blank in this version. These fields are currently being completed by teams of district teachers.

Figure 1: Screenshot of a standards page in Filemaker Pro

Figure 2: Screenshot of a benchmark page in Filemaker Pro

In order to maintain a consistent and accurate database, teachers will only be able to access and use the information without being able to make changes to the database. While entering information will be the responsibility of one or two teacher-consultants or their secretaries in the district’s central office, teams of teachers will work together to develop the information about each subject standard and benchmark. In addition,
changes to the database will primarily occur when a subject is due for review under the district's curriculum review cycle (Figure 3). This means that major information will be entered for all subjects during the first year, followed by revisions for individual subjects at regularly specified intervals. Plans are to make the CD-ROMs available to subject-area teachers each August with the newly updated benchmarks and materials for their areas. Due to the cost, it will still need to be determined whether to give each teacher an individual copy or to give grade level teams one copy. Teachers having Internet access at school or at home could also work with the database by downloading information and using it for lesson development.

Figure 3: Curriculum Development and Renewal Cycle

In conjunction with the development of the electronic curriculum is the piloting of an electronic gradebook for reporting out on student success with subject standards. The district has made the purchase of Easy Grade Pro for all teachers in the district based on earlier pilot studies conducted last year. Previously, some of the teaching staff had used various grading programs for doing grade reporting, but various limitations forced the district to look for a more complete reporting program. Easy Grade Pro appears to meet this need. Teams of subject consultants and classroom teachers have been testing the use of this grading program with the district's standards and benchmarks and have found a great deal of support from the users. Figure 4 shows a reporting screen with fictional student scores.

Easy Grade Pro allows teachers to input class lists from several other electronic sources. This facilitates the switchover from the other grading program currently being utilized in the district. Also, grading schemes may be set up as letter grades, pass-fail, rubric scores, and percentages to give several different views of student proficiency. In fact, each student in a class may have a different grading notation or approach to meet the individual needs of diverse learners. Numerous reports and graphs may be generated from these student scores, providing teachers with a myriad of ways to show students and parents about academic progress.

This poster presentation will show screenshots from the various programs, provide samples of reporting formats, and demonstrate hands-on use of the programs. Suggestions will be welcomed about future improvements to the system. The intent of this session is to provide K-12 schools personnel and teacher education faculty with the opportunity to see how one district is developing electronic methods for developing curricula and assessing student performance.

THE DILEMMA OF TEACHER TRAINING

Alfred Bork
Educational Technology Center
Information and Computer Science
University of California
Irvine, CA 92697-3425

Introduction

In 1957 the Soviets put up the first earth satellite, Sputnik I. For education in the United States this was a traumatic event. Until that time, many (but not all) people, including the popular press commonly denounced Soviet science as ineffective. The fact that it achieved this major technological development, visible in many parts of the country, before we did led to much trauma about the quality of science education in the United States.

One reaction was a major organized curriculum effort in American education, the major such event in our history, mostly funded by the United States government. It lasted about 15 years. Many of the courses developed cost millions of dollars to produce, so the curriculum efforts were well funded. I would estimate that close to one hundred million dollars were spent in these extensive efforts, more by today's prices. Major individuals participated in their development, including major figures in science and education. The concentration was on the east coast, but it was a nationwide effort. Books were the most common product, with some production of films and other items.

Some initial efforts were in elementary science, including such major products as the Science Curriculum Improvement Project (often called SCIS) at the University of California, Berkeley, directed by Robert Karplus. A similar project was the Elementary Science Study at MIT. These courses were very different than existing practice at the elementary level, with much more emphasis on the processes of science, and much less emphasis on memory. Mathematics courses followed, also with new approaches.

High school courses were developed, and even a few university courses. I was involved in one of these, the Harvard Project Physics course for secondary school. One project, Man a Course of Study, a fifth grade sociology course, brought this period to an abrupt end, for political reasons. This was a very interesting story, but not relevant to this paper.

Although many of the resulting courses were widely praised by scientists and educators, most of the products were not successful in practical usage. Only the biology courses, produced by the Biological Sciences Curriculum Study group are in common use today.

This well-funded failure led to much agonizing about what went wrong. Some of this thinking appeared earlier, but we are still hearing the reasons for lack of success. Probably everyone, including me, 'knows' why failure happened.

One such reason commonly given for this failure was of considerable importance at the time, and is the primary concern of this paper. Since these new courses were different than older courses, it was believed that teacher training was essential to prepare teachers for this new task. Not only the content was different, but with many of the courses the entire philosophy of what the student and teacher were supposed to do was strange to many teachers, different than their previous training.

A major effort in training teachers in these new courses took place. It is difficult to estimate the funds that went into teacher training for the new courses, since the funding came from so many sources. I have seen an estimate that teacher training costs for the post-sputnik courses were seven times the cost of development, which would make the total over five hundred million dollars, a huge amount. But mostly the courses were not helped by this large effort. Teacher training was not effective, and most of the major post-sputnik efforts died.

We continue with such efforts in training teachers, for all of education. It is a major part of the educational funding of the National Science Foundation, and other major federal agencies.

Almost every new school movement is matched with a corresponding training activity. But, in spite of occasional glowing reports, it is seldom successful. Training teachers is a common problem with education generally. One might say it is the Achilles heel of education.

An Impossible task

I wish to argue that inservice training for a sufficient number of teachers for new curriculum and learning methods is impossible by present means, and perhaps by any means. It is a myth to believe that we can effectively train enough teachers. I am basing this argument primarily on the United States, but I believe that similar factors apply worldwide.

The central problem is numbers—too many people in this country and on earth. With so many people who need to learn, our current systems for learning employ large numbers of teachers. In the United States there are now about three million teachers in 90,000 schools. We have about 48 million students, of ever greater diversity. But most of our thinking and strategies in these matters is based on older traditions when the numbers were much smaller.

The numbers change everything, in ways that we are only beginning to understand. Others have noted this.
Sober thought also tells us that any suggestion that some two million teachers be retrained to change what they do in classrooms must be called wishful.

Leslie Hart
Human Brain and Human Learning
1983

We still spend enormous sums on inservice teacher training. Whenever something does not work, it is the recommended solution, just as with post-Sputnik developments. Major organizations, both nationally and in the states, support this approach.

Currently teacher training is being heavily touted for the use of the Internet in classes, as it becomes clear that Internet connections in all schools often do not lead to improved learning. An article in the New York Times of July 3, 2000, reports that 95% of schools in the United States now have Internet connections. Once more, the cry in this article and in many other places is that we should train the teachers. One more, the teacher training is not necessarily appropriate. A friend, about to get into computers in her class, is in a course to prepare for this that is teaching her about bits and motherboards!

The results of teacher training are very variable. Some teacher programs turn out to be very effective, but this is a small number. As with much education, we look for success and try to imitate it. But these good examples often depend on the existence of special situations, such as a very superior teacher involved in the training, not duplicable elsewhere.

Often the teachers are thrown in different directions every few years in these training programs. Several years ago California elementary teachers were told that they should integrate all subjects by establishing a common 'theme' for all areas. A friend chose 'trails' as her theme. But this approach was quickly downplayed. Teachers are tossed around with little consistency from year to year, making a difficult task even more difficult.

This variation is particularly bad with the critical elementary areas of reading and mathematics in the elementary grades, where the battle for different approaches has gone on for a long time. The pendulum often swings, although it would seem that research could settle the issue.

One approach that has been tried many times is the 'trickle down' approach, with a variety of names. It recognizes that we cannot reach all teachers directly. The idea is that we will train a few teachers, and they will train other teachers at their schools. This may proceed for many generations. I was involved with one such effort involving educational technology for a school district in southern California. I had a chance to talk to teachers in the third generation, after I had run the first generation. I could find almost no relation between the two generations; nothing I did survived. I know of no large-scale evidence that the trickle down method works. It does not work as a method for reaching effectively large numbers of teachers.

Such efforts are generally poorly evaluated, with regard to their long-range effects in improving learning. This is a common problem in many areas of learning, even though some agencies insist on built-in evaluation as part of the project.

Although the sums spent in this direction are very large, they never are enough to reach all teachers. We can wonder if they will ever be enough, given the numbers of teachers we are now faced with. It seems unlikely. So teacher education is a dilemma: We need it, but we cannot afford it. The situation is much worse in the poor parts of the world.

The pattern is as follows:

1. We develop new curriculum, new ideas for improving learning.
2. These do not work
3. The suggested solution is to train the teachers.
4. This does not work.

SOLUTIONS TO THIS PROBLEM

Given that current methods of addressing the problems of inservice teacher training are inadequate, how do we proceed. There appear to me to be two ways out of this dilemma, both making effective use of the computer. Both are expensive at the beginning, but have possibilities for greatly reducing the long-term costs of learning. Both involve bold new directions, which little current experience, so both involve possible risks. They need major experimental efforts to demonstrate their effectiveness or lack of effectiveness. I see no other possibilities, but I welcome other ideas.

These two suggestions are related, in that they both involve expensive use of carefully prepared computer-based learning material. In the first case teachers are the learners. In the second the students are the learners. In both, distance learning is a natural delivery method. In both, the highly interactive units would adapt to the individual user. In both the learning material could be used anywhere at any time. One involves tutorial computer-based units for teachers, and one computer-based tutorial units for students.

1. Teacher training via interactive computer material

Several years ago we made several unsuccessful efforts to obtain funding for computer-based learning units for teacher education in educational technology. Just before this we had conducted at Irvine an expensive training session of this kind, taught in a conventional fashion, funded by the state of California. I did not think it was too effective, in spite of high costs. A quick calculation suggested that this was far too expensive to scale to all teachers in the state, the country, or the world, if we brought all these teachers to Irvine. Further, the manpower to do this for all teachers would not be available. Hence I planned the proposals to do all this through the computer.
Such an approach does not need to be training in educational technology, although it was natural because computers will be required because of the subject matter. It could be done in any area.

Since the second suggestion also involves computer-based learning, I will postpone the discussion of the details of computer-based tutorial learning units, including how such material is developed.

2. Computer-based tutorial learning for students

The second approach, students learning through interactive computer material, is a much more radical approach to teacher training, because it removes the need for most special training of the teachers. It is based on the possibility of distance learning, both in schools and informal environments, using a new form of learning material. It would require a radical change in learning, compared to our current situation.

It would allow, after sufficient learning material is developed, far fewer teachers than we now need. So the educational systems would be very different than those today. Learning would be tutorial.

As with the first suggestion, almost no material of this kind exists at present. In the next section the notion of tutorial computer-based learning is developed further.

TUTORIAL LEARNING FOR TODAY

Tutorial learning with human tutors has a long history, but because of the expense involved it has always been used with a limited number of students. A skilled tutor works with one or several students. This situation does not resemble a lecture in any way. Often, as in the case of Socrates, the tutor proceeds by asking questions. With good tutors this approach has proved to be a very successful learning strategy, with students of all ages.

But tutorial learning with human tutors is far too costly to be possible for all learning, and we could never find enough tutors for our large populations today. But it is possible and practical if the computer can serve the role of the tutor. We have been developing such computer-based tutorial units, on a small scale, for over thirty years at the Educational Technology Center at the University of California, Irvine. It requires no technology or learning approaches beyond that available today.

Here are the critical features of such learning modules.

1. A very high degree of interaction

Tutorial learning is active learning, student centered. Although computer material is frequently called interactive, to achieve the tutorial format we need a higher degree of student-computer interaction than is commonly found today. Interaction refers both to the frequency of interaction, and the quality of each interaction, as discussed in the next two sections.

One important consequence of active tutorial learning is that students can discover much of their knowledge rather than being told it. Examples will be given later.

2. No long speeches on the part of the computer

Frequent interaction means that the time between two student inputs should be short. Our testing in public libraries shows that the maximum interval between two student inputs should be no longer than twenty seconds.

This implies that computer and student "speeches" should be limited, as in human dialogs. So we do not want in interactive material long pages of text, as in most Web sites today, or long video sequences. The interaction should resemble a conversation, not a series of long essays.

3. Use students' natural languages for interaction

The highest quality of interaction between two humans comes from our natural languages, perhaps the most powerful of all human tools. We seldom use pointing and multiple choice for human communication, so it should not be used with computers, a radical departure from today. This use of languages should be in both directions, student and computer.

Student input should be in the free-form natural language of the student. Thus the student might reply to a question from the computer or ask a question, in English or in another language.

Until recently this was possible only through typing. Now reasonable voice input is possible, with commercially available inexpensive speech recognition engines. Speaking is much more natural for humans than typing. With very young children it is the only approach possible.

4. Seek and help with individual student problems

A key to learning with tutors is that the tutor is constantly seeking student learning difficulties. The tutor needs to understand what problems are likely in each situation, and to find ways, usually through asking questions or giving problems to solve, to determine just what difficulties are to be found at each moment in learning.

This is the principle pedagogical purpose of the frequent and high quality interactions just mentioned. Once such difficulty is located, the tutor proceeds to assist the student, checking to see if this assistance was effective. This is a continuing frequent activity in learning with tutors.
Another way of viewing this helping process is that assessment is intrinsic to the learning material, occurring frequently and indistinguishable from learning. Its purpose is to decide what learning material is required next. The student is not aware of taking tests.

5. Assure mastery for all learners

This frequent mediation for student learning problems can be continued until all students learn the material fully, to the mastery level. Benjamin Bloom and his students showed that mastery is possible with tutorial learning, in extensive experiments in the Chicago public schools. Several different learning sequences might be necessary, as not all students learn in the same way.

Since all learners succeed, we can have a much more positive view of learning, encouraging lifelong learning.

6. Anywhere, Anytime, all students

Presently we could reach very large numbers, with CD ROM or the Internet, with such learning material, assuming computers are available to the students. In the near future, with satellites, special inexpensive computers, and solar powered computers, we can expect to reach almost everyone on earth.

With distance learning the students can be anywhere. Learning can start and end at any time, with computers maintaining the records. Students can proceed at their own paces.

7. Distance learning

Although tutorial learning modules could be used in traditional schools, universities, and training centers, most of the future use would reach people wherever they are. Students might be in homes, libraries, shopping centers, community centers, museums of various types, or in specially build learning facilities. They could be sitting on a swing in a yard, on the beach, or in the middle of a field of poppies. Distance learning liberates us from particular learning locations.

Distance learning should be in a form that can reach very large numbers of students.

8. Peer learning

A valuable learning approach involves students helping each other. Learning circles can be established either locally, or remotely electronically. Student records stored by the computer will assist this process.

9. Intrinsic motivation

As students involved in distance learning will not be subject to the pressures and threats of standard classes, the learning materials must keep students interested in learning. Since everyone succeeds, the experience of learning can be enjoyable for all.

Learning modules must be intrinsically motivating, keeping students at difficult tasks. A high degree of interaction will be of major help here, as active learning keeps students involved. Other motivational approaches may be useful in holding attention, but the focus should be on learning rather than entertainment.

An important part of formative evaluation, part of the development process, will be to verify that the student’s attention is maintained for long periods. In testing units in informal environments like shopping centers, where students are under no pressures to continue except their interests, we can record where many students leave the program, and rework such sections until they are motivationally strong.

10. Very large numbers of students

Our world now has six billion people. So educational activities need to look toward very large audiences, many cultures, and various languages. Types of distance learning suitable for groups of twenty or thirty, increasingly common in United States universities, will not be adequate to the needs of our society.

Since very large numbers of people would be involved, the units would need to work without teachers, as well as with teachers.

IS SUCH LEARNING MATERIAL POSSIBLE?

The picture presented for tutorial computer-based learning is very different than most learning today. To some it will appear, I am afraid, as a fantasy. But I believe it is a realistic possibility for the near future. I begin with examples of such material from the Educational Technology Center at the University of California, Irvine.

As mentioned, we have been developing tutorial material for over thirty years, with mostly much more primitive equipment than now available. An example is the Scientific Reasoning Series, developed about a dozen years ago. There are, in the form sold by the IBM K-12 group, twenty hours of student material. Other material developed was not marketed commercially.

Examples from this Series can serve to illustrate the possibilities for tutorial computer-based learning. In one, a program called Heat, the aim is to have all students invent the scientific concept of heat, starting with everyday knowledge about temperature. The program begins immediately asking the student how she or he measures his own temperature, and waits for a free-form answer. The student may need to be prompted if she or
he does not answer in a reasonable time. The program continues in this questioning form for about one hour, one of the shorter programs in the Scientific Reasoning Series.

Other examples from the series show the possibilities of students discovering their own knowledge. One example is Families. The aim is to have students discover important scientific laws, Mendelian laws of genetics. The student makes experiments with imaginary animals, Nors. The computer is always watching what the student does, and offers advise only when necessary. All students discover these important laws. This is one of the most difficult programs in the Series, taking about two hours for a typical student.

In another program students discover the simple laws of electrical circuits, such as the need to have a closed circuit to light a bulb. This program is based on modules developed in the elementary science projects in the post-sputnik development. They do not use equipment at the display, but students are urged to do this on their own.

I remind the reader again that these were done many years ago on computers with far less capability than contemporary computers.

DEVELOPING TUTORIAL LEARNING MODULES

I will not discuss in full detail how such units are developed. The system we use was developed beginning thirty years ago at the University of California, Irvine, and the computer science group at the University of Geneva, in Switzerland, joined with us about ten years ago.

Creating tutorial learning requires a different development strategy than is common today. Four stages are involved, management, design, implementation, and evaluation. The designers are very good teachers in the area involved, working in groups of about four. They do only the design; they do not program, for example.

Further details can be found in the Irvine-Geneva paper at the Web site mentioned at the end of this paper. Other papers there also describe the development process.

COSTS FOR TUTORIAL LEARNING

The cost of learning needs careful consideration. Learning must be affordable for all. The cost for an hour of student learning is the most important figure.

At least three factors are involved in determining costs, the cost of development, the cost of delivery, and the cost of the management structure.

1. Development costs

In the post-sputnik development mentioned at the beginning of this paper, a course cost millions of dollars. A course at the United Kingdom Open University costs a similar sum to develop. Most recent development in the United States, such as the Web-based university courses, costs much less, but one can raise questions about quality of these passive courses. The computer-based learning literature is full of useless statements that it takes three hundred or so hours of time to produce one hour of student time, again a low figure for quality material, and not a reasonable way to approach the costs of development.

Development is not the whole ball of wax, so considering this alone in computing costs is very misleading. The Open University has long demonstrated that expensive development of quality material can lead to low costs per student.

2. Delivery costs

Conventional university courses have little development costs, but high delivery costs, because of the salaries of professors. Self-study such as reading a book has a low delivery cost.

An interesting factor in delivery costs is the number of students who can learn with the approach used. With some kinds of learning, delivery costs increase with the number of students, but another possibility is that they decline.

Management costs

In a conventional school these include all the administrators, often a considerable number, and all the record keeping. With computer-based distance learning the computer maintains all the records and does the administrative work, at a low cost per student.

Tutorial distance learning can reach large numbers of students, with low costs per student. With large numbers, expensive development is coupled with low delivery costs.

BACK TO TEACHER TRAINING

After this interlude to discuss tutorial computer-based learning we return to the problems with teacher training. I suggested two ways out of the dilemma presented by the typical failure of teacher training, computer-based learning for teachers, and computer based learning for students.

We should try both of these approaches. It may be that both will be needed, at least in the immediate future.

Careful research
Conduct extensive longitudinal studies on the results.

Abstract: This paper reports the findings of a study on the use of technology by administrators at two universities. Instrumentation included a survey and interviews which investigated various factors (including time spent using technology, types of technology used, how administrators used technology in any classes in which they were teaching, and their awareness of how university faculty are using technology).

Introduction

Throughout the country, universities are implementing plans to integrate new technologies and teaching/learning strategies into their classes. As a part of these plans, they are developing computer/technology competencies for their students, as well as for their faculty members (Algozzine et. al, 1999). Faculty are asked to not only integrate technology into their content, but into their teaching methods, research agendas, and daily routines. Several universities and colleges are now concentrating on the task of designing and developing technology competencies for their faculty members (Hill & Somers, 1996). As university campuses become more technology-intensive and courses use more technology, we are finding that many faculty members require and request training in using various technologies. To assure that their faculty can meet competencies, many universities offer workshops, training sessions and one-on-one mentoring. These 'faculty development institutes' provide much needed skills which help faculty to attain these competencies. Accrediting bodies such as NCATE are also emphasizing the importance technology, "NCATE standards now expect its accredited schools of education to provide adequate access to computers and other technologies, and expect faculty and students to be able to use it successfully (NCATE, 2000)." On a whole, many university faculty members have answered this call for increased technology use by improving their technology skills and demonstrating those skills in their teaching methods. But, how are university administrators improving their computer/technology skills? And, what are they doing? What, if any, competencies might be needed? This paper will attempt to answer some of those questions and hopefully shed light on the use of technology by university administrators.

Survey and Interview Process

In this study, administrators from two universities (Auburn University Montgomery and Emporia State University) were given a survey and were interviewed about their daily technology use. Interviewees included department/division chairs, deans, associate deans, assistant deans, and vice-presidents. In addition to a survey on technology use, the researchers used a questioning protocol which included open-ended queries regarding technology use in 1) daily administrative duties, 2) teaching duties, 3) class scheduling and student record-keeping, 4) awareness of faculty use, and 5) faculty training needs. Results from the surveys and the interviews were then compiled and categorized, resulting in the findings below.

Findings
Interviews showed that administrators at both universities used various technologies in both their work and their classes. However, the use of the technologies was often dictated by various administrative duties. For example, administrators at one university were using Banner to access administrative records, including class scheduling and student records. Administrators at another university were using a UNIX-based system to access the information needed for administrative duties. Almost all of the administrators surveyed at both universities were using standard productivity software (such as word processing and e-mail) during their daily duties. It was found that the administrators had access to the Internet and most used the Internet at least one time each day.

The researchers also found that administrators who were teaching used a wide variety of technologies. Web-based instruction was being used by some of the administrators. For example, several of the administrators at one university were using WebCT as part of their coursework, either incorporated into the regular classwork or as a method of offering their courses on-line. Most of the administrators at both universities who taught classes were using software such as PowerPoint as part of their use of technology in their classes. However, the use of technologies by administrators who taught classes was sometimes limited by the scope and number of classes taught by the administrators. These administrators were usually teaching a class load which reflected their duties as both teachers and administrators. Very few of the administrators regularly taught classes in a computer lab where all of the students had access to computers. Instead, they included computer lab time in their classes, when appropriate. For example, one administrator taught a health and nutrition class and brought her class to the computer lab to demonstrate how to use the MacDine program (a nutrition-based program). Students then used the program as part of their normal class assignments.

Administrators at both universities were exceptionally aware of how their faculty members were using technology. This awareness is partly driven by the emphasis on technology use by accrediting bodies. The administrators see the need for further faculty training and are addressing this need by creating training opportunities and faculty training institutes. Some of these institutes are delivered campus-wide, while others are contained with colleges and departments/divisions. Although faculty needs are being addressed, administrators’ technology training needs seem to be neglected. Unfortunately, many administrators feel as though they are falling behind their faculty in technology skills and use. In order for administrators to lead their faculty into the 21st century with new technologies and teaching paradigms, they must identify their own technological skills and address those needs with training, just as they have addressed the needs of their own faculty.

Implementing an Instructional Management System: Final Report

Dr. Ray Cafolla, Florida Atlantic University, Educational Technology and Research, USA, cafolla@fau.edu
Dr. Perry Schoon, Florida Atlantic University, Educational Technology and Research, USA, pschoon@fau.edu

Abstract: The national trend toward the use of high-stakes testing to make schools accountable for the standards students have mastered has forced school districts to take steps to ensure that the curriculum taught in the schools is based upon the standards the students will be tested on. This paper discusses the results of implementing a sophisticated Instructional Management System (IMS) to help accomplish this task. IMSeries is a sophisticated relational database that was implemented to change the paradigm of how teachers think about the lesson planning process. Rather than concentrating on what the students will do, this project encouraged teachers to begin by thinking about what the students will learn. By using this system, teachers were able to track which standards were mastered by each of their students and design their lessons based on individual students' needs. This paper presents an overview of this three year project in the hope that the lessons learned will be beneficial to other districts interested in exploring the use of computer systems to support instructional decision making.

Introduction

In the fall of 1997, the School District of Palm Beach County was awarded a Goals 2000 Professional Development grant. A major part of this grant was to select and implement an instructional management system (IMS) to help align the district's curriculum to Florida's Sunshine State Standards. The process of selecting the IMS has been reported in detail both at the International Conference of the Society for Information Technology (Elias, Cafolla, and Schoon, 1998) and in the Journal of Technology and Teacher Education (Elias, Cafolla, and Schoon, 2000). The purpose of this paper will be to present an overview of the final results of this three year project. Given the expense and time spent in selecting and implementing a sophisticated IMS, we feel it important to share the lessons we learned with others that might be considering similar systems.

Background

The nation school reform movement has focused on the use of high-stakes testing to ensure that students have mastered minimum performance standards. In Florida, the standards are called the Sunshine State Standards (SSS) and are measured by the Florida Comprehensive Assessment Test (FCAT). Like all of Florida's school districts, Palm Beach was required by the State to align its curriculum with these standards. To accomplish this task, school district staff led by the Office of School Improvement decided to investigate the use of a technology based Instructional Management System (IMS).

As educational institutions attempt to restructure and redesign the school and its culture, they need a means of unobtrusively, continuously, and automatically gathering information and making it available to various decision makers. Data such as attendance, schedules, curriculum, assessments, resources, grades and performance evaluations are needed on a daily, monthly, and annual basis. The importance of the information generated and how it is used to support instructional decision making is obvious.

The vision of the Palm Beach school district was to develop a technological infrastructure with the ability to support genuine change in the way that teachers thought about teaching. A system that could serve as a means of revitalizing the process of continuous school improvement. The district applied for and received a Goals 2000 grant to engage in an effort to bring about significant school improvement by using technology in "...the acquisition and use of information for data-based decision making, Information Management Systems (IMS's) are of fundamental importance..." (Carter, 1997). Carter goes on to state "It is necessary to put the curriculum "on-line" in order to address adequately the close monitoring and reporting of student progress and performance against outcomes" (Carter, 1997). The District's goal was to select a system that was "...designed to align the Sunshine State Standards, curriculum, instruction, and assessment to address individual needs of the students and track their progress achieving the Sunshine State Standards." (Cartlidge, 1998).
To identify an appropriate management system, the school district formed a Design Team charged with the responsibility of identifying, evaluating, and testing various systems. In addition to Palm Beach district personnel from the Office of School Improvement and the participating schools, the Design Team had consultants from Florida Atlantic University and the Area Center for Educational Enhancement. As noted above, the identification, evaluation, and selection of the management system IMSeries have been reported elsewhere (Elias, Cafolla, and Schoon, 1998; Elias, Cafolla, and Schoon, 2000).

Professional Development

One of the major components in implementing the IMS was concerned with preparing teachers to use the system to make instructional decisions. This training had several components. The first was the challenge of teaching the participants how to use the software. While all of the participants had some computer skills prior to being accepted into program, IMSeries is a complex relational database that requires several days of training to use.

More important than simply learning the software was changing the way teachers think about lesson planning. From the work done for this project and a similar project, the importance of linking outcomes to assessments eventually became clear. With the implementation of IMSeries at each school, it became obvious that the teachers desperately needed continuous, on-going staff development on unit and curriculum design in addition to IMS training in order to input meaningful activities, assessments, questions, etc. into the IMSERIES database and more importantly to align the curriculum with the Sunshine State Standards. Most of the participants still centered lesson planning around the activities the students would engage in. In the new paradigm, the teachers had to be taught to begin with the Florida Sunshine State standards that would be covered. Participants had to learn to begin by using IMS to determine which objectives needed to be taught. Numerous professional staff development sessions were thus organized to provide the curriculum training.

Understanding the instructional design process was the single most important component of this project. The implementation of an Instructional Management System may have resulted in no significant changes in student performance if not for a systematic change in the process by which faculty created and delivered instruction. Data from the study suggest that the project did not effectively begin to meet its' goals until curriculum design became the number one focus. The approach is currently changing from activity-based instruction to standards-based instruction. As one project teacher stated, "This project has changed my way of thinking 180 degrees. I have become more creative and thorough. By being trained to use the instructional management system, I now approach my unit design from the standards and benchmarks first and then I decide on the activities to meet those benchmarks."

Summary of Implementation Accomplishments

During the project, 84 units meeting the curriculum design criteria were developed by project partners. Fifteen of the units came from teachers at the three pilot schools, while the other 69 came from District curriculum writing teams during the summers. In addition, 57 additional units were created by university students. The total units to date that meet the curriculum design specifications are 141. However, individual pilot teachers also have units under development in the schools' databases. The databases at the individual schools contain the work that the pilot teachers completed during the project. A summary of the units by school is listed in Table 1.

Impact

Implementing an IMS served as an impetus to changing teacher paradigms in curriculum design based on aligning standards and benchmarks to assessments and then selecting instructional activities to serve as the vehicle to reach those standards. As a result of the project, various instructional departments began to address curriculum design from a different perspective. Teachers are now learning to make instructional decisions based on what they want students to know and be able to do based on standards and benchmarks. IMSeries provides teachers not only with a way of measuring whether students have achieved objectives, but also get a sense of how they got there.

This project has also been an impetus for curriculum unit design at the university level. Several district staff members also serve as adjunct faculty at Florida Atlantic University and Nova Southeastern University. The curriculum unit design based on IMSeries has been the focus of their instruction in multiple content courses. Students producing curriculum units for coursework are teachers in Palm Beach County and those units are being prepared for Internet access.

Adapting IMSeries challenged district paradigms on data collection procedures and methodology. Before IMSeries was implemented, no elementary school in the district had the capacity to receive data from the mainframe. Data from the PC environment were not permitted to exchange data with the mainframe to prevent data corruption. This project set up and tested a new FTP procedure to allow attendance data to be exchanged between the schools and the district. The school district is implementing this new procedure district-wide. This has had a positive impact on the IMSeries project since the mainframe to school data transfer has reduced time and efforts for several offices.

Conclusion

This project began with the goal of using an instructional management system to gather, manage, and analyze crucial school district data. However, everyone involved with this project has discovered that an instructional management system can be much more than just a software system to manage information. It could turn out to be a major vehicle for changing and improving how teachers plan and assess curriculum, as it has been in Palm Beach County. The potential of this system is tremendous.

The challenge of high-stakes testing has made it incumbent on school districts to ensure that the curriculum that is actually taught in the schools is aligned with the standards the students will be tested on. The age of accountability is full upon us and, like it or not, schools, teachers and school districts will be judged based on student performance. Given thousands of students and hundreds of educational standards, making sure that each student has mastered each standard is daunting- for humans. For computers, however, it's simply a data base problem. Private businesses have used Management Information Systems to provide data to support decision-making. It is time for schools to begin using these types of systems to support making educational decisions.

Abstract: This paper describes the decisions and procedures that occurred when a traditional graduate level technology course was moved from the classroom lab setting to a partially on-line course with web enhancements. What we developed was an expansion of our initial plan and something quite different, far more complex, and more labor intensive. We knew that if we wanted schools to be different, we must prepare teachers differently ... significantly differently (Carroll, 2000). Our web enhancement efforts quickly triggered the development of an on-line educational support hub and the establishment of several on-line communities. Our on-line hub “E3-Learning” quickly expanded to provide resources and discussion boards for faculty, students, along with technology directors, library and media directors, and classroom teachers from 35 school districts. Within six weeks of the decision to initially “take one course on-line” the enhancement site e3-learning agreed to provide statewide technology standards discussion boards for 13 participating universities, Ohio SchoolNet, Ohio Board of Regents, and the Ohio Board of Education.

The Project

Project E3-Learning was receptive to developing a new educational model and delivery system, but it was not predicated on developing a new model. Initially we sought to simply use WebCT to offer a single on-line course. This, however, was not an idea we embraced for long. Instead, the goal of E3-Learning became the incorporation of wish list items from students and faculty. Two years of archived student input along with current student information, and faculty-generated information was used to identify on-line course content. Where programmatic integrity was not endangered and where technology made a component inclusion possible, wish items were included.

Not all courses and not all course components can be brought to the web easily or effectively (Kelly & Masie, 2000). Thus only for items and in areas where we determined that we could succeed did we initially develop course modules. These modules were based on the ideas and desires of individuals who collaborated with us by using a WebBoard™ and by reviewing successful and unsuccessful on-line and distance education offerings.

Content and modules were made using WebCT™, WebBoard™, and Tegrity™ media equipment and Macromedia and Microsoft software. We were aware of some aspects of a web-enhanced course. In addition to well
noted aspects of the web (anytime - any place education, and extended classroom content) we also decided to leverage the unique and frequently less considered properties of the web. We therefore decided to incorporate social and cultural needs of our students (Kim, 2000).

A “readiness test” was developed and administered to students desiring to enroll in one section of a technology in education course. Students not deemed “ready” to enroll in the on-line section were permitted to enroll in one of three traditional sections of the course. Each Instructor received WebCT training during the two quarters prior to offering the on-line course.

Initial Findings

Student Input. Student requests were quickly considered and either identified for eventual incorporation or deletion in the E3-learning program. Students with e-learning experiences do not like some traditional aspects of e-learning. Students stated that e-learning is basically linear education requiring substantially more reading with the submission of considerable written work. Although students knew that sometimes e-learning consisted of chat rooms and discussion boards, they were not enthusiastic about what they described as tedious and uninteresting participation.” These findings were consistent with Kim’s (2000) presentations. Likewise, those students who had experienced prior e-mail and listserve activities expressed displeasure them, especially when one participated in multiple e-learning courses. Students who responded anonymously reported that they were extremely dissatisfied with a prior on-line learning experience. They, however, reported, that they would not complain because “it was and easy credit.”

Students reported that they wanted 1) an incorporation of interactive social and cultural components, 2) the possibility to partake in synchronous and/or asynchronous sessions, 3) to complete their work on computers that were in their classrooms or in their home (e.g., the same operating system and version of application), 4) time shifting and distance education (less driving time), 5) smaller modules that would permit them to establish a “content load” that would juxtapose with shorter units of available time, 6) online technical and academic support available at least daily during week-days, 7) self checks built into modules, and 8) tracking of WebCT activities.

Faculty Input. The initial class session of the course will be held in a traditional fashion. At the conclusion of the course all students were required to meet with a faculty member. A portfolio was submitted. In addition, follow-up questions and student responses were videotaped. In addition to posting papers, students were required to participate in online discussions. Students were also required to complete a computer skills check sheet. On this questionnaire, they identified their current level of performance and identified a skill level. Satisfactory levels of performance were “ability to model best practice” and/or “employ this application in my teaching”. Each section of the questionnaire also consisted of a narrative section. All students were required to maintain a record of their statement and submit an example for the final portfolio. These were then used as queries during each student’s oral examination. Faculty anticipate that the exit evaluation will be time consuming. We also know that this model will change over time.

E3-learning enhancement webpage.

One faculty member had for two years (at another university) maintained and customized web content for his students. When he joined the faculty at WSU it became apparent that his personal web page was highly regarded by his students and others. While teaching a course load of 44 students during the first term, his web page recorded almost 19,000 visitors and downloaded over 40 megabytes of data per month. This became the template for the E3-learning.wright.edu web site. One graduate student and two undergraduate student workers are currently assigned to assist on this project.

Conclusions

Carrol (2000) artfully describes the concept and appropriate place for disruptive technology in education. We agree that if one enters into the pursuit of educational technology excellence one can well experience a disruptive event. With the “right” colleagues, disruption technology can be quite enjoyable. Tom Peters (2000) recently presented several thoughts one of which we will adhere to as we develop our programs. One of our favorites is

1965-1980 was Ready, Aim, Fire;
1980-1995 was Ready, Fire, Aim;
1995 - ???? is Fire, Fire, Fire.

Preparing Educational Leaders to Cultivate the Meaningful Use of Instructional Technology: Beyond Budgets and Basic Training

Margaret Cassidy
Adelphi University
Communications Department
Blodgett Hall, NY 11530
cassidym@panther.adelphi.edu

Abstract: Bringing new technology into schools is a complex, challenging process for teachers and administrators alike. There is an overwhelming volume of literature on issues like selecting hardware and software, planning budgets, and providing teachers with the basic technology training they need to get started. However, effective leadership requires a sophisticated knowledge of, and sensitivity to, a myriad of other issues, such as the privacy and First Amendment rights of teachers and students, the problem of unequal student access to technology in school and at home, and the proper role of commercial and corporate entities in public schools. This paper will explore these issues, and suggest that educational leaders consider them in their day-to-day decisionmaking.

Introduction

I recently made a visit to a friend who is an elementary school principal. We met for approximately two hours one morning, during which time we discussed a variety of issues concerning the effective and appropriate integration of new technology into elementary education; we also took a walk around the school and chatted with some teachers about what has and has not worked well for them as they have tried to “technologize” their teaching. All in all, it was a very interesting morning for both of us. However, the time was not without its problems. At one point, my friend realized he had an assembly to introduce, grabbed his suit jacket, and tore off to the auditorium in the nick of time. Later, a teacher stopped by to ask for something he had promised her, and he realized he had forgotten to do what he had promised. Then a problem with a parent arose. Before I left that day, he said to me, “Now, here we have been having a very interesting and important conversation that we need to have more of. But in the time I spent having this conversation, I have failed at least three times as a principal.”

As much as I learned about technology and schools in that visit, the most important lesson of the day came in that one statement he made. Anyone who has spent any time at all in a school knows that it is a site of constant activity and unpredictability, where all the energy of faculty and administrators is absorbed by the demands of the immediate circumstances. What that means for educational technology is that the focus of new technology initiatives tends to be on the “mechanics” of implementation—that is, on the nuts and bolts of installation and basic training, on how to make the machines work. Meanwhile, the questions of why to make the machines work, and whether it is even appropriate to buy into the aggressive implementation of educational technology, are rarely discussed. The fact that they are not often discussed, however, does not mean that they have no impact on what happens when new technology is introduced into the classroom. Teachers’ concerns about technology often center on issues beyond implementation and training, on issues that lie at the heart of their sense of professionalism and their beliefs about the relationship between teachers and students. Where technicians focus on giving teachers technical skills, many teachers are thinking about how the technology might change the character of the classroom experience and the nature of their profession—in particular, how it might be used to deskill and deprofessionalize teaching. This is not to say that teachers are, on a whole, or ought to be, opposed to technology; more that they recognize that adding a new technology to the resources available to them is something of a mixed blessing whose implications are quite complicated.

The day-to-day challenges of supervising technological change in public schools are enough to occupy every waking moment of school administrators. Equipment malfunctions, budgeting decisions, hardware and software selection, and staff development all demand regular attention and care, and threaten
to overwhelm school leaders. However, educational leaders also need to develop the habit of thinking about some of the other issues that are of great concern to teachers—for example, issues concerning privacy and professional autonomy, freedom of expression for teachers and students, the inequities of access to technology among student populations, and the commercialism that fuels so much of the push to put new technology in schools. Each of these topics will be discussed separately in the pages that follow.

Privacy

At the same time as new technologies have excited many teachers and offered interesting new ways to engage students in the learning process, they have also threatened the privacy of teachers and students. Computers provide a number of ways of monitoring classroom activity; who is permitted access to these records, and how that information is used, threaten to compromise the privacy of those whose activities have been recorded. For example, it is possible to determine which web sites have been visited on a particular computer, or with a particular account. Taken out of context, many such visits might appear inappropriate or unjustifiable, when there might actually be a perfectly good reason or explanation for the visit. For example, a student might mistakenly find himself at a web site considered to be inappropriate for him because there is a link to it from an acceptable site, but the record of sites visited would have no way of showing that the visit was accidental. A teacher might choose to visit a controversial site—for example, one containing hate speech—not to support or promote the views expressed there, but to learn about them in order to counter them. Again, all a record of sites visited would show is that someone was there, not why he or she was there, and it is possible that students and teachers will be unfairly penalized for misusing their Internet privileges. At the very least, users should be given the opportunity to explain their intent. Still, the mere knowledge that others will know where they have been is likely to have a chilling effect on their Internet wanderings. Howard Rheingold describes this as a “panoptic” effect—that is, when people are aware that they might be under surveillance at all times, they alter their behavior because they believe they are being watched (even if they are not) (Rheingold, 1993).

It is important to distinguish here between holding users accountable for their actions and violating their privacy. It is entirely reasonable to expect all account holders to abide by the rules of the acceptable use policy in force. When violations occur, there ought to be consequences (provided, of course, that the acceptable use policy is fair). However, as long as users are behaving responsibly, they need to be given some latitude in their activities. Of course the standards need to be different for teachers and students. But in an age where it sometimes feels as though anything goes in the name of “accountability,” it is especially important to think about how everyone’s privacy is going to be protected as more and more information about classroom activity is made available to wider audiences. In a recent court case, a parent sued for the right to view the local school district’s web logs, in order to see if the district's acceptable use policy was working (http://www.eschoolnews.com/showstory.cfm?ArticleID=1724). Whether such logs are private or a matter of public record has yet to be determined. However, it is not hard to imagine how such records could be misconstrued if distributed publicly, stripped from the curricular context in which they were first generated.

Another Internet-related threat to privacy concerns “cookies,” which are files placed on a user’s hard drive, upon visiting a web site, that are usually meant to make the user’s subsequent visits to that web site more useful, or more personalized. For example, some web sites ask for the user’s name, and a cookie file is used to enable the site to welcome that user back by name when he or she visits again. Some sites monitor the purchases made there, and provide customized lists of recommended purchases based on that information.

There are many uses of cookies that are perfectly benign, and that pose no threat to the user’s privacy. However, “third party” cookies are those that are used to create targeted advertising based on the person’s web usage—for example, by keeping track of the sites visited by the user, or by asking the user for personal information and then using it, or selling it, for marketing purposes. Although browsers can be set to notify users that a web site uses cookies, most people turn that feature off, because cookies are so common and the constant popping up of the warning window becomes tedious. As a result, most people are unaware of the ways in which their privacy is compromised by third party cookies.

One problem with cookies that bears directly on schools is the question of whether cookie files are a matter of public record. In a recent court case, the publisher of an online newspaper in Cookeville, Tennessee asked for access to the cookie files on the computers of government employees, including public
school teachers. The idea here was that taxpayers had a right to know if these employees were behaving responsibly on the job. However, here is another case, like the case involving web logs, where the files could easily be misinterpreted, particularly with respect to teachers. Internet research on school time, including visits to controversial sites, can be an entirely appropriate part of a teacher's lesson planning or professional development, but there is a good chance that their motives would be misjudged if their activities were made public.

Another school-related problem with cookies (which relates to the problem of commercialism) is that many schools can only afford new technology through partnerships with businesses that provide technology in exchange for the right to expose children to advertising, or to collect marketing data from them. For example, education "portal" web sites provide a kind of user-friendly gateway to the internet, often with advertising on the sites, and often with the collection of marketing data through the use of cookies. One such site, called Highwired.com, claims the right in its privacy policy to "share the personal information you provide to us with third parties who are affiliated with our sites, or who provide services to our sites" (http://www.lightspan.com). Their policy also states that if users supply their addresses and phone numbers, they may be contacted with promotional materials. The policy also asserts Highwired's right "to assign, sell, license or transfer any information, including personally identifying information, that our visitors have provided to us to third parties" (http://www.lightspan.com). One might argue that by stating these policies clearly on the web site, users have been amply warned. However, in this case, the policy is (like many such policies) hidden in a fine-print link that users have to know to look for, or they are unlikely to notice it at all. In an age of school-business "partnerships," one must always question whose interests are really being served, and whether public schools should have to sell their students to advertisers to finance the acquisition of curricular resources. At the very least, school leaders need to make a habit of reading this fine print before embarking on such partnership ventures.

Educational leaders should also be aware of the provisions of the Children's Online Privacy Protection Act of 1998. This law requires parental consent before a web site can gather personal information from children under the age of 13. Many sites had been asking children to complete surveys before entering a contest, or playing a game. Now, children under 13 need parental consent before they can provide such information. Three members of Congress have pushed this issue further, advocating legislation that would require schools to obtain parental consent before accepting free equipment or services from telecommunications companies, or risk losing federal funding (http://www.eschoolnews.com/showstory.cfm?ArticleID=1508). Opponents of this legislation argue that it would hinder valuable partnerships that provide resources to schools; advocates stress that no program that exchanges such resources for marketing data is appropriate in public schools.

Another privacy-threatening idea that has not spread widely, but that is worth keeping an eye on, is a proposal made by former New Hampshire Republican gubernatorial candidate Jeff Howard, who advocated the installation of web cameras in public school classrooms so parents would be able to see what was going on in their children's classes. Web cameras are already in use in some daycare centers and private schools, but have not yet been used in public schools. The American Federation of Teachers opposes the idea, suggesting that if parents want to know what is going on in their children's schools, there are less expensive and more appropriate ways to find out. Another potential problem is that people other than parents might somehow gain access to these web sites (which would be password-protected), which might pose a danger to the children involved (http://www.eschoolnews.com/showstory.cfm?ArticleID=1335).

Child safety is also related to Internet privacy concerns when it comes to the controversy over putting students' likenesses or full names on school web sites. Many schools refuse to do either, fearing that it would put those children at risk. However, many student journalists have opposed these policies, claiming that their rights to free expression have been compromised. The balance between protecting privacy and permitting expression is a complicated one. Although students have long been identified in school publications, those publications have never had worldwide distribution. To what extent do students have First Amendment rights on the Internet?

**Freedom of Expression**

Students do not have unlimited freedom of expression in school, or through official school publications; this has long been a source of frustration among student journalists, who can be censored
when writing for official school newspapers. What many students have discovered, however, is that they can “go underground,” creating online student newspapers that can legally circumvent the censorship of official school papers. The Student Press Law Center in Arlington, VA estimates that there are 10,000 underground high school newspapers on the Internet, much to the chagrin of many school administrators. As highlighted in the first episodes of the new television series “Boston Public,” student-made web sites are often irreverent, and critical of school personnel. Besides the personal offense they sometimes pose to those named or criticized on the sites, they sometimes contain expressions of anger or alienation akin to that found on the Columbine gunmen’s sites, leaving school officials wondering where the balance is between freedom of expression and personal and public safety (http://www.eschoolnews.com/showstory.cfm?ArticleID-1742). Another concern is that when students are censored in official school publications, they learn important lessons about responsible journalism and about libel. By going underground, they find an outlet for their views, but they do not always appreciate the consequences of their expression.

As a rule, courts have upheld the right of students to express their criticisms on their personal web sites. For example, a Missouri boy was suspended for ten days in 1998 because he criticized school officials on his web page, and provided a link to the school’s official site, urging visitors to e-mail the principal. Although he complied with the school’s request that he dismantle the site, he was still suspended, and the ACLU sued the district on his behalf; in February 1999, the courts upheld his right to have the web site. Similarly, a Florida student was also suspended for ten days in 1998 for criticizing his school and school administrators on his web site, but was able to get his punishment reduced with the help of the ACLU. In another 1998 case, an Ohio student was awarded $30,000 from his district when he challenged their suspending him for insulting his band teacher on his web site. In general, then, when students are punished for criticizing their schools on personal web pages, the courts uphold students’ rights to do so.

One form of expression that has not been protected has been that which is believed to constitute a danger to the person being criticized. For example, a fourteen year old Pennsylvania boy made a web page about his math teacher, outlining “Why She Should Die” and soliciting donations to pay for a hit man. Although this was most likely a poor attempt at satire, the courts found it to be a threat to the woman’s safety, and upheld the school’s decision to expel the student. There is a distinction to be made, then, between critical speech and threatening speech; the former is generally protected, where the latter is not.

The issue of freedom of expression involves not only students’ online expression, but the online information to which they are permitted access. It is becoming increasingly common for schools to install filtering software on their Internet-accessible computers, which blocks users’ access to certain web sites. These filters come in several varieties, the most popular of which block access to a list of web sites that is continuously updated as online content changes.

At issue here are the criteria used to block sites. Some filters demonstrate political biases in what they filter—for example, by making pro-life sites available to students, while blocking pro-choice sites. Another issue would be whether teachers can override the block if they deem it appropriate to do so, or whether they are denied the autonomy to make choices for their own students. New York City teachers were recently frustrated by the installation of filtering software that they were not trained to override, and that blocked, among other things, the last chapter of The Grapes of Wrath (where a woman allows a starving man to drink milk from her breast) and web sites on diabetes (because erectile dysfunction is one of the disease’s side effects). At the same time, they have expressed their dismay that many commercial sites, such as the Victoria’s Secret online catalog, are not blocked.

There is also the question of whether filtering should be mandated in public schools. Several years ago, Senator John McCain promoted the School Internet Filtering Act, which would have required schools receiving federal “E-Rate” funds to install filters. There is a certain irony to Congressional interest in Internet filtering, given that they chose to release the Starr Report online. That is, they express a certain disdain for the kind of material that is available online, yet they also contribute to it. As a matter of fact, a Congressional committee on the E-Rate program had to leave a meeting several years ago on “Legislative Proposals to Protect Children from Inappropriate Materials on the Internet” to go vote on whether or not to release the Starr Report.

The E-Rate program, incidentally, is a federal effort to address another serious educational technology issue—that of the “digital divide.” The disparities in access to technology among American children continue to be very disturbing, and need to be in the consciousness of school leaders.
Access

The expression "digital divide" has quickly gained currency in the past few years, referring to differences in access to new technology among different classes, ethnicities, genders, and geographical regions—in schools and communities, and at home. It refers not only to the presence or absence of computers, but to the ratio of computers to users, the type of software available, the existence of Internet connections, the quality and speed of those connections, and the content of online resources.

A 1998 report by the National Telecommunications and Information Administration of the U.S. Department of Commerce named the digital divide as "one of America's leading economic and civil rights issues" (www.ntia.doc.gov/ntiahome/introduction.html); although access is increasing for all groups, it is increasing faster for some groups than others, thereby increasing the actual divide. This study found, for example, that white families were more likely to have Internet access at home than African American or Hispanic families at any location. Americans in rural areas had less Internet access than Americans in suburban or urban areas.

Political responses to digital divide problems have tended to focus on technical aspects of access. For example, the E-Rate program uses income from a tax collected from telecommunications companies to provide schools and libraries with telecommunications services. It emerged out of President Clinton's commitment to connect all American public schools to the Internet by the year 2000, and has provided millions of dollars of funding in the few years it has been in existence. However, the access issue goes beyond providing the technical connections; it also has to do with what people find when they get online, and whether it is relevant to their needs and concerns. A study conducted by the Children’s Partnership found that Internet content tends to be short on exactly what underserved populations say they need the most. For example, when 21 million Americans over the age of 18 have incomes below the poverty line, there is precious little information online about local community services, employment, education, and job training. An estimated 87% of online documents are in English, yet some 32 million Americans speak a language other than English as their primary language. There are very few web sites that are accessible to adults with limited literacy skills. All told, this study estimated that 50 million Americans face at least one of the main barriers to finding the Internet useful—not because they weren't wired, but because there was very little for them online (www.childrenspartnership.org).

School leaders need to be aware of the many dimensions of the digital divide and its implications for school-based computer use. For example, schools in communities where access is limited might think about serving as community access centers for adults in those communities. Educators in communities where there is a wide range in children's home access have to be sensitive to those disparities when creating and grading homework assignments. School web sites and e-mail are celebrated as wonderful ways to communicate with parents, but only if parents have Internet access. Although access is increasing for all Americans, it is reasonable to expect the divide to continue to exist, and school leaders should be mindful of its consequences for students and teachers.

Commercialism

School leaders also need to be very thoughtful about the degree to which they allow commercialism into their schools through new technology. There are several key ways in which new technology stands to increase corporate involvement in schools. For one, the corporate world has an interest in shaping the curriculum so as to include in it the kind of training that they would otherwise have to provide new workers; right now, that certainly includes training in the use of computers. Although one responsibility of public education is certainly to prepare students for life as adults, including earning a living, it is important not to make the primary purpose of public education the efficient training of a workforce. Such a purpose comes only at the expense of a rich and varied educational experience that permits all students to explore their unique abilities and interests.

Second, a "global information economy" requires a high volume of sales of information products and services, and schools are a huge market for them; consequently, a good bit of corporate involvement in educational technology reflects profit motives, rather than the best interests of students. Schools are not only potentially lucrative markets for information industries; they are also good places for those products to
be placed, because their presence in schools confers a degree of legitimacy on them that might increase home sales by parents, as well.

Finally, web sites have become the latest way for commercial interests to spread their message to students, adding "educational" sections to their sites and providing curricular materials online. Classroom materials that have been produced for decades by companies marketing products to children are now distributed via web sites. For example, the web site for M&M's candy provides pie charts showing the proportions of each M&M's color in a typical package, and lessons on how to teach probability through student use of M&M's packages.

A more elaborate chocolate undertaking comes from Hershey Foods, the teacher section of whose web site offers an entire, interdisciplinary, middle school curriculum centering around Hershey chocolate. Among the goals of one unit in the Hershey program are for students to "describe chocolate's place in a well-balanced diet" and "make a favorite chocolate snack or dessert"; teachers are reminded that "Flavored milk, such as chocolate, is well liked by children and helps to increase milk and nutrient intake" (http://www.hersheys.com/consumer/teacher/dream_machine/page_2.html#2). In 1934, Arthur E. Morgan, chair of the Tennessee Valley Authority, expressed his concern about the dangers of commercial involvement schools—dangers which, at that point, he felt had been averted:

Suppose our public schools had been established on a purely commercial basis...There might be no charge to the public for our public schools, the teaching staff might be supplied by the toothpaste manufacturers or patent medicine manufacturers...and they would have textbooks describing the values of toothpaste or patent medicine. (Morgan, 1934, p. 81)

Although his scenario was meant to be regarded as ludicrous, it is not far from many contemporary commercial schemes to tap into a lucrative market, and a captive audience, of schoolchildren. School leaders need to be thoughtful about the degree to which they allow commercially-produced (and biased) curricular materials into the school environment.

Conclusion

In short, then, school leadership in a technological age requires thoughtfulness on many complicated issues. Unfortunately, the more practical level of technology implementation tends to monopolize the time of administrators, leaving these other issues inadequately addressed. Meanwhile, it is these issues that will often make or break technology initiatives in schools, because they are the ones that speak to teachers' concerns about themselves and their students, and that help them decide whether to buy into reform, or whether to resist it. In that sense, then, these issues are at least as important as the more "basic" matters of acquiring the machinery and teaching everyone how it works—matters which must be dealt with skillfully, but which will not, alone, ensure successful implementation of new technology.

Abstract: Leading academic change in our educational organisations requires a paradigm shift at two levels – both in learning as well as educational leadership. One of the central premises behind these much-needed paradigm shifts is my inherent belief that a major aim of education should be to prepare our students to participate in and contribute to contemporary society. To do so, the learning paradigm needs to shift from teacher-centred, “broadcast” instruction to interactive, connective learning in educational organisations. It is an environment that focuses on learner-centred education; embedding technology into the curriculum; and the educational institution becoming a learning organisation where teachers share learning with students. To reach that colourful, compelling dream of learner-centred education, we need visionary, connective leadership in educational institutions – a leadership that connects by two-way arrows, with a paradigm shift from independence to interdependence, from control to connection, from competition to collaboration, and from individual to group.

Introduction

Leading academic change in our educational organisations requires a paradigm shift at two levels – both in learning as well as educational leadership. One of the central premises behind these much-needed paradigm shifts is my inherent belief that a major aim of education should be to prepare our students to participate in and contribute to contemporary society. To do so, we need to go beyond the established traditional teaching and learning practices. In a contemporary classroom, it is the “connective learning” by knowledge workers that is going to prepare our young students for the challenges of the new millennium.

The learning paradigm needs to shift from teacher-centred, “broadcast” instruction to interactive, connective learning in our educational organisations, as illustrated in (Figure 1). It is an environment which focuses on learner-centred education; integration of technology in a seamless manner to support and extend our curriculum objectives; the educational institution becoming a learning organisation where teachers share learning with students; and students are exposed to a curriculum infused with exciting and technology rich learning programs. In a learner-centred model, the New Teacher, who employs meaningful use of learning technologies, becomes a role model in the class and offers creative problem solving experience. The teacher takes the role of scaffold of learning, fostering learning how to learn.

To reach that colourful, compelling dream of learner-centred education, we need visionary, connective leadership in our educational institutions – a leadership that connects by two-way arrows. We need a shift in the educational leadership paradigm from “independence to interdependence, from control to connection, from competition to collaboration, from individual to group, and from tightly linked local alliances to loosely connected global networks” (Lipman-Blumen, 2000, p. 226). The new leadership model in educational institutions focuses less on the individual personality of the leader and more on the group – in all its diversity and interdependence. A connective leader does not indulge in, what the philosopher Jean Baudillard describes, the “dance of the fossils” – a preoccupation with controlling those ‘lower down’ in the hierarchy and focussing on the maintenance of present systems (Clarke, 2000, p. 131). A connective leader sees his environment as a network of peers rather than hierarchies of ranks. He helps to keep people around connected and energised in the new learning landscape – shifting their mindset from schooling to learning, from the traditional structures of sequential, linear understandings of schooling to constructivist, non-linear, hypermedia learning.

Following steps are needed for the process of leading academic change to be effective and meaningful:
Teacher-Centred Learning \[\rightarrow\] Learner-Centred Education \[\rightarrow\] Student-Centred Learning

Teacher as a scaffold of learning, a role-model and a co-learner

Students as collaborators, and directing their own learning

Figure 1: The shift in the learning paradigm from teacher-centred to learner-centred education.

1. Shaping a Shared, Strategic Vision of the Future

Clemmer (1999) reminds us, “Take time to dream!” In each creative mind a dream takes wings and keeps urging, “It could be, It will be...”. In the mind of a visionary leader, it won’t go until the dreamer heeds and shapes it into reality! (Clemmer, 1999, p. 28).

Simply stated, a vision is a realistic, credible, attractive and inspiring future for the organisation. Like a travel poster, a vision does not show how to get somewhere, but it does present a clear and exciting image of what the world might be like when you arrive.

Connective leaders have clarity of vision, which they share with their colleagues. They know that nothing else will unite and enthuse people in an organisation so much as a shared vision for the new connective learning landscape. A vision is not just an idea. It is rather a force in people’s hearts, a force of impressive power. It gives people a sense of common ownership that enables them to cooperate with and support each other in pursuit of their common destiny. When people truly share a vision, they are connected, bound together by a common, lofty goal. A shared vision changes people’s relationship with the learning organisation. It is no longer, “their organisation,” it becomes “our organisation.”

Nanus and Dobbs (1999) tell us that a shared vision empowers people encouraging them to take initiative to advance the common effort. A shared vision is a major source of hope and self-esteem for people in the organisation. Once people understand the big picture, they can see the value of their own contributions. They feel pride in being part of an organisation with an important social purpose. For many people a shared vision gives meaning to their lives and makes them want to go the extra mile to help the organisation achieve the vision.

A connective leader recognises that shared visions emerge from personal visions. This is how the connective leaders derive their energy and foster commitment. Peter Senge (1999) elucidates that learning organisations, that wish to build shared visions, continually encourage its members to develop personal visions. People with a strong sense of personal direction can join together to create a powerful synergy toward what I/we truly want. This is the art of visionary leadership – how shared visions are built from personal visions, “the art of seeing the forest and the trees” (Senge, 1999, p. 127). Visions that are genuinely shared require ongoing conversations where individuals not only express their personal dreams, but also learn to listen to each other’s dreams. A connective leader facilitates this listening in the learning organisation, and ultimately as the shared vision develops, it becomes both “my vision” and “our vision”.

2. Deciding On The Strategic Thrust Of An Organisation: Team Learning

In realising the vision, when it comes to embedding technology into curriculum, you can introduce it, you can give it a sharp focus, you can design it, you can write units of work, you can write endless outcomes of it. But at the end of the day, if it is going to work, it is teachers in the classroom – the barefoot doctors – who will make it work! I think, therefore, it is critical that the strategic thrust of an organisation should be on team learning as a connective leader understands that teams can learn: in sports, in the performing arts, in science, there are striking examples of the team that exceeds the intelligence of the individuals of the team, and where teams develop extraordinary capacities for coordinated actions in order to achieve the organisational vision.

In order to create a learning team environment, the connective leader encourages his members to imbibe the practices of dialogue and discussion – the two distinct ways that teams converse. Senge (1999) clarifies that in a dialogue, different views are presented as a means of discovering a new view. In a discussion, decisions are made. Dialogues do not seek agreement, rather a richer grasp of complex issues through a deep “listening” to one another. Effective learning teams need to be able to distinguish between dialogue and discussion and move consciously between the two. A connective leader acts as a facilitator of dialogue and discussion. As teams develop experience and skill in dialogue, the role of the connective leader as facilitator becomes less crucial and he can gradually become just one of the participants. Dialogue emerges from the “leaderless” group once the team members have developed their skill and understanding.

In an aligned learning team, a synergy develops and the shared vision becomes an extension of the team members’ personal visions. Using Senge’s (1999) metaphor in musical terms, the connective leader works towards developing the learning team as an ensemble. He strives to make the team members reach a state where the ensemble “plays as one.” The music “flows through you rather than from you” (p. 235). In truly aligned team meetings, it is not remembered “who said what” but there is a shared understanding of just getting to a point of knowing what they need to do. In this sense, the word team takes a different meaning: it is a group of people “who need one another to act” (p. 236). Ultimately, the teams learn how to tap the potential of their colleagues as they realise that the IQ of the team can, potentially be, much greater than the IQ of the individuals.

A connective leader recognises that in order to achieve the vision, the strategic thrust of an organisation must remain on team learning. He understands that it is teams, not individuals, that are the fundamental learning unit in modern learning organisations. Unless teams can learn, the organisations cannot learn.

3. Strategic Issues

a) Staff Empowerment Issues

One of the primary strategic issues for an organisation should be to plan a successful staff development program that prepares them for the challenges of the connective learning environment. Teachers need to receive sufficient training and resources to help them effectively plan and execute projects that integrate technology across the subject areas. This teaching model requires them to rethink and reshape their curricula. For many, learning to integrate technology and curricula means mastering a series of challenges, including learning how to use a variety of technology applications; designing technology-enhanced curricula to meet students’ needs; using and adapting online curricula; expanding their knowledge of their subject areas and taking on the new roles of scaffolders of learning and coach. Practical, real-life experiences will be shared with the audience on a variety of issues such as building a staff team of “computing in education trainers” with ongoing staff training, encouraging and rewarding top performance, and providing adequate resources to the staff.

b) Network Issues

It is essential that the educational organisation’s network is conducive to creating a learning environment for students, teachers and parents to share and communicate with one another in a way that facilitates connective learning. Choosing a network operating system is very critical. The key things to consider are flexibility, security, ease of integration and use as well as the cost involved. It is vital that the educational goals are realised by choosing appropriate technology. To do so, it is important to consider how technology that is going to be used to accomplish those educational goals will provide and support a challenging curriculum;
support learning programs for all students; support and provide meaningful professional development experiences for staff; and enhance “home-educational institution-community” collaboration and communication. Our organisation’s case study will be shared with the audience.

c) Curriculum Issues

Embedding learning technologies into Outcomes based, learner-centred curriculum is at the heart of connective learning paradigm. A connective leader recognises that the textual environment has changed in the 20th century and will continue to evolve in the new millennium in which students will spend their adult lives. One of the major changes is that print is, in a sense, being realigned alongside other kinds of texts – mostly visual. We as professionals in our organisation need to adapt to the changing textual landscape – bringing both print and visual texts together in our classrooms. To broaden learning for our young people, we need to make them engage consciously with a range of media texts. This does not mean less reading for our students, as some of us may assume, in a conventional sense. On the contrary, as Andrew Goodwyn (1998) points out, “it means both more reading and more intelligent reading in relation to each other” (p. 131).

As scaffolders of learning, we need to recognise that the students will need support and stimulation as they struggle to make meaning of the wide range of texts. The learning programs, therefore, need to offer, what I call, ‘multimedia scaffolding’ in order for our students to be able to personally engage with the texts and recognise a range of meanings into these texts – print or visual. An innovative, learner-centred unit of work on Shakespeare’s A Midsummer Night’s Dream will be shown to the audience. The unit draws upon an integrated hyper-linked world of a wide range of media texts – such as music, video clips, illustrations, written text, audio recording, web based animations – and invites the reader to make meaning of the texts in relation to each other.

Connective leaders do not oppress themselves with the “Tyranny of the OR” – “the rational view that cannot easily accept a paradox, that cannot live with two seemingly contradictory ideas at the same time” (Collins & Porras, 1999, p. 43). The “Tyranny of the OR” pushes people to believe that things must be done either A OR B, but not both. Instead of being oppressed by the “Tyranny of the OR”, connective leaders liberate themselves with the “Genius of the AND” – the ability to embrace both extremes of a number of dimensions at the same time. Instead of choosing between A OR B, they work out to have both A AND B.

That is why, connective leaders, who liberate themselves with the “Genius of AND”, strive to provide a connective learning landscape that embraces a whole gamut of learning activities such as online lessons by staff using the Intranet (and Internet), online discussions by staff and students, online class work and homework by students using Intranet at the learning organisation as well as from home, online marking of students’ work, creating study notes by students using hypertext, online examination in classrooms, online recording of marks by teachers using the outcomes based multimedia electronic mark book, online reporting and writing of comments using a reporting program, access to student reports by the parents online from home. Specific examples of the work will be shown to the viewers in relation to the above-mentioned learning environment.

d) Student Issues

Don Tapscott (1998) suggests that the new generation (who are growing up with technology) assimilate technology as opposed to the adults who must accommodate it (who have an established thinking pattern). The children of the new generation are active learners engaging directly with the technology by using powerful tools to probe, analyse, organise and synthesise material. In this sense, they are becoming stronger, independent thinkers. It is the ‘receiving’ by students – not the ‘delivering’ – that is crucial. Good teaching ensures students ‘receive’ – that they are tuned into, and make a personal sense of, the information that abounds.

Various aspects of student issues such as student technology leadership; creating study notes using hypertexts (that reinforces the proactive role of the reader who actively constructs the text through the making of navigational choices); online discussions; creating own websites; and using visual texts will be addressed.

e) Wider Community Issues

The wider community must remain part of this picture. Educational organisations can no longer exist in isolation from the larger community they serve. For education to reflect the skills, attributes, and collaborative learning models needed in the adult world, schools must become an integral part of that world. Linking the
greater community to share responsibility for the future of children is the key to achieving a truly connected learning community. It is essential we keep the parents informed about our vision and the strategies to achieve the connective learning environment. This can be achieved through a variety of ways such as conducting parent evenings, having open days, visits by key educationists, video production, brochures, newsletters and through the website of the organisation. Please refer to (Figure 2) for an overview of the Connective Learning landscape.

4. Generating Short-Term Wins

Connective leaders thank, appreciate, recognise and celebrate accomplishments. They realise that short-term performance improvements help transformations in a variety of ways. Kotter (1996) reminds us that short-term performance improvements help transformations in a variety of ways. They give the effort needed reinforcement. They show people that the sacrifices are paying off, that they are getting stronger. For those driving the change, these little wins offer an opportunity to relax for a few minutes and celebrate. A little celebration following a win can be good for the morale of the staff. The process of producing short-term wins can help the management test its vision against real conditions. Quick performance improvements undermine the efforts of cynics and major resisters. Visible results help retain the essential support of management. Short-term wins help build necessary momentum. Fence sitters are transformed into supporters and reluctant supporters into active participants. This momentum is critical, the energy needed to complete the process of change vision.

5. Consolidating Achievements and Evaluating Long-term Trends

A connective leader ensures that his team continues to consolidate achievements of the organisation whilst moving on to new pathways. The visionary leader also keeps in mind the long-term trends as he takes strategic decisions into employing meaningful use of learning technologies in the short term.

![Figure 2: An overview of 'Connective Learning Landscape'.](image-url)
Concluding Remarks

For an effective, connective learning environment in our educational institutions, we need to make a paradigm shift at two levels – both in learning and educational leadership. At the heart of the learning organisation is a shift of mind – from seeing parts to seeing wholes, from reacting to the present to creating the future, from seeing ourselves as separate from the world to be connected to the world, and from employing reactive, teacher-centred instruction to collaborative, learner-centred education.

The new learning paradigm is more creative and satisfying for the teacher. It also empowers the students. It involves embedding learning technologies into the curriculum – a new model of learning – one based on discovery and participation. The new paradigm of connective learning, I believe, has enhanced outcomes for the knowledge workers who ultimately spend more time in collaborative work and creative problem solving; construct meaning in their own minds through interactive learning technologies and become stronger thinkers; become independent and interdependent learners with flexible outlooks; become pro-active risk takers; integrate the 4Rs (Reading, Writing, Arithmetic and Reactive) with the 4Xs of the connective learning landscape (Exploration, Expression, Exchange and Extension); acquire research, resourcing, analytical and presentation skills; and experience a learning renaissance.

To accomplish this powerful dream of learner-centred education, we need a new leadership paradigm that connects by two-way arrows. In a contemporary learning organisation, as I perceive, the connective leader becomes a craftsman of shared vision, a scaffold of learning and a teacher. Although initially it is the connective leader who must initiate and bear the torch of the strategy process for leading academic change, it is the people of the organisation who ultimately make this dream possible. Expecting everyone to share the burdens of leadership, the connective leader sparks in other people self-confidence, creativity, ownership and loyalty. He liberates the leader in everyone. As the implementation process of connective learning landscape proceeds, he monitors progress, keeps the board informed, and shares the celebration of various accomplishments with staff members from time to time.

Whether we are leading our lives, leading our work or leading our organisations, we are continually “going beyond what is” (Essex & Kusy, 1999, p. ix). If we are not going beyond what is, we may be managing what is but not leading others and ourselves into the future. Connective educational leadership “goes beyond what is.” An innovative, visionary leader as a strategist in leading academic change for a connective learning environment must fast-forward his strategies and leadership into the future, now.

Abstract. When school systems find they must adjust what they are delivering because their performance measures show they are “low performing,” how can a system efficiently and effectively adjust the curriculum? Can the web help us test students more efficiently? How can teachers and administrators get meaningful, timely guidance so that they know what is expected, whether or not they are providing needed instruction, and which resources target those needs? This paper describes software applications that provide critical assistance to school systems in responding to the changing expectations being experienced in the emphasis on accountability and meeting “standards” or expectations.

Introduction

Accountability mandates require that districts, schools, principals and teachers focus clearly on those measures by which their students are held accountable. High stakes test results and state standards identify much of what school districts must ensure that their students learn, because these identify the bulk of specific accountability expectations. A critical issue is how school districts can respond quickly, accurately, and with continued flexibility to changing expectations. How can K-12 schools ensure that what we ask teachers to teach—and the resources we provide them to teach with—address the expectations of these accountability mandates? Can information technology help school systems to make sure they are teaching, not only the content of the curriculum required by the state, but also what is actually tested? Can educators and software developers work together to ensure student success? How can these issues be addressed in training pre-service teachers? This article offers four perspectives—District, State, University, and corporate—on using technology to meet accountability mandates.

Kathryn Floyd: The District Perspective

Electronic curriculum management for assisting low performing schools

Like Chicken Little, the public cries, “Our schools are failing! Our schools are failing!” What is the response to those cries? “High stakes” tests in public schools. What’s at stake? Public trust and support for public schools. Results, in the form of improved outputs reflected in student test scores, are demanded by legislators across the nation with the state boards of education enacting offices of accountability. The core issue confronting public education in most states is proving to the public that their students are showing improvement in academic performance: How will we define success? How will we know we have succeeded? Expectations for student learning are created, reviewed, revised, and updated continually.

In a not-too-unusual scenario, new teachers are provided the new curriculum (maybe one document per room, department or school), textbooks for the students, a lesson plan book, a grade book, and class rolls. Far too often the teacher sets everything aside but the textbook. S/he begins looking at the table of contents to decide what s/he will “cover.” If s/he’s a high school teacher, s/he will likely begin devising a semester syllabus to identify what s/he will “cover.” Experienced teachers often look at a newly adopted textbook and related materials to see where the new book fits with what they are accustomed to teaching. If they find too much new material, they may pull out files from units taught in past years and decide how they can still use what they are comfortable with. After all, they are the curriculum experts, right?
Recent studies show that schools can no longer afford to assume individual teachers can fulfill without adequate and very specific guidance. Schools are realizing they must somehow make sure the material in the curriculum and the objectives on the required tests are what teachers are "covering." But first, we must find an efficient and effective way to identify and share that critical information in a written curriculum. We must find a way to revise and update this curriculum, quickly and effectively. Assigning this labor-intensive task to teachers is simply requiring one more mission of those who are already overwhelmed by other responsibilities.

It would be easy to blame the use of norm-referenced tests as outcome measures, an admittedly questionable but publicly-demanded practice to show how local or state students compare to those in other schools across the nation. While all of those concerns may have legitimacy, we must, in the words of Mike Schnoeker, "move beyond a counterproductive criticism of existing tests and move toward a more cooperative and transitional path."

The demand is huge for schools to take the expectations identified by the state and measured in mandated tests and align them in an easily-modifiable and teacher-friendly document. Only can individual teachers focus their energies on instruction of students, on deciding how they can help students learn the skills and material and which resources they will use to do that effectively. The what—the expected outcomes—has really already been largely decided; in most cases it just isn’t a flexible, working document that is really designed to be used.

We must find a way to help all educators use expectations and performance outcomes to drive our improvement efforts. Educators must identify and use those tools that will help them immediately respond to changing expectations. We must optimize our use of every means of helping educators at all levels: identify patterns of weakness, modify the curriculum, and provide the needed instructional and professional development resources so teachers and others can focus on the "how" of teaching and learning—on instruction and on responding to the individual needs of the students. We need to find and utilize tools that maximize the use of information technology to help educators focus on instructional strategies to optimize student’s learning what they are being help responsible for. Teachers need to know where those expectations originate and then be aware of the rewards or consequences if they don’t help students master them. When armed with this information, teachers can adjust their pacing and time allocation. Teachers need help in making quick adjustments and in tailoring tests to determine mastery. In light of all that working with students today demands, we must utilize every means possible to maximize time and opportunity for learning.

Students need to be provided clear, up-front expectations and individualized study sheets to help them learn those areas where frequent classroom and end-of-year assessments show they need additional study. What schools are expecting their students to learn must have wide and intensive stakeholder support based on clear and frequent parent communication. The expectations need to be a clear, readily accessible and adaptable public document, not a "stealth" document. Parents need access to those expectations and to resources that help them help their students attain mastery.

Educators need to have access to information technology tools that reduce the labor-intensive nature of responding to all these needs. Pre-service teachers and leadership personnel need to be trained during their preparation programs about curriculum alignment is, how it is necessary, and how it may most efficiently and effectively be done. Teachers and leadership personnel need pre-service training and in-service professional development in how to analyze performance test scores and related comparative data to use them to modify the expectations, identify gaps and/or overlaps in what is being taught, identify the resources available and/or needed, and allocate resources to the budgetary process to provide what teachers need to help students succeed. In short, what’s expected in the classroom, the reasons why those are the expectations, and the consequences of failure to achieve them need to be clear to all. The results of the measures to determine success, however flawed any one assessment process may be in isolation, need to be studied and communicated clearly so educators, students, parents, and the community can know what’s expected.

Given that information, the task then is to make modifications to ensure greater success. Before I retired as Assistant Superintendent of Pickens County Schools, we adopted Curriculum Designer and its related components, Skills Connection and Home2School, products of EdVision Corporation. Curriculum Designer is a curriculum planning system that enables school and district level curriculum teams to align curriculum with state and national standards and to produce a curriculum continuum for K-12, without gaps or duplications. This software efficiently and effectively identified the expectations from the various curriculum and standards requirements and assessment tests our district was accountable for. Once drafted, our curriculum document could be modified almost instantly whenever the need arose. Skills Connection, a classroom assessment tool, draws on the same databases—some 72,000 objectives—to integrate necessary objectives into classroom assessments without requiring teachers to craft each assessment individually. Skills Connection also provides a Home Study Guide for each skill to assist parents in helping their children study at home. Home2School.com (a free website for parents) provides constantly updated resources and tools to help parents effectively participate in their child’s education. This site includes curriculum resources, tutorial lessons, reading lists, and other information of interest to parents. These software packages are incredible electronic information tools being used by school systems throughout the nation to develop action plans that can truly begin with the end in mind.

In this time when the cries of “The public schools are failing!” resound across our nation, we must do all we can to assist our educators in pre-service preparation, graduate coursework, and in-service professional development to become knowledgeable and skilled in using such tools. Information technology tools such as Curriculum Designer and Skills Connection can help educators immeasurably in working with others in their individual school settings and communities to help with the essential task of restoring schools—and the professionals educators at all levels that work to help them succeed—to a source of national and local commitment and pride.
John Moore: The State Perspective

Using the web to meet accountability mandates

The state of South Dakota developed state standards at great expense over a considerable period of time. These standards were adopted by the legislature and mandated for school districts to adopt and implement. Teachers have to teach the standards. What we didn’t have until recently was a way to measure accountability. No one—at the local, district, or state level—had any way to measure whether those standards were being taught. An external audit showed that there wasn’t a true one to one correlation between the national test (SAT9) and South Dakota’s state standards. The State legislature appropriated money for development of criterion referenced tests. We had the option to write our own tests or to contract a third party to write the tests for us. This section shares how South Dakota schools used web-based assessments to target the instruction level of each student.

South Dakota has an interesting educational situation caused by the distribution of a small rural population over a large geographical area. There are a total of 176 public school districts. Twenty five percent of the school districts have seventy five percent of the student population. Much of the student population is in the eastern third of the state. How could the state deliver a world class education with so many small school districts?

Governor Bill Janklow recognized the unique situation South Dakota was facing and proceeded to wire every public school classroom with a T1 line. To make this project cost effective, prison inmates were used to provide the necessary labor. A local electrician was hired at each school district to supervise the project. Inmates slept on cots in the school gymnasiums. Many prisoners received job offers after being paroled because of this hands-on technical experience.

At South Dakota’s State Department of Education, we’ve heard many wonderful stories as a result of wiring the schools. One elementary teacher observed an inmate who was approached by two first-grade boys.

One of the boys looked up at the inmate and asked, “Are you one of the prisoners?”

"Yup," was the reply.

The boy asked, “Did you kill someone?”

“No,” the inmate replied. “I’ve never hurt anyone.”

Then why are you in jail?” the boy asked.

“Because I didn’t pay attention in school,” the inmate answered.

According to Governor Janklow, South Dakota is now the best wired place on the planet. But that’s only a start. The important thing now is to find ways to use this technology to give students the opportunity for a world class education. One way we’re doing this is offering classes over the Digital Dakota Network (DDN) to students of all ages. This two-way audio-video system (V-Tel) is in operation for the 2000-2001 school year. The idea is to provide options for students who might not otherwise have an opportunity for certain subjects.

South Dakota is also the first state in the nation to provide an on-line state wide assessment. We have entered into a strategic partnership with EdVISION Corporation of San Diego, California, to provide an assessment that is aligned to the state content standards. Performance.com, the web-based assessment tool we’ve adopted in South Dakota, will tell teachers which content standards have been mastered and which need more work. The teacher can click on each standard and get instructional strategies on how to help students master standards. This web-based, computer-adaptive test covers four academic areas: reading, math, science, and language arts. It provides instant feedback to teachers, students and parents. Results are available immediately following the assessment. Student progress over a period of time may be tracked.

These web-based tests are significant alternative assessments to norm-referenced and traditional criterion-referenced tests. They utilize a computer-adaptive model to target the instruction level of each student by altering question difficulty based on previous answers. The reading test, for example, with which we began our statewide implementation of web-based testing, utilizes an expert system to report a proprietary Reading Progression Index (RPI) for students in grades 2 through 12. The test is tailored to each student as the test progresses. The interactive system uses the students’ own responses to determine the difficulty of subsequent reading passages and response questions, without continued exposure to either easy or very difficult questions. The average test time is 30 minutes, although students reading well above their grade level may take more time to complete the test. This means that testing time generally occupied only one class period.

Another logistical boon in web-based testing is that test proctors do not necessarily have to be teachers. The role of the test proctor in web-based testing is to assist with computer use, but not with the test, itself. Proctors monitor the test environment to ensure optimal testing conditions for all students. If the students are not computer literate in terms of using the mouse and scrolling, the proctor may need to take a little time and demonstrate computer use. Before the students begin tests, the proctors explain the purpose of the test, and describe how the test helps teachers gain information about individual reading levels. Proctors also describe the layout and design of the test, as well as its similarities and differences to types of assessments the students have encountered previously. They assess the students’ physical comfort level, their ability to view their computer screens, and their ease with using a mouse. Finally, they follow scripted instructions to guide students through testing.

As with any new process, thorough training is key to successful implementation. When South Dakota adopted web-based testing from EdVISION, we asked their Professional Development team to spearhead certification workshops for our Testing Coordinators. Once this core group of our own educators were trained how to get each student to reach their potential using this assessment, they in turn trained proctors at their own school sites. EdVISION staff wrote a Test Coordinator's manual and a Proctor's Manual for us to distribute as part of the certification process. Follow-up workshops will be held in the spring to help teachers and administrators interpret test results.

Research studies indicate that feedback is one of the most important motivators of students and teachers. One of the most valid complaints concerning external assessments is the amount of time it takes to get the scores returned. Information that could be used to inform teaching practices is unavailable when during critical times. The web-based testing we’ve adopted in South Dakota makes scores available immediately following testing. Thus, teachers can utilize the information interpreted from reports to make immediate changes in the students reading instruction. Teachers across the content areas can also use the information to determine the needs of students and how performance may be effected in these subject areas as well. Parents can be informed so that they can begin to assist in providing appropriate grade level reading materials and reading along with their child to increase reading comprehension.

While South Dakota was the first to adopt statewide web-based testing, it won’t be the last. The new teachers who enter South Dakota and other innovative school systems with a knowledge of web-based assessment will find themselves on the cutting edge of what we’re trying to
accomplish. They will be able to more quickly embrace this assessment tool to evaluate, maintain, and foster their students’ academic achievement.

Terry Bailey: The University Perspective

Technology and Pre-service Teachers

Teacher education institutions are well positioned to provide opportunities for pre-service teachers to learn about becoming successful K-12 educators through content, classroom, and curricular development. As we become a more technology-driven society, it is apparent that teacher education programs must address issues related to computer competency, technology integration, and Internet accountability. Faculty and administrators at Ball State University have used the software described here to introduce pre-service teachers to curriculum alignment and accountability measures. How can we help our teachers enter the field knowing how to align and integrate the skills their K-12 students are required to know?

Faculty and Administrators at Ball State University are using EdVISION’s Curriculum Designer and Skills Connection software to show pre-service teachers how to align and integrate the skills that K-12 students are required to know. EdVISION’S University Partnership program is designed to allow university professors the opportunity to utilize the software in a laboratory setting at no cost to the university. Students purchase a laboratory pack that includes the product manual, support materials, and product tutorial. The program resides on a group of predetermined computers available to students enrolled in the class. The internal security feature in Curriculum Designer is enabled to prevent unauthorized use of the software. EdVISION provides training for professors to support effective implementation of the products into the college classroom.

The University Partnership Program allows institutions like Ball State University to do the following:

- Introduce the power and the possibilities of electronic design and assessment software through curriculum design projects, classroom discussion, and project development to other colleges and universities at professional meetings and in classroom environments.
- Be a research and development “sounding board” for EdVISION as they further develop their products. Discussions with pre-service teachers in university courses and graduate students who are already working in the education field give us valuable information about how software is getting implemented on the job.
- Offer state-of-the-art facilities for online workshops and communication through 1-way or 2-way videoconferencing, video streaming via the Internet, and community portals.
- Demonstrate the EdVISION’s curriculum design and assessment software to superintendents, principals, teachers, and parents at professional meetings and community forums. We want to show how these products can be used as alignment, accountability, and assessment tools in the educational process.
- Provide ongoing training and support to pre-service and in-service K-12 teachers who are using products like Curriculum Designer and Skills Connection.

Pre-service teachers need experience with the infusion of curriculum alignment software into standards-based curricula. Our University Partnership with EdVISION has allowed us to offer a hands-on course in using curriculum design and assessment software. Participants engage in activities that revolve around the idea that learning a concept involves using technology in context. Students understand that setting and following standards are critical components for accountability. Without high standards for what we expect students to know and be able to do, we will not have the kinds of schools we want. Experience and research has shown that high standards and rigorous assessment alone will not guarantee success for all students. For expectations to be met, clear standards must be put into place and followed. The University Partnership program allows pre-service teachers to use software that was designed specifically to help with this implementation process.

Cheryl Reed: The Corporate Perspective

Accountability and .com—can this marriage be saved?

How can schools get the funding needed to ensure student success? If technologies like those discussed here are available to clarify, reshape, and drive our responses to escalating accountability mandates, how can districts get the money needed to purchase them? Are alliances between education and corporate concerns necessarily uneasy ones? Can we teach pre-service teachers and administrators how to get strategic funding?

My company, EdVISION Corporation, has worked with each of the school systems discussed by my co-authors in this article—and, of course, many others—to help them implement reform with software that meets the needs of their specific situations. My colleagues are Ph.D.s, Ed.D.s, former public school teachers and administrators, and former University professors and writers. In the Professional Development Department alone, we have a combined teaching/administrating experience of 110 years. Our company goal has always been to make possible a coherent curriculum for all students, leading to academic success measured by fair and accurate assessment. In short, we are educators who develop software, not software developers who market to educators.

Part of my enviable position at EdVISION is to connect people with resources. I know where the money is hidden. As Coordinator of Proposals and Publications, and formerly, as Assistant Professor of Writing at Penn State University, I have been consistently amazed at the amount of grant money that’s available for educational endeavors. Pre-service teachers need to know that people have money they want to give away—to us! At Penn State, I was always the professor who had work study students, new computer software, stipends for overwork, and travel money for conferences. When my colleagues asked me, “How did you get that?” I’d say, “I asked for it.” In my experience, it was as simple as that.

After many such encounters, I realized that huge amounts of money are available, but most of us receive very little of it. There appears to be a built-in disconnect. Why don’t more worthy projects get funded? Why do so many proposals seem doomed to failure? After getting my own proposals for educational and publishing projects funded, and helping other people to write theirs, I have some suggestions for pre-service teachers to think about.
First, locating grant money takes time out of an already packed schedule. As much as possible, get information coming to you rather than going out to search for it. Many foundations, government agencies, and university websites have free electronic services (like the Grants Net Info listserv offered by the Department of Health and Human Services or the Foundation Center listserv) that will update you about grant foci and deadlines.

Second, decide how much time and money you want to invest finding grant money. Do you want to purchase a hard copy of government grants? Of private funding foundations? Books on grant writing? Do you want to set aside Friday afternoons (for example) to surf the web for grants? Do you want to pay a consultant firm to send you grant updates?

Third, find out what your institution already has available to you. Start at "home" with grants tailor-made to your situation, then branch out to larger opportunities. Find out what kinds of listservs, websites, and notification services your institution may have already purchased. Then, use these resources!

Fourth, apply only to those grants that mirror your goals. Most of us have a vision that we want to accomplish. We hope that the grant-funding institution can see it in "our way." Yet, we have a much better chance of success if we analyze what a particular organization wants to fund, and see how our vision fits in with theirs. Think of the funding organization as the larger framework into which your request fits rather than the other way around. For example, if you think technology would solve a problem in your school, but the funding organization warns, "We are not looking for solutions which merely throw technology at a problem," you'll want to describe your project in a way that shows how technology will be integrated into the solution. How will your plan prevent the technology you buy from becoming "shelfware"—never utilized or implemented? How will technology help the people who will be implementing your plan?

Fifth, don't let the educator's ingrained shyness about asking for money get in your way. Use a business model when writing grant proposals, not a scholarly model. Let's take a close look at the difference between these two models: in my experience, the way you present a project is one of the major factors in whether or not a grant gets funded.

The scholarly model. Many writers—passionate about the school reform they want to enact—simply don't like to ask for money. They prepare their requests for funding the way they would prepare a formal scholarly article:

1) Pose an interesting research question.
2) Support your argument with several references to other scholars.
3) Show how it gets enacted in your own situation.
4) Very gently suggest a possible conclusion—but leave it open for interpretation and further discussion.

These gentle, scholarly proposals aren't likely to be funded. The people reading them may see you have a real heart for your students, but they will have no idea what it is they are being asked to fund, or why, or how to evaluate whether or not your project has been successful.

The business model. Now let's look at a business model. The writer follows this plan:

1) State the problem or issue. State what you want to change in one or two lines. "The Stellar Students Academy needs a curriculum aligned to state standards if we want to maintain our top ranking among schools in this state."
2) Make a promise. What will solve the problem? Again, state it briefly—you can expand a bit later. "The adoption of an electronic curriculum will help craft a dynamic set of objectives so that students are taught the objectives on which they'll be tested."
3) Describe a process. This is the "this is how it all works" section, and depending on page limits set by the funding organization, it can be from several paragraphs to several pages. Use bolded headers, white space, charts, and other methods that organize material visually. Answer the questions asked in the foundation guidelines. Be able to describe how you'll fulfill your promise in some detail. What intervention is being attempted? Who will be involved? What kinds of changes in teacher schedule, workload, computer resources, etc. will this involve? What software needs to be installed? Who will do that? What timeline do you envision for implementation? What changes will have to be made in the existing system, schedule, or budget in order for your plan to work?
4) State your estimated costs—in work hours and dollars. Include cost sheets, implementation timelines, technical requirements, and plans for staff development. Will you have to pay the installers or staff trainers?
5) State evaluation criteria. What tangible success look like? Why is this plan the most likely to achieve this goal? Offer a way for outcomes to be measured tangibly—test scores, workshops given, documents produced, parents involved.
6) Restate your promise. If this project gets funded, the organization can expect to see...—This is important because—.

In most cases, grant writers are visionaries pitching ideas to pragmatists. Grant writers see a vision of what can be, and are willing to make whatever changes are necessary to make their vision happen. Grant writers envision transformation, innovation, new ways of seeing. Funding organizations, on the other hand, take a more pragmatic approach. What can work in the present system? How can we gain the most with the least amount of expenditure? Why should we fund this project over that one? How does this project fit in with our overall foundation mission? If there is any place that the marriage between academe and "com" is strongest, it is in grants that propose schools adopt savvy new technologies. Communicating academic funding needs to government and private funding organizations is, in the words of business writer Geoffrey A. Moore, the "chasm" that teachers and administrators attempt to cross when they seek funding for technological innovation in their school districts. If we can help our pre-service teachers understand how to articulate clearly their vision for reform, we will have unleashed dynamic change agents into a school system already undergoing a massive transformation.
Community Innovations for SITE: Who is doing what with Clearinghouses and On-line Tools Development?

David Gibson and Bob McLaughlin

MirandaNet and London University Institute of Education, UK  
c.preston@ioe.ac.uk

Gary Marks  
Association for the Advancement of Computing in Education, USA  
gmarks@aace.org

Abstract: This interactive panel session aims to inform the further creative development of SITE's web sites. It will be particularly relevant to groups within and beyond the USA who are developing "clearinghouses" and/or new "on-line tool sets" for technology in pre-service and graduate teacher education. The session will also consider ways in which SITE can collaborate with related on-line communities.

The session goals are:  
- Exchange information and contacts with one another  
- Get a better sense of the recent landscapes of on-line development  
- Enable participants to envision and form new alliances and partnerships  
- Facilitate better use of resources  
- Create an atmosphere for more focused planning and deployment of new capabilities  
- Open the possibility for broader applications and co-learning among innovators  
- Consider collaborative links with leading edge scholarship in technology and education  
- Link with the SITE survey of teacher educators' needs and potential contributions

Background

Niki Davis' keynote paper 'SITE: A Site of Educational Leadership for the Emerging Knowledge Society' for this SITE 2001 conference suggests that SITE can model behavior for the emerging knowledge society (in press). Within it she describes the background to this innovative session:

'Most recently, I have begun to lead the further development of SITE's web site to support our objectives of committee and community support. David Gibson of the Teacher Education Network (TEN) PT3 catalyst project looked for collaboration with SITE during the 2000 conference, recognizing what the National Interagency Civil-Military Institute (NICI) web site and tools might bring to enhance teacher education (http://www.nici.org). As a result I have undertaken to lead a needs analysis of SITE membership and to investigate how NICI web tools might be used to support SITE, especially its working committees.'
The Center for Innovative Learning Technologies (CILT) conference provided another opportunity to address SITE needs (http://www.cilt.org). Part of the work of the professional development sub-group at that conference resulted in a successful seed grant proposal for SITE-CILT collaboration, which will particularly support SITE membership needs for scholarly collaboration. The convergence of these two small projects and AACE's commitment to web development to support our scholarly community will be an important interactive session during the SITE conference. The goal of the session is to design an ongoing environment to continue SITE committee work arising from meetings of the committee and our new Saturday Town Meeting. The needs analysis is underway. We hope that all SITE delegates will participate in both sections: needs and contributions. The aim is to create a range of complementary synergies between these two, so that all participants benefit. The survey will become available on the SITE conference web site in early 2001 and will inform the redevelopment of SITE's web sites for the conference, committees, and other activities.

This SITE Session

This interactive panel session is designed for SITE participants interested in developing our on-line community. It will be particularly relevant to leaders of national projects, PT3 implementation and catalyst grants and other groups within and beyond the USA who are actively building or planning to build 'clearinghouses' and/or new 'on-line tool sets' for technology in pre-service and graduate teacher education. The session will also consider ways in which SITE can collaborate with related on-line communities, including CILT's Knowledge Network (http://kn.cilt.org), The PT3 Teacher Education Network project linked with National Interagency Civil-Military Institute (NICI) web site and tools might bring to enhance teacher education (http://www.nici.org), ISTE's Subject Interest Group (SIG) for teacher education. Beyond the USA, MirandaNet provides support in collaboration with industrial sponsors (http://www.mirandanet.ac.uk) for change agents leading the deployment of new technology in school and teacher education in the UK and in the Czech Republic.

This interactive session aims to inform the creative development of SITE's web presence(s), and to do so in a way that does not ignore equity issues in its language and coverage.

The goals of the session are to:
1. Exchange information and contacts with one another
2. Get a better sense of the recent new landscapes of on-line development
3. Enable participants to envision and form new alliances and partnerships
4. Facilitate better use of resources
5. Create an atmosphere for more focused planning and deployment of new capabilities
6. Open the possibility for broader applications and co-learning among innovators
7. Consider collaborative links with leading edge scholarship in technology and education
8. Link with the SITE survey of teacher educators' needs and potential contributions

The discussions will also draw upon SITE's existing web site presences, which are the SITE conference web site and the on-line journal of Current Issues in Technology and Teacher Education. Glen Bull and Jerry Willis jointly edit this on-line journal under the SITE umbrella. However, the content sections within the journal are edited and controlled by the appropriate content association, with the whole publication organized by AACE (http://www.citejournal.org). The first issue of Current Issues in Technology and Teacher Education includes articles that discuss the challenges of on-line publishing. Although this interactive session aims to focus on on-line community development, rather than on-line publishing, similar issues impinge. These include the evolution of appropriate cataloguing (and/or a system of metadata); protocols for collaboration; and robust archiving including multimedia.

Outcomes
It is hoped that the outcomes of this interactive session will prime energetic developments on-line to create better facilities for SITE to support participants' need for their teaching, professional development and research. In doing so care will be taken to build upon web sites and scholarly collaboration, rather than to duplicate them. It is also planned to document these scholarly activities and publish them in academic papers, hopefully including the SITE on-line journal Current Issues in Technology and Teacher Education.

Acknowledgements

The scholarly development is supported though the PT3 Teacher Education Network catalyst grant from the USA Department of Education and a seed grant from CILT, as well as participating organizations and individuals. We thank them all.
The role of school administrators in the process of effectively integrating educational technology into school learning environments: New research from the mid-west.

Ian W. Gibson
Department of Administration, Counseling, Educational, and School Psychology
Wichita State University
United States
igibson@twsu.edu

Abstract: The study reported in this paper examines the role of administrators in the integration of technology into the learning environment of three school districts in the mid-west region of the United States. The outcome of the study provides information that will assist school district and building administrators in developing a greater awareness of their role in supporting the use of technology in the instructional environment. School administrators, instructional staff and technology coordinators participated in this qualitative study. Data collection strategies selected for this qualitative study were focus groups and interviews. Conclusions and recommendations derived from these data are presented in the form of administrator role responsibilities.

Introduction

Based on an analysis of research similar to that reported by Stegall (1998), stating that school administrators did not mention technology leadership as an area of administrative responsibility during an analysis of their perceived areas of responsibility, the research described in this paper focuses upon the administrator’s role in the process of integrating technology into teaching. This is a topic with a surprisingly short history. Bromley (1998) provided the reasoning for this phenomenon. Rather than starting with a determination of what schools should accomplish and then asking how technology might be used to achieve those goals, Bromley suggests that computing initiatives have most often been based on the attitude, “This technology exists, we’ve got to have it” – that is, educational computing has largely been technology driven rather than curriculum driven. As a result, putting computers in schools has all too often meant getting more of the same, only automated: electronic workbooks, computerized tracking of student “progress,” and so on (p. 128). Given that this situation was once a widespread phenomenon across the country, it is not too difficult to understand the reasons why administrators did not consider deep involvement in this process to be necessary. The fact that many administrators are not comfortable with technology, and have participated in leader preparation programs that did not include reference to or use of technology adds to a lack of administrator involvement in the process (Gibson, 2000; Maurer & Davidson, 1998; Roden, 1997; The Office of Technology Assessment, 1988; 1989; 1995). As greater awareness of the potential of technology to positively impact learning has grown, and recognition of the need to transform the way schooling has occurred has increased, and the variable rates of technology adoption around the country have been recognized, the need for involving the whole educational team in the process of integrating technology has become a pressing reality.

Recent literature on educational leadership has sharpened the focus on technology issues facing educational administrators. The number one issue in the effective integration of educational technology into the learning environment is not the preparation of teachers for technology usage, but the presence of informed and effective leadership. Confirmation of this statement can be found in the literature on professional association web-sites related to establishing technology standards for administrators. Further evidence that what administrators do or fail to do makes a critical difference in the effective use of technology in schools can be found in the national movement to develop technology standards for school administrators. The question, “What should administrators know about and be able to do to ensure successful integration of technology in P-12 schools?” is being addressed by the Collaborative for Technology Standards for School Administrators(<www.iste.org> or<www.enets.org>.

In his keynote address to the Expert Forum on Technology Standards for Administrators (Denver, Oct. 2000), Latham, Director of Assessment for TeacherUniverse suggested that the key to the technology vision was leadership. With the same thought in mind, standards advocates have suggested that developing national
technology standards for school administrators is the beginning of the process of preparing school leaders to be capable and knowledgeable participants in the process of effectively integrating technology into learning environments.

The Research Process

Following analysis of the literature, and recognizing the need for leadership in their own school technology situations, a research team comprising students enrolled in a Master of Education program, specializing in Educational Administration and Supervision, at Wichita State University, Kansas, and a professor teaching in the program, recognized the need to consider administrators' roles in the process of integrating technology into school processes. A research study was designed to address this issue.

The purpose of the study was to analyze the role of administrators in the process of the integration of technology into the instructional environment of three school districts in which members of the study team were currently employed. The data collected were to be synthesized with information gleaned from the literature to form the basis of a guide to administrators interested in enhancing the success of the technology integration efforts of their building and districts.

The study addressed the following questions.

1. When integrating technology into the instructional environment, what is the building administrator's role as instructional leader?
2. What administrator supported processes are necessary when integrating technology into the instructional environment?
3. What building or district level structures are necessary for teachers to effectively integrate technology into teaching?

The research was qualitative in design and incorporated the collection of data using interviews and focus groups with instructional staff and administrators. Instructional staff included teachers, as well as those who were acting in the role of technology consultants for school districts.

The Research Design

The nature of the research, and the research questions implied a need for data to be rich in description, focused on individual perceptions and detailed in the analysis of the topic in question. As such, a qualitative design was chosen to match these expectations. Drawn from a naturalistic approach to educational inquiry (Erlandson, Harris, Skipper, & Allen, 1993; Lincoln & Guba, 1985; Patton, 1990), this study design adopted a discovery-oriented approach to data collection intended to minimize investigator manipulation (Patton, 1990). Data collection strategies able to provide the richness of data and the variety of perspectives necessary to understand the complexities of the situation under study (Erlandson et. al., 1993) were selected. The need to gather data on this topic using a variety of approaches was also necessary to support the trustworthiness of the data collected. The study team adhered to the need to triangulate the data collected (Lincoln & Guba, 1985) and increase the credibility of the findings through the use of focus groups and interviews. Teachers were randomly selected from each of the three schools to participate in one of three school-based focus groups. Focus groups were conducted when a minimum of six teachers agreed to participate. Principals and technology coordinators from each school participated in interviews. With the permission of all participants, each data collection activity was audio-taped to assist in accurately capturing all responses. Data from these activities were unitized (Erlandson et. al., 1993) and subjected to the process of constant comparative analysis advocated by Lincoln and Guba (1985). This process was assisted by the use of a relational database allowing repetitive manipulations of the data until naturally occurring themes and categories emerged. The themes and categories created the framework for analysis of the administrator's role in technology integration.

Research Results

Categories and themes emerged during the data analysis process, indicating the areas of greatest concern for the respondents from these three mid-western school districts. Comments from study participants clustered around common themes related to existing practices, planning, curriculum issues, resources, staff issues, communication, support, obstacles, professional development, and implementation. These emergent themes...
have been maintained in the organization of the recommendations for school administrators presented below. Each statement is designed as a recommendation that all school administrators should follow.

1. Existing Practice
   Become aware of existing practices in the building, in the community, and in the outside world
   Support teachers and students enthusiastic about technology usage
   Recognize the time investment of technology users
   Celebrate all technology achievements

2. Planning
   Ensure a current inventory of hardware/software/infrastructure
   Document current technology practices
   Be aware of teacher skill levels
   Establish a Technology Planning Committee
   Develop a shared vision for technology in which everyone has an active role.
   Support the development of an evolving five year technology plan which includes a vision, mission, funding, goals, roles, timelines and responsibilities
   Re-evaluate and update the technology plan annually
   Incorporate technology into the school improvement plan
   Encourage research, risk taking, and dreaming when planning and integrating technology.

3. Curriculum Issues
   Provide support and time for analysis and planning for integrating technology into curriculum documents
   Encourage and structure collaboration on, and communication of technology curriculum issues, changes and techniques throughout the district/building
   Provide opportunities to visit other schools to evaluate alternative approaches to curriculum integration
   Provide access to documents, expertise, and ideas about technology and curriculum integration issues

4. Resources
   Be aware of the need for resource allocation in the areas of hardware, software, finance, access to information, training, time, technology support personnel and planning.
   Develop an inventory of district and building level equipment
   Create an awareness of technology needs as they relate to the achievement of student learning goals
   Support budget decisions tied to the establishment and maintenance of technology configurations and personnel sufficient to support the needs of teachers and learners
   Provide time for teachers and administrators to think about and learn to use technology effectively
   Collaborate in the development and maintenance of district and building level technology plans
   Be a financial advocate for teachers technology (hardware, software, training) needs
   Utilize business expertise, community partnerships, and grant opportunities to support technology needs

5. Staff Issues
   Become familiar with staff technology issues and needs at the district and building level
   Address concerns related to teacher expectations, training, building and district support personnel in a timely and proactive manner
   Support teachers as they struggle with integrating technology by recognizing frustrations and offering solutions, personal assistance and expertise
   Design support structures and solutions for specific situations and needs
   Employ a technology specialist whose primary responsibility is to support classroom teachers
   Provide opportunities for identified teachers to participate in specialized training to develop teacher-based technology leadership in the school
   Encourage the development of, and use of student and teacher expertise in supporting school technology goals

6. Communications
   Communicate the district/building technology vision and plan to all stakeholders
   Communicate past successes and new initiatives to all stakeholders
   Communicate the need for continual technology change and school improvement, and its connection to learning,
Ensure mutual understanding and buy-in for district/building technology visions
Formalize communication between technology personnel at all levels, teachers, and administrators

7. Support
Provide funding for on-site technology support personnel
Actively listen to and respond in a timely manner to technology problems in the building
Be the voice between teachers' technology issues and the district office
Actively encourage teachers to incorporate technology into their classroom
Empower the staff to correct their own technology problems
Increase support staff as the use of technology is increased
Become aware of and use community technology resources

8. Obstacles
Find additional funding through grants, capital outlay, and other resources to supplement technology purchases and technology support mechanisms
Provide time for grant writing, technology plan development and maintenance, planning and conducting professional development, and learning how to implement technology into the classroom
Insist on consistency of computer configurations—hardware/software, infrastructure
Be aware of the reasons for and the various forms of teacher resistance
Develop appropriate incentives for teachers to be involved in implementing technology
Change attitudes within the district/building which lead to a reticence to provide financial support and professional development for technology integration
Be aware of and overcome technology related logistical problems within the school (e.g. wiring, power, space, security, etc.)
Be prepared for administrators and teachers unable to adjust to the change technology brings to education
Be prepared to constructively deal with 'educator fear of technology'
Have specific resources and techniques available for those experiencing difficulty integrating technology into the curriculum

9. Professional Development
Assess teachers' technology needs
Allow staff input into in-service topics prior to making decisions
Plan various types of professional development experiences
Provide time for on-going, results-based professional development
Provide time for collaboration on lesson planning, class implementation issues, and learning about hardware and software with other staff members
Hire an on-site technology expert to mentor the staff
Allocate sufficient funding for high quality professional development
Protect professional development budget allocations
Support staff risk taking
Model technology usage and risk taking

10. Implementation
Provide the opportunity for co-workers to collaborate
Allow staff time for implementation
Schedule on-going professional development sessions
Champion the technology vision so parents, teachers, and students see the relevance of technology to their learning processes
Develop staff buy-in to the technology vision
Incorporate technology into school goals
Allocate budget authority to support the technology vision
Provide time for staff to learn how to integrate technology

Conclusion
The results of this small study describing the perceptions of teachers, technology coordinators and administrators in three mid-western school districts in the United States mirror much of the material found in current literature on the topic. This study confirms the importance of an administrator's role in this process.
similar fashion, Mahmood and Hirt (1992) concluded that of all the variables impacting the integration of technology into schools, none was as important as support from school and district administrators. In describing goals necessary for creating a technology-effective, and integrated learning environment, McPherson (1995) focused upon the crucial role of school leaders and the need to create dynamic leadership and organizational support for the process. These and other writers have recognized that a key barrier to the use of technology in schools is the lack of administrative support (Maurer & Davidson, 1998; OTA, 1988, 1989, 1995; Rodin, 1997). This study has confirmed that administrators need to know how technology can restructure the teaching learning process and the importance of their role in the process.

Other writers have provided guidelines to assist administrators in successful technology implementation. These guidelines reflect the findings of this study. Stager (1995) suggested that administrators: work with the living; eliminate obstacles; stay on message; work on the teacher’s turf; plan off-site institutes; provide adequate resources; avoid software du jour; practice what you preach; celebrate initiative; share learning stories; help teachers purchase technology; and cast a wide net (p. 80). A further pair of goals are provided by Meltzer who suggests that technology should be used in conjunction with greater emphasis on learner-centered pedagogical strategies, and that it must be integrated into the fabric of the school program“ (p. 23-24). The research reported in this paper has suggested the need for a greater emphasis upon the role of school administrators if the investment in training teachers to integrate technology effectively into learning environments is to be fully realized.

Instructional Technology as a Support System for Principal Certification

Dr. Cathy C. Kaufman
Administration and Leadership
Indiana University of Pennsylvania
USA
ckaufman@grove.iup.edu

Abstract

This session describes the creation of an electronic learning community for candidates in one Principal Certification Program. Individual web pages using a template to match program objectives enabled students to incorporate the Internet as a window through which to look in on the internship learning experiences of other aspiring administrators.

Technological Needs

Lou Gerstner, CEO and chairperson of IBM, claims that nothing matters more for the future of American schools than finding great principals to lead them. But like most organizations, schools are experiencing major transformations in the way they have traditionally conducted business. Although the role of the school administrator is commonly cited as the central to such changes, this role itself is in the midst of major transition. It requires institutes of higher education to rethink the preparation of a new genre of educational leaders who can effectively connect curricular, technological, and community needs. This project describes the creation of an electronic learning community for candidates in a Principal Certification Program at Indiana University of Pennsylvania who, by virtue of their age rather than their credentials, frequently have fewer electronic experiences than those for whose instructional supervision they are accountable.

Learning Objectives

The change that having a web page window and custom designed template geared to program competencies brought to this program reflects the distinction between technology being an “informating” (Zuboff, 1988) rather than
an automating tool. Automating technologies make existing work more efficient. Informating efforts, however, stretch people to first think differently about the work they do and then to redesign that work. Most aspiring principals in this program have high levels of competence in the automating components of their professional life such as computerized grading, course scheduling, manipulating demographic transportation data, budgeting, and integrating computer assisted learning. Using the Internet in an informating way, however, set the stage for principal candidates to learn from each other’s experiences during their supervised internship in a way that had not previously been possible. Until this change, students in a program that is performance-based followed their university course work by returning to their school districts to complete an administrative internship. The collaborative relationship and the important network of conversation recognized as central to adult learning traditionally ended in transition from university to public or private school environment. Web Pages enabled these aspiring administrators to have a window into the internship experiences of their classmates thus providing greater opportunity to sustain the benefits of collaborative learning that benefits both individuals and the organization of which they are part.

Ideals central to collaborative cycles of deep learning (Senge & Kim, 1997) mesh well with the Principal’s Program at Indiana University of Pennsylvania that is anchored in applied leadership in action. Students fulfill program goals and state certification requirements through enacting actual improvement in their school districts in the six areas of: curriculum management, instructional supervision, organizational management, evaluation and research, technology and innovation, and human relations. The development of a template reflecting students’ experiences in each of the six performance categories expanded our use of technology in the program itself and built a more synergistic element into the program in which an individual experiences add value in term of the more informed practices for the entire group. Throughout a seminar in School Administration, candidates formulate projects in each of the program’s six core competency areas. This resulting Action Plan must meet the approval of the candidate’s on-site mentor and must therefore reflect attention to the context of the school district in which the student completes his or her internship. The Action Plan addresses specific university and state requirements, but with enough flexibility that the circumstances and challenges of a wide variety of school districts fit constructively within the framework.

- Curricular projects must address standards and changing assessment instruments, the inclusion of special needs students, and the match of school curriculum to the workplace.
- Instructional Supervision projects require implementing useful staff development workshops and exploring supervisory techniques go beyond inspection oriented checklists and that differentiate in opportunities for
ongoing professional growth for both experienced and novice teachers.

- Research and Evaluation projects require principal candidates to present to an audience a report on student achievement, to develop a grant proposal, and to design, conduct, and report on survey research that address a local educational concern.

- Human Relations projects must bring the community into the school environment to provide insights into how teachers and students spend time together. A parallel project in this area must demonstrate the candidate’s leadership in facilitating service learning in which students address a community need. And one of these projects must incorporate the issue of school safety.

- Technology and Innovations requirements involve regular electronic communication with faculty supervisors, participation in district technology committees, proposing a plan to upgrade technology training needs, and using the Internet to explore school leadership sites.

- Candidates must demonstrate an understanding of the Organizational Management of schools through a working knowledge of collective bargaining procedures, maintenance of custodial responsibilities, work schedules for special teachers, building compliance with safety codes, school emergency plans, transportation scheduling, master scheduling, budgeting, disciplinary codes and school law.

This well-defined but flexible infrastructure provides a program architecture that integrates the capacities and beliefs of a diverse group of veteran educators who share common administrative goals.

A Cycle of Deeper Learning

Our approach to the informing dimension of technology also reflects a “deep cycle of learning” (Senge & Kim, 1997) that successfully integrate opportunities for capacity building, practice, and further research. Personal home pages enable candidates to share projects through which they are mastering the previously described competencies. This builds an electronic window through which they can learn from both novice and experienced school administrators. Their administrative capacities are thus vicariously expanded into environments in which they have no direct personal involvement but the opportunity to scrutinize the successes and the struggles of their peers. Access to an electronic resource base that parallels the program’s six competency areas enhances the research element of deeper learning cycles within this learning community. This insures that aspiring principals will have electronic as
well as traditional research and literature from which to expand their knowledge during the required period of internship.

Conclusions

In the transition from experienced teacher to novice administrators, reconfiguring traditional portfolio documentation of core competencies in the program enabled aspiring principals to

- keep pace with current changes in curriculum, supervision, and school law,
- share strategies for dealing with contemporary school and community challenges,
- empower peers and staff members through providing greater access to information and to each other.

Managing Change
To Flexible Learning Using Online Technologies: Bridges To Cross, Lessons To Learn

Marie Kavanagh
Senior Lecturer,
Department of Commerce,
The University of Queensland (Ipswich Campus).
m.kavanagh@mailbox.uq.edu.au

Abstract: Universities around the world are involved in dynamic change as they seek to take advantage of the potential of the internet and information technology to provide learning opportunities which are independent of time and location. They must develop creative solutions in order to cope with changing educational requirements in an increasingly demanding global market. Yet many of the early attempts to use information technology and the internet for teaching have been nothing more that unreflective rebadging of material or repackaging of the more traditional modes of learning. To be successful, effective educational methodologies need to be anchored to the diverse material circumstances characterising different groups of learners. The challenge for universities offering programs of study is to provide avenues for learning which are reflective of the needs of its ‘learning community’, take advantage of the benefits which information technology provides while keeping in mind the outcomes desired for programs.

One of the more significant responses has centered on the development of educational programs for flexible learning. The philosophy underpinning this new mode of learning goes beyond a traditional, narrow, delivery/teacher focussed approach, to one which encompasses an educational philosophy and a set of strategies, designed to center around the learner by encouraging flexible, interactive learning using a variety of media and technologies. This approach has resulted in a radically different tempo with both educators and students being plunged into a new educational environment which requires different mindsets and methodologies.

This paper is an analytical reflection on the policy and management issues necessary to champion a change to flexible learning. It highlights the bridges that will be crossed when redesigning and developing programs across a number of disciplines to increase student access to a wide variety of stimulating learning resources and delivery media. It discusses the resources and structures required to achieve what is often a significant cultural shift and changing of mindsets for parties involved. More importantly it describes lessons to be learnt along the way.

INTRODUCTION

Over the last two decades there has been a steady roll-out of new information technologies such as multimedia-capable computers and CD-ROMs. The rapid growth of the internet has resulted in enthusiastic claims for technology’s ability to provide high quality education for all. As such, educational institutions worldwide are experiencing a paradigm shift as they are encouraged to go virtual with implications for the manner in which information technology is incorporated into educational programs. This paradigm shift involves “the rejection of one set of values and ideas about education and the adoption of a new set with regard to what constitutes effective pedagogy” Schubert (1986). Underlying this paradigm shift is an emphasis upon the student, how the student learns and a move from content delivery to the process of learning the content. In order to fully exploit the potential of online technologies to allow learners meaningful and effective participation in the emerging knowledge economy, educational communities, which include both teachers and students, need to make major adaptations and innovations in teaching and learning approaches.

The primary result of advances which have been made in various technologies is that educational institutions worldwide are rapidly embracing more flexible modes of program delivery. Images of students sitting at rows of desks where the teacher at the front of the classroom is the focus of attention as the conveyor of information to be copied down, memorised and then reproduced for exams are fading. The use of IT allows for a high degree of diversity in terms of learning activity, methods of interaction and collaboration with others, as well as reflection, areas which have been identified by learning theorists such as Biggs & Telfer (1987) and Laourillard (1993) as key aspects of learning. This facilitates the need for more learner-centered approaches to course design and delivery which increase student access to a wide variety of stimulating learning resources and delivery media rather than teacher-centered approaches. Importantly, while innovation is a key, any educational program must continue to provide suitable training and education for students such that they are “workplace ready” upon graduation.
Educational institutions are not just vehicles of instruction. A university for example, as a state of mind means social and cultural interaction and students will go to great lengths to socialise with each other in good old fashioned real reality. Before embarking down the 'cyberschool' trail there is a need to clarify for both staff and students what is meant by terms such as flexible learning and flexible delivery. Dissatisfaction may occur if staff are not properly trained and merely try to translate existing teaching and learning practices to a new medium (Daunt, 1997). Students entering courses that have been advertised as being delivered via electronic platforms to allow flexibility will have certain expectations as to the extent of that flexibility and what it means for them and the resources that will be available to them. It is important to note that some of expectations may be unrealistic.

Effective use of technologies in educational programs requires more than just an automation of existing practices. It should involve planning to generate online teaching strategies designed to ensure learning results in a 'change in understanding' (Alexander, 2000). For many this involves a significant cultural shift for both the teacher/instructor and the student. The appointment of suitable leaders to champion and manage this shift is critical to the successful transformation of programs from traditional to flexible methods of teaching and learning. The availability of a suitable level of resources and infrastructure from the outset to support and assist programs undergoing change, particularly in terms of staffing levels, will also have a marked impact on the quality of programs which evolve.

The first section of this paper highlights the need to understand the model of flexible teaching and learning to be adopted within a particular educational institution; the second section reflects on policy and management issues which arose as part of the process of shifting the paradigm in order to develop and deliver programs on a hi tech, flexible learning campus in one of the departments involved; and the third section looks at the process which evolved in order to design subjects for a flexible learning environment.

UNDERSTANDING FLEXIBLE TEACHING AND LEARNING

It is generally accepted that there appears to be variation and a deal of confusion surrounding the interpretation of the terms 'flexible learning', 'flexible teaching' and 'flexible delivery'. In fact all of these terms are interrelated and should be integrated into programs in varying degrees to cater for specific requirements of programs and to achieve the best possible learning outcomes for students in an environment which allows them choice according to their own circumstances. At the same time the knowledge resources and skills capabilities of academic staff involved in the process needs to be considered so that staff may guide and manage within the bounds of their own comfort zone. Underlying the whole process should be a sound pedagogical justification that the innovations promise benefits and that the changes to the status quo are desirable.

Some research shows that the more traditional forms of delivery (lecture/tutorial/oncampus attendance) are no longer meeting students' access needs and preferences whereas technology based delivery frees students/learners from the time and place dependency of traditional delivery methods (Bates 1995, McCann et al, 1998; Owston, 1997). One of the most significant challenges for program designers and developers is to ensure that programs are developed to incorporate the requirements of 'flexible delivery' and 'flexible learning'. There is a tendency by some to use the terms interchangeably. However a clear understanding of both terms is necessary before effective program development can begin. Cunningham et al (1997) suggest that if the focus of programs is to improve student learning by enhancing the learning of experience and not merely to use different techniques or technologies to deliver content then:

- It is important to distinguish flexible learning from flexible delivery ...The former implies a focus on the core activity of education, the learning Process of the individual student, and student choice regarding the methods Employed in that process. By contrast, flexible delivery is an administrative Term which implies a focus on the modes in which content can be distributed So as to relieve students of the time/place/space determinism of on-campus Education, and on administrative systems which respond to consumer needs.

- Flexible delivery has been seen by many as the white knight of educational training (Kay, 1997). In its true form it allows students the ability to enroll at any time and start learning straight away, regardless of location. The concept of semester is no longer applicable. It is replaced with "continuous enrolments" to allow the student to participate in learning at any time from home, work or a study center, or anywhere. The focus is squarely on individual learning. Brown, 1997 claims that students will benefit from taking a more active approach to their learning and will increase their self discipline. The use of computer-mediated communication systems can extend and support active, purposeful learning. Computer networks empower connectivity and communication and allow learners to define their own paths through the learning material (Nikolova & Collins, 1998). They also enhance group work by producing an interchange of ideas, increasing the level of dialogue and negotiated solutions between learners (Light, 1993).

- Boud, Bridge and Willoughby (1975) and Fenwich (1985) discuss individualised learning in terms of the five degrees of freedom that students should be allowed in learning: freedom of content, method, pace, sequence and assessment. Being mindful of 'designing learning experiences to fit the context of the media to be used, including the value of interactivity, the incorporation of visual material' (Benson & Vincent, 1997) to cater for individualised learning, in this paper the term 'flexible learning' rather than 'flexible delivery' is preferred. Technology is used primarily to support learning and to provide more effective learning experiences rather than deliver 'off campus'.

The concept of flexible learning described in this paper lies along the continuum between traditional face to face lecture/tutorial in-class methods and distance/open learning methods. Programs developed involve a number of flexible modes of learning. Students may choose to access material in a variety of ways. New technologies are used to create communities of learners who can interact and communicate electronically with each other and with teaching staff at any time of day from any.
place; to allow increased dialogue where learners can clarify, challenge and build on ideas and concepts and see the relationships between them (Laurillard, 1995). At the same time student self access to learning resources is combined with face to face group sessions incorporated into programs throughout the semester to allow students to work collaboratively in small groups and workshops to regularly reflect on their learning. Assessment also involves different modes. Students are expected to be able to analyse, to synthesise, to reflect, and to abstract meaning. Mere tesis of retention are no longer suitable. Students are required to participate in group sessions, use the bulletin board, complete interactive quizzes on the subject sites and undertake formal exams.

**POLICY AND MANAGEMENT ISSUES**

At the outset the shift from one mode of teaching and learning (traditional face to face) to another (flexible learning) presents a significant change and challenge. The extent of such a change will result in the need for more resources (time, money, effort), a planned vision for the future, and a degree of resistance (Carlopio, 1998). The key to successfully managing this challenge is a well planned and executed system of action. Mouritzen (2000) outlines four measures of management which are critical: Processes and Products, Employees (staff), Customers/ Clients (students), and Technology. These four components are discussed below.

**Processes**

What is particularly relevant to managing a change of this nature is a systematically planned and coordinated approach (system of action) at both the macro (institution) and micro (department/school) levels. At the outset the move needs to have the full support of the institution, be centrally driven and appropriately funded, with facilities and resources made known. These facilities and support units should include a centrally funded academic support unit which comprises a team of instructional designers and educational multimedia services personnel. This unit provides services across all departments/schools to assist academic staff to develop programs by combining knowledge of teaching and learning with an understanding of the educational potential of new technologies (Brown & Grigg, 1999). Imperative to the ongoing success of programs being developed and delivered is a centrally funded, responsive information technology (IT) section to service the needs of both employees and clients.

At the department/school level a program director (or program champion) needs to be appointed to oversee the development of programs or courses. It is the role of this person to champion change and ignite innovation (without overselling it); to manage time frames, budgets and costs; to ensure academic staff are supported in their endeavors to move from one mode to another in terms of time, training and resources; to ensure that programs developed are educationally sound; and that plans for the introduction of technology into teaching are made judiciously and driven by the 'learning' agenda rather than by technology (Alexander, 1995). This person acts as an interface between central administrative committees and staff involved in developing programs, must possess sound facilitation and management skills and plays a pivotal role in the whole process.

**Implications for students (clients) and staff (employees)**

Trigwell (1998) suggests that the effectiveness of particular teaching strategies is highly dependent upon a range of factors such as context of learning, the teacher's conception of learning, the planning and design of the learning experience (objectives, assessment) and the characteristics of the learners themselves. Moving to effective technology based teaching requires a shift in the teaching and learning approaches that are used if successful outcomes are to be achieved. This will often entail an adjustment for both staff and students. Staff move to become learning facilitators or mentors away from the traditional role of dispensers of knowledge. The emphasis shifts from content to concept and outcomes. This often involves an unsettling of strongly held convictions about the manner in which they teach and embrace learners in the learning experience. "Tried and true 'instincts' honed in years of teaching experience are not necessarily transferable online", (Benfield, 2000, p.1). It also involves enticing them to move away from sometimes erroneous presuppositions about what flexible learning using information technology entails to encompass a broader perspective which involves a multi modal approach to content delivery and learning. Many staff are naive and assume that the task is one of simple conversion of existing programs and designing programs for flexible learning is easy. This is not the case. Programs need to be reconceptualised using additional resources (Phillips, 1998) and greater interactivity (Lander, 1999). There is a need to ensure that academics 'hasten slowly' and are not expected to move too far too soon in terms of embracing change and new technology.

The move to more student-centred approaches to program design and delivery methodology in education has focused desired outcomes on the students' abilities to think critically, solve problems and work collaboratively. Laurillard (1993) argues that the learner, through active participation in both arriving at, and articulating their personal understanding of new ideas and concepts, constructs knowledge. Students must become "self directed students... keen and capable of setting their own goals and standards with or without help from experts. The appropriate teacher function here is that of consultant and resource person" (Berge, 1998, p.1). It also requires a degree of trust from both staff and students. Staff need to trust that students will take responsibility for their learning and achieve satisfactory outcomes; students need to trust that this approach to learning will provide them with satisfactory outcomes. (Luck, et. al, 1998). There also needs to be an assurance that students too are not moved too far, too soon in terms of embracing new learning methods which rely primarily on web based methods.
Flexible learning programs are both more labour intensive for staff and very demanding for students as they are expected to become more responsible for their own learning. With the introduction of flexible programs, students will have to grapple with the intricacies of bulletin boards, online quizzes, WWW discussion groups, self-access to learning resources. There should not be an implicit assumption that students possess the necessary learning and technical skills to enable them to cope in a collaborative online learning environment. Students will possess different levels of experience in relation to working in groups and level of computer skills. The first activities in programs should be designed to build group cohesion and coach computer skills involving the use of e-mail, WWW and WebCT.

There should also not be an implicit assumption that staff possess the necessary time and skills to develop and deliver quality programs and make informed choices about appropriate learning strategies, mix of delivery mechanisms and appropriate use of technology (Lundin, 1997). Many teachers lack confidence in using technology and should be encouraged and assisted to view technology as a device to enhance exploration and learning not just an additional thing to include in workloads. A change of mindset should be constructively effected.

In order for programs to succeed it is imperative that appropriate training and guidance be provided for both students and staff. Staff will require support from instructional design and IT teams to assist in the design and development of subjects. Training for both staff and students to enable them to manage new technologies becomes a critical issue. For example, sending messages is far more permanent than talking; interaction and communication online requires different skills i.e. there is a need to have something to say before you say it. Dealing with the daily deluge of online correspondence is a skill in itself. Self paced training manuals need to be developed to coach both staff and students in the use of new technologies and methods of learning. Hands on training sessions pitched at different levels of expertise are essential. Orientation programs should be designed to explain the complexities of an online teaching and learning environment. Students need guidance in the ‘appropriate’ use of online communication tools such as bulletin boards and chat rooms.

Choosing the Technology

Using the most appropriate technology to get the message across is often the hardest hurdle to cross. Brown & Teague (1998) argue that living in this technologically rich information age, it is hard not to be lured by the dazzle of technology. The danger is that program developers are attracted to technology for technology’s sake. Developers should not lose sight of those questions of fundamental importance to the business of education and ask instead “what do I want my students to learn and what delivery options will best help them learn it”? Evans & Deschepper (1998, p.358) suggest that “Online can be many things. It can range from simple email contact to video conferencing. It can include chat sessions, frequently asked questions, bulletin boards. It can be technology rich, interactive CD etc. What it is NOT is a replacement for human interaction and face-to-face contact”.

Program designers need to bear in mind that technology is merely the medium of delivery not an educational end in itself. Programs should be designed to include appropriate learning strategies and mix of delivery mechanisms to:

- cater for all the learners' needs
- accommodate the requirements of the subject matter
- take account of the lecturer’s expertise and choices and
- ensure the feasibility of reaching learners where they are at no ‘additional’ cost per person.

Alexander (1998) suggests that we should decide to use technologies such as multimedia or the WWW only when that use provides new opportunities for students to learn – to visualise, to understand, to see complex relationships in ways that are not possible using any other media. The aim of the new technologies should be to promote independent, self-motivated learners. They should be capable of initiating, selecting and using appropriate strategies for acquiring, retaining and transferring knowledge.

The major advantages of the internet for improved learning are in the potential for interactiveness, the access to world wide resources and the possibility for flexible learning styles. Owston (1997, p. 29) identifies that ‘the key to promoting improved learning with the Web appears to lie in how effectively the medium is exploited in the teaching and learning process’. However there are situations where delivery over the internet may not be the best option e.g. if you want students to follow an intellectual argument then the printed page is probably best; if you want them to follow a visual process then a VHS tape may be superior to a video clip which takes considerable time to download.

Products/Programs

The approach underpinning the design of educational programs for flexible learning should emphasise active and collaborative learning rather than the traditional one-way flow of instruction; should allow students choice in how, what and when they access and study a range of learning resources; and promote regular communication and interaction with their teachers and with fellow students. In addition, surveys of various academic stakeholders and discussions with industry should be undertaken prior to embarking on the program design. For each subject a team of writers is assembled including the staff member responsible for each subject, a research assistant in the area, an instructional designer and an information technology support person. All writers involved in the development of subjects are required to attend training sessions to assist them with
subject design and development skills and the use of web courseware. Regular meetings of writers involved in the development of subjects for the whole program are held to discuss a variety of issues. These meetings allow for an interchange of ideas, an integration of content across subjects and a support base for those involved in the design and development process.

The Process of Designing and Delivering Programs

It is important to remember when designing subjects that the pedagogical background of subjects may differ. So too, may the mindset and skills level of the teaching staff member in charge of each subject vary. Teaching staff must be confident that they can cope with the manner in which the subject is designed which includes an understanding of the capabilities of the courseware used so that they can manage the subject effectively. Five processes or stages became evident when developing and offering programs for flexible learning:

- **Development** - The development phase involves two stages: During the first stage staff need to engage in a collaborative and dynamic approach to planning and designing curriculum. This involves working together to ensure subject content builds knowledge progressively.

  Stage two involves making decisions about the learning model to be adopted in individual subjects. This stage raises issues concerning the notion of academic freedom, the level of maturity and skills of students to cope with new learning methods and technology and the availability of resources to cater for innovation. This has implications for the subject resources which will be included as part of the writing of the subject. It is important during the development stage that pedagogy and not technology governs the overall process.

- **Delivery** - The subject is offered to students using the new delivery methods and technologies. It is useful, but not essential, to have the academic staff member who led the development team coordinate and/or deliver the subject for the first time. If this is not the case, what is most important is that the staff member responsible be totally informed and comfortable with all teaching and learning modes which have been incorporated into the subject and be competent in terms of the use of the technology. Depending on the amount of traditional contact (face to face), which has been included in the subject, it is usually critical that student access to subject sites is linked to enrolment in the program i.e. as students enroll in the subject they are granted access to the relevant subject sites. This is particularly relevant in subjects where there is very little face to face contact so that students may access and begin using material immediately. Instruction for students about navigating each subject site is essential.

- **Evaluation** - The effectiveness of each subject in the program must be evaluated by using the standard evaluative tools provided by the university. Where these are not appropriate and/or do not fit the new teaching and learning model adopted, individual instruments must be designed. These will include teaching and subject evaluations, contextual tools which measure the subject's effectiveness against similar subjects, and representative student and staff focus groups which discuss the strengths and weaknesses of the subjects offered for the first time.

- **Refinement** - At the completion of the first semester of offer, as a result of feedback from students and academic staff, adjustments and improvements are made to each subject with assistance from instructional design and IT support members of the team. Subject sites need to be updated to ensure material is current.

- **Maintenance** - This process will continue for the duration of the life of subject. Each year modifications made necessary by external changes in government requirements, technology upgrades, etc will occur. The end result is one of ongoing improvement to ensure that subjects delivered remain at the cutting edge in terms of content, flexible learning methods and technologies.

It is important to note that the amount of staff time necessary to complete each of these processes will depend upon the nature of the subject and the length of time the subject has been running. Staff workloads need to be adjusted to enable appropriate attention to each of the stages involved in designing and delivering programs online.

CONCLUSION

In summary, while the move to flexible learning using online technologies presents great opportunities, potential for exciting innovations and generally produces better learning outcomes for students, it also presents great challenges. The potential of information technology and the internet to create communities of learners across boundaries will continue to have a significant effect on the design of educational programs worldwide. The object of the lesson is to ensure that the integration of information technology into programs is premised upon learning and interaction and not just delivery of information and that the process of designing, developing and delivering programs is structured and properly managed. In the end effective and exciting teaching and learning require both staff and students to learn new skills, to cross bridges, to challenge and be challenged. The learning curve is often very steep. Making implementation a fulfilling experience for all concerned involves a systematic and comprehensive approach which balances the needs of the organisation with the needs of all the individuals involved in the process. The goal should be to achieve an appropriate balance of technical and professional support which enables both staff and students to use the new technologies to achieve enriched learning experiences in an environment which is complex and demanding.
Webfolios: Authentically Assessing Prospective Educational Leaders on the Web

Lori Kim, Ph.D.
Division of Administration and Counseling
California State University, Los Angeles
United States of America
lkim@calstatela.edu

Abstract: Technology was incorporated in portfolio assessment to create webfolios, portfolios on the World Wide Web. The webfolios project was implemented in the very first preparation class for the prospective educational leaders. The article first briefly describes the webfolio project, followed by the presentation of the results of the project evaluation, in terms of its strengths and weaknesses. The article also reports the result of the collaboration aspect of the webfolios through feedback. The article ends with conclusion and recommendations.

Introduction

There is a growing concern expressed in a broader meaning of accountability to include assessment of student learning outcomes. Educators are directed to choose and apply assessment practices that inform their instruction and communicate to multiple audiences (National Association of State Boards of Education 1988). Portfolio assessment is recognized as an authentic assessment that evaluates the student in the process of performing real tasks with relevance to his or her education (McAfee & Leong 1994). A portfolio is an organized, goal-driven documentation of professional growth and achieved competence over a period of time (Campbell et al. 1997). Students are responsible to take a more active role in their own learning as they make decisions on what to include in their own portfolios as evidence for their learning, using multiple methods from multiple sources over time (Shaklee et al. 1997). In order to provide such a learning experience for all students, teachers need to facilitate practices of active learning, such as collaborative learning, problem solving, and the use of interactive technology (Cornerstones 1997).

An innovative instructional strategy of student assessment was piloted at California State University, Los Angeles in the very first class for the prospective educational leaders in the Administrative Services Credential Program. Technology was incorporated in portfolio assessment to create webfolios, portfolios on the World Wide Web. The webfolios not only provide access to students and faculty the most current resources available through the World Wide Web, but also empower them to be active partners in the learning and teaching process. Because the progress of webfolios construction can be observed on the Web, on-going feedback exchanges among peers, faculty, and other browsers become possible. This capability of presenting student learning over time or the progress of student accomplishment to the public, webfolios become a valuable assessment tool to demonstrate our accountability to the public.

The article first describes the webfolios project briefly, followed by the presentation of the results of the project evaluation. The article ends with conclusion and recommendations.

The Webfolios Project

The Webfolios Project was implemented in an induction course for prospective school administrators, with a goal of creating student portfolios on the World Wide Web, thus demonstrating course knowledge and technology skills. Students were to prepare their individual induction plans in webfolios, including at least four elements--Vision Statement, Vitae, Academic Plan, and Professional Growth Plan. Students received
training on developing webpages: Creating a home page, Linking files, Inserting graphics, and Formatting. The course was taught in a computer lab with a network access where students could obtain resources available through internet. As webfolios were being created and revised by the students, they were uploaded in a curriculum website housed in the university’s website. The final product of student webfolios can be accessed from the Cal State LA’s curriculum website at http://curriculum.calstatela.edu/courses/edad500.

Strengths

The results indicated that webfolios had many strengths in addition to those of traditional portfolios. As in the case of portfolio assessment, students commented that their webfolios showed continuous growth and helped them organize. The effectiveness of the webfolio would be meaningful only when it accomplishes the goals of the course, which is for students to create own induction plans in portfolios. The instructor wanted to ensure that additional feature of integrating technology would not impede students from developing their induction plans in the portfolios. The result indicated that students accomplished the goal without being too concerned about the means, technology format, as evidenced by following comments. “The process of developing the webfolios is very hands-on, and brings us face to face with our preparation or lack thereof.” “I could easily view where I am now and where I will be later.” “I got to see a reflection of my strengths and weaknesses.” “The webfolio was representative of who I am.”

Accountability was one of the most frequently mentioned strengths of the webfolios. Many students commented how the webfolios demonstrated their knowledge of current technology, such as learning about many resources available through internet, communicating through email, and creating web pages. Students were also quite pleased about the opportunities to present their portfolios as well as their knowledge of technology to a wider audience. A student expressed the excitement of realizing this benefit of the webfolios in her comment, “It has become an up-to-date means of presenting oneself. The webfolio provides innovative ways for one to present and evaluate candidates.”

Almost every student mentioned about the accessibility of the Web as a strength of the webfolio. Students considered webfolios as “opportunities to ‘show your stuff’ all over the world.” The majority of the students were quite conscious of the opportunity for their prospective employers to access their webfolios. Students thought webfolios demonstrated current technology skills, organizational skills, and administrative knowledge in an impressive visual presentation. Two students’ comments represent overall feelings of the students. “Webfolios communicate innovation to prospective employers and more employers have access to your information without you having to mail out packages.” “It’s free. What better way to promote yourself career wise!”

Unlike traditional portfolios where students often agonize in the process of developing portfolios but find satisfaction of accomplishment in the end, the process of creating webfolios was entertaining. More than 90% of the students commented how fun and convenient the process was. Students found the activity fun and interesting because they found it challenging yet were able to master each step and accomplish beyond their expectation on their own. Initially, students only expected have a simple document in each section of their webfolios as required in the class. However, each time they accomplished something on their webfolios, such as inserting a graphic or changing fonts, their webfolios looked nicer, more impressive, and more visually appealing. It was this enjoyable aspect of the activity that also contributed to upgrading the technology skills of the students. More than 95% of the students responded that their technology skills were increased. Many of them indicated that they no longer had the fear about technology and became very confident and willing to explore more on technology.

The students also noted how convenient it was to have all of their information on one computer disk. One student commented, “the webfolio provides room to add growth of portfolio without having to carry a lot with you.” In addition, students also noted how easy it was to update information, revise the content, or reorganize the materials in the webfolios. A student added his sales pitch for the webfolios, “it organizes your documents for you.”

Another strength of the webfolios deserves serious consideration as educators reflect on the authentic assessment of student learning. As Duncan (1996) points out, authentic assessment is based on meaningful performances that are drawn from “real-world” contexts. When students are helping each other to perform better without being concerned about the competition of their grades in class, authentic assessment of student
performance is actualized. This collaboration was often mentioned by the students as a strength of the webfolios. Students not only helped each other with technology problems, but they also enthusiastically exchanged newly acquired knowledge about resources available through internet, such as graphics and valuable websites. Throughout the quarter, they supported each other with comments of encouragement, suggestions for improvement, and commendations for good work. Many students commented about how valuable sharing information and feedback comments were.

Weaknesses

There were some barriers to overcome for webfolios to be implemented in university classrooms in general. The first weakness of the webfolios was that students must have access to a computer with internet. Some students had no access to a computer or the Netscape Editor outside the classroom and found it difficult to spend extra time on their webfolios away from school.

Another weakness of the webfolios was the extra time and effort required to train students on technology skills of creating webpages. The process of creating webpages was especially time and energy consuming for those students with limited technology skills. Some of the students commented that they could not have finished their webfolios without extra assistance provided by the instructor and the technology assistant.

The next weakness is a side effect of the accessibility strength of the webfolios. Because webfolios are accessible to anybody who visits the website, students had to be careful about private information. Students were advised to delete private information, such as home phone numbers, address, information about their references, and other private information that they did not want to publicize so widely. Many of them included their email addresses in place of phone numbers and addresses. “References available upon request” replaced the list of references. One student expressed concerns about possible plagiarism since she was linking the courses in the academic plan web page to some of her well-written papers for the classes.

One of the greatest barriers to overcome for the full implementation of webfolios may be the university policy regarding authority access to the websites. The university provided a space in the university curriculum website to build the course website. However, according to the university policy, only the instructor was authorized to update or make changes in that particular website. This policy created frustration both for the instructor, who had a burden of uploading 22 students’ work each time any change was made, and for the students who had to wait to see the changes on the Web until they were uploaded by the busy instructor.

Feedback

As mentioned earlier, collaboration among students in the process of developing webfolios was evident as they shared their resources and internet information beyond the course required exchange of feedback. More than 90% of the students responded positively about the feedback comments received. The other 10% of the students who expressed negatively about the feedback received comments either too sparingly or untimely.

The feedback seemed to have served the purpose of providing another set of eyes for different perspectives. As mentioned by one student, “the comments were mostly good ideas which came from a ‘fresh’ viewpoint.” Students also mentioned that the comments were frank, helpful, appreciated, and “caught some of the errors.” Based on the comments received, students were able to reflect upon their own work and consider implementing the changes suggested. Students wanted more than brief comments, such as “nice job” or “great work.” They appreciated the comments that indicated why the webfolios were “nice” or “great.”

Students especially enjoyed the exchange of comments because of the non-judgmental nature of the activity. Unlike the comments received by the instructor, students were able to easily disregard the comments that they did not agree with. As one student commented, “yes, the feedback comments made me think about the changes... but the decision was left up to me. They were given to me as suggestions, but I had to decide whether the change was to be made or not.”
Suggestions

Advice provided by the students for those who would be doing webfolios in the future was classified into four categories: (a) Personal Encouragement; (b) Getting Help; (c) Organization; and (d) Webdesign. The first category resulted from the fact that it was the very first attempt to create webpages for most of the students. Their advice was to pay attention to the directions, be patient, and take time to be accurate. As one student commented, "Take a deep breath. It isn't as scary as you think. Pay attention the first time carefully and you'll be amazed at how easy it is at house.'"

While the second category about "getting help" still had to do with their being novices in creating webpages, it seemed to have evolved from their collaborative experiences with peers. Frequently mentioned advice was to work with a partner, talk with other students about input and ideas, and "view other people's web pages to get some ideas to make improvements on yours." The target source of getting help was expanded beyond the technician and the instructor to include peers, in general, as well as unknown webdesigners whose web pages were available on the Web.

The third category on "organization" covered two facets of webfolios, i.e., issues dealing with portfolios and technology aspect of the webfolios. Advice such as keeping files in order, planning ahead, and starting early applies to both traditional portfolios and webfolios. Other suggestions, however, covered specific issues dealing with creating webpages of the webfolios. Students suggested not only to "keep all of your files together and under one program so the linking process will be easier" but also to "become familiar with the names of your files or addresses that you use on a regular basis." As in the case with all other computer files, students also emphasized the importance of saving everything on multiple disks.

Finally the last suggestion demonstrated the knowledge acquired by the students from developing their own webfolios. Students remembered to point out the lack of spell-checker in the Netscape Editor. "Proofread constantly." In addition to the advice on technical issues like "link information from one source to another to give additional information," there were many professionally sound recommendations such as "be very creative, create an eye catcher, but be brief" or "add something that gives your homepage individuality and ties in to a little story/tidbit about you personally." Some students not only demonstrated competence as webdesigners but also the improved skills in providing feedback. "Add graphics sparingly because too many graphics will detract from the most important content of your webfolios, YOU.'"

Conclusion and Recommendations

The California State University has recently established policy goals, including university accountability in its Cornerstones Project to ensure provision of educational excellence in a teaching-centered, collegiate institution and to demonstrate effectiveness to the public (Cornerstones 1997). The focus of the Webfolios Project, or student portfolios on the World Wide Web, centers around this important issue of accountability through appropriate assessment of student learning outcomes and communication of assessment to multiple audiences.

The evaluation study of the webfolios seems to indicate that webfolios may be used as means to demonstrate accountability to multiple audiences. As in the case of traditional portfolios, students can assess the growth of their learning over time and demonstrate their accomplishments in their webfolios. In addition to increased technology skills, students praised about easy accessibility and convenience of portfolios on the Web as they found unique opportunities for collaboration as they shared information, resources, and on-going support throughout the course. Building one other to grow in knowledge and skills instead of competing against one another during the process of assessment helped students make assessment truly a part of learning. Webfolios may indeed become an authentic means of student learning outcomes.

From the results of the study, it is recommended that university policies be revisited regarding possible plagiarism through easy access in the World Wide Web and authorizing students access to upload their own webpages on the Web.

The completed student webfolios discussed in this article can be viewed from the Cal State LA's curriculum website at http://curriculum.calstatela.edu/courses/edad500.

Abstract: The panel members will discuss and demonstrate through interactive videos and cd-rom some of the experiences along the journey implementing the technology integration projects (TIPs) and utilizing educational integration approaches in both the LITE (Linking Interactive Technologies and Educators) Institute and the WebMaster Institutes to achieve the desired outcomes of the ILC (Interactive Learning Campus). The three roads taken by DIAL to enhance teacher use of technology are: Technology Integration Projects (TIPs), LITE Institute and the WebMaster Institute program. The WebMaster program is a skill-based program while the TIPs projects and the Master Teacher Cadre meet on demand needs for curriculum and professional development and the LITE Institute encompasses the entire program for longevity and sustainability of technology use in the schools and communities.

Components of the Interactive Learning Campus (ILC)

Introduction

Learning on demand. Teaching has been called the noblest profession, the loneliest and the most critical for the future of our democracy. With the importance and challenges of the profession, how do we support these teachers? How do we help them to grow? One of the approaches the Interactive Learning Campus has taken is to offer professional development "on-demand" as teachers respond to the challenging task of creating student centered technology assisted curriculum. Teachers working with design teams of students, parents and partners are pushed by the requirements of the task, the diversity of opinions and the potential of technology.

How do teachers meet this challenge? They learn by doing. A web-based structure provides a framework for co-development and student use, and a rapid prototyping process supports the action/reflection cycle that is at the core of learning. Regular opportunities for reflection are provided through storytelling meetings, in which the teams think out loud with about their vision, ideas and questions.

Inquiry is based on the learners' questions, as they work toward a goal. Team members discuss, reflect, test out and refine their ideas. The IBL (Inquiry-based-learning) Website and the rapid-prototyping process support inquiry through the co-development of ideas by the design teams. This models the processes students will use in taking the courses.
As the design teams figure out how the content and the technology come together into course modules that will provoke student inquiry, they are asking the questions that drive their own professional development:

- What is your vision of this course? How will students be different? Vision map;
- What are the key ideas on this topic? Goals map;
- What is interesting to students about these topics? Scenarios;
- What are the knowledge bases that will support students' inquiry? Knowledge Bases;
- How do students learn through these modules? Digital Portfolios;
- How will these courses fit into the curriculum? Concepts Skills and Curriculum alignment;
- What is the role of teacher in the use of these courses? Teaching with Inquiry-based-learning.

The Interactive Learning Campus is based on an action/reflection culture. Since part of culture is the stories we tell ourselves, we have built storytelling into the process of building our learning communities. These stories are the oral history of our understanding. They are dynamic and evolving. The stories help us understand each other in our understanding. Storytelling activities include: meet and make the thinking visible of the group; provide an ongoing record of the group's thinking; support individual story telling of teachers doing curriculum design; provide a context for developing waves of innovators; tell the stories of development to those implementing the courses.

**Technology Integration Projects (TIPs): The Curriculum Road**

Technology Integration Projects (TIPs) are the principal vehicle by which DIAL will implement broadly based systemic changes that will constructively alter the landscape of rural K-12 education. The intent of the Consortium is to create a new learning environment through its Interactive Learning Campus - increasing access to high-quality information and improving teaching and learning through engaged learning practices. There are ten essential areas of emphasis complementing DIAL's commitment to distance education and engaged learning. These will be implemented on a phased basis: Curriculum Development, Technology Integration, Project Management, Telecollaborative Development, Interdisciplinary Courses, Just-in-Time Professional Development, Preferred Learning Styles, Automated Assessments, and On-Demand Information Access.

The TIPs participants within DIAL schools have access to a variety of support systems during the entire curriculum development and technology integration process. In addition to the local students, parents, partners, and community resources available to the teachers, the DIAL professional staff will work closely with the teams. Currently five (5) first round of projects (Pathfinders) are nearing completion and a second round of six (6) projects (Trailblazers) is beginning development.

**The Master Teacher Cadre: The Professional Development Road**

The major focus of the Master Teacher Program is to build the human capacity throughout the consortium to fulfill the defined outcomes of the Interactive Learning Campus: 1) increased access, 2) improved teaching and learning, and 3) enhanced community development. The Master Teacher Program will enhance human capacity of educators by: developing skills and processes that encompass engaged learning theory, creating comfort and models for distance education technologies, and identifying and practicing effective leadership and communication processes.

The Master Teacher Program is designed to use distance technology as a viable alternative to all levels of formal schooling: primary, intermediate, secondary, and post secondary. The program models this with the delivery of the graduate courses offered via a variety of distance technologies. The program centers around using engaged learning practices and an integrated educational approach working with three partnering universities to deliver the graduate programs. The partnering universities are The University of Nebraska -Lincoln, The University South Dakota, Vermillion and Dakota State University in Madison, South Dakota. The program utilizes learning theory that encompasses engaged learning and is related to the constructivist approach to andragogy. Practices that support engaged learning theory implement: understanding multiple intelligences and how the brain works, team building and teaming practices, a board sense and vision for student assessment. Skills, models and technologies practiced within the masters program serve as a model to schools throughout the consortium and the state of South Dakota.
The Master Teacher Program will provide training, practice and theory for the participants. The outcome of the programs will create and promote effective leadership and communication in their schools and throughout the state. Leadership theory and skills that embrace the concepts of team and collaborative efforts are essential to success of the outcomes of the Interactive Learning Campus. The goal is to enable small shifts and transitions in current education perspectives to happen. This will in turn lead to some very forward thinking teachers and principals who are able to create some areas for experimentation and flexibility.

The WebMaster Institute: The Digital Road

The WebMaster Institute program utilizes an integrated educational approach incorporating the New Jersey Institute of Technology and the University of South Dakota. The NJIT WebMaster 2001 Program is designed to accommodate the flexible needs of teachers and students who participate in its academically rich, distance learning courses. The program is designed to be self-placed and self-paced, consisting of three 30-hour training modules: Web Author, Web Graphics - Photoshop, and Web Graphics - Flash. Both teachers and students will complete the program via distance. The selected teams will be registered in the courses, be given unique account names and passwords to enter the courses. NJIT uses WebCT as the courseware tool for the online delivery of their courses. All participants receive the WebMaster 2001: WebMaster Fundamentals Certificate from NJIT. The University of South Dakota is granting graduate credit for the coursework completed by the teachers with an additional course on integration of the web-based skills. In addition the University of South Dakota is granting dual credit to the student team members. Each of the students receives one high school credit along with six college credit hours, which transfer in as two-three credit hour courses.

The goal of The WebMaster Institute is to have five teams of teachers and students, from each of the Consortium’s thirty-three school, receive certification. This will result in 165 teachers and 165 students being available for joint internships within their schools and communities, as well as for the delivery of web-based courses through The LITE Institute.

1. It is possible for parents, school technologists and partners to also take the courses simultaneously with teachers and students. They will receive certification training through DIAL as well.
2. The WebMeister program is targeted for the student members of the team, resulting in dual credits for 10th, 11th and 12th graders.
3. The WebMeister-Junior program will reach down and enable 5th through 9th grade students to participate fully with their teachers in WebMaster Institute curricula.
4. Every team will have the opportunity to apply their knowledge in community-based internship during or upon completion of the coursework.

The LITE Institute (Linking Interactive Technologies and Educators): The Interstate System

The principal dissemination vehicle for the delivery of these curriculum units is The LITE Institute, which focuses its services on: (1) capacity-building of K-12 educators, administrators, technologists, and librarians using traditional, distance, and just-in-time formats; (2) skills-building through curriculum development and technology integration courses and consultations, emphasizing high-quality course content, distance education, instructional design, and engaged learning best practices; and (3) evolving and emerging automated assessment technologies, tools and techniques, using such advancements as neural networks. Quite often, these are viewed as worlds within themselves. DIAL’s goal is to merge these into everyday best practices within the Interactive Learning Campus.

The LITE Institute is a statewide technology-based resource. The overall strategy of the Institute requires seamless integration of four areas of contribution:
1. professional and staff development initiatives,
2. curriculum development and technology integration services,
3. comprehensive, cross-disciplinary distance learning courses, and learning assessments.
Summary
The three roads diverge in terms of the route they take. But unlike Frost's roads, our roads all end up uniting in the Interactive Learning Campus. Each initiative builds skills and contributes to the development and sustainability of the campus. As webmaster teams build technical skills, TIPs teams build Inquiry Based Learning Modules and the LITE Institute offers connections with a larger community, we see the campus grow and build new byways and highways to create interdependence in our learning community.
Software Agents for Distance Education and Institutional Support

Abstract: In this paper the author explores the use of software agent technology to provide options and solutions for the challenges facing educational institutions that have limited or fixed resources. One of the challenges examined is that of providing quality instruction to increasing numbers of students, including those with non-traditional scheduling requirements without straining current resources. Other challenges include optimizing the existing network infrastructure and supporting institutional business goals.

Introduction

Educational institutions have three major sets of overarching goals, those relating to the quality of instruction, those relating to the quality of the supporting organizational infrastructure and those general business oriented goals that affect all of the others. Concerns and challenges within these sets of goals can be successfully addressed by the application of agent technology.

Software agents are network-enabled applications that are being called “the next great wave of innovation and development across the Infosphere comprised of the Internet, Intranets, Extranets, World Wide Web, and countless other networked computer systems...This technology is expected to eventually have an effect as profound as the World Wide Web” (1997). If properly developed and fully utilized, this technology could prove to be not just a solution for existing problems or a method for achieving institutional goals, but a resource that could strengthen the institution’s competitive position.

Pedagogical Agents

The instructional goals include the development of methods that retain or improve the effectiveness of instruction. This includes addressing all learning styles and personalizing instruction according to individual needs, while accommodating students who are geographically dispersed and increasingly require non-standard scheduling (Latchman, Salzmann, Gillet, & Bouzekri, 1999).

These goals can be addressed through the thoughtful application of pedagogical agents. A pedagogical agent is an agent that acts as a guide or instructor for education and training purposes. The primary function is to support humans in accordance with the application of pedagogical theory within learning environments. They will act upon the environment and interact with the user in ways that will facilitate learning, while dynamically responding to spontaneously occurring opportunities for instruction and personalized tutoring. This is possible because the agent monitors the progress and current knowledge of the student in each task. The agent has knowledge of the skills that are needed for the task, as a human expert would demonstrate them. It then compares this knowledge with the student's performance of the same skill.

Pedagogical Agents can be built with fuzzy logic and neural network components that will allow them to recognize the learning pattern of the student and from that pattern, predict what the student’s response will be. This allows the agent to prepare personalized corrective strategies and materials regardless of the number of students being taught. The agent can independently choose to apply these strategies before the student realizes that there is a knowledge deficit in a given area. Such a system will track changes in the student’s responses and bring them in line with the expert’s responses as they are coded into the agent’s
knowledge base. A well-trained neural module would also allow the agent to differentiate between actual learning problems and errors made from carelessness or fatigue (Lively, 1992).

Agents can also be used in realistic simulations that provide multimodal instruction for both distance and traditional education environments (Lester, Rickel, & Johnson, 1999). These simulations can be used at anytime, by single students or with groups. Faculty staffing issues can be further addressed by using the agent capabilities that allow them to teach autonomously (Johnson, 1997). This allows the ratio of students to instructors to increase without affecting the quality of the instruction. This quality of instruction is enhanced through the use of personalized tutoring capabilities available with some agent applications (Rickel & Johnson, 1997).

For example, Adele is an animated pedagogical agent developed at USC’s Information Sciences Institute’s Center for Advanced Research in Technology for Education (CARTE) (Johnson, 1997). She is used for medical education in the areas of family medicine and graduate level geriatric dentistry. She was designed to run on conventional desktop workstations with conventional interfaces. In order to expand the agent’s effectiveness, she runs in a student’s Web browser. In this way she integrates Web-based resources with other learning materials and serves as a guide through the lesson.

When operating in Advisor mode, Adele will interrupt any student action that is not in accordance with standard practice. She then suggests a different approach or action, or refers the student to a resource, such as a video demonstration, audio clip, or Web-based reference material. Regardless of the mode in which she is operating, Adele makes full use of opportunistic instruction by providing hints or references in all appropriate situations. She will also provide immediate responses when students ask “why” questions. In this way instruction is simultaneous with problem solving, and the student can immediately use the information.

Adele employs a hierarchical representation where the preconditions and effects of each step are explicit. This structure also includes sets of possible actions a student might take at different points in the program. She explains process steps in terms of motivating facts about the domain. For example, her response to a question about why an X-ray should be ordered would include reasons why X-rays are important in this type of case.

Adele’s persona includes several behaviors as well as the ability to have new behaviors added. Actions and communications are generated using a behavior state approach. This consists of a library of searchable behavior fragments including visual segments showing her repertoire of movements, audio clips accompanied by a commercial speech synthesizer to serve as utterances, and occasionally segments of other background sounds, such as music. A behavior-sequencing engine dynamically joins selected fragments at run time. The result is that Adele displays seamless behavior and appearance to the student.

Projecting Adele’s seamless behavior is a technical challenge due to the latency associated with Web-based applications. The solution places the agent’s reactive behavior on the client machine. A solution for this is to move the student-monitoring part of the application to the client machine. Although this places more processing on the client, it is still at a level where any platform with a reasonable amount of memory and processor speed can successfully execute the program.

Learning Environments

Current advances in the technology for both agents and virtual environments have combined to provide many options for implementation within the learning environment. One such option is a simple, easily constructed, text-based Multi-User Dimension (MUD). These environments are substantive, provide opportunities for rich educational interactions and are scalable so that many learners can participate simultaneously (Kiss, 1997).

Since many mobile agents are designed to travel between MUDs in order to allow users to communicate in real-time, they must be capable of functioning in unfamiliar environments. In order to do this they must
either have advanced reasoning capabilities or they must be able to get information from the environment itself. Agents can access some information by making queries, but frequently, this environmental data does not include definitions of its own semantics, and cannot be understood by all agents. One approach to facilitate interaction within unfamiliar environments for users and agents is that of creating annotated MUDs.

Whether human or agent, the inhabitants of well-designed spaces can find implicit clues concerning the purpose and operations of objects within their environment. This type of clue provides agents with an understanding of the meaning and context of the MUD. In this way an agent can directly query the environment in order to determine appropriate behavior within that space, available activities, and recommendations for exploiting the environment in accordance with its goals and abilities. Since it is not necessary to learn the space, the agent only has to interpret it. Annotations also ensure that the agent always has current information and is able to immediately make use of the knowledge, which results in a more rapid response.

In this approach, the environment can be modified in any way, and the agent responses will automatically change according to the annotations provided. At this time there are five types of annotations that can be integrated into MUDs and other environments (Doyle & Hayes-Roth, 1998).

- Emotional annotations provide information about either events or environments, and explain acceptable responses.
- Responsive annotations provide either domain specific actions or suggest the use of behaviors built into the agent in order to explain appropriate behaviors.
- Problem-solving annotations describe puzzles included in the MUD; provide hints about them that the agent might give the user through speech or action. When the puzzle has been solved, the annotations will update the agent with the current information.
- Role annotations inform the agent about actions or events that are relevant to its performance of specific functions within the environment. In this way the agent can combine its personality with domain-specific behaviors so that the user perceives and integrated, believable character.
- Game playing annotations describe the status of a game or any bounded multi-user interaction, and inform the agent of its performance within it. They will also suggest moves to the agent that are based on its skill level, personality and motivations. This category is dynamic and requires that the environment compute real time responses.

These annotations help to support a dynamic, constructivist environment to enhance student learning.

**Infrastructure Support**

Institutional support goals include such items as the optimization of existing classroom technology and network infrastructure. Both wide and local area networks can be optimized without additional staffing or extra hardware investments by employing network management agent applications (1999c). These applications can also automate daily tasks such as network and database backups, batch processing, mail sorting and scheduling (1999b). Network agents are also used to map dynamic networks, routing paths, and for allocation of distributed resources. Application, data and transaction security, as well as user access can be monitored and enforced according to the rules activated in agent applications.

Equally as important for educational institutions, is the ability of highly efficient agent search applications to reduce the network load associated with the traditional search and retrieval methods used for on-line research (Knapik & Johnson, 1998). The benefits of neural network enhanced information retrieval agents are even more evident when the technology is applied to Web-based searching. This hybrid virtually eliminates the massive bottlenecks and information latency that accompany current search tools. This is especially true of those meta-search tools that distribute the information retrieval between many services. This is because traditional search tools broadcast user queries to several information sources simultaneously. The results are then merged and all are made available to the user. Often the desired
information is located by only one tool, and the others utilize the network in order to return irrelevant data, which must then be manually sorted by the user.

Frequent users of these services know that the complexities of tagging and searching the information result in different findings being produced by different engines. Since the search engines cannot differentiate data patterns and characteristics, they frequently return non-applicable data. Agents with neural network modules can cut through the useless information using advanced pattern recognition capabilities, can discover and map information in its current location. In this way, dynamic information can be cataloged; and mis-catalogued, or poorly tagged information can still be identified regardless of what the original structure of the data was.

The search agent known as WebCrawler uses a collaborative approach. It reduces search time by posting all queries at a central location, and allowing other agents to access them. The agents then collaborate on those for which they have high priorities or qualifications. This collaboration can take the form of exchanging information or breaking the query into small segments, each of which is then executed by different agents (Knapik & Johnson, 1998).

Another approach to information filtering and retrieval by an assistant is found in BUZZwatch. This is an agent program that traces trends, themes and various subjects across real-time applications and archived information. It is an expert in data mining and text analysis that can facilitate research by combining time and series analysis. In this way it can help a user track the development of a subject through chat rooms, newspaper archives and on-line texts (1999b).

The Expert Finder finds information by tracing experts in any field requested by the user. In this way people can benefit from the knowledge of individuals of which they might not otherwise have been aware. This allows communities to leverage the combined knowledge of all members and allows the user to find an expert who can help with any problem.

An organization can also choose to mange its data with agent applications. This is becoming more attractive and necessary as traditional databases give way to huge and complex data warehouses and 3 dimensional repositories. In this environment, agents are critical for preventing data corruption and retrieval problems. This is accomplished through enforcing data constrains that reject out-of-range data, systemic deletions, duplications and other illegal operations.

Agents responsible for data integrity verify memory, I/O ports, actuators and other items during otherwise wasted CPU cycles. Some run in the background, testing referential integrity of data values. When problems are found, the agents can either issue reports about them or fix the error, depending on their specific parameters.

Many organizations are discovering that agents can perform backups of distributed databases without the databases being taken off line. The agent freezes tuples of data, records changes in a file, then executes incremental backups by merging the changes into the database. The Lotus Notes backup agent also fulfills the function of notifying the Database Administrator concerning issues such as available server space.

Business Support

The general goals of educational institutions parallel those of any business, and focus on functioning within constrains imposed by budget, staffing, facilities and other fixed resources. Methods to increase the personal productivity of staff and faculty would also be included within this set of goals (1999a). This might be addressed by the use of reliable automation for repetitive office and organizational support tasks. Another way agent technology helps support staff productivity is through the use of Personal Digital Assistants (PDAs).

Agent technology is growing at a remarkable rate in the area of personal digital assistants. These agents help in the business environment where they maintain user appointments, plan work processes, and
collaborate with the user to perform complex tasks. They are also used extensively for mail management and in information retrieval situations where it is critical to sort through large amounts of data in order to find specific information. This is especially important in education where the amount of information available for research and teaching grows at an exponential rate.

Many of the agents designed for information retrieval and filtering are enhanced with neural network modules. These represent a hybrid form of retrieval agent with capabilities unrivaled by any other current approach. They enable the learner to access the precise information needed because they can be trained to search for specific items that match the users desires and preferences. The agent is optimized as the user provides data about the relevance of specific findings and then compares it to what they are actually looking for. The associative mapping capabilities from the neural technology allow the agent to remember the location of material that displays the characteristics of the desired information. This allows agents to search in a manner well beyond the scope of technologies using page tags and keywords.

The increasing use of digital assistants from different platforms and with different standards has highlighted concerns about possible problems due to agent incompatibilities. Carnegie Mellon University has taken a proactive approach to the problem and is building agents that will facilitate the communications between incompatible types of agents. These are called matchmaker agents, and they are designed to translate using a new capability description language. This allows them to serve as intermediaries between agents requesting services and those providing them. Currently digital assistant research includes all aspects of daily management and information, such as personal calendar managers, financial portfolio managers, and joint mission planning for large organizations (1999a).

Organizations that endorse the use of personal digital assistants not only help employees become more productive; they also gain an extra bonus in the area of network performance. This is because less bandwidth is required for these agents than is needed to use traditional databases that have vector space model information retrieval mechanisms. This translates into reduced communications costs for the institution and provides quality results to the user in less time. These advantages will become more apparent as the amount of accessible database information increases (Yoo, 1999).

Management must also ensure that the initial cost of any new technology support for the organization or for instructional methodology is offset by the benefits as determined in a cost of ownership, return on investment, or cost benefit analysis. Agent technology also provides solutions for these concerns (1999a). Because many agent applications run on common platforms or are cross-platform, using them does not require expenditures for major hardware upgrades. Although the overall costs are dependent on the specific technology and its implementation, the wide range of readily available applications addresses nearly every need and budget.

Conclusions

Overall, the advantages of agent technology for educational institutions cannot be overstated. This technology is able to positively address every major institutional goal while using a minimum of resources. Overall, the advantages of agent technology for educational institutions cannot be overstated. This technology is able to positively address every major institutional goal while using a minimum of resources.

The application of pedagogical agents is an area that should be explored by all schools and universities. If properly developed and fully utilized, this technology could prove to be not just a solution for existing problems, but a resource that could strengthen the institution’s competitive position.

Abstract: This paper reports both the processes and outcomes of the University of Wisconsin System's effort to facilitate technology integration throughout its thirteen teacher preparation programs. The context and rationale for the effort, the change strategies employed, and the results of institutional and system planning are explained. The paper also reflects on lessons learned from the planning effort. The planning effort has been conducted within a context of organizational change characterized by facilitation, engagement, and decentralization.

Introduction: Context and Rationale

A former member of the University of Wisconsin Board of Regents noted that bringing about change in the university system was tantamount to "moving a battleship with your bare hands" (Weinstein 1993). The regent's frustration was with changing the direction of a large and complex system within a culture of faculty governance and the reluctance of institutions (and their curriculum) to change with the times and be more responsive to external stakeholders.

The topic of technology in teacher education can elicit similar frustration from policy makers and school district representatives. The state of Wisconsin is no different from other states in placing significant investments and emphasis on the technology proficiency of its students and teachers. The state is investing hundreds of millions of dollars in information technology hardware, software and infrastructure in K-12 schools. Furthermore, the state has estimated that approximately $20 million are expended annually in a combination of federal, state, and local funds in teacher professional development in technology (1999 TEACH Wisconsin).

In spite of these investments and expectations that they will promote greater student achievement, there is cause for concern. The National Center for Education Statistics reported that only twenty-three percent of both new and veteran teachers were "well prepared" to integrate educational technology into the curriculum (1999 NCES). And a state-wide assessment of the LoTI or Levels of Technology Integration survey (1999 Moersch) indicated that only seventeen percent of teachers surveyed in Wisconsin currently integrate technology into the curriculum (1999 TEACH Wisconsin).

The Change Process

To address concerns about technology preparation of new teachers and the continuing professional development of practicing teachers, the University of Wisconsin System initiated an effort to develop and promote best practices in technology throughout all of the institutions within the system. (The system is composed of fifteen institutions; thirteen of them have teacher preparation programs therefore those institutions were the focus of this effort.) This broad-based and inclusive planning effort was created to address concerns of external stakeholders as well as issues raised within System Administration about the extent to which the universities were integrating technology throughout the curriculum, including field experiences. System and institutional leaders had frequently been chided by legislators and other external constituents with anecdotal reports of how teachers were ill prepared
to use technology in today's schools. In addition to the anecdotal reports, the surveys cited above were used to exert pressure on the system to address the issue of technology in teacher education.

The framework for this effort was systemic; i.e., it was conducted at multiple levels of the organization. Both UW System Administration and individual institutions were expected to facilitate desired change. Wisconsin, like other states, has a consolidated system of higher education that was created to join state and teachers colleges with the land grant institution, as well as the urban institution. The state government merged the previous systems to provide better planning and coordination, curb growth, provide more effective and equitable distribution of state resources, avoid duplication and competition among institutions, and ultimately to better serve state citizens with improved access and planned resource allocation (Glenny, Berdahl, PaLtridge 1971; Glenny 1977; Halstead 1974; Millard 1981). Moreover, technology is an area of academic planning in which coordinated planning and policy are frequently deemed necessary (Olcott 1996; Zeller 1995). In spite of these expectations, there is inherent tension between a central system administration and the individual campuses when trying to facilitate change; according to the literature, the very act of coordination can be viewed as a challenge (if not an attack) on institutional autonomy. If faculty perceive that decision-making—especially about fundamental curricular decisions such as technology integration into teacher education—are shifting from them to a central administration or bureaucracy, the hostility and tension will increase (Dearing 1972). More importantly, the goal of improved and more responsive programs would not be realized.

Given the role of System Administration and the need to manage tensions between the administration and institutions, the planning and change process was conducted at multiple levels with significant opportunities for discussion through facilitated iterative processes at individual campuses and system-wide. The initial impetus was top-down with the creation of a high-level task force that included representatives from state agencies, school districts and the universities. The Senior Vice President for Academic Affairs of the system, with the support and encouragement of the system president, created the task force. The task force was charged to (a) review standards from national and professional organizations for benchmarking purposes; (b) review state technology standards for PK-12 students; (c) collect information on current practices in UW programs to have data for assessment and decision making; and (d) work within the context of fundamental changes in teacher education program approval, licensure, and professional development. (See the Wisconsin Department of Public Instruction's Web site for information about reforms to teacher education: www.dpi.state.wi.us/dpi/dlsis/tel/restruct.html).

The Best Practices Task Force began data collection by surveying the institutions to obtain baseline information about current practices. Institutions reported on the following: (1) What courses and/or experiences are used to develop teachers' understanding of the uses of technology for the subjects they plan to teach? (2) What are the schools of education plans to assure that their faculty are (a) knowledgeable about current practices related to the use of computers and technology, and (b) able to integrate technology into their teaching and scholarship? (3) What are their plans for faculty professional development and training in technology? (4) What resources are available to support computing, educational communications, and instructional technology in teacher preparation programs? (5) How are schools of education working with schools and colleges of letters and science to address these technology issues for beginning and practicing teachers?

The results of this survey showed considerable variation in how institutions were addressing these key issues. For example, many institutions were still relying on discrete courses in instructional technology, rather than developing models for systemic integration into the curriculum. Moreover, while some institutions articulated comprehensive plans for faculty development, others merely cited a listing of workshops. The evidence of university-wide planning and responsibility for teacher education technology development was also inconsistent and of uneven quality. It was evident from this initial scan that much work needed to be done at multiple organizational levels to advocate for technology infusion throughout the programs. Therefore, the Best Practices Task Force developed an institutional, team-based strategy.

In addition to the top-down approach, strategies and processes also were enacted at middle levels of the organization. Institutional teams were developed to discuss issues, collect data, and develop institution-specific plans to integrate technology throughout the teacher education curriculum. The teams consisted of administrators and faculty from the university and local PK-12 districts, as well as technical and instructional design support staff. The teams were required to submit reports to system administration around the key areas of teacher proficiencies, faculty development, and infrastructure requirements. A survey of the literature that was conducted at the inception of the project revealed that these three areas needed to be addressed in any comprehensive approach to technology in teacher education. All thirteen teams from throughout the university system met three times using compressed video technology. The discussions were co-facilitated by the system PK-16 director and rotated among selected...
faculty. At the compressed video meetings, campus teams shared issues, progress and results, and submitted one-page summaries of their discussions around the critical issues. The team-based effort culminated in a face-to-face statewide conference of all team members. The conference time was divided into discussions for functional groups and institutional teams. Individuals from across the system were placed into functional groups (deans, higher education faculty, technical support, etc.) and were asked questions designed to stimulate discussion and planning across institutions. The institutional team meetings were structured to enable the teams to initiate specific goals and action steps to develop their institutional plans.

Finally, each campus submitted a report to System Administration that outlined the campus plan to integrate technology into teacher education. Those plans will become the basis for a White Paper that will be submitted to the Board of Regents in February 2001. Besides reporting on the status of technology integration into teacher education, the White Paper will highlight institutional best practices. It will also contain specific system-wide policy and program recommendations. It is anticipated that the Board of Regents will incorporate these recommendations into a larger UW System PK-16 initiative and an action agenda.

Since effective change must be multi-directional, bottom-up approaches were also used to stimulate pilot, proof-of-concept projects at the individual faculty level. The system has provided incentive funding for teacher professional development projects that involve UW and PK-12 faculty working collaboratively on projects that utilize technology within the curriculum. In addition, the system has provided funding for fellowships that support UW faculty working collaboratively with PK-12 faculty on research projects that examine the impacts of technology on teacher behavior and student learning. The VIT2AL Web site (www.vital.wisconsin.edu) contains a description of these programs as well as descriptions of all projects funded via these initiatives.

The following figure illustrates the entire change process:

![Figure 1: System-Wide Planning for Technology in Teacher Education](image-url)
Outcomes: Results from Planning and Data Gathering Processes

The institutional teams addressed three questions separately in campus-based discussions, in three system-wide compressed videoconferences, and in their final campus plans submitted to System Administration. Those questions were (1) What do we want our teachers to know and be able to do when they leave teacher preparation programs? (2) What do our faculty need to know and be able to do to teach our students to use technology appropriately? (3) What are the infrastructure needs to accomplish student and faculty proficiency? Although these were dealt with separately, we were constantly reminded of the interrelationships between these issues.

Using a constant comparative method of analyzing the qualitative data from institutional reports (Conrad 1993; Maxwell 1998), six guiding principles emerged that informed and permeated the discussions of student skills and proficiencies, faculty development and leadership, and infrastructure requirements. Those principles included: (1) Caring and competent teachers would use technology with quality instructional practices and deep content knowledge. (2) Standards would form the basis for technology in teacher education; these would include adhering to ISTE's National Educational Technology Standards and Performance Indicators. In addition, Wisconsin's Model Academic Standards and technology standards for PK-12 students would inform teacher education practice. Technology integration would be part of systemic, standards-based reform. (3) Student-Centered technology integration would respond to needs of diverse learners and would focus ultimately on high achievement for all students. (4) Integrated technology throughout the curriculum, instead of technology grafted onto the curriculum through discrete courses would help ensure a systemic and long lasting impact on teaching and learning. (5) Lifelong Learning can be facilitated in technology-rich teacher education for both students and faculty by helping to foster learning communities. (6) Forward Thinking must always be a hallmark of technology planning; this encompasses not only includes keeping current with technological breakthroughs and changes, but in continuously improving curriculum and educational practice.

In terms of the teacher proficiencies, the institutional reports revealed that most students entering teacher education programs had a basic level of technology skill proficiency. However, it should be noted that programs were very sensitive to issues of the Digital Divide and students coming from socioeconomic or educational backgrounds that would impact negatively on their technology skills. Therefore, the plans provided support and remediation for students. The focus of the findings on teacher proficiencies resulted in identifying core proficiencies that would be articulated at the Beginning, Professional, and Master educator level (consistent with teacher education rule changes). Those proficiencies included (1) the collaborative use of technology; (2) technology as a learning tool; (3) responsible uses of technology (including ethical and legal issues); (4) and evaluating content.

Faculty use of technology would, at a minimum, require technology skills on par with students. But obviously the role of faculty as instructional leaders needed to be addressed. These leadership dispositions for higher education faculty were identified as mastering skills and core proficiencies, leadership consisting of initiative, collaboration and mentoring, and curriculum review and revision.

Discussions of institutional responsibility for infrastructure built upon the UW System's 1999-2001 Instructional Technology Plan in its requirements for equipment replacement cycles, wiring, software, technical and instructional design resources. What was unique to this plan, was the issue of university faculty working in collaboration with school districts and the resulting issues of unequal technical resources.

The Board of Regents will act upon the recommendations that have emerged from this process by the end of this academic year; without significant influx of resources (through reallocation and/or procuring new funding) and continued leadership it is unlikely that the effort will result in widespread, systematic change. Recommendations concerning teacher proficiencies will include the adoption of system-wide standards linked to categories of beginning, professional and master educator; measures to support students who need assistance to meet entry level requirements; technology proficiencies documented in student electronic portfolios; and teacher proficiencies tied to student achievement. Faculty leadership and professional development recommendations must
include strong advocacy concerning the importance of technology integration into decisions regarding hiring, tenure, promotion, and merit. In addition, recommendations will foster better collaboration between schools of education/letters and science. In terms of infrastructure, recommendations will include the targeting of discretionary resources in course redesign (at campus and system levels) to teacher education, and system-wide academic systems to support faculty in the development of Web-based courses and resources. Finally, System Administration will recommend a long-term commitment to disseminate best practices through System-sponsored activities and resources. The Board will be encouraged to support a major budget initiative in the next biennial budget process (2003-2005) in teacher education, with a significant component related to technology integration.

Discussion

This has been an ambitious effort in system-wide planning within a context of facilitating policy and program change rather than mandating them. Lessons in leadership and change can be learned from this process and its results:

1. Stay focused within the organization. While there was initial pressure to engage private colleges and the technical colleges, we decided to focus our work internally, within a sphere or a circle of control where we could manage expectations and potentially bring about the most significant change. We plan to engage other providers later, in the next iteration of the ongoing planning and implementation processes.

2. Invite external stakeholders (state agencies, school districts, etc.) early in the planning stages to identify issues and engage support. External stakeholder involvement was crucial to maintaining a systemic approach to technology integration, lest the planning process become too focused on technology per se, rather than on technology for educational goals and outcomes.

3. Keep data collection simple. We used one-page worksheets for each of the campus reports on the major themes. While these worksheets did not yield detailed data, they did provide snapshots of the status of campus efforts; broad themes and trends could be identified. In a planning process that results in a system-wide effort, it is more important to have broad strokes than to have detail.

4. Anticipate variability and be prepared to explain variation and unevenness. The individual campus plans had to account for variation in mission, resources, and the regions in which campuses were located, among others. The challenge in a system-wide plan is to accept and even encourage differences, while encouraging systemic change. However, it must be noted that not all of the differences in campus reports could be attributed to justifiable differences. Many institutions' plans demonstrated less than a committed effort to address technology integration in a systematic way.

5. Employ multi-functional teams to include faculty, administrators, technical and instructional design support, as well as school district representatives. The multi-functional approach provides a process framework for underscoring a significant aspect of technology in education: that faculty can no longer operate as independent contractors. The success of their work is very dependent on teams of designers, technical support personnel and administrative leaders. In addition, we recommended that teams be represented by faculty who were novices in technology use as well as those described as experts. It was an important reality check to have novices (and even skeptics) involved in the planning process.

6. No one model or approach would work within a diverse system. This model of system-wide planning is consistent with general trends within the UW system, trends toward devolving decision-making from the central administration to the institutions, providing more incentives and rewards for institutional entrepreneurship, allowing more flexibility and experimentation. The current relationship between the central administration and the campuses is less governed by the need to regulate, mandate, and control and more consistent with organizational change that is facilitated, encouraged and supported. However, there continues to exist a larger regulatory environment that mandates rules for teacher program approval, for example. This process can be analyzed within a framework suggested by Dolence and Norris (1998) in which they contrast the processes of Industrial Age organizations with Information Age organizations. They characterize Industrial Age organizations with regulatory, centralized, faculty-centered, subsidized, dependent and existing
within a static and certain environment. Information Age organizations are decentralized, dynamic, student-centered, permissive and entrepreneurial. Unfortunately, the Information Age model does not totally square with the reality of technology planning within the state; evidence of both models exists within the current structure (both UW and the larger state environment) and any planning process must account for the ambiguity and tensions between these two.

Conclusion

This process began with an expectation of strategic change within a complex system. At this stage, it is a work-in-progress. Recommendations must be endorsed and implemented and continued work within the system and external to it must occur. Nevertheless, the process may be as important as the final product(s), whether those products be policy recommendations, funding, or programmatic directives. In the ambiguous, complex, recursive nature of planning in higher education, the very act of elevating an issue to the forefront of discussion, publicizing institutional activity and plans, inviting comparisons between and among institutions, can have a powerful impact on organizational change.

Abstract: The purpose of this study is to examine the relationship between leadership, self-efficacy, computer experience, attitudes, and teachers' implementation of computers in the classroom. A total of 160 elementary and secondary teachers from eleven school districts in Central Pennsylvania identified certain factors that may influence their practices of using computers in their classrooms. Three types of computer uses were identified and the variables of experience and knowledge, perception of leadership, self-efficacy, and attitudes toward computers were related to teachers' use of computers. Regression models demonstrated that with low and middle computer uses of clerical/management and academic use, self-efficacy demonstrated significance. As the computer use moved to advanced uses, such as web-page development and desktop-publishing, experience and knowledge, professional development and leadership became significance factors.

Purpose

Educational change does not occur as a result of an introduction of a new innovation, it occurs as the result of implementing the innovation in the classroom (Hall & Hord, 1987). Implementing computers into the classroom can only be effective if the teachers use them. Certain variables exist that influence, either positively or negatively, teachers' practices of using computers in the classroom. These variables include teachers' perceptions of leadership, teachers' self-efficacy, teachers' past experiences and knowledge, attitudes toward computers and certain school and teacher characteristics. This study looks at the influence and relationship these variables have on teachers' practices of implementing computers in their classroom.

Many schools are currently in the process of preparing strategic plans that integrate technology into the curriculum. Regardless of the content of each school's Technology Plan, the number of computers that sit in the classrooms, or the amount of money spent for technology, it is the teachers' actual practices in the classrooms that determine what role, if any, technology will play (Callister & Dunne, 1992).

This study examined the relationship between leadership, self-efficacy, computer experience, attitudes, and teachers' implementation of computers in the classroom. Facilitating technological change is not effective unless ultimately the teachers' practices are changed to include technology. This study provides insight into the relationship and influence certain variables have on teachers' practices of implementing computers into their classroom.

Theoretical Framework

This study roots itself in the theoretical and conceptual constructs of change theory in education (Jorde-Bloom & Ford, 1988; Hall & Hord, 1987). Conceptually, change does not occur in education with the introduction of an innovation; change occurs when the innovation is actually implemented (Hall & Hord, 1987). In order to facilitate this change process, change facilitators need to understand what influences teachers' practices of implementing an innovation.
Studies have identified the need for leadership and support to be present in order to achieve successful educational change (Brown, 1993; Leithwood, 1994; Schmitt, 1990). These studies differ in the style of leadership that is most effective in implementing change. Some studies support the motivational tactics of Transformational Leadership to induce change (Brown, 1993; Leithwood, 1994). Other studies favor the more direct style of Transactional Leadership (Fairholm & Fairholm, 1984; Schmitt, 1990).

Other studies suggest efficacy is an important factor to the success of this type of curricular change (Dawson, 1998; Jorde-Bloom & Ford, 1988). The teacher is the one that ultimately delivers the curriculum to the student. If the teacher is uncomfortable with the change or feels there is little chance of student improvement, it is likely that the change will not occur, or it will be instituted incorrectly (Callister & Dunne, 1993).

Although the two variables of leadership and efficacy are important to implementing change, research exists that also supports the role of prior knowledge and experience as an important influence in implementing change and using a computer (Jorde-Bloom & Ford 1988; Levine & Donitsa-Schmidt, 1997; Shashaani, 1997). Still, other studies are present that suggest attitudes toward computers (Levine & Donitsa-Schmidt, 1997), and sex (Shashaani, 1997) may be variables that might impact teachers' efficacy and actual practices of using computers and accepting change. For change to be effective, facilitators must be cognizant of all the variables associated with change. The end result of a positive change in this case is teachers using computers.

This research hypothesizes that practices of teachers are influenced through a series of perceptions. The first perception is based on Bandura's (1977) Theory of Self-Efficacy that implies teachers tend to use practices and strategies that they feel can be effectively delivered by them and that will have a positive impact on student learning (Dawson, 1998). These self-efficacy traits or beliefs are usually built as a result of past practices and experiences (Duffee & Aikenwood, 1992).

This study conceptualizes further that certain variables such as perception of leadership also have an impact on teachers' practices (Hall & Hord, 1987; Huling, Hall, Hord, & Rutherford, 1983). Huling, Hall, Hord and Rutherford (1983) have indicated that a certain style used by the principal has a much greater innovation implementation rate. General attitude towards an innovation (Bandura, 1986; Levine & Donitsa-Schmidt, 1997) may have an influence on efficacy (Bandura, 1986) and perception of leadership (Bass, 1981). It is the relationship of all these variables that influence teachers' practices of deciding whether to implement the innovation.

Study Design

Public school districts were researched to determine their technology utilization and possible participation in this study. Minimum technological standards for this study required school districts to have Internet access to all buildings and for each building to have either an Internet ready computer lab or an Internet ready computer in every classroom.

A total of 160 elementary and secondary teachers from eleven schools districts in Central Pennsylvania participated in this study. Almost 29% of those surveyed represented elementary teachers who taught all subject areas. The remaining teachers represented specific subject areas ranging from 10% language arts teachers to 3.1% computer science teachers. Approximately 28% of the respondents were male, over 56% were under the age of 46, nearly 51% had less than 15 years of experience, and nearly 48% stated they received over 20 hours of professional development in computer training.

Each participant received a six part Likert Style survey that included sections on computer use, computer experience and knowledge, perception of leadership, self-efficacy, attitudes toward computers, and various teacher and school characteristics. The survey was designed using multiple instruments from other studies dealing with leadership, and teachers' use of technology (American Institute of Research, 1998; Bass & Avolio, 1995; Becker & Anderson, 1998; Dawson, 1998; Knezek & Christensen, 1997; Milken Family Foundation, 1998a, 1998b; U. S. Department of Education, 1998).

Factor analysis was used on all variables for data reduction methods. Reliability levels were obtained as follows: for computer uses .76 to .89, for experience and knowledge .82 to .93, for perception of leadership .69 to .92, for self-efficacy .90 to .97, and for computer attitude .94. Pearson Product Correlation and Multiple Regression models were used with significance levels at p < .05.

Computer usage was broken down into three categorical uses: clerical/management use, academic use, and advanced use. All three-computer uses require teachers to adapt their practices in one way or another. While all three uses require teachers to adapt to this innovation, clerical/management uses such as grade
reporting, word processing and e-mail were considered the least invasive procedural change for teachers to make. In essence, these are the computer uses that are least likely to have a major impact on the traditional ways of teaching. The researcher considered this a basic level of use. Academic uses such as drill/practice, remediating deficiencies, improving writing skills, and challenging bright students were considered intermediate use. Advanced uses such as web-page development and desktop publishing were considered higher order computer uses.

The study asked questions regarding the teachers’ experience and knowledge about computers, the teachers’ perception of leadership as it relates to technology implementation, the teachers’ self-efficacy in computer use, and the teachers’ attitudes toward computers. The researcher addressed questions relating to school and teacher characteristics such as age, sex, average class size, and professional development.

Findings

Approximately 92% of the teachers in this survey use computers to assist with one or more of their responsibilities as a teacher. Significant positive correlations were noted between: (a) application/Windows experience and transformational/reward, (b) application/Windows experience and self-efficacy in instructional, Internet, and computer application use, (c) application/Windows experience and computer attitudes, (d) Macintosh experience and self-efficacy in Internet and computer application use, (e) Macintosh experience and computer attitudes, (f) transformational/reward and self-efficacy in instructional and Internet use, (g) transformational/reward and computer attitudes, and (h) computer attitudes and self-efficacy in instructional, Internet and computer application use. A significant negative correlation was noted between computer attitudes and idealized influence (See Table 1).

Self-efficacy demonstrated significant positive influence on all three-computer uses. Self-efficacy in instructional use of computers demonstrated significant positive influence on all three-computer uses. Self-efficacy in Internet use demonstrated significant positive influence on academic and advanced uses of computers. Self-efficacy in computer applications demonstrated significant positive influence on clerical/management use of computers.

Attitudes toward computers demonstrated significant positive influence on academic, clerical/management and advanced uses of computers. The highest influence of computer attitudes was on clerical/management use (See Table 1).

Table 2 summarizes the results of the multiple regression models used for this study. A multiple regression model that identified 43% of the variance in the dependent variable clerical/management use of computers found significant relationship between clerical/management use and the independent variables self-efficacy in instructional use and self-efficacy in application use. A multiple regression model that identified 38% of the variance in the dependent variable academic use of computers found significant relationships between academic use and the independent variables instructional self-efficacy and access to the Internet. A multiple regression model that identified 46% of the variance in the dependent variable advanced use of computers found significant relationships between advanced use and the independent variables sex, professional development, application/Windows experience, and transformational/reward leadership styles. The results of this study demonstrated that as teachers move up the ladder of computer use, the significance of variables such as access to computer tools and self-efficacy diminishes, while the importance of experience and knowledge, perception of leadership and the characteristics of teachers increases. These findings support the research on Levels of Use and Stages of Concern (Hall & Hord, 1987) regarding the implementation of innovations.
Educational Importance

Each of the independent variables has demonstrated either an influence or a relationship with all three-computer uses. While the impact of each independent variable varies with each computer use, each indicates a particular observation. Given the assertion that the use of computers ranged from the lowest level of use, clerical/management use, to the highest level of use, advanced use, the regression models indicate that the significance and relationship of the variables, to the specific use, changes.

The independent variable self-efficacy demonstrates significance in the regression model for the dependent variable clerical/management use. The regression model for the dependent variable academic use shows a relationship with self-efficacy and access to Internet. The regression model for the dependent variable advanced use shows a relationship between experience and knowledge, perception of leadership, and the teacher characteristics of sex and professional development.

As we moved up the ladder of computer use the significance of access to computer tools and self-efficacy diminishes while the importance of experience and knowledge, perception of leadership and the characteristic of teachers increase. This supports the research on Levels of Use and Stages of Concerns (Hall & Hord, 1987). The Levels of Use model basically identifies that people exist at differing levels of use when an innovation is implemented depending on certain variables. The Stages of Concern model suggests that a very different sequence of concerns emerge from experienced versus inexperienced users.

Lewin (1951) realized that when change occurs, there will be forces for change and forces against change, and that change will occur when forces for change outweigh forces against change. Lewin observed that change occurs only when attitudes and behaviors are different than they were before. To support change we need to understand what factors influence attitudes and behaviors. This study offers insight into the importance of understanding the factors that influence the implementation of innovations.

By realizing that certain factors have an influence on teachers' decisions to implement an innovation, leaders and change facilitators can begin to understand what they can do to help promote the implementation process. They can do this by understanding what factors influence teachers' decisions to implement an innovation, how the leader's interactions affect those factors, and how to promote the implementation by positively influencing the factors involved in teachers' decisions to implement the innovation.

The factors under consideration for this study included experience and knowledge, perception of leadership, self-efficacy and attitudes toward computers. While only one of these factors, perception of leadership, is under the direct control of the leader or change facilitator, the actions of the leader can influence the other factors (Bass, 1981; Dawson, 1998; Jorde-Bloom & Ford, 1988).

This study also gave insight into the understanding that teachers implement innovations such as computers in differing degrees and levels (Hall & Hord, 1988). As a result, factors that influence each level of implementation will likely change. Therefore, leaders must understand this phenomenon and plan the change process accordingly. While experience and knowledge, self-efficacy, and attitudes toward computers are perceptive traits decided by the teacher, the leader's action, or lack of action, would have an effect on those perceptions and ultimately the implementation of the innovation.

Abstract: Training future educational leaders utilizing a variety of multimedia produced modules provides an excellent opportunity for introducing the benefits of well-designed courseware and the possibilities of exploring interactive computer-based instruction. This paper discusses the development of a software program that will be used at the graduate level by current and prospective leaders in the educational environment. This unit of instruction consists of content delivered in an educational organization course dealing with administrative theory developed with the Authorware program.

Introduction

Teaching leadership theories could provide a more pleasant and easier task when the instructional units are supported by interactive multimedia-based activities that stimulate learners to engage in higher order thinking (Alessi & Trollip, 1991). According to Thomas & Marium (1999), "Playing games in a graduate class for instructional leaders may seem childish. But the 'proster theory' asserts that the upper most part of the brain functions best when the environment is supportive and non-threatening" (p. 727). This unit was designed using the systematic approach for instructional design suggested by several authors, (Kemp, Morrison, & Ross, 1998; Dick, Carey, & Carey, 2000; Newby, Stepich, Lehman, & Russell, 2000) through an in-depth process, spanning two semesters.

Authorware, by Macromedia, was used to produce the instructional CD. One unit of instruction was designed for adult learners enrolled in the Educational Leadership Department at the Lebanese University, Beirut, Lebanon. This CD could also be relevant for use in American universities. Macromedia Authorware was selected as the program of choice because it allows for the development of interactive instructional units without the technically demanding task of computer programming (Kellogg, 1999). A demo of the CD will be provided along with a discussion of the process involved in the development of the unit.

Instructional Objectives

1. The learners will be able to state the definition of "Servant Leadership."
2. The learners will be able to recognize the six characteristics of the servant leadership.
3. The learners will be able to compare and contrast servant leadership with more traditional leadership styles.

The content for this unit came from an educational leadership course taken at Florida Atlantic University. The Servant Leadership theory posits that "It begins with the natural feeling that one wants to serve, is to serve first. Then conscious choice brings one to aspire to lead" (Greenleaf, 1970, p.1). This module was developed to engage the learner in a multi-sensory and interactive introduction to Servant Leadership theory. Servant Leadership has six characteristics (Laub, 1999). They are:

1. Display authenticity
2. Value people
3. Develop people
4. Build community
5. Provide leadership
6. Share leadership/vision

Project Rational

As the integration of technology into the teaching and learning process continues to be adopted into all educational environments, it becomes increasingly important to support instruction with the use of technological innovations. The aim of this project was twofold: (a) to integrate technology into instruction; and (b) to prepare the students to be instructional leaders in using technology.

The four stages of the instructional unit include:
1. Review the results of the assessment that the learners had in the previous class.
2. Introduce the Servant Leadership concept.
3. Present the six characteristics of the Servant Leadership.
4. Involve the learners in interactive activities that review the whole content of the class.

Models of Instructional Technology Leadership in U.S. Schools

Mary B. Shoffner, Ph.D.
Middle Secondary Education & Instructional Technology Department
Georgia State University
United States
mshoffner@gsu.edu

Abstract: Recent studies indicate that half of all teachers who have access to technology in their schools do not make use of it in their instruction. The time has come for states and school districts to examine the potential of instructional technology leadership in the schools to address teacher training and support needs. In considering what type of roles instructional technology leaders might play in the schools, it is prudent to examine what models are already in place. An exploratory national survey was conducted to determine the presence of licensed IT professionals in school-based settings. Results were gathered through multiple channels: via the Internet, e-mail, and telephone interview. Results and implications of the study are presented.

Introduction

Although significant strides have been made in the effort to increase technology integration into K-12 classrooms, efforts still fall short. According to a recent study by the National Center for Educational Statistics (2000), "Nearly all public school teachers (99 percent) reported having computers available somewhere in their schools in 1999; 84 percent had computers in their classrooms, and 95 percent had computers available elsewhere in the school" (p. ii). However, these same teachers were not necessarily making use of these technology resources in their instruction. "Approximately half of the public school teachers who had computers or the Internet available in their schools used them for classroom instruction" (NCES, 2000, p. i). Only half. The question remains, where are we falling short?

Initial concerns that preservice teachers were not being adequately prepared to integrate technology in their instruction are being addressed. Several factors have been cited as hindering new teacher use of technology. These include inadequate training in the proper technology skills and methods, lack of technology modeling on the part of their university faculty, lack of positive technology experience in school settings, and university faculty out-of-touch with the technology explosion in schools and how it is effecting teaching practice (Kent & McNerney, 1999; National Council for Accreditation of Teacher Education, 1997; Persichitte, Tharp, & Cafarella, 1997; Office of Technology Assessment, 1995; Byrum & Cashman, 1993). The re-design of entire teacher education programs is called for. The Preparing Tomorrow's Teacher's to Use Technology grant program has awarded greater than 75 million dollars to address this specific problem. In addition, standards have been adopted to serve as benchmarks to measure new teacher technology and technology integration skills. In June 2000, the National Educational Technology Standards for Teachers (NETS-T) were introduced and adopted by the National Council for Accreditation of Teacher Education (NCATE) effective for site visits beginning 2001.

However, the NCES study, Teachers' Tools for the 21st Century (2000) reported that less-experienced [new] teachers were much more likely than their more experienced colleagues to indicate that this [college and graduate work] prepared them to use computers and the Internet" (p. iii). 84 percent of novice teachers (3 years classroom experience or less) indicated that college and/or graduate work prepared them to some extent to use computers and the Internet. It would seem that inroads are being made into preparing tomorrow's teacher workforce.

But what can be done to assist today's teachers? Nearly half of all teachers who have access to technology do not make use of it in their classrooms (NCES, 2000). What barriers do they claim hinder their progress? While most inservice teachers indicated that time (82%) and access (78%) are still primary issues, training and support are also largely cited as barriers (NCES, 2000). Teachers cited lack of support regarding ways to integrate telecommunications into the curriculum (68%), inadequate training
opportunities (67%), lack of technical support or advice (64%) and lack of administrative support (43%) as additional barriers to successful technology integration. As districts race to address at least the access issue, purchasing hardware and software, perhaps it is time to address training and support for the practicing teacher. The time has come for schools to establish instructional technology leadership positions.

NCATE recognizes standards for technology literacy at two levels beyond that of the typical teacher. The first is the Basic Endorsement in Educational Computing and Technology Literacy. The second is the Standards for Advanced Programs in Educational Computing and Technology Leadership. While the technology literacy endorsement focuses on the classroom use of technology, the technology leadership standards indicate the preparation of an educator who would act in an instructional specialist role, both training teachers and consulting with teachers and supporting teachers in effective technology integration in the classroom.

Description of the Study

In considering what type of roles instructional technology leaders might play in the schools, it is prudent to first determine what models are already in place. An exploratory national survey was conducted to determine the presence of licensed IT professionals in the school-based setting. Results were gathered through multiple channels: via the Internet (searching state department of education websites), through e-mail with identified licensure agencies or IT officials at the state level and IT licensure preparation programs at the university level, and by conducting telephone interviews with licensure agencies or IT officials in the department of education of states studied. Questions addressed the following areas:

- Does the state have a certification or licensure for the IT professional in the school?
- What is the type and title of the certification (what is the job title)?
- How long has this licensure been in effect?
- Is a teaching certificate required as a prerequisite to the IT licensure?
- If present, what are the IT licensure requirements?
- Does the state also have Library Media Specialist certification or licensure?
- If so, how does the role of the IT "specialist" differ from that of the Library Media Specialist?
- If present, does the state determine the model of IT "specialist" placement, or is it determined at the district level?

The results of the study are presented below.

But first...

Due to the lack of consensus on the terminology and the definition of IT professional in different states, the interviewers requested information on the licensure rules for not just IT specialists, but also technology coordinators who may play similar roles to instructional technologists. During the survey, some interviewed officials required the interviewer to clarify the term "instructional technology specialist" since this job title was not adopted in their states, and they were not familiar with the role played by IT specialists. In order to gather as much data as possible, the interviewers supplied an informal and broad definition for IT professional, and in the later interviews requested for licensure information on any kind of "technology person in public schools." In this paper, the term "IT professional" is used to refer to the variety of titles applied to the certified instructional technologists in this study, and the roles they may fulfill in school-based settings.
Results

States with Instructional Technology Certification or Licensure

Of all fifty states surveyed, seven states were identified as possessing licensure requirements for instructional technology (IT) professionals in the schools. Those states include Pennsylvania, Maine, Massachusetts, New Hampshire, New Mexico, North Carolina, and Wisconsin. In addition, at the time of the study, the Vermont State Board of Education was processing a proposal for Technology Coordinator Endorsement certification, anticipating adoption for the 2000-2001 school year. These eight states have already formulated explicit licensure rules for IT professional, and this licensure information served as the focus of this study.

Lack of Standardization on the Type and Title of the Certification

The eight states differed from each other in terms of the type and title for IT licensure. IT related certifications were in the form of an endorsement or add-on to an existing teaching certificate in three states: Maine, New Mexico, and Vermont. In the other states, however, IT certifications were stand-alone licenses. Moreover, the states adopted a variety of titles for IT related certificates. Only three states (Pennsylvania, Massachusetts, and North Carolina) adopted the term “Instructional Technology Specialist” for IT certification. Three states used the term “coordinator” as part of the title -- “Technology Coordinator” in Vermont, “Instructional Technology Coordinator” in Wisconsin, and “Information Technology Coordinator” in New Mexico. The remaining two states used a variation of “computer teacher” for IT certification. In Maine, the endorsement for “Computer Technology Teacher” also applies to district-level technology coordinators. New Hampshire requires that technology coordinators obtain “Computer Educator” certification. A licensure official in New Hampshire commented that it was considered convenient to set up one set of rules and apply them to both computer teachers and technology coordinators.

Certification for IT Professionals: A Recent Phenomenon

Instructional Technology certification has a short history. The earliest state to implement IT certification was Pennsylvania in 1987. Wisconsin issued an IT certificate for audio-visual directors effective starting from 1986, but this license was terminated in the new licensure rules approved in February, 2000, because it is believed in Wisconsin that “Instructional Technology specialist position has focused on the effort to increase the ability of all teachers to use technology effectively,” and all teachers should be competent in technology. In Wisconsin, a licensed teacher can act in the capacity of IT Specialist without further licensing. Except for North Carolina, which implemented IT certification in the early 1990s, the remaining states adopted IT certification only recently: Maine and Massachusetts in 1996, and New Mexico and New Hampshire in 1999. At the time of this study, the state of Vermont was still processing the proposal for an IT Coordinator certification.

Variations on Teaching Certificate as a Prerequisite

The eight states vary as to whether a teaching certificate should be a prerequisite for obtaining an IT related certificate. By definition, the three states which award IT certification as an endorsement or add-on to the initial teaching certification require prior initial teaching licensure (Maine, New Mexico, and Vermont). In Wisconsin, IT certification is an administrative certification, and requires initial teaching certification as well as three years teaching experience as a classroom teacher. The remaining states did not explicitly specify the prerequisite of a teaching license at the state level if the applicant completes a master's degree or equivalent program in IT related field, but the other alternative to the certification (when the applicant does not have a required degree) necessitates a standard teaching certificate. Moreover, the absence of explicit requirement for a teaching certificate for those who hold a relevant degree does not necessarily mean that teaching license is not required. An official at the Bureau of Teacher Certification in
Pennsylvania responded that a teaching certificate could be a local school district's prerequisite or that of an institute of higher education which offers the program of study even though it is not a state requirement. Furthermore, in the state of North Carolina, a teaching certificate is not mandatory before acquiring IT Specialist certification, but it is directly related to the pay for IT professionals, who need at least 2 years teaching experience to attain master-level pay.

**Similarities and Differences on Licensure Requirements**

Regardless of the disparity of the states with respect to the types and titles of IT related certifications, the eight states share some similarities in licensure requirements. First, a dual emphasis was put on both the technical competencies and the knowledge and abilities of the IT professionals to integrate computer technology into the curriculum. Second, IT professionals are expected to perform a wide variety of roles instead of simply functioning as computer technicians. They are required to be proficient not only in computer and technology operations, installation, and maintenance, but more importantly, in the areas of technology application in teaching and learning, educational and technology-related research and theories, facilities and resource management, professional development, and technology leadership.

While the eight states agree on a broad role for IT professionals, their licensure requirements differ from each other in terms of the degree of specification and the points of emphasis for the required knowledge and skills. Maine underscores computer proficiencies, which are broken down into many sub-areas in the licensure rules, whereas the teaching-related knowledge is mentioned only briefly. New Mexico attaches special importance to the research abilities required of Technology Coordinators.

**Differentiation of the Role of IT professionals from that of Library Media Specialists**

Many of the IT graduate programs originated from audio-visual programs, and IT professionals employed in the schools were traditionally regarded as media services personnel. This tradition was believed to have deterred the development of the field of instructional technology in school-based settings. In this study, we found that the role of IT professionals is distinguished from that of Library Media Specialist in all the eight states. In addition, all eight states recognize and award IT professional and Library Media Specialist as two different certificates. In the states studied, Library Media Specialists are found to work usually in the library and are responsible for the production, management, and organization of library media. In contrast, IT professionals are concerned with technology support and curriculum integration, especially the use of information technology in education. Since the certification for IT professionals and the discrimination of the role of Library Media Specialist from that of IT professionals are fairly recent trends, real-world practice as yet does not reflect this in some of the eight states. In New Mexico, where the endorsement for Information Technology Coordinators was just approved in September 1999, many of the IT Coordinator positions are still served by Library Media Specialists. In Vermont, where the endorsement for IT Coordinator was not yet adopted, the interviewed information technology official stated that a Library Media Specialist can be assigned as a IT Coordinator as long as she/he meets the new standard for IT Coordinators.

**Absence of Statewide Staffing Model for IT Professionals**

There is no consistent model of staffing for certified IT professional in the schools from state to state, or even within certifying states. Unlike the standard for Library Media Specialists, no state reported any statewide model of required staffing for IT professionals. It is up to the local school district to make the decision on whether or not to fund and staff IT positions. Moreover, since IT certification is a rather new practice, staffing is a very flexible situation in many states. It varied from district to district and school to school. Pennsylvania did indicate that the IT Specialists most often worked at the district-level, and would often supervise non-certified computer technicians at each school. In addition, Pennsylvania school districts may employ IT Specialists in the field, particularly in larger schools. In Vermont, some small schools have no IT professional assigned, but some bigger schools do.
Implications of IT Certification

While few will argue the need for increased instructional technology training and support for inservice teachers, there is no agreement that certified IT professionals in the schools are the answer. Interviewees raised several arguments both for and against IT certification.

Potential Benefits of IT Certification

Potential benefits of IT certification were offered by officials from states awarding certification as well as from those that did not. One official proposed that the presence of IT certification itself brings validation and credibility to the use of instructional technology in the classroom. As more states require IT competencies for teaching certification and certification renewal, the importance of these requirements are supported by the employment of licensed IT support personnel. The differentiation between IT Specialist and Library Media Specialist roles allows the Library Media Specialist to focus on what they were trained to do, instead of "wearing too many hats." Another official offered that state-level certification might lead to consistent terminology, roles, placement, and especially pay for IT professional employed in schools. Where IT certification exists, districts and schools have established criteria to make informed hiring decisions.

Arguments Against IT Certification

Not all agree with the concept of certified IT support positions in schools. One interviewee stated that if state mandates for IT competency for initial and renewable teaching certification are successful, that certified IT support personnel would not be needed. Teachers who are particularly proficient or computer savvy could fulfill these support needs when they arise. Along this same line, some states prefer to focus on technology (hardware, software, and networking) needs, and to leave the instructional support role to existing Instructional Specialists. These states prefer to hire IT personnel based on technical certifications (such as Microsoft) that are awarded elsewhere.

Conclusions

Growing Attention to IT in all States

Although only eight states were found to have established or are in the process of establishing certification for Instructional Technology, the emphasis on integrating technology into education was evident in all states. Officials in many states currently without IT certification expressed hope that certification for IT professionals can be adopted in their states. Moreover, almost all of those interviewed indicated their states were attaching an increasing importance to the technology component in education. In addition, officials from many states stressed an increasing attention to raising the technology competency of all teachers.

As more states address technology integration as a required teacher competency for initial licensure and licensure renewal, it is likely that existing instructional support levels in place in schools will be strained. As each state strives to increase technology integration, we must consider how to best meet the needs of inservice teachers in terms of training and support. What must be kept in mind is that teachers will need training in more than hardware and software, but especially in the areas of learning environments, alternative assessment, cooperative learning, information literacy, visual literacy, lifelong learning, and self-directed learning. We must also consider that technology changes, and as such, the training and support of inservice teachers in technology integration will need to be continual and on going. A certified instructional support person trained in instructional technology and teaching methods may be the answer.

Abstract: As we prepare teachers for technological competence necessary in this new century, we must assure that those who administer the educational systems in which teachers work also have the technological competence to support the work of the educators. This paper discusses how technological competence has been infused into the context of the curriculum of a doctoral program which prepares superintendents and other leaders based on AASA and Pennsylvania standards. The curriculum consists of eight domain areas, plus research skills. Technological competencies have been infused into the leadership curriculum. This paper describes those competencies, with descriptive examples of technological infusion.

Introduction

In 1993, the Duquesne University School of Education in Pittsburgh, Pennsylvania founded the innovative Interdisciplinary Doctoral Program for Educational Leaders (IDPEL). Based on the American Association of School Administrators (AASA) Standards, leadership research, and two years of planning with faculty and practitioners, this cohort program produced a first class that greatly improved upon the national ABD (All But Dissertation) rate, and raised the professional status of most of its graduates to CEO, Assistant CEO and other executive level leadership positions. As subsequent cohorts follow a similar path, this program, committed to continuous improvement, recognized the need to systematically infuse the use of technology into the leadership curriculum of the program. This paper describes the program itself, its major curricular objectives, the technological objectives that have been infused into the curriculum, and provides examples of technological outcomes.

The IDPEL program is based on the following mission and belief statements:

The mission of the Duquesne University Interdisciplinary Doctoral Program for Educational Leaders is to develop educators who will have the vision and the skills to move the American educational system to prominence in tomorrow's world. This will be accomplished through an innovative partnership program linking competence and the learner, University faculty, practicing educational administrators, and community leaders.
The mission and all the instructional activities of the Interdisciplinary Doctoral Program for Educational Leaders (IDPEL) strands are rooted in several strongly held assumptions and beliefs:

1. Leadership skills can be developed;
2. A competency-based instructional approach is most appropriate in an adult learning environment;
3. A partnership among University faculty, school practitioners, community leaders, and the learners promotes a more dynamic and relevant learning environment and network of participants (also known as the Community of Scholars);
4. The network established among Community of Scholars members may take the form of large group meetings, small task force and colloquium groups, and small and large group dialogue and meetings via electronic technology;
5. Educational leadership must be grounded upon ethics and moral values;
6. A direct relationship exists between demonstrated competency and future behavior;
7. Cohort grouping provides for cooperative learning and ongoing support systems;
8. The combination of action and reflection best facilitates the integration of theory and practice;
9. An interdisciplinary approach provides the basis for a more comprehensive educational perspective;
10. Analytical skills form the basis for managing change in education;
11. Action research and problem solving are critical skills for effective educational leaders;
12. Instruction is best delivered in a variety of formats;
13. A mentor-apprentice relationship is significant in the development of educational and leadership skills;
14. The nature of adult learners requires the development of innovative scheduling patterns;
15. The need exists for a periodic updating of practicum skills.

Because of our belief in the importance of group process to the leadership of successful organizations, our program is cohort-based. We accept a cohort of approximately thirty students only every three years, so that faculty may provide sufficient support to students in their scholarly endeavors. Each student also has a practitioner mentor over the course of three years of coursework, that person is an executive level educational administrator. This level of support has greatly contributed to the academic success of cohort members. One major indicator of this is the fact that the inaugural cohort that began in 1993, and just passed our seven year statute of limitations, can boast a completion rate of almost 90%, far exceeding the national average for doctoral programs. The second cohort appears to be following in their footsteps with two-thirds of the group completed by only the beginning of their fifth year (inclusive of the three-coursework years.)

The cohort, which consists of currently practicing “middle managers” in education (e.g. principals, education related human service organization managers, university faculty, etc.), attend all courses together in a unique “eight days a semester and two weeks in the summer” schedule. The cohort is further broken down into “advisory groups” of approximately four to six individuals each, each group heterogeneously developed based on results of the Gallup Leadership Perceiver and observation during an initial two-week course. While each student in the program completes individual activities and assignments throughout the coursework, advisory groups also complete projects together. This enables us to discuss and refine group process skills so that they enhance and complement the content skills found in coursework and mentoring.

The coursework in which students engage is based on eight leadership domain areas outlined by the American Association of School Administrators, plus the domain of research skills. The eight domain areas are:

1. Leadership, Values, and Ethics
2. Policy and Governance
3. Instructional Management
4. Planning, Quality, Organizational Problem Solving, and Finance
5. Communications and Human Relations
6. Program Design, Implementation and Evaluation
8. Leadership and District Culture

741
Each of those domains is further defined into ten or more specific competencies, all contained on a "Practicum Checklist." This "Practicum Checklist" becomes the basis for the mentoring relationship over a three-year period between student and practicing educational administrator. By developing a portfolio of artifacts, combined with signatory responsibility of the mentor to assure that the student has practical knowledge of each area, we complement the theoretical base for these program areas provided within coursework.

Although it is now difficult to imagine, the first cohort began at a time when even e-mail was not a commonly used technological function. Therefore, while we did assure that even those first cohort members had e-mail accounts with the university, there was no systematic attention given to the technological skills needed by emerging executive level leaders. Therefore, as a new cohort was about to begin, Dr. Helen Sobehart, Director of the Interdisciplinary Doctoral Program for Educational Leaders, and Dr. Larry Tomei, Special Assistant to the Dean for Technology, collaborated on relevant technology for the Leadership Curriculum. Dr. Sobehart was the recently retired superintendent of a large suburban school district known for it's technological capacity. She knew first hand about technological skills necessary to be an effective superintendent. This included knowledge of technical capacity to support both instruction and management functions. Dr. Sobehart and Dr. Tomei reasoned that aspiring superintendents enrolled in the doctoral program would best gain these skills and knowledge by using them in the context of content area coursework throughout the program. Therefore, the first requirement of the program is to participate in a listserv structured for the cohort by which all program announcements and information are shared. More importantly, however, as the program progresses, students learn and apply not only various management packages as they relate to administration, but electronic communication skills, website development, technological planning, and electronic portfolio development. They also, of course, use various research packages and ultimately develop a web-based process for sharing and updating dissertation information with committee members.

The major curricular course goals of the program, and the related technological competencies are listed below. We also list software packages, websites, and other resources by which the technological competencies are met.

**Strand: Professional Seminar**

Relevant IDPEL Objectives:
- The knowledge base which differentiates management functions from leadership with a long-term vision.
- The ability to understand the function of and develop a relationship with all other human service agencies and organizations that parallel education in society.
- The commitment to influence the attitude and understanding of all participants in the educational enterprise.

Tech Objective:
- The use of basic tools to communicate and conduct research as a community of scholars and leaders.

Tech Competencies:
- Office Productivity Tools
- Internet as a Resource
- Electronic Mail
- Web CT, First Class

Sample Outcome:
- Everyday use of large and small group listservs and other discussion tools to implement program.

**Strand: Leadership and Ethics & Statistics and Problem-Solving**

Relevant IDPEL Objectives:
- The knowledge of ethical traditions in a multicultural society as they affect leadership in schools.
- The ability to relate personal and professional values with a functional code of ethical behavior that characterizes all types of populations in a civilized, post-industrial society.
- The commitment to create an ethical community in the school, community, and beyond.
Tech Objective:
-The use of tools to discuss, survey and quantify issues related to ethical behavior.

Tech Competencies:
-Databases for Research/Surveys
-Scanning Technology
-Listserver as Forums for Ethical Discussions
-Statistics Software

Sample Outcome:
-Design, implementation and analysis of survey regarding ethical behavior

Stand: Society and the Individual
Relevant IDPEL Objectives:
-The knowledge of the cultural, sociological, political, legal, scientific, economic contexts, and educational trends in which districts will operate in the 21st Century.
-The ability to analyze, synthesize, and assess those cultural, sociological, political, legal, scientific, and economic conditions that will impact current and future education decisions.
-The commitment to provide a broad vision of the total community.

Tech Objective:
-The application of various technologies to conduct lessons and research trends.

Tech Competencies:
-Teaching with Technology in the classroom of the future
-Teaching in the 21st century

Sample Outcome:
-Design and presentation of PowerPoint lesson on completed community project.

Strand: Planning, Quality, and Finance
Relevant IDPEL Objectives:
-The knowledge of educational planning process.
-The ability to identify problems and use data available in the planning process.
-The commitment to wed research tools and methods to the solution of actual problems.

Tech Objectives:
-The ability to effectively plan and budget for the use of technology for instruction and management.

Tech Competencies:
-Technology planning for schools districts
-Internet as a Research Tool
-Spreadsheets
-Use of Web Home Pages for Districts

Sample Outcome:
-Semester long problem based work with real school district, resulting in community presentation package, incorporated financial analysis, research analysis, research synthesis, addition to/development of district website and/or other integrated tech to support problem solution.

Strand: Managing Environments
Relevant IDPEL Objectives:
-The knowledge of the effects of the school environment on the educational enterprise.
-The ability to use technology in the operation of the physical plant to facilitate a positive teaching and learning environment.
-The commitment to provide a broad vision of the total community.

Tech Objectives:
The use of technology for decision-making in school environments and to expand the environments in which learning and management take place.

Tech Competencies:
- Administrative software for the school plant
- Technology decision-making: hardware and software
- Policies and procedures for implementing technology
- Distance Learning for lifelong learning

Sample Outcome:
- District technology plan incorporated into facilities plan.

Relevant IDPEL Objectives:
- The knowledge of curriculum design, deliver, and evaluation of instruction and learning outcomes for students and staff.
- The ability to conceptualize and communicate the total educational program to all constituents.
- The commitment to meet the needs of all constituents.

Tech Objectives:
- The ability to use and evaluate electronic systems for assessing student, employee and program progress.

Tech Competencies:
- Electronic Portfolios for Assessment
- Internet Research on district achievement
- Electronic curriculum design and development
- Assessing instructional technology
- Teaching as Intentional Learning

Sample Outcome:
- Development of electronic portfolio for student or Human Resource use.
- Development of web-based dissertation communication process.

Strand: Leading the Dynamic Institution
Relevant IDPEL Objectives:
- The knowledge of the changing society and its effects on the administration of the educational institution.
- The ability to recognize societal changes and to be able to foster institutional change.
- The commitment to promote change in order to foster excellence.

Tech Objective:
- The ability to apply previously guided technological knowledge and skill.

Tech Competencies:
- Practical "Educator in the Workplace" program (technology-supported)

Sample Outcome:
- Establishment of technologically supported international relationship with corresponding colleagues or schools.
- Development of major RFP response for organizational changes/growth in actual organization.

To support the infusion of technology and provide the skills required to master the desired competencies, numerous handouts, web sites, and journal articles are provided. Some of the most important resources will be discussed during our presentation and include:

<table>

</table>

744
The above statements are only a representation of the major work completed by IDPEL students. For example, the Cohort of 2002 travels to Oxford University in March 2001 to spend a week collaborating with educational leaders from several countries through an International Leadership Conference in which Duquesne’s Leadership Institute has been a partner for over a decade. Those collaborations will result in some international publication, but more importantly, ongoing electronic exchange of ideas, curriculum, products, and friendship.

Another example is an RFP response being developed for School Board training related to technology decisions often faced by Boards, and research related to the possible unintended effects of technology on the teaching/learning relationship. The most critical aspect of all, however, is that our students graduate with the vision, knowledge and skills to lead 21st century educational organizations, organizations which are often teaching students who “played with” computers at the same age many of us “played with” Legos. We learned to build real structures, our future leaders must learn to build virtual ones.
Move To The Top Of The Class
A Comprehensive Technology Staff Development Program

Abstract

Teachers have increasing demands on their time and energy and need a staff development program that offers flexibly and a "just-in-time" approach that provides the skills they need when they need to acquire them. In order to offer this level of staff development, the Move To The Top of the Class program will combine 45-minute mini classes delivered during the teacher's conference period in conjunction with just in time, anywhere, any place on-line courses. This paper will look at the mechanics necessary in the delivery of this type of innovative staff development program.

"There is nothing more difficult to take in hand, more perilous to conduct, or more uncertain of its success than to take the lead in the introduction of a new order of things."

Niccolo Machiavelli

Background

While Birdville ISD has had an on-going staff development program in technology for a number of years, 3 high schools and two middle schools were targeted for intensive staff development this previous year. The program consisted of courses developed to deliver 45-minute mini classes covering a wide range of subjects throughout the year. Though the program was considered a success several issues were brought to light in the implementation, management, and participation level. With the continuation and expansion of the technology staff development program for the coming year, now encompassing an additional 26 campuses these issues need to be addressed to improve upon the overall program. The issues are:

- Technology as a whole is too much to learn
- Failure to communicate course information to the faculty and staff.
- Lack of faculty input into selection of courses.
- Lack of access to the technology being taught in the courses.
- Lack of time to enable practice and reinforcement of new skills.
- Lack of follow-up support for implementation into the instructional program.

The additional campuses, which are elementary, generate other issues to be addressed:

- Need to switch from Macintosh platform to Windows platform.
- Need to address elementary instructional needs and teaching strategies.
- Need to identify technology appropriate to various grade levels.
- District mandating attendance.
Implementation of technology standards for all teachers.

Based upon what has been learned from last year's program and the new issues that lie ahead, a combination of offering the individual campuses on-campus courses in conjunction with on-line courses was developed.

Goals

Based upon a needs survey conducted by the district and on-going communication with district technology staff, the following goals were established:

- Improve staff productivity and develop positive attitudes in the utilization of technology
- Empower teachers in the use of technology as an effective instructional tool to impact teaching, learning, and student performance
- Provide an innovative, efficient and effective technology staff development program

Objectives

In order to help participants who are likely to be overwhelmed and frustrated by a wholesale approach (Nichols, 1998), the objectives of the Move to the Top of the Class program are:

- Educators will have a higher level of participation in technology staff development opportunities.
- Educators will be motivated to participate in extended development opportunities.
- Educators will demonstrate a positive attitude towards the use of technology.
- Educators will develop a sense of community.
- Educators will achieve basic professional competency using technology as a work tool to improve staff efficiency.
- Educators will integrate appropriate technologies into the instructional setting.
- The Program will improve the management system.
- District and program staff will improve communication channels between teachers, administrators, facilitators, and consultants.

Attached is an action plan for each goal (table 1). Outlined in each action are the benefits, responsible person, staff requirements, assessment and timeline.

Program Description

"If technology is to be widely used, teachers and administrators need training. Trying to use technology must be a part of every entry-level teachers preparation and should continue throughout the teachers career so that he or she can keep abreast of developing technologies" (National Governors' association, 1991).

In its second year of implementation Move to the Top Of The Class, a series of on-campus and on-line courses, is designed to prepare teachers to integrate both the Internet and classroom computer applications into daily lessons. The series of courses will teach technology skills to teachers through the same project-based learning activities they use in their own classrooms. As teachers progress through the courses, they will develop technological skills and -- more importantly -- strategies and materials they can put to immediate use in their classrooms. The emphasis is on supporting classroom instruction.

Teachers are frustrated because learning computer skills requires the ability to absorb so many different concepts and also requires a great deal of time to practice and experiment before they feel confident enough to involve their students (Fisher, 1998). This program allows the participant to absorb small amounts of information at a time and all the time they need to practice and review through on-line involvement.

Method Of Distribution
Two methods will be used for the implementation of this staff development program. All participants will have the option to work through various Move to the Top Of The Class courses at a scheduled class time with an instructor in their school’s computer lab using the On-campus Method. Educators will have the additional option of participation using the On-line Method. Using this method they access the Internet in basically the same course.

**On-campus Method**

On-campus courses will be instructor lead and offered the top of every conference period at the campus for approximately 45-minutes in length. Participants are invited to attend as applicable during their conference periods. The skills taught for that course will use project based "student centered" activities. Each course will have templates available for direct use in the classroom.

**On-line Method**

Broadly defined, distance learning offers a delivery mode in which the physical classroom, the instructor, and the students are not all present in the same time and location. Distance learning delivery systems can be categorized as those that help eliminate barriers posed by location, those that help eliminate barriers of timing and those that help eliminate both spatial and temporal barriers simultaneously (Levenburg, 1998).

*Move to the Top of The Class* on-line courses deliver instruction through the Internet and offer interactivity, personalization, and the flexibility to learn anywhere you can access the Internet. The participants can learn at the learner’s own pace and are not required to attend scheduled on-campus courses while still obtaining district credit. Thus, the on-line course provides "education on demand" giving the participant flexibility that allows them to fit course work among other demands on their time. Also, it allows the participant an opportunity to preview the courses, to ascertain the content of the course, and to check the level of prior knowledge needed for the course for the purpose of assessing the worthiness of the participant’s time and attendance of an on-campus course thus freeing the participant to attend or participate in other courses.

Additionally students interact with one another and with the instructor in the discussion board. Along with discussions there are other on-line activities designed especially for the course. Other various on-line program features are electronic mail, on-line resources, and course materials.

How to participate, how to access the courses, what to expect, and how to find help are all important aspects of an on-line course that must be addressed. There is a guided tour of the on-line courses along with on-campus instruction lead, if you choose face-to-face interaction to familiarize yourself with the on-line courses. The orientation tour on-line or on-campus will cover the discussion board and the use of email from the on-line site also. There is a FAQ link to help with questions you might have along with phone numbers and e-mail addresses of the Program Administrators.

The design of the on-line course site is hierarchical in nature and therefore an easy structure to follow. Each course has all materials pertaining to it inside the folder for that course. All available templates and such are available to the on-line participant just the same as the on-campus participant.

**Methods of Interaction**

The On-campus Method allows educators to interact with other campus members where relationships are already formed therefore interaction is easy to achieve. Educators in this environment have common background and bond.

The On-line Method has participants from anywhere in the district participating therefore many methods are used to build a sense of community. It is important to create the comfort level for learners that will encourage them to contribute, explore, and communicate with people that they may never see in a face-to-face situation (Lassiter 1998). Discussion boards give that opportunity for participants to interact. Couple a *Move to the Top Of The Class* course with a moderated on-line discussion group and a powerful staff development tool is created.

In the On-line Method, participants can complete specific activities, post projects for others to view, or use the discussion group for follow-up discussion from an on-campus course. Participants involved can build a collaborative community through a discussion board to which instructor and participants will post messages. Discussions may include: topic of the course, sharing information found on the Web, strategizing with peers about the best way to implement a lesson in the classroom, or responding to a problem or issue posted by peers or the instructor.
Getting to know someone across a table requires social interaction skills that teachers are usually well skilled at, but across a telephone wire? A useful technique for on-line courses is to have participants introduce themselves to the group, share their experiences, tell what each hopes to gain by participating, and describe that knowledge or skills they can contribute to the group learning process (Lassiter 1998). Also, using the added resources links page participants can explore other forms of communicating with one another with programs like ICQ, Paltalk, and Net-meeting.

**Methods Of Instruction**

The On-campus Method will tend to be more lectures formatted with the constraint of the 45-minute time frame to work within. The “sage on the stage” instructional mode will be predominantly used to convey the skills for the course.

The On-line Method requires individual study and one-on-one interaction with the course instructor and on-line contact with other participants. When designing Web-based educational programs for adults, it is important to create an on-line environment that is conducive to learning, and one that encourages and support the self-directed learner. (Lassiter 1998) The instructional process is designed to be both highly interactive and personal. The on-line instructors will provide information, facilitate participant's activities, and identify resources. Since participants communicate one-on-one with the instructor, the instructor to some extent serves as their tutors, a much more intimate process that is not often experienced in classroom instruction. Thus, the role of the instructor in the on-line courses will be that of the tutor-facilitator, rather than one of lecturer.

**Methods Of Evaluation**

Several methods of evaluation will be used for each course independently. An evaluation of the time on task and the participant's presence at the course will be recorded by logging-on to Educator, the on-line system program. All courses will use the assessment log included in Educator for the evaluation of time on task and the participant's presence. The time factor of 45-minutes scheduled for an on-campus course is automatically attributed to the participant for all on-campus courses. On-line participants will be evaluated for time on task by the use of the access logs in Educator, but times will vary based on the levels of participation.

An evaluation survey will be used as an assessment at the completion of each on-campus and on-line course. The evaluation survey allows the participant to assess their understanding of the philosophy presented, content presented, participation in course, and an overall assessment of the course. Certificates will be issued directly to the participant present at the on-campus course. On-line participants will be issued, per on-line course, certificates based on their on-line assessment log of equal or greater times on task of 45-minutes. These certificates will be delivered to their respective campus consultant for distribution to the participant. Using the access logs, totals will be kept of all participants time on task for all courses on-campus and/or on-line attendance and certificates will be issued to the Move To The Top Of The Class teachers with the highest totals for each campus.

**Implementation**

Implementation of this program will begin with a presentation about the program to campus principles at their monthly meeting. Having administrative buy in to the program is essential to the success of any good staff development program. Logistical concerns will be addressed such as the scheduled on-campus course dates; staff surveys forms for input into the decision process, campus logistical information for consultants, and the designated site facilitator for each campus. The instructor often finds it beneficial to rely on a site facilitator to act as a bridge between the students and the instructor (Willis, 1995). Choice of courses and their descriptions will be provided to the principals along with a survey results form to convey their campus's selections. In addition to the principal, the campus staff must be addressed. A positive introduction to the faculty is also essential to the overall success.

Each consultant will be assigned a campus and given the dates and subject for the on-campus courses. Simultaneously on-line courses will be aligned to the appropriate ESC Educational Technology Specialist for
the facilitation of that course. The program will be publicized including all key elements such as delivery methods; methods of interaction; instructional modes; evaluation methods; along with courses and dates by the district, site facilitator, and campus administrator to all district employees. A variety of formats will be used to publicize the program (Table 1).

Conclusion

Although critics argue that schools are rushing to jump on the latest education bandwagon, it appears evident that educational environments cannot survive without implementing electronic media and instructional technologies. Indeed, today's schools are in a period of transformation (Fisher, 1998). Technology is the tool that is changing the world of teaching and learning. This transformation is being reflected by the Education Service Center Region XI in cooperation with Birdville ISD by providing for district teachers through the Move To The Top Of The Class staff development program not only ways to build the knowledge and skills needed to be proficient in the use of technology, to use technology in curriculum planning, and designing student learning activities that integrate technology, to engage students in “student centered” learning experiences, and to communicate and collaborate to promote the use of technology to improve teaching and learning but delivering this training in smart ways to allow the participant flexibility to fit course work among other demands of their time. Support for this transformation is offered in the forms of face-to-face on-campus courses with a consultant for each campus, and on-line versions of the on-campus courses and an on-line instructor for each course. With the support of the administration to encourage teachers to participate in the on-campus and/or on-line courses the hope is to offer non-threatening training and support for all participants.

Abstract: The purpose of this paper is to identify trends which are likely to come to fruition in the near term future and generate implications for the educational professional. The trends focus upon the information communications revolution and one subset, the coming Instructional Technology (IT) revolution. Ideas have been abstracted from the author’s forthcoming chapter in the International Handbook on Information Systems. (In Press). H. Adelsberger, Collis, B., & Pawlowski, J. (Eds.). Berlin: Springer-Verlag.

Introduction

Humanity has passed through several major eras, based on technological advances, which have changed society dramatically. Examples include changing from 1) hunter to agrarian, 2) quill pen to printing, 3) agrarian to industrial, 4) manual to electrical, and 5) bits to digits (the digital revolution). The latter is also called the information technology communications (ICT) revolution and we are currently engaged and embroiled in its infancy. The four main waves of innovation since the 18th century include the Industrial revolution in Great Britain, fueled by steam power from 1780s to 1840s (and took 100 years), railway age from 1840s to 1890s, electric power and automobile from 1890s to 1950s, and the information age (1950s--).

After each of these major social revolutions became fully diffused into society, periods of relative calm, peace and stability ensued, interrupted by the occasional war. During each of these transitions to the new order of things, however, there was major chaos, upheaval, and uncertainty. For example, the transition to the age of electricity witnessed the major dislocation of slaves in the United States as the spread of rural electrification made them too expensive to maintain. The industrial revolution witnessed one of the greatest mass migrations in history as people left rural areas to form burgeoning urban areas which led to the growth of social support systems.

We are currently embroiled in the next major revolution, stimulated by the microcomputer and attendant digitization. This has been referred to as the Information Communications Technology (ICT) revolution. This revolution is resulting in significant changes in the way people and organizations communicate and function. It is radically changing, in both qualitative and quantitative ways, how we carry out our day to day activities.

One might ask, what does the future hold for educators with respect to the Instructional Technology (IT) revolution which is rapidly sweeping across the globe? Predicting the future beyond lunch is a risky business filled with uncertainty. There are simply too many twists and turns ahead in the road. Some have opted for developing vision of what the future should be like, rather than to predict it. Alan Kay, now Disney fellow once remarked that the best way to predict the future is to invent it. Another alternative (to ignoring the future and dealing with it as it comes) is to identify possible major events, how they might unfold, and prepare for them all. This is called the scenario approach.

The Scenario Approach

The first scenario, at one extreme, is that nothing will change significantly from the current state of affairs. A teacher from the early 1900s who was magically transported to a current classroom would feel quite at home. The appropriate strategy might be to maintain a low profile in the trenches, keep your helmet pressed down around your ears and keep your head low. It is regularly practiced by many who are...
either within a few years of retirement or view their role as stewards of the institution who will turn it over to their successors in the same fine shape they received it. Some have suggested the lack of wisdom of this approach.

Universities won't survive...higher education is in deep crisis. Already we are beginning to deliver more lectures and classes off-campus via satellite or two-way video at a fraction of the cost [of traditional courses]. Today's [campus] buildings are hopelessly unsuited and totally unneeded. (Drucker, quoted in Green, 1999, p 15).

In a series of studies of campus computing in the USA, Green paints a somewhat dismal picture of the preparedness for this change when he says "the evidence suggests that as an "enterprise," higher education remains mostly unprepared for the consequences of this coming convergence." (1999, p. 11).

The other extreme end of the scenario spectrum is that the ICT revolution will dramatically effect how instruction is delivered in a major and revolutionary fashion. A teacher of today, transported into this new future, would be bewildered, out of place, and find difficulty determining what to do or say. The viability of this scenario of the future of education is based on machine and intellectual technologies which have been promised and are being tested at this time, plus successful experiences on smaller or non-educational scales than proposed in the following scenario.

Below are some guidelines to prepare educators for the IT society based on a review of current and projected technological and sociological developments.

**Specialize in Change and Reform**

If IT is not "rocket science" and can be implemented by any educator with proper support, particularly that which is provided in the context of the interdisciplinary team (see below), why has it been so little used? One answer whose credibility is growing is that IT represents a major innovation and the diffusion of innovation involves change. Bates has argued that

New technologies are associated with postindustrial forms of organization based on highly skilled and flexible workers with a good degree of autonomy organized into relatively small and flexible operational units. In contrast, universities and colleges have been characterized by a mixture of agrarian and industrial forms of organization, with hierarchical, bureaucratic, and relatively inflexible organizational structures and procedures...the introduction of new technologies for teaching will require a major shift toward postindustrial forms of organization for universities and colleges." (Bates, 2000, pp. 1, 2).

It behooves us to learn all we can about the process of diffusion of innovation (change), whether it comes from a managerial, administrative higher education framework (e.g., Bates, 2000), a business leadership framework (Kotter, 1996; Senge, 1990), a sociological, psychological framework (Rogers, 1995), or an educational technology framework (Fullan, 1991, 1992, Szabo et al, 1999). This leads directly to the second role.

**Understand Innovation Rules and How They Apply to IT**

IT must be respected as an innovation and its diffusion (Rogers, 1995: Szabo, 1996; Szabo & Anderson, 1997; Szabo, Anderson & Fuchs, 1999). This approach begins with an examination of those factors which characterize successful and unsuccessful innovation diffusion, from a variety of fields of human endeavor. It then constructs a system to optimize the effects of those factors. This paper looks at twelve characteristics of innovation and implications for the IT educator.

1. Innovation is warmly accepted as an abstract concept but rejected as an operational outcome (the rational behavior of individuals and institutions is to promote stability and resist change). As one vice-chancellor observed "I don't have time for cultural change." (Bates, 2000).
2. The vast majority of innovations fail—they never become widely adopted.
3. Most innovations aren't—they are merely tinkering with the system. "Schools and colleges are as productive and innovative as were Soviet collective farms." (Dator, 1993).

752
4. Innovations which become successfully diffused often have changed significantly to the point where they are barely recognizable. The telephone arose from an effort to help hearing impaired, etc. This underscores the importance of local control and empowerment to enable people to adapt the innovation to their particular requirements, along with the 'global brain' structure to disseminate the adaptations.

5. Historically diffusion of innovation has taken significantly longer to happen than we remember or hope for. It doesn't fit neatly into the five year appointment cycle of administrators or term of politicians. An example from machine technology is the mouse, which was developed in 1964 but did not diffuse into the computing scene until the introduction of Apple's Macintosh, 20 years later. For more on the man who developed the mouse, look at the Stanford Review of [Doug] Englebart's work at http://unrev.stanford.edu.

6. When will diffusion of innovation, particularly of IT, happen? Precision predicting is not possible. However, an estimate can be made, based on the time between the invention or development of some innovative idea and its widespread diffusion. This 'incubation time' has been pegged at roughly 20 years for high tech innovations (e.g., the mouse was introduced in 1964 and set the standard in 1984 with Apple's Macintosh) and educational innovations have larger incubation times. For the sake of argument, I'll choose 50 years for the latter. If we agree that instructional technology is a blend of a high tech and an educational innovation, we might conclude that the incubation time will be longer than 20 years but less than 50. When do we start marking time? Let's take the 1960s, the beginning of the early computer assisted instruction programs developed for digital computers. This yields a likely range of incubation time from 1980 to 2010 and puts us, at the time of this writing, well within the expected period of mass diffusion.

7. The innovator is a dedicated keeper of the dream with total focus. The commitment to bring the innovation to life, the ability to inspire and motivate others is characteristic of all successful innovations. Due to the vision-driven nature of innovation, since no one has gone there before, innovation must be guided by a strong, concrete and shared (Senge, 1996) vision.

8. There is a school of thought that innovation can't be managed-it must be led (Kotter, 1996). The main tool in the hands of administrators is policy-formation and it works well in running an institution. However, there is almost no evidence that innovations arise because of administrative policy and it can be argued that administrative policies may be out of step with innovation and inhibit the creativity needed to innovate. As noted futurist Paul Saffo (1997) observed

"we are all preoccupied with trying to get standards established, and that's a good thing. But few people realize that once standards are established they stay around for vastly longer than we would wish and are used for purposes we never intended. And that's where vertigo comes in because if people realized the consequence of the standards karma they would be completely immobilized."

9. One view of innovation is that is simply the testing of many good ideas and discarding those which don't work. This means successful innovation is characterized by a great deal of trial and error and discarding failures; however, this activity is easily labeled failure. The majority of institutions and individuals do not tolerate failure and people who are supervised by them tend to be risk-aversive.

10. Innovation as an end has limited value: innovation as a means to an end have tremendous value. The value of IT will come not from itself, per se, but from the extent to which it can help educators 1) do what they normally do to improve learning (e.g., providing quick and detailed performance feedback) and 2) step up to new opportunities and applications previously not addressed (e.g., increasing access to specific learning by specific individuals in specific locations).

11. Related to the previous point, people and institutions pass through three identifiable stages which they encounter an innovation—play, use, create (PUC). The play stage is learning about the innovation—what it can and can't do, how to access and use it, how to trouble shoot. If learning is successful, the use stage begins in which the innovation is employed to help people accomplish task they already do, such as word processing for handouts, assignments and test items, spreadsheets for accounts and student marks. Only when a certain comfort/competence level is reached does the individual and institution begin to use the innovation to help do those things that couldn't be done, or even imagined earlier. For example the use of IT to provide access to education, training and information in a distributed learning environment (sometimes referred to as any time, anywhere, or just in-time education). "...teachers, even those most enthusiastic about teaching with technology, typically pass
through several distinct stages before they become educational technology integrators and innovators. (CEO Forum, 1999, p. 13). Corporate researchers have also identified a similar cycle of technological innovation. It has happened that an innovation’s value was not appreciated because it was in the first stage, for example, the suggestion that a powerful use of the microcomputer would be as a storage and retrieval device for recipes in the kitchen of a home.

12. A critical mass of users, 50% by one estimate, is a common hallmark of success of an innovation. Since the IT culture cuts across all subjects, grade levels and barriers of time and geography, every educator is a potential user. One quickly concludes that, using conventional methods, there are not enough trainers or time to provide all the basic training needs, let alone address the on-going requirements of support, upgrades and so forth. To simply provide the necessary training to this large audience requires new initiatives and new solutions.

Focus on the Intellectual Technology, as Well as the Machine Technology

It is often stated that IT is too expensive. Exploring this notion further results in the conclusion that in education, machine technology costs are quantifiable and add-on, while the supposed benefits (increased achievement, effectiveness, attitude and access) are neither 1) easily quantified nor 2) valued in a practical, applied sense in education (which faculty member’s increments or other rewards are based on how much their students achieve or how quickly)?

While it may be true that it is a zero-sum game for machine technology (money spent on IT must come from some other part of the budget), the intellectual technology represented in the employees of the university or college is a rich, renewable and expandable resource. And it is this technology which creates the programs which drive the learning process which is presented by the machine technology.

Predict Directions Computing is Going and the Implications for Education

Networking

The global network of interconnected servers and clients will enable every educator (and student) to not only obtain resources from any location in the world, it will also enable every educator to contribute resources where they have expertise.

Broadband Transmission

The first infrastructure technology element is broadband communication which will enable the transmission of interactive and multimedia computer files significantly larger than anything we have today outside the research laboratory. At the time of this writing, governments are selling expensive licenses (average cost in Britain of $7B per license; Wilhelm, 2000) for third generation (3G) broadband frequencies which will significantly increase the ability to transmit large (e.g., full motion, full color video) files using wireless technology.

Wireless Communication

Wireless communication will permit full access to all educational services we now have and more, from any place in the world without a physical connection. On the day everyone has a single access number and full multimedia capability on a portable wireless device, we will have to rethink how, when and why we communicate with students, colleagues, administrators, suppliers, and experts.

Internet Appliances

"Internet appliances are part of a new wave in consumer electronics that is fusing elements of wireless phones, audio-visual entertainment devices and traditional PCs into gadgets that are more portable, accessible and fun" (Burns & Bickers, 2000, p. 30). One such device resembles a 20 by 29 cm notepad with a digital screen, pencil-like pointing device and wireless connectivity. This prototype hand-held device and presumably its successors (1) are made possible by microchips with high power but low power consumption, (2) will enable complete, interactive, multimedia-based courses of instruction to be received anywhere, and (3) will become relatively inexpensive if the forecast high volume consumer demand drives down prices.
One implication is that the costs of distance education compared with conventional learning will become exceedingly attractive, especially when one considers the tradeoffs of the time and inconvenience and lost opportunity costs of relocating to an institution of higher education.

Databases

The next technology is exemplified by the VISA credit card phenomenon which operates with vast interconnected server-driven databases which collect, store, quickly analyze and regurgitate on demand, information requested by authorized users, clients, and administrators in report format which they specify and control. Imagine the existence of master, world wide educational databases which contain detailed information about every conceivable aspect of educational life everywhere on the globe. Educators will have to create, maintain, and use these databases for the benefit of their students, profession and livelihood.

New Models of Operation Infrastructure

The final infrastructure component is a function of the human rather than technological concepts. This involves a major reconstruction of the educational systems of the world. Indeed it will require a major cultural change (Bates, 2000, Szabo, 1996).

The advent of the Internet is a massive, even unprecedented exercise in managing change...Success requires changing the model for how to organise the work and lead the organisation. It requires challenging traditional assumptions about organization, communication, decision-making, operating style, managerial behavior -- and then defining a new way. That is a human problem, not a technological one." [emphasis added].

CMC may result in a major leap forward in the development of the global brain. It certainly seems to be playing a role in the development of the operating system called Linux. Anyone can change the code to improve or extend its functionality, but the changes must be made available to other users. Theories of learning which place high value on knowledge construction through dialogue with others and reflection may benefit from enhanced CMC in the forms of computer conferencing, e-mail, list serves an other facilities which have yet to be developed.

Preserve Conditions of Intellectual Freedom and Open Political Institutions

The Post Industrial Society and its current incarnation, informationalism, promise men and women greater control of their social destinies. "But this is only possible under conditions of intellectual freedom and open political institutions, the freedom to pursue truth against those who wish to restrict it. This is the alpha and omega of the alphabet of knowledge." (Bell, 1999, lxxxiv). But this requires action based upon reflective thinking. "In times of rapid technological change, reflective practice is virtually an occupational necessity for everyone (Guiton, 1999, p. 52).

Respond to Changes in Educational and Social Goals

We are already witnessing increased demand for intellectual education and training for service, professional and managerial employment, coupled with decreased but nevertheless existing demands for skilled and semi-skilled workers. These latter will be reduced by such technologies as performance support systems and expert systems, which in turn will require building. There will also be a growing need to retrain and re-orient workers displaced by informationalism and provide entry into the market.

Another area of concern to educators is a somewhat uncomfortable concept--market share and competition with other educational institutions, commercial firms, and international alliances. Does your institution want a market share of the education and training industry, and if so how much? In the early days of the Internet, it will be easy for institutions to capture a nice share of the student market, but there are signs that will change as competition heats up.
Develop and Use Technology to Communicate

The capacity and speed of communications networks has increased massively. In 1970 it would have cost $187 to transmit the Encyclopedia Britannica as an electronic data file across the US. Today, the entire contents of the Library of Congress can be sent across America for $40.

The benefit of being online increases exponentially with the number of connections, which increase as communications costs plunge. Robert Metcalfe's Law states that the value of a network grows with the square of the number of users. (Economist, 2000). The birth of the Internet started in 1990 and the browser in 1993. The number of users worldwide has already climbed to more than 350 M and may reach 1B in 4 years. Seven million pages are being added to the Internet daily.

Computers aren't just for number-crunching anymore. They have become powerful but limited tools to support a wide range of communications. Consider the role of reflection and expertise among members of a class and how those elements can be used to enhance and enrich the educational experience of the whole class. Consider also access to scholars and the latest updated information on everything in the world you want to investigate.

Break Free from Conventional Bonds and Thinking

The term horseless carriage was used to define the first automobiles-a blend of the old and new. But retaining the old, while providing some level of comfort, may have hindered the appearance of the new. The view of the early airplane as a vehicle to transport individuals over short distances likely hindered the development of mass travel which we currently enjoy. Perhaps the term distance education will conjure up images of the classroom in different regions, led by a teacher, and have a stifling effect on the culture change necessary.

One way to break from conventional bonds is to look at things from a different perspective. It has been said that a chicken can be defined as a device which an egg uses to reproduce itself. There are myriad details of how this could or should take shape; too many to include here. An extensive review of immersive instruction through virtual reality technology may be found in McLellan (1996). The outcome, however, is that any student can access the best education in the world from any location in the world in any time zone. The global brain will be strengthened. Now if we could just make similar progress and expand results like these into the arena of ethics, morals, and the realm of spirituality.

Change is guaranteed but what that future will look like must wait until it happens. It is likely however that change will continue at a rapid, even accelerating pace. Several other conjectures come to mind. First, unlike most of the rest of our economic, social and cultural environment, education has to date been largely untouched by the sweeping changes arising from the ICT revolution. It seems likely that this will change; that ICT will ultimately have a transforming effect upon the way we conceive of and deliver educational services.

WANTED: A MIRACLE WORKER - a Consideration of Some Issues Arising From the Leadership of Entrepreneurial Activity in Information and Communications Technology in an Academic Setting.

Lynne Walker
Associate Dean, Faculty of Education, University of the West of England, UK

Abstract This paper seeks to explore notions of leadership in relation to the role of the Project Director of a nation-wide in-service ICT training and development for teachers provided by a University Faculty of Education. In examining leadership and the management of change the paper seeks to focus upon the dilemmas inherent in managers leading entrepreneurial activity in an academic environment. The paper also attempts to highlight some lessons learned, key issues requiring resolution and future papers to be written.

Wanted: a miracle worker who can do more with less, pacify rival groups, endure chronic second-guessing, tolerate low levels of support (if not outright opposition), process very large volumes of paper and work excessively long hours. He or she will have carte blanche to innovate, but cannot spend much money, directly hire personnel, or upset any constituency. Internal processes will frustrate a rapidly evolving project and the need to make key decisions in a split second. External quality assurance agencies will never leave you alone. Honourable failure is expected, success will be hard to believe. (after Evans 1992). Welcome to the surreal world of entrepreneurial activity within a university faculty of education in the UK.

Traditional revenue sources for universities in the UK are under downward pressure with year on year “efficiency gains”. The nature of work within higher education is undergoing enormous and rapid change in the UK, and with little precedent to guide us, we academic managers are reinventing our professional role as we go. The cause stems from the new environment we are facing wherein competitive pressures are forcing universities to adopt new strategies, familiar to business and industry - mergers and acquisitions, reductions in staff, performance-based rewards - but heretofore almost completely unknown in education. Communities of scholars are becoming independent budgetary units. Government policy, student and community demands, corporate interests and technology have all stormed the walls of the university and we find ourselves in a classic double bind. Entrepreneurial activity is expected, indeed it is essential to survival, but our internal systems are not geared to it, nor is our culture - risk taking is increasingly necessary but creates suspicion and conflict in regard to the real role of university, intellectual and educational leadership.

Leading entrepreneurial activity in an academic setting is, for me at least, as much about managing change as it is about providing a service and making money. Many people make the mistake of assuming that change is a rational activity, undertaken by rational people. As I see it, the real challenge for both managers and managed is that most change is power coercive, forced upon us by external agents and agencies and it is that which produces antagonism and stress and an aversion to change.

Successful management of change requires certain qualities of what is most often referred to as leadership, as well as the ability to deal or negotiate successfully with vested interests and/or significant individuals. The status of an individual change agent is crucial, notions of credibility and the status of knowledge all play their part in ensuring success or failure of change, as indeed does communication.

For me there is an additional problematic issue in that leadership traditionally has been studied using male norms as the standard for behaviours. There is a whole edifice of conventional gendered expectations of management, with which to contend. Women managers are especially vulnerable to criticism when such stereotypical expectations are not met. Woman as leader requires a competent self, creative aggression and the ability to get things done that make life better (Cantor and Bernay 1992). In my view the leadership vision needs to consist of pointing to the more distant mountains and engaging as many as possible in a collaborative process of action, enquiry, reflection and improvement on the journey. A consequence of this might be that the peaks climbed may turn out to be different to the original first intentions. But ownership of change is a pre-requisite to successful innovation, there must at least be enthusiasm for the proposals. Leadership is creating a state of mind in others
Some lessons learned, issues to resolve and academic papers to be written

* There is no definitive answer out there about how to engage in entrepreneurial activity linked to the e-learning revolution. It is of course possible to gain insights, ideas and inspiration but the road to "success" is an extremely complex one and is due in great part to the cultural conditions of the institution in which one operates.
* Dealing with resistance can be very stressful. People attack you and your precious ideas and seem to show no respect for you. Ignore the temptation to get even with them, even though you know they need the money you are earning in order to keep their jobs.
* Be hopeful, certain that something makes sense regardless of how it turns out, hope is the strength to continually try.
* We need to engage in a structured dialogue about how emerging technologies can be employed to enhance the reputation of the university and the student experience.
* Universities are not businesses in the ordinary understanding of that word.
* Really important issues of public policy v economic perspective go against university culture.
* The development of technology-reliant training and education worthy of our reputation as the university with the seventh highest teaching quality ratings in UK is costly and risky, especially when the management and organisational infrastructure required for making such investment and development decisions are not well developed.
* Many of the possibilities created by new approaches to delivering e-education are not natural extensions of the traditional relationship that exists between academic staff, their academic homes and their publishers.
* The impact of technology, especially the internet, upon leadership behaviour will be profound. Can anyone lead by email?
* What counts as success? The nature of work in ICT, particularly courseware development, emphasises the value of productivity and aesthetics and when we analyse the process of production it can be seen that these often displace educational criteria. How can we ensure that education, in particular student learning, is of paramount importance - I believe this to be a research priority.
* The main determinant of success for our clients (teachers) has been the quality of the content, and in particular the pedagogical focus of it, and not the technology. This has in turn presented us with a niche market opportunity!
* There is an urgent need for most UK universities to decide what form their engagement in e-learning will take. The resultant ability or lack of it to assimilate change will influence the capacity to reconcile the mission, values and ideals of the academic community needs with an awareness that the student or "consumer" of the future is likely be an educational "channel surfer".
* The impact of ICT creates new roles and power structures, the title "Web Master" is but one example of a job title that highlights a range of complex gender-related issues that would benefit from further exploration.
* If as Kouzes (2000) believes "Collaboration will be the critical business competency in the Internet Age", then academic communities are in a strong position.
* The application of free market ideology to higher education does come at a price - the undermining of the purpose of universities is part of it.

...I also learned what makes a web page sticky!

Abstract: The implementation of instructional technologies is creating a number of new careers in education. Three are instructional technology director, instructional technologist, and instructional technology technician. Also, numerous positions are required when institutions develop instructional technology modules in-house. This paper provides a brief overview of the major instructional technology positions, as well as a description of a faculty technology liaison and the details of an instructional technology director job description.

Overview - Instructional Technology Careers

**Instructional Technology Director.** The director and his or her assistants will supervise and direct all aspects of the instructional technology team. The director's major responsibilities include facilitating or overseeing institutional instructional technology planning and instructional technology implementation, recommending an instructional technology infrastructure, establishing faculty technology development programs, initiating instructional technology prototypes, recommending standards and policies, and facilitating instructional technology assessment. Harris and Waterhouse provide an example job description for an instructional technology director in Figure 1. (2001)

**Instructional Technologist.** The instructional technologist assists faculty with the integration of instructional technology to enhance teaching and learning. Instructional technologists might also be responsible for assisting faculty in the development of technology enhancements, which would entail a variety of responsibilities. Assisting faculty with development would most likely include the multiple roles of trainer, instructional designer, graphics artist, Web developer, and project manager. An instructional technologist's major responsibilities include faculty technology development, recommendations on infrastructure upgrades, consultations with faculty on Web-based instructional design and pedagogical issues, as well as the facilitation, evaluation, and reporting on technology prototype initiatives, and other duties as applicable.

**Technical Specialist.** The instructional technology technical specialist is mainly responsible for ensuring that the instructional technology infrastructure is functional at all times and that faculty and student technical difficulties are addressed in a timely fashion. Technical specialists typically assist faculty and staff with technical difficulties with software and, in some cases, with hardware if such support is not provided by the information technology department.

**Faculty Technology Liaisons.** The faculty technology liaison is a faculty member who devotes a portion of his/her time to instructional technology efforts by serving as a mentor to his/her peers and by assisting colleagues with the use of instructional technology. It is best if faculty liaisons are full-time faculty who are provided course release time to serve as the departmental instructional technology team member. These individuals are vital members of instructional technology support teams as well as their respective academic departments.

**Development Team.** The scope of the institution's development efforts and the level of sophistication of the products developed may require one or more of the following employees: (1) Project

Figure 1. Director of Instructional Technology

Function of the Position: The Director of Instructional Technology is responsible for leading the institution's instructional technology efforts and for serving as liaison on instructional technology initiatives to administrative and academic departments. The Director oversees the planning, coordination, implementation and evaluation of appropriate instructional technologies to enhance teaching and learning. Specifically, the Director leads initiatives in faculty technology skill development and Web-based instruction. The Director of Instructional Technology also serves as a liaison to the executive leadership of the university on instructional technology initiatives.

Principal Duties and Responsibilities:

- Develop and maintain relations and facilitate communications between the Instructional Technology department and academic departments.
- Develop and maintain relations and facilitate communications between academic departments and the Information Technology department.
- Make recommendations on behalf of academic departments to the information technology department on infrastructure needed to support the implementation of instructional technologies.
- Serve as liaison to executive leadership on instructional technology initiatives.
- Insure that current instructional technologies are researched and that appropriate instructional technologies are recommended.
- Insure adequate training and resources for faculty to develop instructional technology skills.
- Solicit and evaluate software/hardware products in the area of instructional technology.
- Promote instructional technology collaborations among faculty.
- Propose and implement appropriate prototype projects to promote the study of innovative uses of instructional technology.
- Insure that the effectiveness of instructional technology prototype projects is evaluated and that needed revisions are implemented.
- Facilitate an ongoing instructional technology vision for the institution.
- Oversee the instructional technology planning process for the institution.
- Stay abreast of emerging instructional technologies and make recommendations on needed updates.
- Make recommendations to academic leaders on policies and faculty issues that promote faculty's acceptance and use of technology.

Special Skills Needed:

- Education: Master's degree in instructional technology or instructional design required; doctorate preferred.
- Experience: At least 5 years teaching in higher education and a demonstrated track record in the use of instructional technology.
- Outstanding ability and vision in the application of instructional technologies.
- Outstanding organizational skills.
- Outstanding interpersonal skills.
- Outstanding oral and written communications skills.

References

It is a pleasure and an honor to introduce a new section in the SITE2001 Annual. This is the first year we have had a strand devoted to electronic portfolios (EP) in teacher education, although a number of past editions have included excellent reports of their development and use. In the mid-90s I was involved in the development of the Teachers for Tomorrow Program at the University of Houston. Our interns collected, sorted, and organized materials, lesson plans, reflections, and other relics of their preservice days. From this they winnowed the best examples and developed a paper portfolio. A few photos, a video, and audio tape or two were the extent of “multimedia” in their presentations. How exciting it is to read the current developments in portfolios and recognize how far we have come in such a short time.

As in all sections this year the papers are arranged alphabetically by first author; however I will introduce them in categories for the reader. The papers in this section may be placed in three groups: Overview and Development, Graduate Program Use, and Preservice Program Use.

Overview and Development

Begin your exploration of this section with an article by Zembal-Saul, Dana, and Haefner, Penn State University, USA. While the authors report a case study of preservice teacher use of EP, their research provides an excellent overview and foundation in the underlying value of EP use. It also emphasizes the reflection of growth that may be shown in this type of portfolio. Having established a foundation look next at the paper by Galloway, Indiana University Northwest, who describes specific issues and procedures for the development and maintenance of EP. Based on the guiding principle that virtually anything can be represented electronically the author provides suggestions for methods and formats, soft as well as hard.

The third article by Rodney, Knee, and Musgrove, Florida Atlantic University, USA, addresses many of the early technical issues encountered when building EPs and outlines a practical solution to creating EP using the CDROM. They note the methods make portability, replication and updating CDROM portfolios easier for students and educators alike. For a final paper in this subsection, read Hornung, Lehigh University, USA. This report forms an excellent parallel to the third article in that the author addresses the human issues. She provides ten guidelines for the collection, selection, reflection and presentation of a portfolio. Although initially designed for a preK-5 setting these guidelines are of equal value for teacher educators planning the implementation of electronic portfolio.

Graduate Program Use

Two papers in this section of the Annual are centered on the use of electronic portfolios in graduate teacher education. Interestingly, both are web-based. The first, by Pierson and Rapp, University of Houston, USA, reports use of EP in a Master's program where the students develop their portfolio throughout their master’s work and then compose a summative “epilogue” as one part of their comprehensive exam. In the second article, Sparrow, Florida Gulf Coast University, USA, describes how students are required to create and maintain an online portfolio as an alternative to a traditional comprehensive examination. Their program is delivered in an online format, and students are located around the world. Portfolio assessment provides an attractive alternative to exams by offering an authentic assessment of student knowledge in the quickly changing world of educational technology.

Preservice Program Use

The remaining six papers look at the development and application of Electronic Portfolios in preservice teacher education. The first two articles describe how EPs are developed throughout the students’ college education. Christensen, Gegelman, Groeiers, and Holcomb, Valley City State University, USA; report on the EP structure and guidelines that are built around the adopted VCSU Abilities of aesthetic engagement, collaboration, effective citizenship, global awareness, problem solving, technology, and wellness. This university provides each and every student with a laptop computer and requires all graduating...
education majors to develop an electronic portfolio as a graduation requirement. In the second article, Ring, University of Florida, USA, reviews the development and implementation of the electronic portfolio. Each student’s electronic portfolio is viewed as a dynamic, interactive document that is developed over the student’s entire college experience and may continue to develop indefinitely.

The next article, by Olsen and Dimond, Brigham Young University, USA, reports on the initial portfolio development by two undergraduate cohort groups, formed at the beginning of their junior year and remaining together while they complete their methods courses and teaching practicum. All students in the cohort begin creation of their electronic portfolio as they come into the program as juniors and continue through student teaching.

The fourth paper, authored by Strickland, Williams, Jenks, and Zimmerly, Idaho State University, USA; describes the design of an IT course constructed around the portfolio process, and coordinated with a course of educational planning, delivery and assessment. The authors report the results the first two semesters of their research with the use of EP.

The authors of the fifth paper, Ray, Wright, Stallworth, and Wilson, University of Alabama, USA, report perhaps the most exciting and relatively unusual EP development team. The team consisted of secondary education language arts and social studies faculty, instructional technology faculty, and graduate students from both disciplines. Students were evaluated on their electronic portfolios that consisted of websites, digitally edited teaching episodes, databases, concept maps, and more.

The final paper from Zhang, Randolph-Macon College, USA; describes a pilot project designed to meet preservice teachers request for more opportunities to apply technology skills for teaching and professional use. Four volunteer preservice teachers use and will learn various instructional technology skills for the development of their multimedia portfolio.

Portfolios: The Plan, The Purpose, A Preview

Val Christensen, Valley City State Univ., USA; Patricia Gegelman, Valley City State Univ., USA; Larry Grooters, Valley City State Univ., USA; Linda Holcomb, Valley City State Univ., USA

We live in a technology-enhanced world. As a leading Teacher Education program in the state of North Dakota, Valley City State University (VCSU at http://www.vcsu.nodak.edu) has taken on the initiative to promote technology and train teachers for this world. In February of 1996, faculty at VCSU began using IBM notebook computers. The university became the second campus-wide notebook university in the nation during the fall of 1997.

Valley City State University provides each and every student with a laptop computer. This access to technology was the impetus for encouraging students to produce an electronic portfolio. Recent university requirements state that all graduating education majors will produce an electronic portfolio as a graduation requirement. This portfolio showcases the skills and abilities adopted by the university. Presentation of portfolios is evaluated by small groups of faculty as an exit exam. The University's 2000-2002 Bulletin states:

“As part of their graduation requirement at VCSU, all students must develop a digital portfolio that illustrates the intellectual and job-related abilities they have developed while studying at VCSU...Currently, students prepare their digital portfolios on CD-ROMs. The portfolio presents the best work each student has completed while studying at VCSU, work that illustrates the student's significant achievement of at least five of the eight VCSU Abilities. Some of these Abilities are major-specific, and some relate to the student's minor field, general education, or co-curricular activities.”

Valley City State University faculty members have specified eight abilities that form the foundation of the student portfolio. These eight abilities are based on the Secretary's Commission on Achieving Necessary (SCAN) Skills research, but have been modified to meet the needs of this University. Each of the abilities also identifies specific skills that are required (See table below). During the spring of 2000, faculty members at VCSU developed a rubric to establish levels that must be met for each skill beginning in the general education courses and developing further in the courses for the students major. Progress is tracked at check-points by advisors and through completion of class projects.
The Teacher Education Program Handbook lists twenty objectives designed to prepare entry-level teachers. Three objectives are included as examples of how the program matches to the university abilities.

The program is designed to prepare entry-level teachers who:

1. are competent in communication skills of listening, reading, writing, and speaking;  
   ABILITIES MET: Collaboration, Communication, Problem Solving, Wellness

9. possess the knowledge of how to motivate students to want to learn;  
   ABILITIES MET: Collaboration, Effective Citizenship, Problem Solving, Wellness

17. possess the knowledge and skills to be effective classroom managers;  
    ABILITIES MET: Collaboration, Communication, Effective Citizenship, Global Awareness, Wellness

The elementary education department has mapped out projects that take place in each class that meet these skills and abilities and can be used in the student’s electronic portfolio project. (See excerpt below.) Students then select projects for five of the eight abilities and demonstrate these in their senior electronic

portfolios. The reflection process plays a major role in demonstrating these abilities. In addition to the five abilities, all education majors must meet the three education abilities, which are based on the University’s teacher education model. The theme of the model is “Teachers as knowledge-based decision makers”. The abilities of Planning, Implementing and Evaluating are the focus of this theme.

Elementary Education Major
Mapping Plan for Abilities and Skills

The following includes courses, projects, abilities, and skills designed to assist students who major in Elementary Education. Students may choose any of the projects listed below to meet requirements for their portfolio. (Minimal portfolio requirements include one skill from each of the eight ability areas.) Students must also demonstrate the teaching abilities of planning, implementing, and evaluating. Demonstration of the teaching abilities can be completed in one teaching situation or in three different situations where the ability is demonstrated individually.

This senior electronic portfolio is currently required for the exit exam in the teacher education program at VCSU. A one-credit senior electronic portfolio class is offered in each department during each semester to aid students in the development of their portfolio. (See sample syllabus.) These classes review the expected layout of the portfolio, the types of projects that can be used and some of the technical skills required, as well as the intended audience that they are developing the project for. In addition, a handbook for the senior electronic portfolio project has been developed which includes how-to steps and examples (http://www.vesu.nodak.edu/offices/titleiii/portfolios.htm).
This class is designed to help you complete your required portfolio for graduation. Six two-hour class sessions are planned for Monday afternoons between 4 and 6 PM.

Session 1
- Discuss the relevance of the portfolio project as a capstone activity and importance to student.
- View sample portfolios discussing their strong and weak points.
- Talk about resumes.

*Assignment:* Write Resume and scan picture into laptop.

Session 2
- Discuss the Departmental requirements of Abilities
- Construct Main Menu slide and link to resume. Decide background, color, etc.

*Assignment:* Create a portfolio file on laptop and start collecting projects and storing them in this file.

Session 3
- Discuss audience for portfolio (personal or employment)
- Discuss non-linear format of the portfolio.
- Create a storyboard of projects for the portfolio.
- Pair projects with appropriate abilities.

*Assignment:* Complete storyboard and continue creating portfolio in PowerPoint.

Session 4
- Discuss reflective statements and their importance to the portfolio.
- Make a stronger connection between projects and Abilities.
- Demonstrate creating audio and video for PowerPoint.

*Assignment:* Write reflective statements and insert into portfolio.

Session 5
- Portfolio should be near completion.
- Address needs of students to that they can finish

*Assignment:* Complete portfolio for viewing.

Session 6 (meet individually with instructor)
- Class views portfolio, offers input, and makes suggestions

*Assignment:* Perfect portfolio for exit evaluation prior to graduation.

At the end of the semester, a day is reserved for graduating seniors to present their portfolio to a small group of faculty members. The faculty members then accept or reject the finished electronic portfolio. This process is still evolving with much evaluation and feedback instigating new change. (See Assessment of a Digital Portfolio.)

Abstract: This paper is provided to motivate and assist readers in establishing an electronic portfolio (EP) based on a guiding principle: Virtually anything can be represented electronically. This is not a step-by-step procedural or reference document as much as it is an explanation of important technical issues in the development of an EP. The value of an EP is discussed and compared to traditional formats, including helpful information for constructing and maintaining a professional portfolio in an electronic, technology-based format.

Introduction

Considering today’s trends toward competencies over courses, as teachers must document and demonstrate those competencies, a portfolio is becoming almost more important than a transcript. As we evolve toward portfolios, so too must teachers adapt to a computerized environment – thus, electronic portfolios (herein called EP). Virtually every pre and inservice teacher should have an EP. Warner and Maureen (1999) suggest that by developing an EP, teachers will learn important computing skills and knowledge that can directly impact integration into the classroom. But, it is believed that, frequently, a lack of understanding or knowledge of computing prompts teachers to compromise or settle for something less than ideal technological achievement. And, without reliable or sound leadership from advisors and faculty, inexperienced teachers are likely to weaken or undermine their goal of an electronic portfolio. Many faculty advisors in higher education are still not technology users and will likely fail to motivate and lead, let alone actually guide teachers to create an EP.

This paper is therefore provided to motivate and assist readers in establishing their EP (Campbell, Cignetti, Melenyzer, Nettles, & Wyman, 1997; Dampier Australia Primary School, 2000). This is not a step-by-step procedural or reference document as much as it is an explanation of important issues in the development of an EP.

What Value Is An EP?

It is a mistake to ignore the value and usefulness of an EP. A common phenomenon among most users of technology, benefits are discovered as a result of being users of technology that may not be initially obvious. Kind of a “being in the right place at the right time” notion. For those who already maintain a technological lifestyle it may be that an EP is a natural extension of their daily life and may be easily established. However, most teachers are not yet that involved and may need more awareness of the benefits provided by an EP.

It is useful to compare with non-electronic formats. Papers, documents, class assignments, tests, instructional materials, etc., can all be packaged in a variety of traditional ways. For example, common methods include ring-binders, folders, even boxes for storing large quantities of papers. Photographs are sometimes placed in photo albums or their original envelopes from developing labs. Video tapes, usually VHS format, are also included in storage boxes often large enough to hold all of these kinds of materials. So, with such a large collection of bulk, regardless of the convenience of binders and plastic containers and convenience products of all sorts, consider the following comparisons with this more traditional approach:

(a) Distribution. Consider applying for a job in another city, or providing one’s portfolio to various agencies or organizations. Without the use of UPS, Federal Express or DHL, how does one quickly distribute such bulk to the interested parties? Too, with only one “original,” once delivered it may be permanently gone. Retrieving the materials can be as difficult as giving them out. This may seem overly dramatized for portfolios made up of little more than a single ring binder. Not so. Although, possibly less significant, the problem is the same. A zip disk or CD-ROM containing a complete EP can be easily reproduced and quickly distributed as often as desired without any
need for retrieval at all. Even easier would be a Web-based EP that can be provided to interested parties as quickly as a word over the phone or a simple email message over any distance.

(b) **Quantity/Economy.** There is always some cost involved in reproduction of anything. Computer media has diminished in cost considerably. At the time of this writing, zip disks are under $10, blank CDRs are around a $1 each, all without buying in large quantities. Any comparison with photocopying paper portfolios shows the economy and practicality of an EP. A Web site is in many cases completely free. In some cases, where a base fee is required, expansion and addition to the site costs nothing extra. None of these factors are true for traditional formats.

(c) **Replication.** It's much easier to make multiple copies for distribution. Both zip and CD media will hold large amounts of information of all types and they can be easily replicated. Computer files can be copied as easily as drag & drop. CD's are even easier to recreate once a CD "image" is created and saved. A new CD of a complete EP can be created with as little as two or three clicks. On the other hand, a Web page doesn't require any replication at all and is readily accessible to the whole world.

(d) **Size.** This is the most obvious advantage. The amount of material that can be placed on a zip disk or CD is equivalent to many binders or boxes and yet takes up virtually no space at all. Today, it is literally possible to walk around with a complete library in your pocket.

(e) **Security.** A computer file is far from secure. Any computer file can be easily lost either through oversight and error to more technical media failure. But, combined with the ease and economy of replication, backup copies can be easily created and stored in different places. The permanence and security of an EP is in the numbers. By producing a sufficient number of backup and storage copies, quickly and easily done, an EP can be maintained securely forever.

(f) **Maintenance.** Most electronic material can be easily modified. Certainly, any records can be updated with new material but some records are considered permanent. Generally, electronic computerized material is more easily modified and maintained. Of course, a video or sound clip, aside from minor editing and enhancements, is naturally limited to the original sampling. Quality can sometimes be modified whereas content is permanent. Nevertheless, the simple matter of copying, organizing, modifying and storing electronic material far exceeds the efficacy and utility of traditional hard materials.

(g) **Versatility.** Electronic media is obviously more versatile than traditional hard materials. That is, a ring binder of material is much more difficult to convert to an electronic format than to produce a hard copy from an electronic version. Even to directly replicate a set of hardcopy materials into additional hardcopies (photo copying) is still more difficult and costly than producing a hard copy from an electronic original. I.e., having an EP means you have both whereas having only a hardcopy version limits one, because of obvious practicalities, to only the one original.

(h) **Quality.** Certainly not the least concern is the higher quality provided by modern computerized formats. Research has shown that even hand-written material is evaluated higher than typed material but neither is considered as professional or high quality as computer-generated products. Video, sound and photo material, even when transferred to hardcopy, has improved to rival original/traditional formats.

**Electronic Documentation**

A guiding principle is suggested: Virtually anything can be represented electronically. It must be assumed that a given entry can be represented in electronic form - even if not originally created in that form - so one addresses how to achieve proper form and structure rather than to resist or deny the objective. I.e., it is important to pursue a complete portfolio, with virtually any desired component included, in a form that would, for example, fit entirely on a CD-ROM. Note that even a fully posted Web site can usually fit on a single CD.

How to begin? An electronic portfolio can be very difficult to generate from scratch to accommodate previously stored material, documents, events and historical notes or products. It is very important to start early and generate portfolio artifacts in an electronic format from the beginning and to continue that processes throughout all subsequent work. While every student should have an EP, it is up to the individuals to do it themselves so the...
student or teacher must take the initiative, invest the time and do the work. Working one step at a time, generate and/or store the materials yourself. Specific strategies are suggested in Figure 1:

1. Virtually every single experience or product can exist and should be documented electronically.
2. Identify specific artifacts that denote accomplishments for each and every standard.
3. Produce the appropriate abstract or summary of each artifact when its identified as a portfolio entry.
4. Gather or develop electronic artifacts EA. when you first complete the project - don't procrastinate.
5. Distinguish between a developing portfolio DP. – work in progress – and the final or professional EP.
6. Organize a developing portfolio DP. according to the standards or principles of your program.
7. Store all electronic artifacts EA together with backups safely stored in completely separate location.
8. Frequently review the organization of your EP - every 2-3 months, or whatever is manageable.
9. Regularly review and update file formats for each EA to stay compatible with developing software.
10. Regularly review and update the media used for storage to stay technologically current.

Figure 1: Electronic portfolio (EP) development and maintenance strategies.

There are obviously more common sense notions about caring for computerized material but these 10 guiding principles will help facilitate transformation into an electronic lifestyle. Some of the implications and details for these strategies are discussed in a more concrete fashion below.

Details

An EP can be very difficult to create from scratch. It is very important to start early and generate portfolio artifacts in an electronic format immediately and to continue that processes thereafter. While every teacher should have an EP, only the teacher can do it. Take the initiative and, one step at a time, generate the materials needed. Start now and do the work for each potential artifact as they’re created or as they occur.

EP Formats

Your final EP can exist in various media formats and will likely need to change formats from time to time. One reason is to stay current (see Strategy #9, Figure 1) and the other would be to provide material to a target audience in the format they need. Consider the following:

Floppy Diskette holds only very little (1.44 megabytes). This is not practical as a storage medium. In many instances, floppy drives are no longer included on today’s machines. Too, many single graphic files and certainly sound and video files are much larger than a floppy’s full capacity. Still, for smaller files, floppy diskettes are still useful for transferring and moving information.

Zip disk holds a lot of information in one of two common formats: 100 or 250 megabytes. It is conceivable that some EPs could contain more than 100mb. For example, in the case of numerous video or sound files. It would not be likely for mere print media (word processed files) to fill this much space. In any event, two 100mb zip disks could be used and information arranged in a fashion to make it user-friendly – for example, placing all print media on one and audio/video on the second.

Jaz disk wow, holds a great deal of information (1 gigabyte) but is not likely to be widely available. It is not practical to send a EP to an administrator or program director (maybe when applying for a job) if they do not have a compatible device.

CD-ROM Virtually all computers today (some older may not) have the ability to at least read a CD-ROM. Acquiring access to a CD “burner” for creating permanently Recordable (CD-R) or ReWritable (CD-RW) CDs is becoming more common. A CD-ROM at 650 megabytes would hold all
material for virtually any EP. The price is right. The size is right. The compatibility is right. Goldilocks would be happy.

**Video Tape**

Traditional VHS tapes (analog video material) are still thought by many today to constitute a technological presence. That is, some believe that having portfolio material included on video tape (classroom teaching, presentations, etc.) constitutes having one’s portfolio in a technological format. Even the newer digital formats (digital-8mm), while higher quality, still constitutes a non-computerized media and therefore has inherent limitations: hard to distribute, costly to reproduce, awkward to access. While such recordings are a natural part of recording events, such material should be viewed as raw data from which presentable excerpts are distilled – ultimately, digitized into computerized presentations.

There are other media available today including so-called super diskettes, portable/removable hard disks, and even “thumb”-drives. However, these items above are still the most commonly available media among average professionals.

**A Beginning: Easy Stuff**

The most obvious material that is EA ready would be any word processed document. It's already electronic. Certainly, the instructor may have required a paper version but keep the electronic version as well and transfer it quickly to your DP. That is, take each word processed artifact and copy it to your portfolio storage area (organized by the standards or principles to be demonstrated). This storage area or working portfolio is developmental (DP) would likely be modified regularly.

Create a word processed Table of Contents file (start one today) in which each EA is listed by file name. It should also show all related files together and where on the disk (or other media) the file(s) can be found (path). Not only is this of obvious use to other readers, after several semesters you too will be glad to have this guide. The format or style of this can be easily modified later but at least there will be a working DP and that's the most important thing.

**Anything in Electronic Format? – Really!**

Often students fail to realize that virtually anything can be represented electronically. Of course, it would be a big mistake to hand write your term paper and hire someone to type it on a typewriter leaving you no electronic format at all. But, even this can be scanned and stored on disk as an image file. The point is anything can be represented electronically.

OCR - Optical Character Recognition... means that scanning a document can recreate the material in a character-by-character format as if it was originally typed into a word processor. However, unless you are very, very proficient at using this type of software, it can be quite difficult and somewhat impractical. Scanning the document is fine but it will likely remain in a "picture" format.

Consider the following examples:

**Example 1**

Consider a possible worst-case example. Students in a mathematics class learn to cut and fold paper to produce dice then to be used to practice and reinforce mathematics concepts of probability and statistics. Even this can be included in your EP (even on a CD). A simple photograph or two of the materials, manipulatives, maybe including a student using the materials, could be scanned and stored electronically. The EA would include the electronic picture and maybe a word processed anecdote or announcement describing its design and use (like an extended caption for the photograph) and any data from pilot testing or suggestions for using the activity and manipulatives. In other words, anything can be represented electronically.

**Example 2**

You're teaching in a classroom and recording on videotape to document strategies, a lesson plan, classroom management or other issues. Often, videotape is considered a major part of an EP but its problems are described above. Videotape cassettes should become peripheral components of a portfolio that exist separately and in some other location. If your final EP is to be on CD then how can this format accommodate (and represent electronically) the video material from the videotape? A representative sample portion, 2-3 minute segment(s), could be digitized into a computer file playable by most video computer software and thereby included in the EP.
One format would be AVI format (audio/visual integration) and is very common. Today, a more condensed format that saves a great deal of space without sacrificing quality is MPEG formats. To do this, video-capture hardware and software are required and are usually add-on components to a traditional computer setup. Pure sound files would be WAV or the more compressed MP3 (mpeg) formats. Again, the point is clearly that virtually anything can be computerized – and should be if its to become part of the EP.

**Filenames**

Filenames can be an important factor in managing your system as quick and efficient file recognition can be important. Various products associated together should share similar filenames, including the summary or reflective abstract. For improved organization, name the abstract file similar to the artifact file(s). For example, if the artifact has a filename such as "Lesson Plan.Doc" then name the supporting abstract something like "Lesson Plan AB.Doc" Or, if the artifact has a filename like "Teaching Video.AVI" with a written summary named "Teaching Vid Sumry.Doc" then name the supporting abstract something like "Teaching Vid ABS.Doc" That way, sorting displays will keep the files close together in a list. Too, the reader can easily associate the files that go together and can find abstracts of other EA because the same style is used throughout the EP. For more information on filenames, see the section below on versatility.

**Folders**

While many arrangements can suffice, it is suggested that a series of folders be created which correspond to the standards or conceptual framework of the program. For example, the Indiana University Northwest, School of Education has a 9 part conceptual framework for its undergraduate program (Indiana University Northwest, 2000) and a 5 part framework for its graduate program. Maybe name specific folders for each standard or program areas and place EA within each of these folders. Of course, material could be further organized within those folders based on the nature of the EA itself. It might be advisable to describe the assessment/evaluation context and maybe include any associated evaluation rubrics. In any event, structuring your EA according to the standards or framework of your program may be important to convincingly support your achievements and competencies.

**Good Habits**

It is not acceptable to simply put each semester's data disk in a shoebox with all those of previous classes. There are a million ways to fail in developing your EP and none of them are technological. They are all a matter of organization, habits, commitment and procrastination. The files themselves must be copied to the storage area of your developing portfolio (DP). Ultimately, it doesn't matter if this is a zip disk or a hard disk folder so long as it is maintained and developed. Always have one central location for the DP - not a home computer for some things while other files are kept on your laptop computer.

All - repeat - ALL disks fail. If "Murphy's Law" ever had a home its in the world of technology. Don't wait for it to fail - save it early! Don't wait to lose it - back it up! Don't wait for it to disappear - keep a copy!

**Versatility**

As technology changes in the future, any file may need to be readable by someone with slightly different technology. Most state-of-the-art word processors are cross-platform (works on PC's and Macs both) and will likely be available for years to come. While this author suggests Microsoft Office tools (word processor, database, spreadsheet, etc.) as the most versatile and reliable cross-platform software tools, many Word Perfect users might suggest Corel products. In any event, maintain files in a versatile and latest-version format. As new software products evolve from old, stored files in the DP may need to be updated or converted. Do not hesitate. This is part of the regular and frequent maintenance discussed above.

Sometimes files need to be in multiple formats. The filenames themselves denote specific file formats. For example, "Letter.Wpd" - the W.P.D. indicates that it is likely a Corel Word Perfect word processed data file. There are many ways to convert one file type into an alternative format - like changing a BMP file into a JPG file (both are graphics files). Figure 2 provides a list of very common file formats and the typical filename extension associated with that file type (of course there are many, many more). Remember, file formats can usually be converted from one to another with minimal loss of appearance or function. Some skills are involved but help resources are available on campus, on the Internet and more.
Figure 2: Filename extensions as indicators of file types.

Miscellaneous Notions

Material throughout the EP can be hyper-linked together (easy in Ms-Word) and to the table of contents to make viewing everything more convenient and efficient.

Use a digital camera to take pictures of products, events, situations and more that should be in the EP. You can also use any regular camera and then ask when developing that your photos be produced and returned on a disk or CD (already in electronic format). Or take the paper photos and scan them into a computer to be saved on disk.

For any "computer" tasks you're not able to perform yourself, help is available at campus computer services, from professors and friends and even your local Kinko's.

Other material beyond the EA that support program standards might not be prescribed by other portfolio outlines. Nevertheless, such peripheral and ancillary material can also be stored electronically and may even be included in the final EP (space permitting) under a head of "other."

Electronic Portfolios:  
A Glimpse into a Child’s Education

Claire Smith Hornung  
Lehigh University  
United States of America  
c1h61@lehigh.edu

Abstract: Electronic portfolios use the purposeful collection of students' work, progress and the achievements of the paper portfolio and puts them together using technology that enhances and expands the delivery of the portfolio. A collection of multi-media work is far easier to present electronically than to find the perfect container to hold a students artifacts from preK-5. Electronic portfolios can include graphics, video, and sound, in addition to all that is included in a paper portfolio. There is no limit to these portfolios. Its creation is guided by the imagination of the creator. Similar to the paper portfolio, students can take a lead role in using technology to develop their own electronic portfolios. The Moravian Project involves incorporating electronic portfolios as an assessment tool for students and teachers alike.

Introduction

Approximately ten years ago, educational portfolios were introduced into academia. Teachers would collect student work. Sometimes the student would take an active role in this selection of work. The collection of student work models that of an artist and the artwork they completed. Artists use these portfolios when interviewing for jobs or pursuing advanced degrees in art. Students with an academic portfolio might use a portfolio for the same purpose. These portfolios would show a selected audience information that can provide far different insights into a students performance than a letter of reference or a report card. Therefore, as this movement worked its way further into classrooms, so too did the idea of using a portfolio, over time, for student assessment.

Portfolio assessment is the purposeful collection of student work that includes efforts, progress, and achievement to document growth over time and focus on the processes involved with learning (Weldin & Tumarkin 1999). While there might be as many different variations of portfolios as there are learners, most fall into three main categories: the celebration portfolio, the growth or project portfolio and the status report portfolio (Stiggins, 1997). All three types of portfolio have merit and benefit both teachers and students. However, the target audience for each of these types of portfolios vary and the type of portfolio selected to be used should be kept in mind by the creator.

Electronic portfolios use the purposeful collection of students' work, progress and the achievements of the paper portfolio and puts them together using technology that enhances and expands the delivery of the portfolio. A collection of multi-media work is far easier to present electronically than to find the perfect container to hold a students artifacts from preK-5. Indeed, electronic portfolios can include graphics, video, and sound, in addition to all that is included in a paper portfolio. There is no limit to these portfolios. Its creation is guided by the imagination of the creator. Similar to the paper portfolio, students can often take a lead role in using technology to develop their own electronic portfolios.

A Project at Moravian Academy

The Lower School teachers at Moravian Academy (preK-5) have been encouraged for the past 7 years to collect student work to create paper portfolios. These portfolios travel with the children through to the fifth grade. However, not all teachers followed through on selecting artifacts and sending them on to the next grade teacher. At present, portfolios were paper-based, not electronic.

The goal of this project is to establish guidelines so teachers and students will know what to select from each student and that each portfolio collected will follow the same criteria. Students will also take part in
reflection and assessing their own work. In addition to establishing the guidelines for the teachers at each grade level, the project focused on implementing electronic portfolios as the next logical step to incorporate the enhanced technology that the school had to offer its teachers and students. The impact of this project would change the entire focus of these paper portfolios. Teachers will invite students to take part in the selection of pieces for their portfolio. This participation will allow them to reflect on why they choose these pieces. Therefore, the students will have far more ownership over their learning. Personal ownership over learning is key to the learner and is a key goal for our project.

Guidelines for Portfolio Implementation at Moravian Academy

The Pennsylvania Department of Education developed guidelines that can be used in portfolio implementation. In his text on student-centered assessment, Stiggins (1997) presented several guidelines to keep in mind when developing a portfolio. His list of “active ingredients” describes successful ways to incorporate a portfolio for student assessment and achievement. When the guidelines for Moravian Academy were developed several suggestions from both the Pennsylvania Department of Education's and from Stiggins' research were considered and fit into our criteria of Collection, Selection, Reflection and Presentation:

1. Maintain a sharp focus on what is the purpose and the target of the portfolio. Think big. Start small.
2. Rely on quality assessments as the foundation for quality work.
3. Plan in advance what the portfolio will tell by setting guidelines for what is placed in a portfolio.
4. Plan in advance how it is that a portfolio will be used within an existing curriculum.
5. Insure that administrators, teachers, students and parents have ownership over the project in some way and are supportive from the beginning.
6. Establish specific criteria for the assessment.
7. Share the entire process of implementation with the students: collection, selection, reflection and presentation.
8. Involve students in the process of selection.
9. Involve students in the process of reflection.
10. Setup a time line with due dates for works to be included (be flexible with this timeline).

At present funding is sought for the implementation of this project. A pilot study was conducted with one classroom and general guidelines were followed. This portfolio was then used by the student for self-assessment and by the teacher during parent-teacher conferences. Teachers at Moravian Academy will work with education students from Lehigh University to implement the guidelines of the project. The students from Lehigh will work with each team of three Moravian teachers in grades preK-5 to implement student portfolios for each child. The Lehigh student will be responsible for training the teachers in the creation and maintenance of electronic portfolios, using the template and guidelines established from the pilot project. These students will also serve as resources and trouble shooter if problems should arise.

Conclusion

While an electronic portfolio or even a paper portfolio may be described and supported, through research, as a strong and viable academic tool, not all educators will have the desire or the need to adopt this tool. Understandably, it takes time, effort, and additional energy to develop school or classroom guidelines to integrate portfolios. Yet, many of our schools fail our students because of a lack of appropriate and proper assessment of individuals. Many students are not successful with standardized tests. Others perform better after reflecting on their own work and the strengths that go with their own learning styles. Portfolio assessment developed with strong guidelines allows for the strong test taker and the reflective learner to find success in their accomplishments. This success can provide educators and parents, alike, with an insightful and, perhaps, enlightening glimpse into a child's education.

Abstract: This paper is a report on the work that has been done by two undergraduate cohorts in the David O. McKay School of Education. Approximately thirty students are formed into a cohort at the beginning of their junior year and remain together while they complete their methods courses and teaching practicum. All students in the cohort begin creation of their electronic portfolio as they come into the program. Electronic portfolios have been created and analyzed for the purpose of helping preservice teachers formulate and articulate their beliefs regarding the education of elementary students, and to collect evidence of planning, management, teaching strategies, and assessment that would be in harmony with those beliefs. This departure from traditional paper portfolios utilizes video clips of students' teaching, other visuals, written plans, and assessment to show their teaching abilities.

Introduction

As teachers of the Planning, Management, Teaching Strategies, and Assessment course for elementary education majors at Brigham Young University, we were asked to explore ways technology might be integrated into the course. The course is part of the cohort experience which goes throughout the students' junior year while they are also taking other methods courses and completing their teaching practicum.

Strengths and weaknesses of the course were analyzed. In so doing, the question arose as to the real value of one of the assignments: student paper portfolios which were created to promote reflection, and as a means of presenting to prospective employers an idea of the strengths and beliefs of the student. In surveying students who had previously completed the course, almost all reported that employers showed no interest in looking at their portfolios. Principals frequently commented to the instructors that they looked like a voluminous looseleaf of papers that would require too much time to gather pertinent information about the student's teaching.

It was decided that electronic portfolios might offer a better alternative for students to showcase their teaching skills. The use of concise, personal philosophical statements which would show their beliefs in the various aspects of teaching, coupled with still images, audio, and video clips, seemed to be a more authentic and interesting means of communication, as opposed to the traditional paper portfolios.

The Project

The prospect of electronic portfolios was discussed with the students, and for the first semester it was decided to give students the option of doing either an electronic portfolio or the traditional paper portfolio. Even though students were assured that their choice would not make a difference in their grades, all thirty students chose to utilize the electronic format.

Categories for demonstrating teaching skills were discussed, and eight categories were decided upon with the flexibility given to students to change, add, or delete areas based on their need and preference. The
eight categories were: Effective Teaching; The Learner; Parent and Community; Diversity; Personal and Professional Development; Assessment; Classroom Management; and Curriculum. (The first semester, most students chose to use the suggested categories; many students in the second semester cohort chose other categories to better reflect their individuality.)

The evolution of the project has been dramatic. During the first semester, many major difficulties were encountered, which included: the instructors' ability to use the technology; the availability of the necessary hardware and software; sufficient time for instructors to assist students with video transfer and compression; and students who lacked the technological skills to independently accomplish the project.

During the first semester, the computers and software required for video capture and compressing were only available in a graduate lab, which was inaccessible to our undergraduate students. Thus much of the teachers' time was taken up with compressing files and burning CDs so the students could import those files into their presentations. During the second semester, there was no change in the availability of hardware and software (with the exception of the purchase of two digital video cameras and a digital still camera); however, planning and organizing differently improved the efficiency of the project's implementation.

Results

Feedback on the value of electronic portfolios was sought from six principals in the public schools where students were placed, along with colleagues and administrators from the David O. McKay School of Education. Most of the principals were excited about the possibility of the video portion of electronic portfolios, which they believed would allow them to get a better feel for the student's personality and ability to relate to students. The principals preferred a CD as the medium to view the portfolios. Only one principal said he would not be interested in seeing an electronic portfolio, but stated the reason was that he did not have the necessary computer skills to view the portfolio. However, he felt that knowing the students had the skills to create an electronic portfolio would increase his interest in hiring them.

Feedback from staff and administration in the School of Education was, for the most part, positive. Suggestions for improvement were offered. The criticism most often heard was the lack of evidence of student reflection. As one student shared his electronic portfolio with his instructors and an administrator he stated that, "The most valuable thing that came out of this was not doing the portfolio itself, but what I learned about myself and my teaching beliefs." However, that reflection was not evident in his portfolio. Since then, personal discussions with other students have revealed they also shared the same sentiment as the student just mentioned. Based on the feedback, as future students are assigned electronic portfolios, reflections on their teaching will be included.

Future Project

B.Y.U has received a PT3 Federal Technology Grant which will provide much needed help for the expansion of this project. However, some of the greatest support has come from the administration in the David O. McKay School of Education. Upon our request, the following kinds of support are being given: (1) two digital video cameras were provided for student use; (2) a still digital camera was purchased; (3) multiple workstations for our undergraduate students are at the moment being set up, including necessary computers, compression software, video capture software, video editing software, CD burners, and Zip drives; (4) necessary technological skills will be taught to our cohort by the Instructional & Psychology Technology instructor. The administration has also offered to provide the needed assistance required by our students in the computer lab.

It is projected that creation of electronic portfolios will be done by all students in the College of Education at Brigham Young University.
Implementing Web-Based Portfolio Assessment in a Graduate Instructional Technology Program

Abstract: Web-based portfolios are a solution to presenting learning in our Masters program because they allow students to play a key role in directing their own learning, to demonstrate creative design, and to conveniently access work on any platform. Students store learning artifacts on a department server, and confidentiality is guaranteed through a Web-based form that automatically enables password protection. New students take a required course to learn about technical procedures related to maintaining the portfolio, as well as strategies for selecting portfolio items and for composing personal reflections on their work. Students review and reflect on their own learning during each course so that they will have a clear timeline of their own learning. As students' understandings mature, they create connections among discrete learning artifacts, designing various interfaces to customize the presentation for multiple audiences. During their final semester, students review the entire portfolio to select items that demonstrate achievement of program objectives and write reflections to accompany each item. Students will compose a summative “epilogue” as one part of their comprehensive exam. Despite some anticipated challenges, initial informal feedback from students is positive, so we remain committed to further developing our portfolio assessment process.

The appeal of performance portfolios continues to grow as a form of assessment for authentic activities in Pre-Kindergarten to higher education settings. We have previously described our ongoing investigation of Web-based portfolio assessment as a requirement for students in our graduate Instructional Technology (IT) program (Pierson & Kumari, 2000). Our initial plans for a portfolio strategy in our IT program began with a series of goals: What should a student graduating from our IT program know and be able to do? What kinds of evidence will verify that the information and skills have been learned, and how would we be convinced that goals have been met? What hardware, software, and networking will support successful portfolios, and how will they be compiled? And, in general, how effective is our program at preparing future instructional technologists? These questions are aligned with successfully implemented portfolios discussed by others (Barton & Collins, 1993; McLellan, 1993; Niguidula, 1997).

The new portfolio assessment process has now been implemented in our Masters program, and already practice has both confirmed some of our plans and caused us to reconsider other strategies. We have framed our current understanding of the process with Barrett's (2000) stages of electronic portfolio development: Defining the Portfolio Context and Goals, The Working Portfolio, The Reflective Portfolio, The Connected Portfolio, and The Presentation Portfolio.
Defining the Context and Goals

Purpose and Benefits

We began by defining why we felt Web-based portfolios were a solution to presenting our students' learning. A distinct advantage of portfolios is the student ownership of learning. We have recently redesigned our program with clear performance objectives that students will meet upon graduation, and it was important for us that students play a key role in directing their own route toward demonstrating proficiency with the objectives. Electronic portfolios are an ideal collection and presentation format since the artifacts of learning in our program are almost entirely digital products, and the Web-based format holds particular promise as it allows students to demonstrate creativity in presentation and organization (Watkins, 1996), permits flexible access from anywhere by the student, faculty, fellow students, and potential employers, and eliminates issues of software incompatibilities on multiple platforms (Mills, 1997). We anticipate that portfolios compiled throughout a graduate program will make the connections among discrete courses explicit, eliminating the prevalent perception that course products are produced in isolation merely to receive a grade. Finally, we look forward to the ongoing feedback on the effectiveness of our program that portfolios will provide our faculty. Such feedback, we believe, can directly feed continuous improvement and development of the program.

Structure and Storage

Electronic storage options are numerous, however we felt the Web the most promising primary storage format due to its flexibility, accessibility, and compatibility. Upon acceptance into the program, each student is given permanent disk-space on a department server to be used for the duration of his or her studies. Students are the managers of their own portfolios, however a consistent hierarchy of file organization based on our course numbering system is encouraged throughout the program to ensure orderly storage and easy faculty access to assignments. The Web environment gives students the option to store learning products in the most appropriate format, including word processing, electronic presentation, HTML, multimedia, and even PDF.

To encourage honest reflection on their own learning, students are guaranteed that their reflections will be kept confidential. Therefore, designing a plan for secure storage of student work was a priority from the beginning of our planning. Students voiced early concern as they participated in the planning process that the Web environment would leave their work artifacts and written articulations open to the public. They worried that their original ideas could fall into competitors' hands, or that potential employers could stumble onto incomplete forms of work in progress, possibly giving false impressions of their abilities and jeopardizing future career options.

Restricting access to sensitive or personal material in the portfolios presents a unique challenge in system administration. The portfolio files are housed on a Linux server, which can be very daunting and cryptic for users not familiar with UNIX-based command-line interfaces. Rather than make such file manipulation a requirement for all students from the beginning of their programs, we chose instead to make the technology as invisible as possible. Enabling password protection normally involves creating encrypted password files and Hypertext Access Restriction files for the various directories. The account administrator developed a Web-based form that allows students to easily enter their Linux login name, password, and desired Web password along with the password protection options they wish. Most students create a "portfolio" directory within which they place individual course directories. It is this main portfolio directory that is generally protected, thus simultaneously protecting all files beneath that level. A ColdFusion backend engine translates the users' requests into commands understood by the Linux operating system which in turn sets up all of the appropriate files, permissions, and encryption data automatically. An added feature of our system allows faculty access to student assignments without having to keep track of every individual password. Each faculty member's unique IP address is added to the access restriction files so that the server automatically recognizes the computer and grants access to the files without prompting for a password. These storage and security options continue to be refined as we think through creative solutions to new challenges. Our goal is to keep requirements as consistent as possible so that students will not have to spend time reworking portfolio structure in place of focusing on other coursework.
Required Introductory Course

The compilation and evaluation of performance portfolios is something most of our graduate students have not personally encountered, so to ensure a smooth transition to quality work selection and collection, we have restructured our Masters course offerings to include a beginning required course called “The IT Professional.” Along with teaching basic technical skills necessary for success in the rest of our courses and assimilating our students into our program as a cohort group, this course serves the vital purpose of introducing the portfolio concepts and procedures. Students receive instruction on technical considerations related to maintaining the Web-based portfolio, such as organizational guidelines, file transfer procedures, and procedures for storing learning reflections. Students establish the focus of their portfolios by writing individual goal statements, exploring strategies for selecting portfolio items to represent a range of work quality and type, and learning to compose personal reflections on their work.

The Working Portfolio

Once the portfolios are established during the first semester in our Master’s program, students collect and store learning products in accordance with course objectives in subsequent courses. As all course objectives have been written with reference to the overall IT program objectives, the portfolios likewise remain aligned. All faculty are moving toward explicitly stated requirements in the form of rubrics, often developed collaboratively with students. The use of rubrics focuses student attention on course expectations from the beginning so that they will be better able to frame their own learning and progress in relation to the course.

We recognize the need in the final portfolio product for a balance between student-selected items chosen to show personal learning and those items suggested by the faculty to demonstrate learning in accordance with program goals (Snyder, Lippincott, & Bower, 1998). For this reason, students will be encouraged to save everything created in relation to each course so that they will have a variety of items from which to select when chronicling their learning at the end of their programs.

The Reflective Portfolio

Our IT portfolios will be useful only if they transcend merely pleasing displays of completed work to instead make compelling arguments of a student’s knowledge and skill. All courses require students to review their own learning progress, either for each assignment or at end of each semester, and to write a reflective essay describing their understanding of their learning at that time.

During the initial semester of this reflection writing, many of our students have struggled with this process. Few have been asked to think purposefully about their own learning prior to this course, and they have questions about what to include, how deeply to comment, and how detailed to write. In the required IT Professional course, we discuss components of reflection, and contrast exemplary and weak reflection examples. As instructors, we hesitate to give students the detailed prescriptions they desired, such as specifically how long reflections should be and what the finished products should look like. We have compromised by coming to a common, yet flexible, reflection structure:

1) Identification: what course objective the reflection refers to
2) Context: for what purpose the item was created (i.e., created specifically for this course requirement or created for a professional purpose and modified for the course)
3) Procedures: the steps that the student followed to create the product
4) Evaluation: how the student perceives the quality of the product, including strengths and weakness
5) Goals: any plans the student has for continued learning in this area.

In addition, following the first semester of the course, representative examples of reflections for each of the objectives will be available for future students to refer to as models. We frequently encourage originality in format, and have seen students take advantage of the opportunity to display their unique skills. While some reflections rely effectively on text alone, others incorporate screen captures of other work documents, images, and audio. We hope
to progress in our own understanding of what constitutes acceptable demonstration of competency as students continue to stretch the limits of the standard course assignments.

Reflections written during each individual course retain students' immediate thoughts and concerns, so that at the end of the Masters program, students will not be required to guess at their thoughts months, and sometimes years, previously. Reflections are written so that students will have a clear timeline of their own learning, and are viewed only by the course instructor for the purpose of better understanding the student's progress and needs. In essence, each student is developing an individual theory of instructional technology as it relates to his or her own understanding.

**The Connected Portfolio**

By compiling the portfolios in a Web-based environment, students are able to not only store information and products, but to use the hyperlink capability to organize the presentation in such a way that demonstrates their unique understanding of their own learning. Students are charged throughout the process to be the managers of their own learning, and as their understandings mature, these connections among discrete learning artifacts can be flexibly reconfigured. Once basic Web-editing skills are gained through experience in the program, students can easily design a number of different front-end interfaces that will customize the presentation of their work for multiple audiences. Faculty may be guided through the portfolio in one way for, for example, and future employers may initially see something very different in look and organization. Considered along with the selected items and written commentary, the electronic interface and the navigational sequence serve as the ultimate demonstration of creative design and systematic development expected of IT graduates. The Web as both a technology and an interface enables the student ultimate control in portfolio creation and management.

**The Presentation Portfolio**

During their final semester in the program, students will be asked to review their entire portfolio, including the reflections written in each course, to select those items that they feel demonstrate their achievement of the IT program objectives. They will write reflective captions to accompany each item to rationalize the inclusion of the item in the presentation portfolio and to include personal reflections about attaining their learning goals. These captions will provide a unique comparative thread among skills and projects, enabling faculty or other audiences to evaluate learning products with the assistance of a student's “voice.” Final portfolios will be stored in an accessible and portable format, such as CD-ROM.

It is our hope that the portfolios will ultimately highlight the interrelations among instructional theory, research, and practice evidenced in the products of learning and, furthermore, enhance the ability of each student to articulate these ideas. Such individual examination of learning evidence and subsequent reflection is not typical in our existing traditional written comprehensive exam format (Bali, Wright, & Foster, 1997; Barton & Collins, 1993), and we envision a time in the near future when portfolio assessment might replace the written comprehensive exam as a graduation requirement. This assessment would better reflect the constructivist teaching and learning philosophy and project-based nature of our program. As a trial of the effectiveness of student reflection on their own learning as a measure of achievement, students will be required to compose a summative “epilogue” as one part of their comprehensive exam to address specifically posed questions about their portfolio intended to synthesize understanding of theory and practice. Successful completion of the portfolio will conclude with the final step of a portfolio consultation with faculty advisors.

**The Portfolio Process to Date**

Masters students who began our program in Fall 2000 with this new portfolio requirement are presently completing their degrees, so we recognize that challenges will continue to arise. We have assessed portfolio components in individual courses, but have not yet reviewed entire portfolios; grading consistency and additional time commitments with this alternative assessment procedure may still pose problems. Initial informal feedback from students is positive, however, so we remain committed to further developing and strengthening our portfolio assessment process.

Abstract: With the implementation of national standards addressing technology, teacher preparation programs are faced with the issues of preparing teachers to effectively use and to seamlessly integrate technology across content areas. A team teaching approach at the University of Alabama required its secondary methods students to produce electronic portfolios during spring 2000. The teaching team consisted of secondary education language arts and social studies faculty, instructional technology faculty, and graduate students from both disciplines. This effort of modeling technological best practices resulted from numerous team meetings, intensive planning, and consistent project evaluation.

Introduction

The secondary education methods courses at the University of Alabama have traditionally incorporated technology on a limited basis. However, as the result of a team teaching approach, and in answer to technology integration needs the preservice teachers were required to attend technology seminars as part of regular classroom and methods work. Students were evaluated on their electronic portfolios that consisted of websites, digitally edited teaching episodes, databases, concept maps, and more. Through pretest and posttest surveys, the students were assessed on their perceptions of an electronic portfolio's value and their ideas of how technology can enhance teaching and learning in
future classrooms. This session presents a discussion of the results from these assessments, procedural details, and the challenges and successes experienced by the teaching team and the students. Examples of student produced portfolios were presented along with ideas for developing a similar project in a variety of educational settings.

As educational technology standards are implemented, it becomes increasingly important for teacher preparation programs to model and to use technology. This presentation shares research from the trials and successes of how a teaching team and preservice teachers created electronic portfolios to increase use and applications of technology in the classroom.

**Literature Review**

Lankes (1998) defines electronic portfolios as a "purposeful collection of student work that exhibits the student's efforts, progress and achievements" (p. 18). Electronic portfolios differ from traditional portfolios in that information is collected, saved, and stored in an electronic format (Barrett, 1998). Electronic portfolios allow students to demonstrate problem-solving and critical thinking skills using authentic and performance based assessment (Campbell, Cignetti, Melenyzer, Nettles, & Wyman, 1997, Meyer, 1992). While more research is required to assess the effectiveness of electronic portfolios with pre-service teachers, existing research suggests that there are benefits to be gained from use with pre-service teachers (Herman & Morrell, 1999).

Numerous advantages related to the use of electronic portfolios are suggested by the literature. Bull, Montgomery, Overton, and Kimball (1999) write that electronic portfolios promote learner self-evaluation even as they maximize the use of diverse learning strategies. Barrett (1997) agrees with this assertion adding that electronic portfolios allow students to demonstrate problem-solving skills even as they are compelled to take responsibility for their learning. Campbell, Cignetti, Melenyzer, Nettles, and Wyman (1997) argue that out of this learner responsibility comes a degree of control over the learning process and over the process of becoming a professional educator. The work of Herman and Morrell (1999) support this assertion as well. Throughout the process students are actively involved in their own assessment (Cole, Ryan, Kick, & Mathies, 2000).

The effective use of the medium requires ongoing evaluation (Barrett, 1998; Cole, Ryan, Kick, & Mathies, 2000), both on the part of the instructor and of the student. Cole, Ryan, Kick, & Mathies (2000) conclude that the central advantage of all portfolios, not just electronic, is that the instructor is able to assess the student's process of learning. Evaluation, requiring teamwork, creative thinking, and reflection (Bull, Montgomery, Overton, & Kimball, 1999), goes beyond the limits of the traditional classroom. Herman and Morrell (1999) argue that electronic portfolios shift the balance from teacher-centered learning to student-centered learning. Multiple sources of evaluation combined with self-evaluation encourage pre-service teachers to recognize and address individual strengths and weakness (Corbett-Prez & Dorman, 1999; Herman & Morrell, 1999).

Herman & Morrell (1999) are convinced that electronic portfolios encourage students to
"review their individual teaching values and frame the issues that they feel are vital to the learning process."

Barrett (1998) and Lankes (1998) maintain that electronic portfolios are an attractive method of alternative student-assessment. However, issues relating to this electronic format must be addressed before requiring students to engage in this type of assessment (Corbett-Prez & Dorman, 1999). Research suggests that the implementation of an electronic portfolio project requires considerable investment of time and effort on the part of the instructor and the student (Linn & Baker, 1992; Cole, Ryan, Kick, & Mathies, 2000).

Findings

The team teaching approach assisted in the overall success of the electronic portfolio integration project and has continued to be a model at the institution of this study. The evaluation process was important and has helped to enhance the accessibility of and support in using the technologies for teaching and learning. Efforts have continued and since technology is ever changing, the evaluation process of how to effectively use technology as tools for teaching and learning must continue. To that end, our teaching team remains committed to reflective planning for, using, and evaluating technology in instruction. As our efforts grow to include more faculty, in-service teachers, and pre-service teachers in other content areas, we are excited about the possibilities and understand the challenges. Our focus remains good pedagogy; therefore, our technology efforts will continue to be research-based, reflective, and appropriate across the various content areas.

The implementation and Integration of Web-based Portfolios into the Proteach Program at the University of Florida

Gail Ring
Office of Educational Technology
University of Florida
United States
gailring@coe.ufl.edu

Abstract: This paper describes the development and implementation of the electronic portfolio program in the College of Education at the University of Florida. Beginning in the fall of 2000 all students entering the Proteach Program were required to develop electronic portfolios. Prior to this initiative an elaborate infrastructure was designed to support both the students and faculty involved with this innovation. Each student’s electronic portfolio is viewed as a dynamic, interactive document that is developed over the student’s entire college experience and may continue to develop indefinitely. It will contain illustrations of how the student has met Florida’s Accomplished Practices, the student’s professional goals and achievements, biographical information, and a personal teaching philosophy. Methods of developing electronic (online) portfolios are shared, ways of integrating these portfolios into practice are discussed, and an illustration of sample contents is reviewed.

Background

Preparing teachers for the 21st century has been a concern for both political and educational leaders in this country for the past two decades (Dede, 1995, Papert, 1999). This problem is compounded by the fact that “today a very substantial proportion of people are engaged in work, in jobs that did not exist when they were born and that number is increasing” (Papert, 1999). NCATE has challenged higher education to incorporate technology across the entire teacher education program, not just as a “computer literacy” class added to the existing curriculum (NCATE report as quoted in Piper & Eskridge, 2000). In addition, the National Council of Teacher Accreditation (NCATE) requires its accredited schools of education to provide adequate access to computers and other technologies, and expects faculty and students to be able to use it [technology] (Major Themes of NCATE Standards, 2000).

In the past, professors were held accountable for what students learned. If parents or accreditation organizations wanted to know what students were learning, they asked the professor for a list of course objectives or an outline of the curriculum. Florida’s Department of Education began measuring mastery of the state’s accomplished practice standards by examining samples of students’ work. Students’ work is also the focus of assessment procedures used by many private funding agencies.

Because student work is to become part of the evaluation of our institution, we decided to develop an infrastructure for the development, storage, and presentation of student documents. In our model, each student will create, manipulate, refine, and collect evidence of his or her academic accomplishments. We intend to emphasize this procedure throughout the entire program of study.

In the literature, the word portfolio is usually accompanied by the word assessment. In our view, the descriptor “assessment” severely limits the potential of an electronic portfolio, and creates a perspective on the portfolio building process which undermines its distinctiveness and perhaps much of its value. Portfolios should help “learners become integral and conscious participants in the learning process” (Courts & McInerney, 1993). We feel that the role of the learner in the learning process is central to the development of electronic portfolios. If we are to use portfolios effectively in our preservice teacher program we must view portfolios as learning tools, rather than as end products. The portfolio itself has powerful pedagogical import and should have the “potential to inform learning” (Krause, 1996).
Purpose

Our students' electronic portfolios will contain proof of their proficiency on a set of Florida Accomplished Practices. These portfolios will then serve multiple purposes: students' self assessment and reflection about their learning, student maintenance collection and selection of the contents of the portfolio (maintenance), and the evaluation of our institutional performance in educating preservice teachers. Each student's portfolio will serve as an interactive document which will become the focus of an on-going reflection process. Students will be making decisions continuously about how to best represent themselves to their instructors, their peers, and their potential employers.

Rather than viewing the portfolio as a product or a container for holding students' work, we view it as an organic, evolving document which informs learning. While summative electronic portfolios can include (a) a representative sample of a student's work, (b) proof of accomplishment of accepted practices, (c) illustrations of outstanding achievement, (d) information about a student's goals and aspirations, (e) personal statements, and (f) a personal vitae and other documents relevant to future employment or academic development, formative portfolios offer a working environment for revision and reflection. Formative portfolios might contain works in progress, sample layouts, collaborative work including the work of others, and reference documents under consideration. For this reason, we believe that electronically stored portfolios should have public sections and secure, private developmental sections.

Structure

Although we want to support and encourage student decision making, it is important for those who must access student portfolios to be able to find specific information quickly and easily. Therefore, the index or home page for each student should be relatively uniform. Figure 1 contains an example of a sample student portfolio:

![Figure 1: Sample Student Portfolio](image)

Each category links to a page or pages developed by the student. Although the format of the index page is clearly defined, content development should remain flexible and student centered. Portfolios are very personal. Student creativity and reflection are important consequences of the portfolio development process. Portfolios not only encourage students to make decisions, they encourage students to reflect on their work. As Krause (1996) states, "Portfolios allow numerous opportunities for the learner to think flexibly and nonlinearly about how and to what degree learning and change over time have occurred." We have discovered that when planning portfolio implementation, there is always a great deal of discussion about student reflection. However, as the process becomes formalized, the portfolio specifications become
more rigid and inflexible. We believe that preserving room for reflection should be a high priority when institutionalizing the use of portfolios.

Support

When the possibilities for acceptable completion of an assignment are widened to include more information channels--for example video, sound, or graphics--support for the student is essential. By building an infrastructure that attends to students’ needs while simultaneously informing the learner, we hope to empower students to express themselves in more ways than text alone. In our model, the instructor of each course provides examples of how the course integrates with standards and/or curricular goals, as well as multiple ways in which this may be accomplished.

Next, instructional design students and/or student assistants analyzed the illustrations of acceptable work provided by the instructors and online support systems were developed. These support systems contain information sheets, tutorials related to the specific skills, descriptions of the accomplished practices or other standards, external links to pertinent references, video clips showing examples, a list of frequently asked questions, misconceptions, typical sample problems, and other helpful information. In addition, brown-bag seminars, workshops, and question-and-answer sessions, as well as one on one meetings with both faculty and students are held to provide additional support for specific endeavors. The goal of the support infrastructure is two fold: to help students improve their performance without making decisions for them, and to attend to the needs and concerns of faculty without adding additional work.

Using portfolios as a forum to demonstrate the accomplishment of given practices transfers a great deal of responsibility to the students. Decisions on how to best demonstrate their competence, such as which information channels to use (video, audio, photographs, text-based anecdotes, etc.) should remain with the students. Portfolio development increases the number of decisions students have to make about specific assignments, goals, and/or tasks.

Conclusion

Portfolios may be used effectively to model 21st century uses of technology to preservice teachers. As we watched our students create portfolios, we noticed collaboration and the sharing of ideas among students. As students began to reflect on their work and their learning experiences, they began to discuss ideas with their peers. Soon a healthy competition developed and their work clearly evolved. Many of them incorporated more advanced web development techniques and spent a considerable amount of time doing so. We are also happy to report that students have begun to drive this initiative. Faculty interest and participation has increased due to their exposure to student portfolios, and collaboration across colleges has occurred because of student suggestions.

We continue to have many questions about portfolio development. As our formal implementation plans are developed, we will attempt to determine how portfolios contribute to student learning. We will try to learn how to support a higher level of student reflection, an increased sense of ownership in our students’ knowledge development, and an increase in students’ self-esteem. We believe that by managing the vast amount of information in their portfolios, by deciding how to build a public representation of their accomplishments and of who they are, and by trying to integrate the various components of their public and personal histories, our students will develop skills and perspectives that will serve them well in the future.

Easy methods and media for creating electronic CDROM portfolios

Desmond Rodney
Department of Teacher Education
Florida Atlantic University
United States
drodney@fau.edu

Dr. Richard H. Knee
Department of Educational Technology and Research
Florida Atlantic University
United States
knee@fau.edu

Ann T. Musgrove
Department of Educational Leadership
Florida Atlantic University
United States
amusgrove@fau.edu

Abstract: This paper seeks to outline a practical solution to creating electronic portfolios using the CDROM, which has traditionally been expensive and inaccessible in educational environments (Barrett: 1994). CDROM portfolios allow for easy updating and are a physical, sophisticated example of student work. They allow for storing large files and data types of students' work. The process of creating CDROM portfolios was at one point complex and difficult to learn and to teach. In this article, the authors outline methods that are in effect easy to learn and to teach. The authors have found that all errors are reduced when the artifacts for the portfolio are organized for presentation, mastered as an ISO 9660 or CD image and the image is then burnt to the CDR.

Electronic portfolios have undoubtedly become a critical component of authentic assessment methodology in education today (Barrett, 1999). E-portfolios as we have come to know them, have become popular among educators in all environments from k-12 to higher Ed. Aschermann, (1999) argues that e-portfolios are “a tangible collection of a student's best work". This perception has made e-portfolios very popular among educators and students. The portfolio provides both teachers and students with examples of what a student can do rather than merely relying upon a transcript of grades or formal evaluation forms.

Today both at the k-12 level and in higher-ed environments, e-portfolios are largely replacing notebook or ring binder portfolios (Lankes, 1995). The media to which we store e-portfolios however are not standardized. Traditional portfolios consisted of three ring binders or notebooks with printed copies of documents (artifacts) organized into specific categories. The content would differ from student to student but the media was largely paper-based. This meant that viewing or authoring a traditional portfolio relied on traditional methods such as word processing, printouts and the reading of documents from the binder. This portfolio required no special software to read or view its pages and was portable by just walking the portfolio from one person to the next.

This paper seeks to outline a practical solution to creating electronic portfolios using the CDROM, which has traditionally been expensive and inaccessible in educational environments (Barrett: 1994). The process of creating CDROM portfolios was also complex and difficult to learn and to teach. The methods outlined here are in effect easy to learn and to teach. Importantly too, the methods make portability, replication and updating CDROM portfolios easier for students and educators alike.

Electronic portfolios offer an important point of departure from traditional portfolios. Through their reliance upon the use of multimedia technology, teachers and students are allowed the flexibility of storing artifacts in different media types (Barrett, 1999). Most e-portfolios today are created with one or a number of
types of software applications. These applications are of two types, generic software packages that can be
employed for the purposes of creating electronic portfolios and commercial packages designed for creating
electronic portfolios (Barrett, 1999).

The most popular type of e-portfolio is the Hypertext or HTML based portfolio. This is largely
because the HTML portfolio is often published to the World Wide Web, where students can view it and share it
with other recipients. In this environment, an e-portfolio becomes a showcase of skill, ability and work quality.
Compared to traditional paper-based portfolios, web-based e-portfolios, for students and teachers alike, become
a tangible expression of high quality work and skill. Carefully organized graphic and multimedia features and
interface elements can reinforce website structure, and ease the user’s cognitive load (Cafolla & Knee, 1997).

HTML web-based portfolios offer ease of editing and updating because students can often update their
webs from home or from the school’s computer lab. The declining cost of software has helped this portfolio-
publishing environment because many HTML editors are free and some come standard on most personal
computers today. Importantly too, HTML based portfolios are convenient because all that they require for
viewing is a standard web browser, which today is free and is also standard on most personal computers.
Students can also produce the projects they create and learn valuable multimedia creation as well. All this can
be done for a very small investment of funds, (Knee, Musgrove & Musgrove, 2000). Despite the convenience,
ease and flexibility of HTML portfolios, there remain a number of disadvantages when they are published to the
Internet. Many school and home environments lack Internet connections that are necessary to view web-based
portfolios. Classrooms that are housed in portables for example, often do not have access to the Internet, it
means that publishing or viewing of web-based portfolios in this environment is not possible.

Security and protection of student work is perhaps the greatest detraction away from web-based e-
portfolios. Banner ad content on free web services is often inappropriate in the k-12 environment. Furthermore,
students’ work is in no way protected. Pages on free webspace providers often contradict acceptable use
policies of school districts where linking to external servers is disallowed. Additionally, viewing many websites
that are published on free services are blocked by proxy servers and firewalls on the school’s Intranet.

A more convenient way to publish HTML based portfolios is on a Compact Disk - Read Only Memory
(CDROM). Traditionally some educators have avoided authoring CDROM portfolios with their students
because of expenses and problems that have been associated with them (Aschermann 1999: Jackson 1997).
Jackson (1997) has discussed the limitations of creating e-portfolios on CDROM, these problems included how
many copies of the CD to create, how would the CD be updated outside of the school environment, how would
the CD be kept compatible across all computing platforms and where would students and schools find the
expensive equipment needed to master CDROMs.

**CDROM Portfolios**

The CDROM presents an important element in electronic portfolio creation for a number of reasons. In
one sense, there is the practical reason and the other is the cognitive interactions which CDROM portfolios
genner. Practically, CDROM portfolios: Are lightweight and small; are portable – can be viewed where no
Internet connection is present; allow for easy updating; are physical, sophisticated example of student work;
allow for quick and easy organization, indexing and searching. Additionally, CDROM portfolios are not easily
limited by external factors such as the deficit of an Internet connection, slow modems, or slow network
connections they allow student work to be protected and their privacy maintained. Furthermore, they allow for
expansion over time and grade levels; they allow for storing large files and data types of students work.

On the cognitive plane authors such as Fischer, (as cited in Chappell and Schermernhorn, 1999) has
noted that the move from a paper based to hypertext portfolios (on CDROM or on the web) affect student
thought processes. They confer that hypertext encourages “multifarious ways of thinking” in juxtaposition to
linear thought processes involved in creating paper-based ring binder portfolios. In this context, therefore
electronic portfolios allow students to: engage in more interactive problem solving skills; engage in deeper
logic order and sequential thinking; engage in project planning and implementation; engage in applying
cognitive theories of thinking and learning.

One important advantage of CDROM portfolios is their size. Most CDROM disks have a 700MB
capacity the equivalent of nearly 500 high-density floppy disks or 300,000 typed pages; it therefore means that
students can store a large amount of data on a CDROM disk. Web published portfolios however are often
restricted by server space due to high volume use.
Problems with creating CDROM portfolios

CDROM portfolios have however been criticized for a number of reasons. Some educators have argued against CDROM portfolios because of the cost of the hardware and software tools that are needed for the creation of CDROM portfolios (Barrett 1994). However from the authors' perspective at this point in time the cost of CDROM Drives and CDR/CDRW media disks have been significantly lowered. This occurrence has provided the opportunity for educational institutions to acquire these tools at a more reasonable cost. Furthermore, CDRW drives have become standard on most personal computers for sale in the open market. It therefore behooves us as educators to tap into the proliferation of these devices by having our students learn effective ways to use them in accomplishing their learning goals.

Others have argued that electronic CDROM portfolios do not allow for easy updating compared to web-based portfolios. We argue however that the methods that we have employed to create CDROM portfolios in fact lend themselves to easy updating and easy learning for students and teachers alike. Another criticism of CDROM portfolios is that they are not portable across different personal computing platforms because of incompatible disk formats.

Hardware considerations

Within a few years CDROM drives have moved from a luxurious accessory to an inexpensive necessity on personal computers. Today Compact Disk Rewriteable (CD-RW) drives are now standard on most windows PCs. CDRW disks and CD-Recordable (CD-R) disks are easily available in most stores (for cost estimate see table 1). In an educational context CD-R media is preferable because of their low cost. It however means that there needs to be a CDROM creation process that is error free, or at least where errors are kept at a minimum. The process we will outline will eliminate, or at least offset many of the technical problems associated with creating CDROM portfolios.

Software Considerations

The most critical component of CDROM creation is appropriate software. As educators we are interested in software that is intuitive, easy to learn and easy to share with our students in restrictive periods of time. In the world of CDROM creation there are two basic types of software, the proprietary kind that ships with the CDROM burner from the manufacturer and retail software that can be purchased, separately from the device. We suggest purchasing Adaptec’s Easy CD Creator deluxe 4. Portions of this software often ships with some CDROM burners; these versions will also work for our purposes. The retail version sells in stores or on Adaptec’s website for $79.00.
In CDROM creation software conflicts are usually responsible for a large number of errors. Software manufacturers usually advise that only the CDROM creation software run at each burn. This can sometimes be inconvenient. We have found too that badly fragmented Harddrives, anti virus software and other software applications also cause the CD creation process to often result in errors. The process that we are outlining below can be accomplished even when other applications are running on your computer.

Creating a universal portfolio – the process

In creating CDROM portfolios the authors have found that all errors are reduced when the artifacts for the portfolio are organized for presentation, mastered as an ISO 9660 or CD image and the image is then burnt to the CDR media. The ISO 9660 file system is a standard CD Rom system authorized by the International Standards Organization (ISO), that allows you to read the same CD-ROM whether you are on a PC, Mac, or other major computer platform. Almost all computers with CD-ROM drives can read files from an ISO 9660 file system (Apple Development Connection 1998).

Making a CD IMAGE

Creating a CD image or ISO 9660 reduces error considerably. Also this approach allows for faster creation of a CDROM portfolio since burning the image to disk is faster than organizing, assembling and burning the files through the CDR software. To make a cd image we use a demo version of CDEveryWhere. CDEveryWhere allows the creation of a CDROM image that is portable across the popular pc computing platforms i.e. Macintosh, Windows and Linux. The program can be downloaded from (http://www.cdeverywhere.com). The version that we use allows for the creation of an image that is 50MB in size the paid version costs $39.95 and allows for a full CD image of 700 MB to be created.

Using CDEveryWhere

After the opening splash screen and the end user license agreement (EULA), the demo version of CDEveryWhere v.1 asks the user to agree to register, if you select register later the opening screen appears. To create an ISO9660 image you must first select the files. Under the source window navigate to the disk that has the portfolio artifacts that have been organized. In our case it is the folder called portfolio that has been selected.

Figure 1: You can navigate to your gathered artifacts in the source window of CDEveryWhere's interface.
The contents of the portfolio folder are then dragged from the Name window into the all platforms tab below.
Please note that if All Platforms is not selected the CDROM will only work on the platform that is selected. We can now create the ISO 9660 or CD image by clicking on the Create CD image file icon as indicated below.

A dialog box asking for a save location appears.  
Select a save location  
Give the image a name.  
Select Create

![Figure 2: Click on the Create CD image button to begin the creation process.](image)

The program then goes through the process of creating the image. A green checkmark indicates the completion of each step in the process. A red arrow indicates that the program is still completing a step.  
When the process is complete, all steps have a green checkmark.  
You then select the Close button.  
When this step is complete the CDROM image is ready to be burnt to a CDRW or Recordable.

Using Adaptec Easy CD Creator. To burn the image to CDROM simply place a cdr or cdrw into your CD
Burner.  
Open Adaptec Easy CD Creator  
The opening screen appears

![Figure 3: The opening screen of Easy CD Creator.](image)

From the file menu choose Create CD from CD Image. The following dialog box appears. Browse to the CD
image that was created. Make sure that the Files of type dialog box is set to ISO image files.
Select Open
The CD Creation Setup dialog box appears.
Leave the settings as they are:
Click on the OK button
The CD Creation Process dialog box appears:
The program then goes through the steps of burning the CD image to the Recordable disk.
When the steps are complete, the Recording Phase indicator goes to 100% and a successful completion message appears. Students could go ahead and end the process by Clicking on the OK button.

Updating the CDROM

A CDROM created in this fashion is easily corrected and updated. The process is simply to edit the artifact of choice, recreate the CD image and then burn the corrected CD image to a new cdr disk. Educators are encouraged to use CDROM based electronic portfolios because they ensure that students’ work will be protected and the privacy of students are safeguarded. In the school, environment CDROM portfolios discourage students from the desire to view external content, some of which may be deemed inappropriate by the school’s authorities.

Online Portfolios for Educational Technology Graduate Students:  
An Ongoing Capstone Project

Jennifer L.V. Sparrow  
College of Education

Abstract: This paper describes online portfolios employed as an alternative to comprehensive final exams for a distance-learning M.Ed./M.A. program at Florida Gulf Coast University. The paper addresses the issues that contributed to the creation of online portfolios. The benefits of portfolio assessment are compared to traditional comprehensive exams. The paper discusses why online portfolios were an attractive option for distance learning students. Additional information is given to demonstrate the development and implementation of online portfolios at Florida Gulf Coast University. The paper describes the computer resources available to distance learning students. The benefits and drawbacks of online portfolios are examined.

Introduction

Florida Gulf Coast University, founded in 1991, is the tenth institution in the Florida State University System. The approximate enrollment is 2,700 with a faculty and staff of 500. The campus is located in Southwest Florida on 760 acres of land. The mission statement of the University encourages the use of distance learning, and the University’s Strategic Plan states that FGCU will develop 25% of its enrollment using distance learning.

The Master’s Degree in Curriculum and Instruction, with a concentration in Educational Technology, is offered entirely online through the College of Education. Students enrolled in the distance-learning program are located around the world. Travel to FGCU is not required and often cost prohibitive for many students. Due to the distinctive nature of the program, faculty and students examined alternatives to the oral or written comprehensive exam traditionally administered at the culmination of graduate work.

Portfolio assessment was an attractive alternative for evaluating student performance. Shannon and Boll (1996) demonstrated that increasing numbers of teacher education programs are using portfolios to document preservice teachers’ experiences and attainment of competencies. The traditional portfolio, of maintaining and presenting information in a hard-copy format, yielded problems in the distance-learning program. Students would have to absorb the cost of shipping the final product to faculty. There could be delays in delivery of the materials. If professors recommended changes in the portfolios, the process of shipping and receiving would have to be repeated, creating more delays.

The development of an online portfolio solved many of these problems. Students were authentically assessed on their learning, shipping and response delays were eliminated, and faculty and students had instant, continuous, and free access to the portfolios. Since the degree had a concentration in Educational Technology, the actual development and maintenance of the online portfolios were a demonstration of student knowledge and ability.

What are Portfolios and Why Use Them?

According to Collins (1990), portfolios consisted of real-world performance products that could be used to assess students. Portfolio assessment is an authentic way to measure student knowledge. The portfolio
is a collection of student work that demonstrates knowledge and skills gained throughout the program. Portfolios have included student papers, video tapes of the students' applying skills and knowledge, photographs of works completed, floppy disks containing copies of computer-based work, learning logs, and other items that students felt adequately represented the knowledge gained throughout the program. Portfolios have gained support in the educational community during the past decade (Koretz, 1998).

State requirements for successful completion of a Master's Degree in Florida include comprehensive written or oral examinations or a capstone project. To meet state graduation requirements, the portfolios would have to act as an equal alternative to comprehensive examinations. These exams traditionally measured students' abilities to synthesize and apply the knowledge they had gained in their coursework. Meadows and Dyal (1998) concluded that the traditional comprehensive exams provide only a cursory glimpse of the students' knowledge and do not adequately address the students' skills and practical experiences. Jonassen (1996) argued that examinations are stressful for the student and make the evaluation process artificial by limiting the supports and resources of real-life situations.

Students in the program expressed a desire to prepare a professional portfolio to more accurately demonstrate the knowledge attained during the program. To be an adequate substitute for the comprehensive exam, the portfolios needed to show students' application of skills and knowledge, as well as their synthesis of major themes of the Master's Degree. Barton and Collins (1993) stated that a portfolio not only allows students to take ownership of learning, but also provides them with the opportunity to demonstrate their ability to address the professional duties and experiences they will encounter. Additionally the experience of developing a portfolio will give educators practice in portfolio development to allow them to model the skills and knowledge to students they will be teaching. Barton and Collins (1993) argued that the implementation of portfolios shifts the entire educational process from a teacher as giver of knowledge to student as seeker of knowledge.

Portfolios are being widely used in elementary and secondary schools as an authentic assessment of student learning. Additionally, many school districts are requiring teachers to create annual portfolios to demonstrate professional development. The use of portfolio assessment at the graduate level seemed a logical progression of what research has proven to be good practice at other levels. As students and faculty discussed the portfolio project, a diverse understanding of portfolios became apparent. Students and faculty viewed portfolios as works in progress, showcase pieces, and as resumes or curriculum vitae. Danielson and Abrutyn (1997) described many different types of portfolios, including assessment, best works, employment, and admissions. Faculty concluded that portfolios could be developed to address all the needs of the students and still meet state requirements for graduation. Faculty and students agreed that the portfolio project would need to demonstrate their pedagogical knowledge as well as their technology skills. Students in the Educational Technology program would have taken many of their courses in computer applications and implementation. These types of projects would need to be included in a portfolio demonstrating the students' knowledge. The collection of work in the students' portfolios would serve as a representation of their knowledge, and as a resume for future professional endeavors.

**Developing Portfolios Online**

A shift away from the learning process as an accumulation of knowledge toward learning as the application of skills has increased the acceptance of portfolio assessment (Simonson, Smaldino, Albright, & Zvacek, 2000). The traditional portfolio format consisted of collecting and maintaining artifacts that demonstrated student knowledge and its application and synthesis in real-life situations. The artifacts could include papers, pictures of projects implemented, floppy disks of computer-based work, video tapes of the actual application of knowledge and skills, learning logs, and any other media that represented student growth (Jonassen, 1996).

Students enrolled in the Educational Technology Online (ETOL) program completed both educational foundations and computer courses. Students were required to write papers, explore various software packages, learn a programming language, and work with computer hardware. Included in a traditional portfolio would be hard copies of the papers, printouts of software as applied to the classroom, floppy disks of programs written, and pictures or videos of work with computer hardware.
Obviously, work from twelve courses could amount to a large collection of artifacts. Traditionally, the portfolio would be contained in a binder, file box, or other storage method conducive to logical organization. There were several drawbacks to this traditional format that did not meet the needs of the distance-learning students. The first issue was that students would have to incur the cost of shipping the completed work to FGCU near the completion of their coursework. Additionally, shipping can be time-consuming and the portfolio could be lost in the process. Once faculty received the portfolios, suggestions and comments could be emailed, but students may wish to recompile the artifacts in their portfolios. This process would involve the shipping the portfolio twice, increasing the costs and likelihood that materials could be damaged or lost in the process. Unless students were to ship their portfolios throughout their program, faculty would not have an ongoing assessment of student growth.

The M.Ed. has a concentration in Educational Technology. It was assumed that students would have the ability to create an electronic version of the portfolio. Other universities have employed CD-ROM's as the storage device for the portfolio (Li, 1999). In addition to CD-ROM's, Zip disks allow students to compile large amounts of information in a single location. The traditional artifacts could easily be formatted to be included on the CD or the Zip disk. Papers, learning logs, and digital pictures could be saved directly to the disk from the word processing software. Regular pictures could be scanned and included on the disk. Computer-based work, including computer programs written, would easily be saved in this manner as well. However, CD's and Zip disks still have to be shipped to faculty for evaluation. While shipping cost would be greatly reduced, feedback could be slow and students would need to resubmit the disk if any changes were made. Faculty would also not have continuous access to the portfolio to assess student growth. Additionally, students would need to ensure that the electronic information they had submitted was in a format that the faculty would be able to view on the university’s computers. Students would need to save the artifacts in a format that is compatible with the faculty’s software.

The logical step beyond the electronic portfolio was to implement an online portfolio. There are many advantages to this format with few disadvantages for the students. First, free web space is provided by the university for the duration of the student’s enrollment. This eliminates the need for student’s to purchase a CD burner or a Zip drive. Students have unlimited space and access to their website. They can update the portfolio at a time that is convenient for them. When students are ready to have faculty evaluate their websites, they simply email the URL to the professor. The professors can immediately examine and evaluate the portfolio. If feedback is given, the professor simply emails the student the comments. The need to ship disks or a completed portfolio is eliminated. The online portfolio is in HTML format, which eliminates the need for students to buy the same software as the university. HTML is the language of the Internet that can be read by any computer that has an Internet browser. Additionally, if students wish to share their portfolios with other students or faculty, they simply give them the URL of the web page. With permission, faculty can use the completed portfolios as models for new students and as a marketing tool for the ETOL program.

The drawbacks to online portfolios are mainly focused on student knowledge of web page design. If students had never designed a web page, the learning curve for beginning the page could be steep. However, one of the students’ courses teaches web page design. Students use the latest web authoring software to make content-based web pages that will be implemented in their classrooms. This knowledge can be applied to the development of the online portfolio. Another drawback is that students would need to have access to either a digital camera or digital video camera, or have access to equipment such as scanners that convert traditional media to a digital format. This is necessary to make pictures and videos available through the Internet.

**FGCU's Online Portfolio Process**

The online Master's Degree offered at Florida Gulf Coast University presented a unique situation for students completing the program. The state mandates that students must pass comprehensive examinations or present a capstone project for successful completion of the degree. Students in the online program were located around the world and travel to the university was often time and cost prohibitive. As an alternative to comprehensive exams, the ETOL program implemented a policy requiring students to complete an online portfolio. In implementing this requirement, the faculty and students addressed several issues pertaining to the development of online portfolios.
Barry and Shannon (1997) recommend six strategies for successful portfolio implementation including, early communication of expectations, limiting the number of components, establishing criteria, teaching self-reflection and self-evaluation, providing adequate time for development, and providing training on the development. FGCU's portfolio implementation process closely followed these recommendations. Student input was a critical factor in the success of the online portfolios.

The first step in implementation included a discussion with the students currently enrolled in the program. Students and faculty recognized the potential of the online portfolios in addressing the desires of the faculty for a more authentic assessment of the students' learning. Students raised concerns regarding their ability to design a website that would adhere to the standards of quality web publishing. Jonassen (1996) recommended developing a rubric that clearly states the desired outcomes of the portfolio. Students created a rubric based on HTML style guides, examination of existing web sites, and the need to present their knowledge in a portfolio-type web page. The rubric was a clear and early communication of the expectations for the online portfolio. The rubrics outlined criteria for content, navigation issues, and models of acceptable web site design.

In their websites, students were encouraged to compose a simple first page that gave personal and academic information. This introductory web page would contain links to pages for each of the student’s courses. Each course page would contain material that students completed throughout the course, or projects that were a result of learning in that course. This provided a simple template for the web site layout. Students were offered flexibility and creativity in the remainder of the web site. Students could choose whatever work they felt best represented their knowledge. This allowed for self-reflection and self-evaluation of the work to be included on the web site. Additional self-reflection will occur as the students maintain the portfolio and communicate with faculty. Students were encouraged to use the rubric to self-assess their web site throughout its development. This was an excellent tool in guiding students in the creation a professional web site.

Information on the portfolio requirement is provided to students when they begin the program. This allows the student several semesters to compile the portfolio material and design the web site. A course in web page design is included in the ETOL program. This course included learning the most recent web page design software. This would allow students to gain the knowledge necessary to complete the online portfolio. Students were taught how to use FTP software to transfer their files to the university’s server. Faculty taught students how to create subdirectories to organize their website and allow for other websites on the university-provided web space. Students were required to begin their portfolios in this course. Several other courses required students to update the portfolio and provide a log of the updates to the professor.

Students in the ETOL program were encouraged to share their portfolios with classmates. Faculty could use specific examples of student work to exemplify best practices. Students included digital video, pictures, papers, projects, and computer programs in their online portfolios. Student feedback indicated that the initial planning and development of the online portfolio was time intensive. Students felt that they had put a great deal of thought and planning into the development of the general outline of the web site. In most cases the extensive planning paid off, as students were able to easily and quickly update their portfolios as they completed projects in their courses. Students appreciated the authentic nature of portfolio assessment to the traditional comprehensive examinations.

Another benefit of the online portfolio is that students were essentially guaranteed a back-up copy of their portfolio. As students composed their portfolios on their home computers, they would be saving the web site on their hard drive. As students uploaded their website to the university’s server, that created an additional copy of the portfolio. The university’s server is backed up nightly, so any catastrophic losses would only be information uploaded in the previous 24 hours. This gave students the assurance that they would have a copy of their portfolios in two places if computer failure caused the loss of files on either end.

Faculty response to the online portfolios was equally positive. They appreciated the fact that they could check student progress in all of their courses throughout the student’s enrollment. Faculty could make suggestions for improvement at any time to help guide students in a direction acceptable at the Master’s Degree level. Faculty shared the online portfolios with prospective students and with other faculty at the university.
Conclusion

As distance learning opportunities expand, faculty and students need to address and adapt to the changing educational environment. Students enrolled in a degree program that is offered entirely online encounter a unique situation for assessment of learning. They may never step foot on the campus, some not even for graduation. This circumstance led faculty at FGCU to explore options to the traditional comprehensive examinations administered at the culmination of graduate work. Research supports the use of portfolios as an authentic assessment of student knowledge and skills. Many researchers prefer the real-life application of the portfolio as opposed to artificial nature of comprehensive examinations.

Faculty and students in the Educational Technology program agreed that an electronic portfolio would best represent their educational and technology knowledge gained throughout the program. Students were relieved of the pressures of comprehensive examinations. The online format allowed students to continually update and revise their portfolios. Faculty could monitor student progress and provide feedback throughout the program. Students and faculty communicated about the portfolios using email, chat rooms, and the telephone.

The initial learning curve of web page design and uploading the site to the remote server was addressed in one of the required courses. Faculty required portfolio updates throughout much of the coursework, preventing students from procrastinating on the project until their final semester. Students were able to self-assess their work through the use of the portfolio web page design rubric. By choosing the material to be included in the portfolio, students were able to reflect on their learning and growth.

The online portfolios provided benefits in addition to an authentic, real-world assessment of student knowledge. Students used the portfolios as resumes when they began looking for technology jobs. The portfolios were an excellent demonstration of students' technology skills. They were easily accessible and simultaneously available through the Internet to many potential employers. Faculty used completed portfolios as models of best practices and to market the program to future students. These professional and impressive web sites are an excellent selling point, demonstrating the technology skills that students mastered upon completion of the program. The ETOL program at FGCU will continue to employ the online portfolios as a reliable and valid measure of student knowledge and skills.

Abstract: This paper outlines the process for preservice students within Idaho State University's College of Education to meet mandated technology certification requirements. The College of Education has created a portfolio assessment process as a method for fulfilling this requirement. The resultant Instructional Technology course (EDUC3111) is constructed around the portfolio process. Evidence comprising the portfolio include tool software integration, educational software evaluation, and foundational standards regarding adaptations for special needs, basic computer/technical concepts and operation, equitable, ethical and legal use of technology, and the application of technology into instructional planning and delivery.

During academic year 1999-2000, there were 291 preservice elementary teachers enrolled in the fall semester and 124 enrolled in the spring semester. Each student submitted an electronic portfolio for assessment by the ITPA (Idaho Technology Portfolio Assessment) assessors. The students, during the fall semester, had a 97.6% success rate, and those in the second (spring) semester, 95.2%.

Introduction

Portfolio assessment has been used from elementary through graduate educational environments. While standardized testing measures can provide a picture of a student on a particular day, at a particular time, portfolios offer the opportunity to capture the student over time. Since this type of authentic assessment is a collection of "purposeful" work (Gilman, Andrews, & Rafferty, 1995; Jardine, 1995; Benoit & Yang, 1996), the assessor can view a continuum of products reflected in the portfolio contents.

A number of researchers (Wesson & King, 1996; Rothman, 1996; Tierney, 1992) believe portfolios allow students to be active participants in their learning and growth, increase self-discovery, and aid in reflection about their accomplishments, and knowledge acquired. For preservice education majors, the opportunity to document the integration of technology into a variety of classroom settings and subject areas, allows the students to reflect on characteristics of the learner, the best use of technology to address unique learning styles, and the points at which these electronic teaching/learning aids should be employed.

This belief in the role of portfolio assessment, coupled with the need to provide technology certification for our undergraduate education students, resulted in the creation of an Instructional Technology course (EDUC311). During this course, students build portfolios, including two student work...
samples from their teaching experience in the corequisite course, Planning, Delivery, and Assessment (EDUC309), a required early field experience.

The Electronic Portfolio Development

Idaho's State Legislature has mandated the integration of technology into the PK-12 classrooms. In response to this, the Idaho State University College of Education created a portfolio assessment process for practicing, certificated personnel in the schools as well as preservice students within its teacher education program.

A group of practicing educators and College of Education faculty produced a rubric for assessment and then benchmarked this in anticipation of the first series of portfolios for review. The schools undertook the task of preparing their teachers through a series of portfolio development workshops. In addition, the College of Education's Technology Outreach Unit also trained teachers in various school districts in portfolio development.

The training and support provided for teachers in developing the portfolios was beneficial and led to a concentration on the use of portfolios to document preservice teacher integration of technology. In the beginning, the course was a required core class for all education majors. While this first effort was important, the connection to the student's field experience was missing. As a result, the College created a corequisite course with the portfolio class. When this occurred, there were changes in the undergraduate technology course to better address the needs of its new corequisite. The joining of the two courses also helped provide an experiential grounding for the contents of the electronic portfolio in that these activities would be tied to a formalized classroom setting.

EDUC311 (Instructional Technology) and its partner course, EDUC309 (Planning, Delivery and Assessment) have concentrated their efforts in supporting the students as they move toward their first field experience and the development of the electronic portfolio. Cooperating teacher classrooms for this "electronic" field experience are selected with two major factors in mind: Identification of master teachers who can model best practices in instructional delivery, and classrooms where technology is accessible either within the self-contained room or through outside resources, such as the library/media center and/or computer laboratory.

The Problem

The goal was to align EDUC311, Instructional Technology, with EDUC309, Planning, Delivery, and Assessment, to form a cohesive reinforcement of practices expected by third year education majors during their first field experience. From the EDUC311 course perspective, the goal was to merge technology integration methodology and experience into the student's early field experience of planning, delivery, and assessment of instruction. A secondary purpose was to supervise students in the creation of electronic portfolios that could be successfully assessed by the Idaho Technology Portfolio Assessment Panel.

Methodology

Even though Idaho State University has in place a prerequisite computer course that all students must take before granted admittance into the College of Education, students arrive in the EDUC311, Instructional Technology, class with gaps in their technology understanding and skills. They also have little concrete information relating to the alignment between the Instructional Technology class and their EDUC309 corequisite. The first few class sessions, then, demonstrate what a technology portfolio is — the contents, the template used, the flexibility built into it— followed by a correlation between the two corequisite classes (EDUC311 and EDUC309). Students are also provided copies of the Idaho Technology Portfolio Guidelines.

The assessment process used by ITPA (Idaho Technology Portfolio Assessment) in evaluating certificated educators and preservice candidates is also the same. It is important to let the EDUC311 students know they will be judged equally with their cooperating teachers and other professionals in the field. Doing this reinforces the "fairness" of the assessment process and helps them see themselves as beginning professionals.
The Instructional Technology course is constructed around the integration of tool software, educational software, and ISTE (International Society of Technology in Education) foundational standards regarding adaptations for special needs, basic computer and technical concepts and operation, equitable, ethical and legal use of technology, and the application of technology into instruction.

Students enrolled in the EDUC311 course are provided a template for their electronic portfolio (see Figure 1). This is a Web-based umbrella with the various forms (cover sheet, release affidavit, student permission form, matrix of standards, software evaluation form, and troubleshooting affidavit) created and ready for student information and completion, as well as a series of menus and submenus and hyperlinks.

![Electronic Portfolio Main Menu](image)

**Figure 1:** These are the major elements contained within the electronic portfolio. All items shown are templates already created and ready for the students to individualize as appropriate for their portfolio contents.

The bulk of the Instructional Technology course is centered on learning integration tactics for technology within the lessons they are developing in the EDUC309, Planning, Delivery, and Assessment, class. Students are asked to identify their instructional setting for EDUC309 placement — student demographics and profiles, subject area to be taught, grade level, access to technology in support of their teaching, etc. Once this is established, all the student’s activities within EDUC311 are created through this focus. Thus, the degree and type of integration activities, the adaptations for students with special needs (e.g., physical, cognitive, and behavioral), equitable access to technology for all targeted students, and methods for outreach to families are dictated by their information about the cooperating teacher’s classroom.

There are eight required entries in the Electronic Portfolio (see Figure 2): Evidence of tool integration in word processing, databases, spreadsheets, electronic presentations, telecommunications, software evaluation techniques, troubleshooting, and technology integrated student work samples to support student-centered teaching approaches. Entries 1 through 6 require learning activity plans to support the integration strategies. As much as possible, it is expected that the integration activities will be student centered.

**Figure 2:** This is an example of the Portfolio Entries Menu where the learning activity plans and evidence of products are placed.
Within the learning activity plans, evidence must be shown for adaptations, outreach to families, and clear assessment plans paired with the listed achievement targets. Any products (e.g., spreadsheets, charts, databases, handouts, scoring rubrics, etc.) must be included with the learning activity plans. Figure 3 presents an example of a submenu. This student included an example of a product (spreadsheet chart example) that directly relates to the learning activity plan. The other item, Gradebook, demonstrates the use of a spreadsheet for management in teaching.

Spreadsheet Submenu

1. Gradebook
2. Spreadsheet example
3. Spreadsheet Lesson Plan

Return to Entries Menu

Figure 3: Example submenu for Entry 3, Spreadsheets.

Students are also required to embed appropriate hypertext links for navigational purposes. In the example in Figure 3, Gradebook, Spreadsheet example, and Spreadsheet Lesson Plan are hypertext links and will lead the assessor to the pages in the portfolio pertaining to each. There is also a hypertext link for returning to the Entries Menu. To further support navigational ease, links are embedded into each of the item (Gradebook, Spreadsheet example, Spreadsheet Lesson Plan) pages for returning to this submenu.

Navigational ease is important for the student, as well as the individual perusing the portfolio. Links and overall structure of the electronic portfolio are considered in the evaluation of the portfolio in the EDUC311 class; however, ITPA (Idaho Technology Portfolio Assessment) assessors only consider the contents of the portfolio as it relates to evidence of expertise in technology integration within the teaching/learning environment. The assessment panel members consider the hypertext links as "conveniences" for them in examining the contents. Should links not work, the assessment members have access to the student's original files, which have been placed in appropriate folders within the electronic portfolio's file structure. Thus, in the worst case scenario, a student can still be successfully evaluated for their ability to use technology in learning activities through the original files.

Results

During the first year (AY 1999-2000) of the pairing of the two courses (EDUC311 and EDUC309), there were 291 preservice elementary teachers enrolled in the fall semester and 124 enrolled in the spring semester. Each of these students submitted their electronic portfolio for assessment by the ITPA (Idaho Technology Portfolio Assessment) assessors. The students, during the fall semester, had a 97.6% success rate, and those in the second (spring) semester, 95.2%. These percentages are significantly higher than inservice teacher populations assessed during the same time periods.

Furthermore, an examination of the technology integrated lessons created and taught by the spring semester students in their EDUC309 field experience displayed a measurable improvement from those submitted the first (fall) semester.

Discussion

The current status of the EDUC311, Instructional Technology, course is one of revision and growth. The alignment of the two corequisite courses continues with plans for greater collaboration and coordination among all instructors for the two offerings. However, even at this early stage of the development process, it appears the process of developing learning activity plans that include technology integration, coupled with the requirement for a minimum of two lessons being taught during the early field
experience, has resulted in a heightened awareness of technology in education. Students are also learning ways to adapt to accommodate the use of technology in instruction.

The College of Education is also embarking on a path of portfolio development beyond that included in EDUC311. Students will be encouraged to develop an “entrance” portfolio, consisting of lower level entries, such as philosophy of teaching, diversity statements, and beginning case studies. The EDUC311 entry will, of course, be the electronic portfolio of integrated lessons, software evaluation, and other elements required for State certification. Beyond this, plans are being made to expand the portfolio concept to include an “exit” section. This would allow students to document their student teaching internship experience, including adding or replacing lessons already created in the electronic portfolio entries, video teaching samples, and greater inclusion of student work and assessment techniques. Eventually, the College hopes to move toward a totally electronic portfolio presence, where students would receive help in placing their “entrance” entries into a digitized format, followed by a full technology assessment portfolio piece (the “development” portion of the educational experience), and, finally, the “exit” pieces gathered during student teaching. The direction for this development aid is not clear at this time. Possibilities include expanding the student teaching internship seminar course to include portfolio refinement, and/or workshops offered periodically throughout the student’s tenure within the College of Education. In either scenario, help would be provided for placing entries into the electronic portfolio, creating and editing images for placement (e.g., digital still and digital video camera material, as well as repurposing VHS video), and refinement of the portfolio to become a professional “snapshot” of the student’s capabilities.

Making the Case for Science Teacher Learning: An Analysis of Argument and Evidence in Electronic Portfolios

Carla Zembal-Saul
Tom Dana
Department of Curriculum & Instruction
The Pennsylvania State University
United States

Abstract: This interpretive case study explores the nature of prospective elementary teachers' evidence-based philosophy statements for science teaching and learning, as portrayed in web-based science teaching portfolios. Evidence-based philosophy statements are explicit articulations of beliefs related to learning and teaching science. The 32 participants authored the portfolios in a web-based environment, allowing them to connect claims in their philosophies with evidence from their work as teachers. In addition to the electronic portfolios, exit interview transcripts were inductively analyzed. Based on the data, the claims in the prospective elementary teachers' philosophies became more science-specific and learner-sensitive over time. Supporting evidence was increasingly drawn from classroom-based experiences, requiring connections among theory and practice. In addition, there was evidence that the technology facilitated substantive reflection by (a) providing a simple means of making explicit connections between evidence and claims; (b) allowing prospective teachers to express themselves creatively without diminishing an emphasis on substance; and (c) providing a means of saving multiple versions (track changes over time).

Underpinnings, Objectives and Significance

Research on teacher development suggests that opportunities to reflect critically on practice can play an important role in learning to teach (Abell and Bryan, 1997; Glickman, 1990; LaBoskey, 1994; Russell and Munby, 1992). Teachers typically do not characterize their work as having a theoretical basis (Sergiovanni & Starratt, 1993). Rather, teachers describe their practice, offer hunches about "what works," and generate principles about teaching and learning from their perceptions of effective practice. It is impossible to effectively engage in the act of teaching without a framework or educational platform (Walker, 1971) -- to guide learning and teaching decisions. Yet, for prospective teachers, the platform is often implicit and contains a web of beliefs, values and propositions that are not necessarily internally consistent.

There is a great deal of evidence that suggests it is difficult to move preservice teachers beyond focusing on surface level features of classroom instruction to more critically reflective practices that can illuminate and refine their platform for learning and teaching (Borko, Livingston, McCaleb and Mauro, 1988; Calderhead, 1989; Feiman-Nemser and Buchmann, 1987; Gore and Zeichner, 1991; Weinsteind, 1990). Calderhead (1989), for example, notes that student teachers have a tendency to avoid opportunities to reflect critically on their practice. He attributed this to several factors, including prospective teachers' emphasis on their own performance, their high level of ego, and their lack of analytical skills and language, all of which are necessary to evaluate their own teaching. Calderhead suggests that teacher educators provide scaffolded tasks of a nature and level such that prospective teachers can perform them, as well as learn from them.

Several teacher educators have proposed such approaches for assisting prospective teachers in critically analyzing and evaluating the teaching decisions they make (Abell and Bryan, 1997; Gore and Zeichner, 1991; Johnston, 1992; Zulich, Bean and Herrick, 1992). For instance, Gore and Zeichner (1991) attempted to use action research as a means of encouraging critical reflection among preservice teachers. Although their analysis of 18 student teacher action research projects indicated that this strategy has only limited success, the authors still support it as a way of structuring reflections. They assert that "it does not make much sense to seek to promote or assess reflective practice in general without establishing clear priorities for reflection." Others agree, pointing out that the key to success in terms of developing more critical reflective practice seems to rest in whether reflections are guided (Zulich et al., 1992).
Portfolios have gained fairly wide acceptance in teacher education in recent years. Dana and Tippins (1998) point out that the broad definition of portfolios in teacher education - a "collection of evidence" that demonstrates some aspect of teachers' knowledge, skills or dispositions - does not necessarily allow for opportunities to engage prospective teachers in meaningful reflection. For example, the following descriptions of teaching portfolios exemplify models that lack reflection: teaching portfolio as scrapbook, portfolio as overflowing container, and the extended resume (K. Wolf as cited in Dana and Tippins, 1998). Dana and Tippins go on to propose a model for science teaching portfolios that is firmly grounded in the literature on reflective practice and constructivism. They describe science teaching portfolios as "spaces where prospective teachers represent their unique constructions of what it means to teach science in ways which permit them to analyze, discuss and evaluate their own teaching practices and professional growth" (p.722).

Therefore, the research reported in this paper explores the nature of prospective elementary teachers' science teaching philosophies, as portrayed in web-based science teaching portfolios. More specifically, the research questions framing this study include: (1) How do prospective teachers describe and support their educational philosophies for science teaching and learning? and (2) What are the central claims of the philosophies and how do they relate to contemporary science education reform ideals?

Participants and Context

The electronic portfolios described in this study were developed by 32 prospective teachers as part of the course, Teaching Science in Elementary Schools. These prospective teachers were participating in an innovative, research-based, year-long internship program that is part of a professional development school partnership between the university and local school district. The course for which the portfolios were developed is one of four methods courses taken during the first half of the internship year. These courses are complemented by an intensive field experience.

Prospective teachers' web-based portfolios were developed throughout the course and included 2 main components: (1) a collection of evidence and (2) an evidence-based philosophy for science teaching and learning. All course assignments were submitted via web-based portfolios and included in the collection of evidence area. Three versions of the web-based philosophy for science teaching and learning were developed. The standard format for philosophy statements was a series of claims about science teaching and learning supported by multiple pieces of evidence (from collection of evidence). Each piece of evidence was then justified in light of the claim that was being made. Prospective teachers' initial versions were developed early in the course and revisited in light of new experiences and learning.

Research Methods

This interpretive case study of the nature of prospective elementary teachers' espoused science teaching philosophies, as portrayed in web-based science teaching portfolios, was done within the research traditions of phenomenological inquiry and grounded theory. Multiple data sources were employed to understand the nature of the espoused philosophies and to provide a way of triangulating findings across data types (Lincoln & Guba, 1985). The primary source of data was 32 prospective teachers' electronic portfolios. Three versions of each portfolio were collected across the semester. A secondary data source was transcripts of exit interviews with prospective teachers.

Inductive analysis was used to construct themes from the data set (Bogdan & Biklen, 1992; Merriam, 1988). All portfolios and transcripts were repeatedly examined to allow emergent patterns to surface (Lincoln & Guba, 1985). Multiple readings through the electronic portfolios and transcripts enabled the researchers to construct themes from the participants' words, which were recorded in margin notations (Miles & Huberman, 1994; Strauss & Corbin, 1990). A qualitative data analysis computer program facilitated the data reduction and analysis process. Developing assertions were tested by seeking both confirming and disconfirming evidence from the data set (Patton, 1990). Differences in the understandings of the researchers were resolved through negotiation until a point of consensus was reached.

Findings & Discussion
Early iterations of the prospective teachers' espoused philosophy statements were vague and not particular to science teaching and learning. Common claims included statements like, "Science learning should be engaging and enjoyable." Another common statement was, "Science learning should be hands-on." Evidence used to support these claims was primarily drawn from personal K-14 learning experiences. Other common sources of evidence included early course readings and learning experiences. Justification tended to be descriptive rather than evaluative. That is, few prospective teachers were able to provide rationales that demonstrated how specific evidence was used to support a particular claim.

Several improvements were noted in the second and third versions of prospective teachers' espoused philosophies. First, claims were more specific to science teaching and learning and reflected ideas consistent with contemporary reform in science education (NRC, 1996). For example, many prospective teachers identified the importance of having children design science investigations, collect data, and develop explanations grounded in those data. Second, a number of claims reflected cognitive considerations associated with learning for meaningful understanding. For example, claims of this type identified the importance of children's prior knowledge and alternative conceptions and the central role they play in developing appropriate and powerful learning opportunities.

Evidence for claims made in the later versions of the philosophies relied more heavily on field-based assignments. However, science-specific claims tended to receive support from learning activities used in the methods course. Finally, justification improved greatly in the later versions. With support and feedback from the course instructor and peers, prospective teachers were able to move beyond generating superficial connections to crafting more substantial relationships between evidence and claims.

During exit interviews, prospective teachers were asked to describe the "value-added" of developing web-based portfolios as opposed to more traditional paper portfolios. Most responded that their skills and confidence for using applications of technology had improved. They felt that this would make them more marketable as teachers. Some of the prospective teachers were able to articulate their ideas about "value-added" in terms of their own thinking and learning. These prospective teachers explained that creating an evidence-based philosophy supported them in making connections among course activities/readings and field-based experiences. The electronic format was described as helping them make explicit connections among claims and evidence easily. In addition, they acknowledged the value in being able to examine earlier versions of their philosophies and reflect on how their thinking had changed over time. Several commented that the electronic version allowed them to be creative and thoughtful without spending significant amounts of time on superficial "cutting and pasting" tasks.

In closing it is important to emphasize that the findings of this study are encouraging in light of the literature on prospective teachers' reflective practices. The findings suggest that developing several versions of an evidence-based philosophy statement may support prospective teachers in engaging in thoughtful reflection. More specifically, as prospective teachers are encouraged to re-evaluate their thinking in light of new experiences and learning, they are supported in making connections between theory and practice. In addition, there is evidence that the technology used facilitates substantive reflection by (a) providing a simple means of making explicit connections between evidence and claims; (b) allowing prospective teachers to express themselves creatively without diminishing an emphasis on substance; and (c) providing a means of saving multiple iterations that document changes over time. Given the important role of reflection in learning to teach, this study warrants additional research on the development electronic, evidence-based philosophies.
A Pilot Project: Integrating Multimedia Portfolio Development Into The Preservice Teacher Education at Randolph-Macon College

Zizi Zhang
Instructional Services Center
Randolph-Macon College
U.S.A.
z2zhang@rmc.edu

Abstract: Randolph-Macon College offers teacher education as a minor program. To fulfill the requirements for teacher education, and to comply with the state regulations, instructional technology has not been taught as a course. Instead, it is integrated into Foundations of Curriculum and Instruction, Educational Psychology, and the capstone course Senior Seminar. Although this method has been relatively successful, preservice teachers request more opportunities be provided for learning new technology skills and applying them to teaching and other professional use. Research findings indicate that creating multimedia portfolio greatly enriches preservice teachers' technology experience. In this pilot project, four volunteer preservice teachers learn and use various instructional technology skills for the development of their electronic portfolios. The results of the study will impact the redesign of the Education Senior Seminar course.

Preservice teachers must be prepared to apply various computer skills for teaching and information management. They are expected to use advanced technology for classroom instruction and presentation. It has become a trend to introduce preservice teachers to the development of multimedia and web sites (Read & Cafolla 1999).

The preservice teachers at Randolph-Macon College attend technology workshops as part of the requirements of the Education Minor program. They learn the basics of educational media and technology at the Foundations of Curriculum and Instruction course. For the Educational Psychology course, preservice teachers learn how to create spreadsheet and databases, and analyze the information for their research paper. They also evaluate computer-based instruction and the resources found on the World Wide Web. In their senior year, the preservice teachers attend the capstone course, Senior Seminar, of which one-third of the class-time is dedicated to incorporating technology into the development of an integrated instructional unit, and publishing the unit on the World Wide Web. The instructional unit will then be used for their student teaching.

Feedback on this technology training curriculum has been positive. The preservice teachers all agreed that the Senior Seminar technology module was especially helpful, where they are encouraged to learn new technology skills and use them in their lesson plans. They also commented that they would welcome more opportunities to create multimedia-assisted presentations, including electronic portfolios.

Portofolio development is a requirement for the Randolph-Macon College preservice teachers. They update their personal portfolios throughout their study in the program, and by the time of student teaching, make the portfolios available for prospective employers to review. The format of their portfolios has been mainly limited to print and artifacts.

The pilot project is intended to encourage preservice teachers to begin to learn and use the advanced instructional technology at an early stage at the teacher education program. The objectives are: first, to enrich the preservice teachers' experience with educational media and technology; secondly, to enhance their evaluation and presentation of their professional growth; thirdly, to assist the participating preservice teachers in the development of quality portfolios using multimedia and the World Wide Web (Milman 1999); fourthly, to investigate the process and effectiveness of multimedia portfolio development. And lastly, based on the
results of the pilot study, to evaluate the current curriculum of the capstone course and make possible changes to the Senior Seminar.

Four sophomore students from the Foundations class have volunteered to participate in the pilot project. At present they focus on studying portfolio models, and learning how to create quality sound and video recordings. They are also working on putting their philosophies for teaching and mini-lesson plans in PDF format and starting a Web site for the portfolio. They will videotape their final presentations for the course, and convert the videos to digital format. They will learn other advanced techniques as they progress with their study in the teacher education program. The techniques will include computer graphic processing, locating multimedia and web-based demonstration teaching materials, and creating digital sound and videos for the Web site.

For the on-going formative assessment of this pilot project, the student teachers keep journals of the development process, and monitor the time demanded for the project. The teacher educators help them examine the content of the portfolio. The instructional designer evaluates whether and how well the process promotes the student teachers' technology proficiency, and help to meet the Technology Standards for Instructional Personnel (1998). The instructional designer also identifies the costs and resource needed for the current project, and the financial implications of electronic portfolios development for all R-MC preservice teachers. The summative assessment will be conducted toward the end of the four preservice teachers' senior year. The participating student teachers will be interviewed. The process, the final products, and the participants' technology skills will be evaluated by the teacher educators, the cooperation teachers, the instructional designer, and possibly their prospective employers. The results of the assessment will be used for the redesign of the capstone course, Senior Seminar, at Randolph-Macon College.

References

As new communications technologies impact higher education, American education must be transformed to meet the needs of an emerging information society. Attaining this goal will require teachers who meet professional standards. Today’s society needs a workforce that can apply knowledge, reason analytically, and solve problems. The faculty must be trained to determine the most appropriate tools for design, support and delivery of courses. The challenge for continuing professional development and renewal to adapt to this changing environment has become critical. The adaptation of existing courses to implement new technologies requires faculty to use recently acquired knowledge and new skills. The standards for teachers supporting these new skills have been developed by the professional organizations governing accreditation in each academic field (NCATE, 2001).

Both the International Society for Technology in Education (ISTE) and the National Council for the Accreditation of Teacher Education (NCATE) have specified the technology skills that teachers are expected to have when they enter the teaching field. These organizational standards provide the foundation for the professional development programs designed for higher education faculty. ISTE suggests that teachers be able to meet these standards: apply tools for enhancing their own professional use and productivity, use technology in communicating, collaborating, conducting research and solving problems, promote legal and ethical use of technology, use technology to support their instruction, and plan the delivery of instructional activities that integrate technology (ISTE, 1998).

The papers included in this section address various approaches available to meet the professional development challenge of these new standards. The papers have been grouped into five areas: 1) Campus Models for Faculty Development, 2) Program Implementation Strategies and Technologies, 3) Online and Other Distance Education Initiatives in Staff Development, 4) Case Studies and Research in Faculty Development, and 5) Pre-Service and PreK-12 Initiatives in Professional Development.

Papers included in the Campus Models for Faculty Development section focus on the integration of education and technology. Since a critical part of training is to expose faculty to models of technology use for integration and application of today’s technology tools, the models presented in these papers are designed to prepare faculty for the transition from the traditional classroom to the technology rich environment supported by the ISTE and NCATE standards. Bohannon’s Course and Faculty Development at Florida Gulf Coast University is designed to promote and support the use of learning-centered teaching practices, the integration of technology into these teaching practices, and the removal of barriers to teaching innovation; thereby, promoting the successful delivery of distance learning. Burrows and Ford describe a faculty development model for the integration of education and technology for medical educators. The skills acquired by the Faculty of Medicine Group will be subsequently transferred to the broader faculty of the University of Manitoba Bannatyne Campus.

Ring and McCallister explore the similarities and differences between two individual technology faculty development programs that have been conducted within the College of Education at the University of Florida. Ziegler, Ziegler, and Burch discuss practical uses of classroom technology. They present a Technology Pyramid model that reviews
the practical application of multiple learning models and the coordination of technology with each learning model.

The second section of papers represents Program Implementation Strategies and Technologies. Successful traditional instructional and evaluative strategies need to be examined and, if necessary, altered to continue their positive effects with students participating in situations with new technologies. These papers highlight activities that are working in our educational system. Frantiska describes the design and development of a workshop to instruct educators on the creation of educational hypermedia via an integrated project. Using the project as the main teaching tool allows for the learning of new skills with immediate application to an end product. Funderburk and Schullo delineate the current best practices utilized for faculty training, support and professional development. The areas of technology review, training, and computing facilities are intertwined to provide the best possible computing environment in support of instruction and research. Gruber, Rees, and McCormick describe their ACTIVE – Authentic, Competency-based, Technology-enhanced, Integrated, Versatile, and Evaluative – curriculum which addresses the need to improve the preparation of preservice teachers by providing instruction that models the integration of technology into classroom delivery. Hofer discusses the grassroots technology staff development provided at the Teacher Technology Leadership Academy in the Archdiocese of Indianapolis. His model is an effective, train-the-trainer approach that provides research-based staff development in technology for classroom teachers. Poff highlights the evolution of a faculty and staff web development program. Stating that the key to successful implementation of such a program is to deliver the training in such a way as to make faculty want to participate in the training, to make the training relevant, and to encourage continual development once the training has been given. Articulating technology needs to administrators and policy makers is the main emphasis of the paper by Rakes and Rakes. They point out the continuing disconnect involving those who recognize the value and growing needs associated with innovation and administrators and policy makers. Staudt describes three Summer Technology Institutes that were conducted to help faculty develop their technology skills to aid in the improvement of their classroom teaching. The goal of these institutes was to produce quality teachers who are well versed in innovative instruction, skilled in technology usage, and prepared to serve the multicultural and diverse student populations of South Texas.

The third set of papers in this faculty development category centers around Online And Other Distance Education Initiatives. Teaching faculty to effectively communicate their ideas, information, course content, and activities through the Internet, video conferencing, and videotaping is vital in today's educational settings. The JASON Foundation for Education, as described by DeWall, supports a yearlong, multimedia, interdisciplinary program involving students and teachers in real-time science expeditions and interactive curricula linked to the national geography and science standards.

The Academy will offer online science content courses to middle level teaching beginning in Fall, 2001. Ekhaml and Russell provide online and print problem-based learning resources for college and university professors to incorporate PBL in their teaching units and to help students work on PBL assignments using these resources. Franklin and Blankson present the investigation of a cohort model in which faculty within a college work together to provide curriculum design and implementation support, online development expertise, shared technology skill improvement, and emotional support for the implementation of online courses. Maki presents the possibilities of videoconferencing in staff development and experiences that developed when teachers participated in interactive lessons instructed via ISDN-videoconference. Suggestions are made for the use of videoconferencing for in-service training and staff development. McVeary and Ehmann describe fundamental challenges that emerge for distance educators in online tutor training programs. Solutions to conquer these challenges are provided. Creating interactive instructional materials using Macromedia's Flash, an interactive session by Utendorfer, will provide the foundation for hands-on experience for educators. Examples of online web-based lessons created for faculty development workshops are described.

Section Four contains Case Studies and Research in Faculty Development. Chambers and Holbeach describe an Australian case study concerning the supporting and development of IT skills of the education faculty and staff. A range of models of professional development, including individual consultations, group workshops, and paid external training, was offered to participants to assist in developing IT skills. Dutt-Doner, Larson, and Broyles discuss the challenge of developing college wide technology standards. Their case study examines the growing pains of one university's College of Education in designing and implementing technology standards. Gold examines the pedagogical role of the teacher in online education specifically with the transition from traditional classroom instruction to online instruction. The paper focuses on the pedagogical training that an online instructor needs to become an effective teacher. Project New Delhi, a video voyage on the World Wide Web, is presented by Kilbane. This multimedia teaching case study challenges preservice and inservice teachers to learn more about issues and problems in American education by exposing them to case studies about India's educational system. Through the design of video and other materials in the instructional
environment, learners acquired new information and reconsider previous notions about education in this country and others. Chisholm and Wetzel explore the pedagogical beliefs of teacher educator who used technology in their teaching. The study used Smart Classrooms that mirrored the configuration found in many local schools where teachers have a limited number of computers. Schmertzing and Schmertzing present a study on the students’ expectations of distance educators and the instructor roles in an interactive televised classroom. This ethnographic study of graduate education students suggests that students assigned new responsibilities to the instructor and expected the instructor to bridge the distance gap between the classrooms, clarify new rules for classroom behavior, and maintain a focus on course content despite the added technology related duties of the instructor. Solberg presents several case studies concerned with organizational learning and the venue for institutional change with online technologies. She presents a model for linking individual change to organization change. Tucker, deMontes, Willis, and Blocher describe a study of faculty perceptions to the integration of systems thinking in the teacher preparation program at Northern Arizona University. The study reports on how open faculty would be to professional development designed to better prepare them to incorporate systems thinking into their teacher preparation courses. Varnak and Tozoglu investigate the idea that technology teacher training is the only solution to improve teachers’ performance in using technology in the classroom.

The last set of papers involves Pre-service and PreK-12 Initiatives. The technology environment that is developing throughout the world is causing an impact on the teaching and learning of the preservice and inservice elementary, middle, and high school teachers. Programs are being conducted to insure the professional development opportunities for these educators. Crawford and Edwards focus on the aspects of a nurturing, creative learning environment for preservice and inservice instructors, including instructional design models that promote self efficacy in technology integration, types of learning activities that work best with educators, and strategies to help implement technology integration and foster a sense of life-long learning. Giordano plans for sustained change by describing an instructional design model for teacher staff development to train teachers to integrate the Internet into their classroom routine. The paper describes the model, discusses the specific elements of the course design and its theoretical foundation, and offers examples of course elements to illustrate the pedagogy. Lundy, Sheldon, Rastauskas, and Woodell outline a framework for transforming technology integration with a public school system from isolated success stories to a district-wide movement. The program encourages educators to become leaders in their own development by taking advantage of outline resources that encourage mentoring and collaboration. Professorial change through technological collaboration is encouraged by the grant described by McGaughey, Radigan, Searle, and Smith. University professors model appropriate use of technology to help pre-service teachers acquire proficiency in the use of technology for curricular purposes. Polney, Squiciarini, and Walter document the key ideas and themes of a staff development trainer model and its applications and benefits with a school district, highlighting the administrative role of the model. Obstacles, challenges, and strengths of implementing technology into a school district are noted.

This collection of Faculty Development papers describe effective initiatives and innovative models that have been designed and conducted to improve the use and integration of technology at institutions of higher education and PreK-12 educational settings worldwide. Taken as a group, the methods and models provided will aid in the effective training of faculty and will address the critical need for continuing professional development and renewal to adapt to our changing technological environment.

Course and Faculty Development at Florida Gulf Coast University

Dr. Harriett G. Bohannon
Director Course and Faculty Development
Florida Gulf Coast University
United States
hbohanno@fgcu.edu

Abstract

The goal of Course and Faculty Development at Florida Gulf Coast University is to support the use of learning-centered teaching practices, integration of technology, and delivery of distance learning by removing barriers. As one of three interdependent support units, Course and faculty development has contributed to the university-wide support system that allows faculty to achieve these goals. This model of faculty development uses ten distinct service strategies to accommodate the needs of a diverse, multicultural faculty. Having ten ways to access support allows faculty to engage in

As a result, during the first three years of operation 71% of the full-time faculty participated in one or more faculty development projects or activities, and 24% participated in six or more. The staff has contributed to the design of 113 web-based or web-enhanced courses, and over 65% of the full-time faculty report that they use the key technology tools for teaching and learning.

Description

In the fall of 1997, Florida Gulf Coast University (FGCU) was born into the technology revolution that has been transforming higher education in this country and abroad. As a new undergraduate teaching institution in the Florida State University System its mission stated that teaching and learning would be characterized by 1) the use of learning-centered teaching practices, 2) the integration of instructional technology, and 3) the delivery of twenty-five percent of its courses through distance learning. These instructional strategies represented a significant departure from traditional teaching practices, but were necessary if FGCU were going to enhance and expand learning opportunities for a burgeoning population of traditional and non-traditional students in Southwest Florida and beyond (Appendix A).

In response to this challenge, the University established the Office of Instructional Technology (IT), a faculty support system. The organizational structure of the Division of Instructional Technology was guided by the premise that the primary barriers to using technology for teaching and learning must be mitigated by a comprehensive faculty support and development system. Toward this end three interdependent units were established: Technology User Support, Multimedia Design Services, and Course and Faculty Development Services. This structure supports a faculty development initiative that is part of a university-wide system of high expectations, state-of-the-art infrastructure, college/university incentives, and comprehensive support services for students, faculty, and staff.

The faculty development program is based on the belief that the majority of faculty members are not reluctant to explore teaching innovations, as the conventional wisdom suggests, but that there are barriers that prevent their best efforts to do so. We believe that systemic barriers demand a systemic solution. Therefore, it is necessary to describe the faculty development program at FGCU in the broader context of Instructional Technology. The interdependencies among Technology User Support, Multimedia Development Services, and Course and Faculty Development Services create an instructional environment where it is possible to achieve
the goals of excellence in undergraduate teaching, and many faculty members report that doing so has been one of the most satisfying experiences of their careers.

Faculty development, as traditionally defined, is essential, but insufficient, as an intervention to meet the goals set forth in our mission. A faculty member with highly developed technical and pedagogical skill cannot deploy a brilliantly designed course if there is no equipment available, if he/she must spend hours each week providing technical as well as academic support to students, if there is no incentive in the personnel review process to acknowledge teaching innovation, and no alignment with institutional priorities. Therefore, "faculty development" has come to mean many things at FGCU. It means the traditional activities such as the skill development workshops, presentations by outside experts, and discussion seminars which are common on most campuses, but it also means individual consultations to solve an instructional problem, collaboration with an instructional design team to create or redesign a course, participation in a formative classroom peer coaching program, taking a self-paced software tutorial online, or requesting a house call. Each of these services promotes the faculty development agenda at FGCU while simultaneously removing barriers that hinder faculty progress. (Appendix B)

The first barrier to using technology is the difficulty of acquiring necessary classroom equipment. This barrier has been addressed at FGCU by equipping all classrooms with electronic teaching podiums that include a computer, document camera, VCR, ceiling-mounted color projector, speakers, jacks for peripheral equipment, telephone, and a control panel that allows faculty to move seamlessly from one form of media to another during the course of a class. When classroom activities are designed using audio, video and multimedia, the faculty members know that the equipment necessary to use those materials will be waiting for them. They also know that a phone call to tech support will have a staff member in the classroom within minutes if some part of that equipment malfunctions.

The second barrier to the use of technology is the need for a faculty member to master many specialized skill sets. These skill sets include knowledge of current instructional technology, application of instructional design theories, programming, multimedia development techniques, graphic design, and web development. This barrier has been addressed at FGCU by providing a staff of instructional designers, programmers, multimedia developers, graphic artists, and web developers who are members of ad hoc development teams that work with faculty in designing and implementing their course development projects. As subject matter experts on these teams faculty members not only produce technology-enhanced courses, but learn to be independent managers of those courses in the process. When faculty members engage in a course development project, they are simultaneously producing a new or redesigned course while learning about the pedagogy and uses of technology that are then incorporated in their course designs. The development team continues the consultation and coaching support for faculty until their services are no longer needed, and the faculty member has become an independent manager of the new course.

The third technology user barrier is "being new on campus". The first months of any job involve discovering "how things get done around here", but new faculty at FGCU must master a long list of digital tools in order to teach in classrooms and even to communicate. Easy and swift access to technology support services is provided by IT staff who serve as liaisons to new faculty, conducting personal conferences to discuss problems and to make connections with the appropriate services on campus to meet immediate teaching needs. This service complements the two days of group technology and pedagogy training that are offered as part of orientation sessions.

The fourth barrier to instructional innovation is the problem of limited time, schedule inflexibility, and learning style preferences. The Course and Faculty Development unit recognized that reliance on group training was insufficient to meet the needs of the diverse faculty in the five colleges at FGCU. The 187 full-time teaching faculty members represent the broadest spectrum of technological skill levels, knowledge of learning theory, and experience in technology integration and distance learning. Therefore, 10 strategies have been adopted for providing faculty development support to accommodate the time constraints and to match faculty with development opportunities that capitalize on their diverse learning styles. The ten strategies are organized in three categories: 1) Group Strategies - skill development workshops, topic centered study groups, faculty led sharing seminars; 2) Individualized Strategies - course development teams, instructional design consultations,
house calls, peer coaching; and 3) Web-based Strategies - online tutorials, online faculty orientation (in development 2000-01), and user group facilitation

This means that a faculty member who wants to develop cooperative learning activities for a class could attend a 3-day workshop, or schedule a one-hour consultation with an instructional designer, or read the online articles, or enroll in an online instructor-led or self-paced tutorial, or lead a course development team in the design of cooperative learning activities, and/or participate in a peer coaching project to have a colleague observe and give feedback on use of a cooperative learning activity. This faculty development structure is intended to accommodate the diverse, multicultural characteristics of the faculty and provide a model of the many instructional options that help diverse learners succeed.

Once the organizational goals were established and the barriers were identified, a survey of the newly hired faculty was conducted to determine their needs. The Faculty Development Advisory Council was convened by the Director of Course and Faculty Development to review the survey results and refine the initial faculty development plan. The members of the council serve as liaisons between the colleges and IT, and participate in the annual planning process. The survey results indicated that there was a large core of faculty with a strong desire to achieve the goal of excellence in undergraduate teaching. Some members of the faculty came to FGCU expressly to focus on teaching and learning as they had been unable to do so in their former institutions where the pressure to publish and procure grants dominated their time. In addition, many students had come to FGCU to be part of this educational experiment and to learn in new ways. The natural synergy of desire and opportunity among faculty and students became the engine for innovation that the legislature envisioned, and resulted in a spirit of entrepreneurship that is seldom seen in bureaucratic organizations. Conversely, that same core of faculty had widely varying levels of technical skill, and ability to apply learning theories. This wide variation mandated that one size would definitely not fit all, but that the model for faculty development would have to be customized to accommodate the wide variety in faculty skill and background. This provided the opportunity to model the instructional principles we were promoting.

The Course and Faculty Development staff consists of a director, three instructional designers and a part-time student worker. The instructional designers serve as project managers of ad hoc course development teams, conduct group training, design online training, conduct consultations, evaluate software products, and produce instructional materials. These teams enlist the services of Media Development as needed. Last year IT merged with Broadcast Services to become a single organizational entity on campus. This relationship provides closer working relationships with WFGU-TV, the local Public Broadcasting System affiliate and WFGU-FM the National Public Radio station, which are both housed in the same facility as IT.

During the first three years of operation seventy-one percent (71%) of the full-time faculty participated in at least one course and faculty development activity or project. Twenty-four percent of the full-time faculty participated in six or more activities or projects. The instructional design staff has served as project managers and designers on 113 course development projects. Many of these courses have been developed for distance delivery, and others are campus-based courses that have technology-enhanced components.

After two years of operation FGCU completed a self-study in preparation for a visiting committee from the Southern Association of Colleges and Schools. The yearlong review of all campus operations involved over one hundred committee members and the collection of survey data from students, faculty, staff and community. Full accreditation was granted in May 1999, and the visiting committee included eight commendations, a record-setting number, in their report. Two of the eight commendations highlighted the effectiveness of the instructional technology support system.

"The committee commends the university for its provision of state-of-the-art information technology in the classroom, and the Office of Instructional Technology for its success in assisting the faculty to make good use of this equipment."

"The committee commends the university for the extent that it has infused information technology into the curricula, and prepared students to use these resources in everyday life and in future occupations."
At the end of three years 100% of the faculty responding to a survey indicated that they used the Internet as a resource for teaching and research and used email for instructional communication. Ninety-three percent use the classroom podiums routinely and create classroom materials with presentation software. Eighty-five percent regularly use the electronic databases that are part of the library collection. More than 50% of the faculty use synchronous collaboration tools or electronic bulletin boards to post and discuss assignment with students, use scanners to create graphic files for class presentations, and use a course web site as the primary construct for a distance learning course or as an enhancement for a campus-based course. More than 25% of the faculty are using digital or video cameras to collect materials for instruction, conducting class in a videoconferencing facility, or using online testing software.

In a student survey administered as part of the accreditation process 85% of the students felt that the instructional technology used in courses contributed to learning, 92% agreed that adequate technology was available to support teaching and learning, 89% agreed that FGCU had created an environment conducive to learning, and 71% agreed that distance learning was an effective alternative to traditional instruction. In the summer of 1999 a survey of all distance learning students showed that 86% of the students would take another distance learning course.

FGCU has been a living laboratory for teaching with technology during the past three years and much has been learned about using these powerful tools effectively. During the summer of 1999 a team of faculty and staff were assembled to identify a set of Design Principles for Online Instruction. The team included instructional designers, faculty who had been teaching online and web-enhanced courses and staff members from Instructional Technology. The team reviewed the literature, reflected on their teaching experiences, crafted a framework, and agreed upon a set of principles for— instructional design, multimedia design, management of online courses, academic and technical support systems. The resulting document became the basis for a series of faculty seminars on campus and presentations at state and national conferences. The University of Guadalajara and the College of Nursing at the University of Louisiana-Lafayette have both used these principles in their faculty development programs during the last year.

It seems impossible that only three years have passed since FGCU faced the challenge of taming the technology tiger and during that time more and more campuses have joined the effort. Like the railways and steel mills of the industrial revolution, technology has become a part of our way of life, and learning to harness its power requires both vision and endurance. At FGCU much progress has been made and yet, we have just begun.
Appendix A

F.G.C.U. Vision, Purpose, and Commitment

Vision and Institutional Purpose

Florida Gulf Coast University is dedicated to providing a learning-centered environment that offers the highest quality educational opportunities for the development of the knowledge, insights, competencies, and skills necessary for success in life and work. To maintain this learning-centered environment, the university as a whole and its units and individuals will actively practice continuous planning and assessment leading to improvement and renewal.

Florida Gulf Coast University is a comprehensive* public university created to address the educational needs of the rapidly growing Southwest Florida population and the increasing number of students who are seeking admittance into the State University System. The university's primary service area consists of Charlotte, Collier, Glades, Hendry, and Lee counties, with specialized programs drawing students from the state and beyond.

The university offers a broad range of undergraduate and graduate areas of study including arts and sciences, business, technology, education, environmental science, nursing/allied health, and public and social services. Professional development and continuing education programs are offered based on need and availability of resources. On-campus offerings along with distance education and partnerships with public and private organizations, agencies, and educational institutions enable the university to extend a rich diversity of higher education opportunities to Southwest Florida and beyond.

The university seeks to employ innovative ideas and technologies in the development and delivery of programs and services. The university also pursues regional and community-based public service activities and projects. To support the roles of teaching and public service, faculty and students are encouraged to engage in a wide array of creative inquiry and scholarship, including applied scholarship that focuses on the unique Southwest Florida environment and other issues of importance to the region and state. The library, which utilizes information technology in the delivery of instruction and information resources, actively promotes student learning and supports the information needs of the university.

Institutional Commitment

Florida Gulf Coast University promotes an institutional culture that:

- Fosters the pursuit of truth and knowledge;
- Affirms academic freedom as the foundation for the transmission and advancement of knowledge;
- Seeks excellence in both educational offerings and services;
- Asserts that learner needs, rather than institutional preferences, should guide decisions concerning academic planning, policies and programs;
- Provides academic, student, and administrative support services designed to meet the needs of the university community;
- Recognizes, encourages and rewards quality teaching;
- Enhances the growth of faculty by supporting teaching, scholarship, service and professional development;
- Encourages collaboration in learning, governance, operations, and planning;
- Establishes mentor/advisor programs, particularly programs for undergraduates that include senior capstone projects or papers;
- Recognizes that informed and engaged citizens are essential to the creation of a civil and sustainable society; and
- Affirms that diversity is a source of renewal and vitality.

Margaret Ford
Academic Computing and Networking
University of Manitoba, Canada
Margaret_Ford@umanitoba.ca

Abstract: A faculty development model for the integration of education and technology was designed and implemented to enhance teaching and learning. There is a great need to assist and provide support to medical faculty who wish to integrate technology into the learning environment. A consortium was formed of the key stakeholders. The educational framework for the Education and Technology Workshop was the Seven Principles for Good Practice in Undergraduate Education (Chickering and Gamson, 1987). Experiential learning theory provided the framework for understanding how technology can be integrated with the principles of teaching and learning (Kolb, 1994, 1971). We will discuss the successes and failures of this model and supply some reflection on future interventions and support strategies.

Introduction

There is a great need to assist and provide support to medical teachers who want to integrate technology into the learning environment. Attendance at the 2000 SITE conference by one of the authors was the impetus for the program. A consortium of key technology stakeholders was organized. Professional development teachers were recruited from the Continuing Medical Education department. A key person to involve in the project was an Academic Computing and Networking instructor who had assisted with other projects. A representative from library services was included, as was a representative from Education Support Services. Supports for integration of computer technology into the classroom, assisting teachers with connections, video projections and trouble shooting was critical to the success of the program.

Program Model

The desired outcome of the program was that the participants be able to use technology in a way that enhanced the understanding of the subject area, without compromising student-centered strategies that actively involved students in the learning process. Technology used without pedagogical consideration thrusts the learner back into a passive role. The program developers chose to use the “Seven Principles for Good Practice in Undergraduate Education” (Chickering and Gamson, 1987) as the framework for the program to underscore the desired outcome. Good practice principles encourage: student-faculty contact; cooperation among students; active learning; prompt feedback; time on task; high expectations; and respect for diverse talents and ways of learning. The program focused primarily on the what, when and why of using technology appropriately and effectively, and secondarily on the how of using technology. Kolb’s four-stage cycle of learning theory (1994, 1971) was used as the structure to sequence the program. The four stages are immediate concrete learning experience, followed by observation and reflection, leading to abstract conceptualization and finally active experimentation. In our program a concrete learning experience with technology was the basis for the participant to make observations about their practice and to reflect on them. Adjunct self-directed web based training was available to participants, as was access to student mentors. The observations were made through self evaluation and peer evaluation of a micro-presentation on the final day of the program. These observations or evaluations provided the motivation for the participant to develop ideas for future practice, thereby creating a new experience. The program offered participants direct experience and
reflective observation using PowerPoint software in an environment that required them to follow principles of effective practice. The focal point or deliverable of the program was a micro-presentation by the participant, on the second day of the program, that was self and peer evaluated for appropriate use of technology that enhanced understanding of the subject area.

Delivery

The first step was to recruit six trainers through a screening process that examined their previous experience with professional development and their level of technological competence. The selected trainers had to agree to conduct one two-day workshop annually for the medical faculty. They then attended a sixteen-hour, three-part program, sequenced over a one-month period, allowing time for preparation and reflection. Student mentors were available to assist participants with their micro-presentation preparation. The second step was the delivery of two faculty wide education and technology workshops. Participants were selected from a variety of health science departments. A condition of acceptance into the workshop was that they have basic technology skills, be present for the full workshop program and agree to be an education-technology resource within their home departments. The program developers acted as on-site resources during the first workshops the trainers conducted.

Outcomes

This faculty development model worked. Involving key players from various departments in the consortium contributed to the success of the program. Both trainers and workshop participants consider pedagogical principles when using technology. Six trainers were prepared and their abilities exceeded the program developers' expectations in terms of integration of technology for enhanced understanding while using good educational practices. The micro-presentations, self and peer evaluations were both positive and constructive. The participants evaluated the program very highly. The trainers facilitated two workshops for eighteen medical teachers who became departmental resources for education and technology. Our goal is to deliver additional workshops in 2001 to advance the appropriate use of technology within good educational practice.

Reflection – What Have We Learned

Technology must enhance learning not distract from it. Faculty development programs must focus on pedagogical considerations rather than on the technology itself. The micro-presentation is a critical element in the program because it forces participants to practice what they have learned. The financial resources available to train faculty is limited and this faculty development model is a low cost, self-perpetuating delivery method.

Developing a Faculty of Education Technology Integration Plan: Initial Stages of a Large Scale Faculty Professional Development Program

Mike Carbonaro, Fern Snart, Cheryel Goodale

University of Alberta

There is a strong consensus among many educators that the teaching of technology should be incorporated across the curriculum at the earliest levels of education (Logan, 1995). Although Faculties of Education tend to realize the importance of technology, they have been slow to respond to the needs of the field (Barksdale, 1996). Thus schools have been forced to compensate for this lack of leadership by developing their own in-service technology programs for teachers. There are a number of reasons why Faculties of Education have been slow to respond to the impact of technology. First, many faculty members require extensive professional development in the area of technology integration so that they can model appropriate uses of technology (Rogers, 2000). Second, faculty professional development programs must be designed so that these programs fit into a Faculty's overall Technology Integration Plan (TIP)—the development of a Faculty TIP is a difficult process, especially given the complex political nature of any university environment. Finally, regardless of the TIP, each Faculty must find the resources to carry out the action items defined in the TIP in order to achieve the goals of the TIP. This paper will describe the University of Alberta’s Faculty of Education TIP and its importance in a comprehensive effort to foster Faculty Professional Development. It will also discuss a newly funded research study of our 120 faculty members with respect to technology integration for teaching, learning, and research.

The University of Alberta has an enrollment of 29,000 fulltime students. The number of students in the Faculty of Education consists of approximately 3,000 undergraduate students and 1,000 graduate students. The teaching staff consists of just over 100 fulltime faculty members and 200 part-time and full-time sessional instructors. The Faculty of Education has enjoyed a long history of integrating technology into teaching, learning and research, beginning in the mid-1960’s. Currently the Faculty of Education runs a fairly elaborate computer network that uses 13 computers as servers (3 Sun computers, 4 NT computers and 6 Macintosh servers). The five student computer laboratories contain approximately 125 computers and over 100 classrooms have been wired with Category 5E Ethernet cable.

A good TIP needs to make provision for both long-term and short-term goals. In a very real sense, a technology integration plan is an evolving document, which is inclusive and flexible enough to enable quick changes based upon rapid changes in the technological world and, yet, specific enough to provide direction for immediate action. It also reflects the reality that, as faculty members in a professional faculty, we not only need to integrate technology into our own work, but, in turn, need to prepare our students to integrate technology into their work in schools and libraries. The following vision statement reflects our Faculty’s long term commitment to technology integration.

Vision Statement: The Faculty of Education will foster an educational environment where technology is an integral part of the teaching and learning process, research and
administration. In this environment, technology will be part of the everyday practice of how students learn, how faculty members teach, do research, and communicate with the field, and how administrative services facilitate activities within the Faculty.

Goals: Goal statements in the TIP are organized under three major headings—the teaching and learning process, research, and administration. Optimizing the teaching and learning process through technology integration is crucial to attracting and satisfying outstanding undergraduate and graduate students, as well as meeting the technology goals of the Alberta Government’s Department of Learning and local school districts, and the professional development needs of teachers, librarians, and other professionals. The research process is being transformed in all areas of educational research as faculty and graduate students make increasing use of information and communications technology. In addition, technology is becoming a focus of research as researchers investigate the impact of technology on the teaching and learning process and the use of digital information and multi-media technologies in course delivery. In relation to administration, the Faculty of Education is actively supporting the implementation of a new PeopleSoft-based administrative information system at the University of Alberta, as well as developing new programs to meet its own specific needs.

The significance of adequate human and technological resources permeates the goals in each of these areas. These resources are essential to optimize the teaching and learning process, research excellence, and administrative efficiency. These resources are also crucial in order to attract and retain high quality personnel in the Faculty of Education and to ensure that the Faculty is able to demonstrate leadership and respond to the communities we serve.

1. Teaching and learning process: The Faculty of Education is responsible for the education of teachers, administrators, librarians, counselors, and other educational professionals. As educators, we are constantly searching for more effective ways to optimize the teaching and learning process. Used appropriately, technology has the potential to increase the quality, efficiency, and accessibility of our programs. We also have a responsibility to prepare teachers for Alberta’s schools. The Alberta Department of Learning has explicitly stated that information technology must be “integrated into education to enhance student learning, and increase efficiency and flexibility of delivery.” The Alberta School Act requires that pre-service graduates of our programs be able to demonstrate that they understand the functions of traditional and electronic teaching/learning technologies, and that they know how to use and engage students in using these technologies. The implementation date for Alberta Learning’s new Technology Program of Studies is the year 2000. Hence, we need to provide both pre-service and practicing teachers with knowledge of computer technology and of methods of integrating computer technology into the curriculum.

A major goal of the Faculty of Education is to integrate information and communications technology across the curriculum in order to optimize the teaching and learning process in courses offered both on-campus and through alternative delivery. As well, the goal is to optimize the learning environments in schools and in the services and operations of libraries and information agencies.

2. Research: A second major goal of the Faculty’s TIP is to integrate technology into the ongoing research processes in the Faculty. This should enable professors in the Faculty to undertake and conduct world-class research programs and, thereby, meet future research needs and requirements.
3. Administration: The third major goal of the Faculty of Education is the integration of technology to optimize efficiency and effectiveness of our administrative services.

To achieve these TIP goals the Faculty of Education has embarked on an ambitious professional development program. The first phase of the program is an extensive needs assessment of Faculty members. It was felt that for faculty professional development of technology integration to succeed we needed to hear the concerns of all faculty members not just the select group of early adapters. An interview questionnaire was created and three interviewers (Ph.D. students) were trained on the administration of the questionnaire. All 120 Education faculty members were contacted and 92 of these were interviewed (on average 1 hour). Data was collected in the form of interviewer notes and tape recorded sessions. These interviews were completed over a four month time frame (May 2000 – August 2000). The data collected from these interviews is now being analyzed. A cursory analysis of the data indicates the following:

1. Faculty members have specific learner outcomes that can only be achieved by a highly individualized program. This will require both individualized support and instructional materials for a very specific set of learner outcomes.

2. Faculty members generally share common learner outcomes with colleagues who closely work in their areas of teaching, learning, and research. This should result in naturally occurring groups of colleagues who share a common set of learning outcomes.

3. Faculty members share common learner outcomes with other faculty members in the Faculty of Education. Groups of faculty members from across the Faculty with common learner outcomes can be addressed on a faculty-wide basis.

4. Faculty members may share common learner outcomes with other faculty members throughout the University. In this case, we would work closely with university wide units (e.g., University Teaching Services, or Academic Technologies for Learning) to develop more general sets of learner outcomes.

The preliminary results also demonstrate that Faculty members require a “just-in-time need-to-know” support structure that can efficiently and effectively meet: a) technical infrastructure support requirement, i.e., hardware and system software; and b) technology integration support with respect to teaching, learning, research, and administration.

Our goal for the coming months will be to thoroughly analyze the interview data. Following from this data analysis process we intend to develop a program of professional development that is “context sensitive” to the needs of our academic environment.

Supporting the Development of IT Skills of Education Faculty Staff: An Australian Case Study

Dianne Chambers & Richard Holbeach
Faculty of Education
The University of Melbourne, Australia
d.chambers@unimelb.edu.au

Abstract
This paper will explore the ways one Faculty of Education has approached the challenge of increasing the uses, in particular the more advanced uses, of information technology (IT) to support teaching through the professional development (PD) of staff. A range of models of professional development (such as individual consultations, group workshops, paying to attend external training) was offered to staff to assist in developing IT skills. The uptake of these different PD models is investigated, and the staff members' perceptions of the development of IT skills, and the preferred PD models for developing IT skills are explored.

Introduction
Over the past decade at the University of Melbourne, Victoria, Australia, there has been strong support, both financial and more generally, for increasing the uses of information technology (IT) and multimedia in undergraduate and postgraduate teaching and in other aspects of academic life. This support has been expressed through generous funding for the development of multimedia resources to support teaching and learning. For example, between 1996 and mid-2000 almost AUD$10 million of university central funds were invested in development and implementation of IT and multimedia projects (Alcorn 2000) and substantial further funding for multimedia developments and for the inclusion of IT in teaching was also provided by faculties of the university. This has impacted on all faculties of the university, including the Faculty of Education, and inclusion of IT is a routine aspect of the daily lives of academics and, for many, a routine part of their teaching. Despite this strong emphasis on the uses of IT over the past decade, there are still some staff in the Faculty of Education (and no doubt in other faculties!) for whom using IT as a regular aspect of their teaching is a challenge from which they have shied away.

The University of Melbourne is the second oldest university in Australia with total enrolments of approximately 30,000 students, with almost 4,000 students enrolled with the Faculty of Education in 2000. Degrees awarded in the Faculty of Education include undergraduate coursework degrees through to research Ph.D. and D.Ed. degrees. There are approximately 100 academic staff and about 80 general staff (mainly administrative) in the Faculty. In 2000 the position of 'Assistant Dean (Information Technology)' was created within the Faculty with a brief that included (among many other things) 'identifying staff IT training needs and developing a strategy for meeting them'. A number of the papers presented in the 'Faculty Development' stream at SITE2000 (e.g., Beiser 2000, Kahn & Pred 2000) explored how similar needs had been addressed at other institutions and the experiences related in these papers informed how IT Professional Development was planned for 2000. This paper will explore how this challenge was taken up and the success of some of the strategies applied to assist and encourage staff of the Faculty to use IT in their academic lives.

Some Models of Professional Development
Professional Development (PD) has historically been developed under two guiding principles - effectiveness and cost. The models of PD that have developed are, in some way or another, a trade-off between these two
principles. For instance, web-based PD has the advantage of being cheap to develop (write once, read anywhere, many times), but depends on self-directed learning (Shotsberger 1997) and may therefore not be very effective across a faculty. One on one mentoring, on the other hand, has a high rate of user approval, but is seen to be expensive.

Perhaps the most traditional form of IT Professional Development (IT PD) is the technology workshop, in which a skilled user and teacher imparts knowledge to a group through a mixture of verbal tuition and hands-on examples. Workshop models of PD have the advantage of meeting many users' needs at the same time, and are most successful when carefully targeted to groups with the same, or similar, skill levels and goals. There is, however, the problem of attenuation of learning between the workshop and the time of implementation (Guskey 1986). The workshop model thus needs to be supported by other models of PD, such as Just-in-Time support, or on-line materials.

Ohio State University recognized this in a report of July 1999 by their 'Faculty Instructional Technology Development Committee' (Ohio State University 1999). The report approached the issue of choosing appropriate models of PD for their faculty from a temporal viewpoint. They noted that the need for PD arises when faculty staff have:

- An urgent need for help ("How do I make my computer open PDF files?").
- A need for help just in time to do a project/course/presentation ("How can I turn these notes into a PowerPoint presentation?").
- A need for long-range planning that involves new technologies ("I need to develop on-line materials to support my students").

To support these three separate time frames, they concluded that the implementation of a number of different PD models was necessary. Some examples of the models that they chose to use are shown below:

**Urgent Need**
- Students trained to be first level of support, with technical assistance from professional staff.
- Central help desk for common applications.

**Just-in-Time**
- Student mentors who organize PD sessions with staff for specific problems.
- Team members for on-going PD in specific projects.

**Long Range**
- Workshops on specific IT issues.
- Consultants to talk one-on-one with staff about issues such as teaching strategies of pedagogy.

In many universities only the urgent and long-range needs have been met — the former through a help desk to respond to technical problems, and the latter through workshops and seminars. This leaves a significant gap in the Professional Development program of a faculty that wishes to move forward in using IT in teaching and learning. In a discussion forum held by the Victorian Professional Development network, Terry Harrington (who runs an Australian Professional Development program with 15,000 enrolments) stated that teachers generally wanted Professional Development that was:

- engaging
- readily applicable
- no longer than it has to be, but not a one-off event (Zbar 1999).

These needs appear to apply equally to staff at higher education institutions. The need for a Just-in-Time professional development model is behind much of the 'mentoring' models of PD. The mentors may be students, peers or experts, and respond to their mentee's specific needs by organising meetings with them in which the mentee's individual PD requirements are met. A US study in 1995 attributed the success of a technology mentor program to the individualized nature of the professional development - a self-paced workload focusing on the specific needs of the faculty member (Zachariades & Roberts 1995).

**Models of professional development offered to staff at the Faculty of Education during 2000**
After attending SITE2000 and further reading on the matter of IT PD for faculty members the following models of professional development (PD) about using IT were offered to staff of the Faculty of Education.

**Group IT PD workshops**
Areas of need for many staff were identified and workshops were offered by the IT PD Coordinator and attendance invited.

**Individual IT PD consultations (one-to-one 'Just in Time' [JIT] PD)**
Staff members telephoned or emailed in a request for help with either a specific need or with a request for developing skills with a certain product or goal. The IT PD coordinator would then visit the staff member in their office for a consultation.

**Small group IT PD consultations**
After staff had identified a common need they organized themselves into a small group (two or three individuals) and PD to meet their needs would be developed for them. This generally happened where staff members were working on a project together.

**Technology Mentors**
Academic staff (volunteers) were paired with technically able students (volunteers) and in ten meetings over approximately 12 weeks the technology mentor (student) identified the IT PD needs of the staff member, developed an IT PD plan, and gave individual tuition to the staff member on these identified areas. The technology mentors were supported in technical areas where required and were provided guidance and support in dealing with material they were not familiar with by the IT PD Coordinator.

**External IT PD**
Staff were invited to request IT PD at whatever level they required and if the PD required was beyond the skills of the IT PD coordinator, or was not offered by the university's Information Technology Service it could be met by an external consultant or by attending an external course. (This would be funded by faculty funds.) It is interesting to note that there was no demand for 'External IT PD', that is for professional development courses offered outside the Faculty or university. It is likely that in the busy lives of faculty members that if PD is not readily available and close at hand then it does not occur. This style of PD will thus not be discussed further.

No charge was made to the staff or to their department for using any of these services (all costs were funded at the faculty level) and as demand increased the staffing providing PD was increased to meet the demands. No ceiling was placed on the PD available to any staff member or department.

**Uptake and Perceptions of IT Professional Development Opportunities**

The goal that over half of the staff of the Faculty would undertake IT PD during 2000 was met, which was very pleasing. There was a higher proportion of academic staff who took the opportunity for IT PD than general staff. This was probably a reflection of the topics covered by the large group IT PD workshops, these focussed on developing and maintaining web sites, which is of greater interest to teaching staff than administrative staff. The uptake of IT PD was uneven across the Faculty, with one department in particular not being well represented. These two issues will be addressed in 2001 by targeting more IT PD sessions for topics of interest to administrative staff and specifically targeting the staff of the department that was underrepresented in 2000.

All staff surveyed that had made use of IT PD opportunities in the Faculty in 2000 stated that their IT skills had been enhanced during the year and all were 'satisfied' (28%) or 'very satisfied' (72%) with the IT PD that they had experienced. Some staff (6) that responded to the survey had not accessed any of the IT PD offered and of these only two felt that their IT skills had been enhanced during 2000. Encouraging staff to access the IT PD available to them will be a key goal in 2001.

Staff were asked to rank in order of their preference the different models of IT PD offered during the year. Only one staff member rated group IT PD workshops as their preferred model of IT PD, with the most popular model (60%) being one-to-one PD (where the staff member was visited in their office). Small group and technology mentors were ranked about equal, each IT PD model scoring approximately 20% as the first preference of staff. That the individualized one-to-one 'home delivered' model of IT PD was preferred is not surprising. The needs of staff were met through these customized sessions that were very convenient (as the time and location was
determined by the staff member) and very time efficient (as the materials covered were tailored to meet the needs of the individual).

**Group IT PD classes**
Scheduled large group (approximately 15-20 people) workshops about developing and maintaining web sites were attended by over 50 staff members (mainly academics) and this proved to be a very useful model of initial PD for an IT topic that was of interest to many people. Staff who attended the group workshop were then emailed to see if they would like a demonstration version of the software installed on their desktop computer. Where this was requested, the software was installed and at this time further PD was offered on a one-to-one basis to suit the needs and goals of the individual. Staff who had the demonstration version of the software installed on their desktop computer were contacted three weeks later to see if they would like a full (licensed) copy of the software installed. This again allowed staff who wished to develop these skills to have further one-to-one PD. This approach of large group workshops followed up with one-to-one IT PD meant that many staff who attended the group workshop could further develop those specific skills they required in the one-to-one PD sessions that followed. One comment about this was:

'I believe my skills level was above the group level (when I started Dreamweaver) and in a one-on-one I was able to improve my skills where needed at the appropriate time.'

**Individual IT PD consultations**
In addition to individual consultations that were 'follow ups' to group PD, many staff requested individual consultations about other areas in which they wanted to develop IT skills. This model of PD was very popular with staff and all staff who utilized it rated it as either 'useful' or 'very useful'. Some comments about this model of PD included:

'The one on one really is best particularly with academic staff who have a vast range of skill levels, and also for the more advanced admin. staff who have previously had little access to someone who knows programs better than they do.'

'My preference is for small groups or one-on-one PD. For technology PD that is related to my job, I generally have specific questions about particular software applications. I only use a few applications that I am unfamiliar with, so my questions are usually related to particular aspects of programs. These questions may not be relevant to other people. Also, it enables the possibility of asking follow-up questions or for clarification.'

Another positive feature of the one-to-one IT PD model is that it is very time efficient. Some comments about this included:

'It was great that ... (name of IT PD staff member deleted) could come and show me what I needed to know. I couldn't fit in a general seminar.'

'One-on-one means you can jump straight to what you need to know...'

**Small Group IT PD consultations**
It is interesting, but not surprising, to note that almost all small groups of staff that requested PD on a particular area were working together on technology-based projects. Considerably fewer staff chose this style of PD compared to group workshops or one-to-one consultations. Perhaps the difficulty of coordinating with another staff member to find a suitable time was only overcome when there was a very strong need, such as working together on an IT-based project. Those staff members that requested small group IT PD found it very useful and relevant to their needs.

'I have found actually working on a project extremely helpful as I can apply it directly to my needs and ask for help as I need it'

'The best way to learn is through engagement with real problems/needs relevant to the user. As such one to one and small group learning is best.'
Technology Mentors
A pilot technology mentor scheme involved nine staff members ('mentees') who were paired with Education students as their technology mentor. A match between the staff member's IT needs and the IT skills of the students was made and it was ensured that the Education student (mentor) was not enrolled in a subject taught by that staff member. The staff-student pair set a schedule to meet approximately ten times during second semester. There was mixed success with this scheme. One staff member in particular was very pleased with the scheme.

'I am delighted with the scheme - in fact I have developed an academic conference paper on it.'

For other staff the scheme was less successful, with one staff member withdrawing due to limited time to meet with her technology mentor, and others expressing dissatisfaction with some aspects of the scheme, including the matching of their skills levels with those of the mentors and timing difficulties. It is felt that if we were to continue a technology mentor scheme, then the mentors would need a greater amount of training in how to be an effective mentor and greater effort be put into matching staff and IT mentors.

Hidden Costs of PD
When considering models of IT PD, as for all expenditure, the balance of cost to effectiveness of each must be taken into consideration. When looking at the IT PD models offered, at first glance the large group IT PD workshops appear to be the most cost effective, as many staff can learn about the material in a single session. The one-to-one IT PD may appear to be perhaps 15 times more expensive, as the IT PD Coordinator is working with a single person at any time rather than with a group of 15. This is not really the case, as when a Faculty organizes a group IT PD workshop it is paying the salary not only of the IT PD Coordinator, but also the salaries of all participants of the workshop. This substantially changes the calculations of costs and benefits, and it is not unlikely that the IT PD Coordinator will be the lowest paid person attending a workshop! When costing PD within a faculty, the real costs of all participants of the PD should take into account, not just the cost of the presenter or room hire. It is likely to be considerably more cost effective for the IT PD Coordinator to spend half an hour in a customized IT PD consultation with a professor, than that professor to attend a two hour workshop where her specific needs may or may not be met.

However, I still believe that large group (15 people) IT PD workshops have many benefits — many staff can be introduced to the basics of an application or a style of teaching in a single session and useful discussions and collaborations may ensue. However, group IT PD workshops need to be supported with follow up individual or small group customized IT PD consultations that allow staff to further develop skills in those specific areas that they have a need or interest in developing. We found that making an opportunity for individual IT PD consultations when installing software onto staff machines following an IT PD workshop was extremely useful. Staff were pleased to be having the software installed (as they had requested it following the workshop) and were receptive to learning about it and to developing further skills in using it for their specific needs.

Conclusions
During 2000 much effort and resources were placed in developing and extending the IT skills of the staff of the Faculty of Education and from survey responses and from anecdotal comments the IT PD opportunities offered were appreciated by staff of the Faculty. With ever-increasing pressures on staff to publish more, dropping staff-student ratios, and pressures to use IT as a routine part of teaching, it is increasingly difficult for many staff to find the time to attend group IT PD workshops. Staff, and in particular senior staff, are more likely to seek help in developing their IT skills if the PD comes to them, at a time that suits, on a specific topic of need, rather than having to fit a workshop into a busy schedule. This 'Just in Time' model of IT PD is not as expensive as it may first appear when the costs of attendees, as well as that of the workshop leader, are taken into consideration.

After trialling a range of IT PD models in the Faculty of Education during 2000, we will continue in 2001 to support the position of IT PD Coordinator who will be responsible for organizing IT PD workshops for staff and for one-to-one and small group IT PD consultations, as these two models appear to be the most successful
for developing IT skills of staff in the Faculty. In addition to continuing these programs, in 2001 particular efforts will be placed in providing more IT PD for general (mainly administrative) staff of the Faculty and for ensuring the department that was underrepresented in 2000 is targeted for IT PD during 2001. These goals will be achieved by organising IT PD workshops of specific interest to administrative staff (who are then likely to request one-to-one consultations) and by organising workshops within the physical space of the underrepresented department and, where possible, in times that have already been allocated by the department as department seminar timeslots. This, too, is likely to generate requests for further one-to-one consultations. It must be noted that important factors in the success of the IT PD program were the strong interpersonal and technical skills of the IT PD Coordinator. That this person has skills that support staff in their learning about IT and encourages and develops confidence in using unfamiliar tools is critical to the success of such a program. Our faculty was fortunate to appoint such a person to this role and the increased confidence of staff in using advanced aspects of IT is evident. Many comments on the survey mentioned by name the IT PD Coordinator and specifically referred to his approachability, skills, and availability. It is interesting to note that the person in this role was not trained in IT as a discipline, but rather has a very strong knowledge of a wide range of software applications and how they can be used to support learning, was keen to learn new applications, and, most importantly, had a wonderful manner that made staff feel that they could achieve whatever they wanted to. This aspect of developing the confidence, as well as the competence, in using IT is an important, and sometimes overlooked, aspect of IT PD.

Abstract: Professional development opportunities must offer a learning environment that creates a nurturing, creative, successful atmosphere for the learners. Instructional design models, learning styles and technology implementation strategies impact this supportive environment.

Introduction

The careful development of a learning environment is imperative towards the success of all learners within a classroom of eager, and perhaps not-so-eager, learners. This is obvious to all professionals within the realm of instruction. However, the thought and care that is focused upon developing a nurturing, creative learning environment for PreK-12 learners may not always be taken with preservice and inservice teacher educators; after all, many professional educators remain so focused upon the PreK-12 learners that we “miss the forest for the trees”, so to speak. Preservice and inservice teacher educators also desire and deserve a supportive, nurturing, creative learning environment within the professional development opportunities.

Professional development opportunities that focus upon instructional uses of technology are examples of environments in which a nurturing, supportive atmosphere will aid the preservice and inservice teacher educators in developing a level of comfort with technology and, slowly, move towards the appropriate and successful integration of technology within their classroom. Numerous aspects lead towards a supportive, nurturing atmosphere in which the creativity and love of learning will present itself; but what specific aspects will aid the professional development opportunities when working with technology? Technology-phobic preservice and inservice teacher educators abound within the education profession but, with appropriate care and guidance, the technology-phobic can become the technology-savvy, learner-centered facilitator in the classroom.

Creating a Supportive, Nurturing and Creative Learning Environment

The fact remains that teachers must attend professional technology development. To embrace technology, teachers must have positive attitudes toward it. It is imperative that instructional technology trainers supply a supportive and nurturing environment. One way to foster a supportive environment is to offer multiple-session technology classes. Technology programs in school districts must no longer take the “treat ‘em and street ‘em” type philosophy where teachers are required to attend one-day workshops. The danger of one-day workshops is the tendency for educators to not use the newly learned technology. In a survey dispensed to an elementary school in the Houston metropolitan area, 89% of the teachers surveyed admitted that they did not use the technology after taking the one-day technology workshop. The same survey also illustrated 75% of those teachers appeared dissatisfied or somewhat dissatisfied with the technology professional development training that they had received. Ehley (1992) found that teachers require multi-session workshops in order to feel successful with the computer. One-day technology workshops have a tendency to leave teachers feeling isolated and frustrated. By breaking up the technology training into three to six learnable sessions, teachers appear less anxious about the computer and can concentrate on the material. In addition, multiple training sessions let teachers learn smaller chunks of material at a time for faster acquisition of the skill.
Another positive component of multiple training sessions is the fostering of relationships between fellow teachers. This bond can reduce feelings of anxiety and frustration and help create a supportive environment for all technology users. The bond can even continue to blossom after the training sessions have ended. The Intel Corporation has just unleashed a successful teaching technology program called, “Teach to the Future” in which an underlying belief that support for teachers does not end after finishing the 40-hour training modules is apparent. Further, Intel has created a lesson plan bank and listserv for all Intel participants to study and use. Through the implementation of supportive, nurturing, creative learning environments and longitudinal time elements that enhance the learner’s acquisition of relevant knowledge and implementation skills, the success of the learning environment can be significantly heightened.

**Instructional Uses of Technology**

Teachers’ attitudes toward technology and computers vary widely in any given school. If teachers see the introduction of computers into their subject as bringing curriculum change with it, they may react in different ways. While some may adopt a resistant attitude to this change, others may see the change as a cure for boredom and see themselves as innovators (Bennet 1980). In addition, attitudes not only affect choices but also can be unconsciously transferred to students through modeling (Martin 1986). Proving teachers with quality instructional uses of technology is an important step in giving teachers sufficient opportunities to acquire and learn technology for the classroom.

One way to show teachers how to use technology is to give them authentic learning situations in their training. For example, one technology specialist sits down with a school group, team, or individual and identifies a teacher’s technology needs. After the initial meeting, the specialist then proceeds to build a CTP or a Classroom Technology Plan for the teacher. In the CTP a list of technology goals are listed along with the real authentic products that will be produced. Real and authentic learning activities are crucial in developing a successful learning environment. Knowles (1984) was one of the first researchers to identify the importance of real and authentic learning situations in adult learning. Knowles felt that adults are motivated to learn after they experience a need in their real-life situation, because adults do not learn for the sake of learning they learn in order to be able to perform a task or solve a problem. To apply Knowles’ theory in education, instead of showing teachers how to use spreadsheets by opening up a program and exploring the interface, a better instructional use would be to create a teacher gradebook. Creating a teacher gradebook is a real and authentic product that the teacher can take back into the classroom and use. The instructional uses of technology are ever expanding; however, the appropriate and successful integration of technology into the learning environment is imperative.

**Conclusions**

A technological revolution is under way that involves teachers. In considering the role of technology in learning, educators are faced with a number of challenges, including how to respond to technology and how to utilize it without diminishing the learning experiences (Field, 1997). The time has come to prepare our nation’s educators with quality, supportive, and nurturing learning environments to learn the technology skills they so desperately need.

The JASON Academy: Explorations in Online Science for Middle Level Teachers

Marily DeWall
Director, JASON Academy
JASON Foundation for Education
United States
marily@jason.org

Abstract: The JASON Academy for Science Teaching and Learning is a new initiative of the JASON Foundation for Education. Beginning in September 2001, the Academy will offer online professional development courses for graduate credit and CEUs to middle level (grades 4-9) teachers of science. Twelve science content courses will include modules focusing on energy, marine science, Earth Systems, and pedagogy. The goal of the Academy is to enhance the science content background of teachers and provide them with the tools to help students learn more effectively.

Beginning in September 2001, the JASON Academy for Science Teaching and Learning will provide online science courses for middle level teachers (grades 4-9), supplemented by “Lab Pack” materials for hands-on science activities with students. The goal of the Academy is to improve the science content background of teachers of science to help them become more effective teachers. Taking advantage of multiple delivery systems offered by advanced systems architecture, the online courses will be tailored to meet individual teacher’s learning and teaching styles. Courses will be integrated and thematic in design, but each will emphasize physical science—an area in which both teachers and students need more concept understanding and practice. The Academy’s initial course offerings will include the following.

- A required introductory course, Introduction to Online Middle School Science (five weeks long and one credit unit) which will provide an orientation to navigating online science and using the Lab Pack materials in investigations with students.
- Eleven content courses, offered concurrently, each 5 weeks long and one credit unit.
  - Light and Heat
  - Electricity and Magnetism
  - Forces and Motion
  - Water Quality
  - Ocean Science
  - Aquatic Ecosystems
  - Structure of the Earth
  - Earth’s History
  - Earth in the Solar System
  - Teaching Project-Based Science
  - Assessing Student Learning and Work
- Lab Packs containing light, temperature, and voltage probeware, software, and student activities will serve as the Academy “textbook.” Teachers will use them with their students to reinforce the science concepts they have learned on-line. The kits will insure that teachers and students have experience collecting and analyzing data using hand-held devices and probeware.
- Pedagogy embedded throughout the courses with inquiry being the overarching mode of instruction and learning. Course modules will be tied both to the National Science Education Standards as well as to state science standards.
- Pre- and Post-Assessments and weekly quizzes and surveys to provide continuous feedback on teacher progress and course effectiveness.

The JASON Academy is forming partnerships with crediting institutions and credentialing agencies in several states to provide teachers with options for graduate credit as part of an advanced degree program and continuing education units to be used for certification and recertification requirements. Responses to a survey of state science supervisors provided valuable contact information for state university crediting and state certification requirements.
In November 2000, the JASON Academy conducted a field test of a two-week prototype of a JASON Academy course on Electricity and Magnetism. Findings included the following:

- Based on experience with the JASON prototype, 100% of the field testers would take another online JASON Academy course
- Overall rating of the course on a 5-point scale: 4.6
- Top reason to sign up for an online course: Expand science knowledge, followed by graduate credit and CEUs toward certification.

Field testing teachers appreciated the flexibility of online learning as well as the colleague interaction and ease of informal presentation format.
The Challenge of Developing College Wide Technology Standards

Abstract: The technology requirements prescribed by NCATE for teacher education programs pose unique challenges when all programs within a college of education and human development enter the self-examination process together. This research study examines the growing pains of one university's college of education in designing and implementing technology standards.

Purpose

The technology requirements prescribed by NCATE for teacher education programs pose unique challenges when all programs within a college of education and human development enter the self-examination process together. As technology competencies become integrated within the curriculum, faculty and student proficiency becomes an immediate rather than long-term necessity. Moreover, professors of education must model the use of technology throughout the curriculum. At the University of Southern Maine, the College of Education and Human Development enrollment shows that 80% of the students are in graduate programs and 25% are in non-teacher education programs including school counseling, clinical counseling, school psychologist, school administration, and adult education. Many graduate students do not have a technology rich background and, as commuting students, have little opportunity to use the university resources. Both students and faculty struggle with the technological changes in curriculum and instruction. This case study examines the growing pains of one university's college of education in designing and implementing technology standards.

Perspectives on Technology in Higher Education

In the 1980s computer literacy emphasized programming skills, computer science theory, hardware platforms, and software applications (Friedstein, 1986, and Ayersman, 1996). Computer literacy was a rather esoteric arena; certainly not for everyone. By the 1990s, computer literacy became inextricably connected to functional literacy with employers expecting college graduates to be computer proficient. A few colleges and universities at the undergraduate level began to set fairly basic expectations for all students, advertised on the school website and in paper publications. Georgetown College and Mary Washington College are undergraduate institutions that have led the way in advising students to meet their technology expectations in advance of enrollment. At the University of Nebraska, the college of education asked all teacher education candidates to be computer competent before entering the teacher education program and the preservice teaching experience. Guidelines for entry-level computer competency skills were written and approved by the faculty in 1991.

However, many graduate students arrive with high levels of anxiety about technology that may affect their academic performance and personal self-esteem. Hudiburg and Necessary (1996) found that computer-anxious
college students often used emotionally-focused coping strategies such as distancing, seeking social support, and escape avoidance. Low computer-anxious students use problem-solving strategies and were more likely to accept responsibility. Attitudinal issues are especially important to the non-traditional students' successful return to college. When they do learn to use computers, they experience greater increases in self-esteem than traditional students (Mruk, 1987).

Faculty, too, have differing attitudes towards the technology revolution. Kasworm (1997) advises college leadership to develop profiles of different faculty as learners with descriptions of how they approach or resist technology. Then a variety of paths for learning can be made available, from workshops to mentoring. Additional studies find that technology can increase and strengthen the ways faculty engage students both in and out of the classroom (Gillette, 1996). Faculty report that the increased time that is required to answer electronic messages is balanced by the flexibility of email over connecting by phone or making office appointments. Electronic conferencing seems to be a double-edged sword. Some students who are quiet in class increase their participation using email and electronic conferencing, needing the additional time and reflection to post either their observations or questions. In order to get increased use, key factors must be present: clear advantages for use, opportunity to overcome computer phobia, excellent support during learning, unique fit with lifestyle, and something to share (Wilson, 1996). One might extend the belief that these factors predict success for faculty as well.

The Process of Developing Technology Standards

A subcommittee of the College of Education and Human Development (CEHD) Technology and Media Committee was charged with the task of developing recommended technology entrance and exit standards for all programs to integrate within the college. In considering how to proceed NCATE technology standards, ISTE standards, and a variety of other universities' technology standards were consulted. It was agreed that the recommended entry standards would represent the technology skills that are necessary for students in any CEHD program to have in order to successfully engage in program/department communication and course learning activities. The recommended program technology outcomes would represent the goals or final outcomes that each graduate will have met upon completion of any CEHD program. And, the standards needed to be stated in such a way that all programs within the college would be able to apply them.

A draft document was presented to the CEHD Technology and Media Committee for feedback. Revisions were made based on this feedback and a second draft was given to the chair of the Faculty Development Subcommittee (FDC) (see Figure 1).

**Recommended Minimal Entry Skills**

- Demonstrate skills using e-mail communication tools
  - Attachments
  - Nicknames
  - Cut & paste from document
  - Utilizing a listserv
  - Signature
  - Organizing messages
  - Sending
  - Netiquette
  - Replying
  - Forwarding messages

- Demonstrate knowledge of and skills in using library databases
- Verify skill in using remote access to university (if applicable)
- Demonstrate skills in using Word Processing productivity tools: cut & paste, spell check, printing, formatting, editing, backing up work
- Operate a computer a system to successfully use software
- Demonstrate an ability to access and use the World Wide Web

**Recommended Exit Skills**

- Demonstrate an ability to load a new program (cd-rom)
- Using help functions and strategies for troubleshooting
• Having skills across computer platforms and applications
• Demonstrate an ability to use multi-media technology
• Create and use spreadsheet/databases
• Search literature databases
• Use electronic gradebook (if applicable)

Students admitted into programs in CEHD self-select into one of the following orientation sessions that will be held prior to the first semester in the program in order to demonstrate mastery of the entry skills:

**Novice orientation & assessment** – for those that need assistance in learning and demonstrating competency in the minimal entry skills

**Advanced orientation & assessment** – for those that need little or no assistance in demonstrating competency in the minimal entry skills

**Non-matriculated students** will be given this checklist of minimal entry requirements. They will also be required to demonstrate their ability to meet these entry skills.

**Figure 1: Draft Entrance and Exit Technology Skills**

The CEHD committee decided that an appropriate next course of action would be to document current faculty use of technology to support teaching, to identify faculty needs around technology, and to gather input from faculty regarding the draft entry standards and outcomes for students in as series of luncheons sponsored by the FDC. The goal was to gather rich descriptive data in order to gain an understanding of the faculty’s experience and their deeply held convictions about curriculum, pedagogy and student needs in such a way as to contribute to the design and implementation of technology standards in higher education.

The following questions represent the major concerns of the faculty in regards to adopting technology standards:

• How should we handle non-matriculated students and these standards?
• Where will the resources come from to support faculty to learn to incorporate technology into their coursework and get the appropriate hardware/software?
• Aren’t technology skills moving targets, having a fast rate of change?
• Will these standards deny people access to CEHD courses if they can’t meet entrance standards?
• Should faculty integrate the teaching of these skills into their class sessions, or should students complete university workshops outside of class time?
• How can these standards apply to all CEHD programs?

With these concerns in mind, a second draft of the “entry standards” were presented to the CEHD faculty at a fall meeting attended by full-time faculty as representative samples of each of three departments: Professional Education, Teacher Education, and Human Resource Development. In the discussion, many of the concerns related to the language used in the document or the method by which students would be evaluated in relation to these technology standards. While the original intention of the standards subcommittee was to have a process by which students would demonstrate proficiency in the entry standards, faculty expressed concern about managing this assessment. Faculty felt strongly that “technology skills” should be changed to “technology standards” to reflect our intent. There was concern about the notion of technology “entrance requirements” to CEHD programs. How could students demonstrate mastery of the entrance standards prior to starting a program? Would non-matriculated students be required to meet these standards as well? Would non-traditional students be “shut out” of courses due to lack of technological proficiency? But, at the same time, how could programs systematically incorporate technology into courses if some students would have met the entry standards and others would not? These issues needed to be resolved before the entire faculty felt comfortable adopting the proposed entry standards.

At a subsequent meeting, the following recommended entry standards were adopted by the CEHD faculty – with the understanding that these were recommended and not required and that they would be included in the CEHD catalog.
so students would be made aware of their existence. But, in the discussion, it was apparent that faculty needed a common set of technology skills that all students could perform in order to systematically move them towards the technology outcomes (See Figure 2).

- Demonstrate skills using e-mail communication tools
  Attachments              Cut & paste from document          Nicknames
  Utilizing a listserv      Signature                      Organizing messages
  Sending                  Netiquette                      Replying
  Forwarding messages

- Demonstrate knowledge of and skills in using library databases
- Verify skill in using remote access to university (if applicable)
- Demonstrate skills in using word processing productivity tools: cut & paste, spell check, printing, formatting, editing, backing up work
- Operate a computer a system to successfully use software
- Demonstrate an ability to access and use the World Wide Web

**Figure 2: Adopted Entry Technology Standards**

Once the entry standards were adopted by the CEHD faculty, a second draft of the recommended technology outcomes were presented at each department meeting for feedback. The feedback was used to modify the outcomes for vote by the CEHD faculty. The focus of this discussion centered around using appropriate language in the document that would reflect general outcomes that all programs could apply. In addition, a general agreement was made that program faculty could determine how these outcomes were systematically incorporated into the coursework. At a spring CEHD faculty meeting, the CEHD Program Technology Outcomes officially adopted (see Figure 3).

As a result of an educational program in the College of Education and Human Development, students should be able to:
- Demonstrate an ability to load a new program
- Demonstrate an ability to use help functions and strategies for troubleshooting
- Demonstrate skills across computer platforms and applications
- Demonstrate an ability to use multi-media technology
- Demonstrate an ability to create and use spreadsheet/databases
- Search and evaluate electronic databases and World Wide Web sites
- Use electronic gradebook, budget software, financial software where applicable
- Demonstrate knowledge of equity, ethics, legal, and human issues concerning the use of computers and technology
- Integrate technology into professional work (e.g. internships, field work, etc.)

**Figure 3: Adopted Program Technology Outcomes**

In addition, a follow up motion was voted on and approved that required the CEHD Executive Council (Deans, department chairs, program directors, etc.) to review the standards and oversee the development of consistent evaluation of these outcomes across CEHD programs. This allows program faculty to determine the ways in which technology standards will be integrated into courses. In conjunction with adoption of these standards, a series of “Technology Day” workshops are being offered each semester to move faculty and staff forward in their own technology skill development as well as their pedagogical awareness of ways to integrate technology in their teaching.

While it may appear that the process of developing integrated technology standards is complete, the technology subcommittee is now working to align the newly adopted ISTE standards (ISTE, 2000) with our already approved standards. In our upcoming 2002 NCATE review our college will be required to demonstrate the integration of the newly adopted ISTE standards into our programs.
Some Reflections Based on our Work

Based on college-wide conversations during the development of technology standards a number of recurring observations become apparent. First, faculty are beginning to use a variety of technology in their professional lives and in the classroom, however, without specific direction. Use is primarily centered around improved organization and student interest. Faculty are not using technology to promote higher level thinking and do not see themselves as pedagogical models related to technology. Second, faculty are most intrigued by the use of electronic communication systems to ease communication particularly with graduate students and in distance learning contexts. In addition, faculty use electronic communication to build relationships that extend beyond the original course. As Gillette (1996) pointed out, ease of communication encourages students to ask more questions and clarify tasks, resulting in an improvement of the ways students are engaged in their learning. In this way, technology can enhance the teaching-learning environment. Finally, the initiation of general technology entry standards and programmatic outcomes has raised specific concerns across programs which includes issues such as: assessing and monitoring technology competencies; computer access by commuting and/or distance learning students; standards as moving targets due to technology innovations; untrained faculty; lack of technical support personnel who have pedagogical understanding. These issues are still at the crux of our struggle in actually engaging faculty in systematically incorporating technology in their teaching and expecting students to produce technology-enriched products.

Recommendations to others considering our work

There are certainly a number of lessons that other colleges can take from our experience in working towards technology standards. First, create a technology plan with standards/outcomes at the core. Once a college is clear about the expectations, appropriate decisions can be made regarding faculty load, budgets, faculty/staff development, needed equipment and support, etc. Second, create technology entry standards that faculty can count on and use in curriculum planning and technology integration. It is important when making a programmatic attempt to integrate technology, that basic prior knowledge can be assumed so that course time does not have to be spent in teaching technology skills. Third, create technology outcomes that allow for program autonomy for course integration and assessment. It was a critical element in our work to make sure that all voices were heard across disciplines in the development of the standards. In addition, it has been essential that the adopted standards fit all the disciplines within the college so that individual programs can take the standards and integrate them appropriately. Fourth, entice faculty support through a better understanding of the pedagogical opportunities of technology as well as training them in specific hardware and software skills. Learning the technology skills is crucial, but developing a better pedagogical understanding of how to incorporate that technology to promote higher level thinking is just as important. Finally, include questions related to technology standards within the college-level curriculum review process. One way to ensure the appropriate integration of technology standards into program curriculum, is to require its inclusion in course syllabi.

Significance

Most colleges and universities do not assess computer literacy as part of the admission process and often do not define computer proficiency for their graduates. This unwritten policy of "don't ask; don't tell" has not served either students or faculty well. Rather than serving as barriers, clearly defined expectations can help students prepare for coming into higher education, use technology as a tool for learning throughout their program, and understand the expected technological outcomes of their education. More importantly, as we raise the bar in terms of technology skills within courses, colleges and universities can then focus their technology mission on educating for the critical use of technology.

References

Abstract: The authors define problem-based learning (PBL), an instructional method used by teachers and professors to teach problem solving and to replace rote memorization and passive learning. PBL's process is explained. The historic association with John Dewey's progressive movement and constructivism are also included. Questions are answered that deal with the changes from a traditional classroom to problem-based learning. Academic achievement, the roles of teacher and student, generating problems and assessment tools are covered. Examples are given for further study.

What is PBL?

Problem-based learning (PBL), a teaching technique or instructional method that was introduced in the mid-60's by Physician and Medical School Professor Dr. Howard Barrows at McMaster University in Ontario, Canada has now been used widely in medical schools, schools of nursing, pharmacy, dentistry and optometry, as well as in some undergraduate and graduate programs of other disciplines in colleges and universities in the U.S. and Canada. Many middle and high schools have also adopted the PBL method to raise student achievement and contribute to school improvement programs (Delisle, 1997).

Dewey and Constructivism

Problem-based learning has its roots in John Dewey's progressive movement. Dewey believed that teachers should teach by appealing to student's natural instincts to investigate and create. Problem-based learning is also considered as one of the best exemplars of a constructivist learning environment. Constructivism is a teaching/learning model that holds the notion that learners should generate their own knowledge through experience-based activities rather than being taught it by teachers (Roblyer, 2000).

The PBL Process

The PBL process is broken down into the following structured steps.

1. The teacher presents a problem.
2. The class is divided into groups.
3. The groups generate ideas/hypotheses.
4. The group members determine what they know about the problem.
5. The students determine what they need to know.
6. The students develop a plan to acquire the information needed from reliable sources.
7. The students use the new information to re-evaluate the problem.
8. The students generate a product such as a written paper, class presentation, or web page.

Some Frequently Asked Questions About Problem-Based Learning

Academic Achievement

Faculty question if content will be learned when using PBL. Palmer (1998) in *The Courage to Teach* shares about a medical school that instituted problem-based learning and found that content scores increased. Palmer thinks it is because the brain works best with information presented in patterns of connection—looking at the patient as a whole and the shared learning—the group is smarter than the individual alone.
Generating Problems

PBL is changing the way that teachers traditionally teach. So more preparation must go into getting ready for class. Creating problems seems to be the biggest challenge for teachers changing to problem-based learning. However, once teachers take the plunge, they find that the challenge makes them feel revitalized. The activity is intellectually stimulating (White, 1995).

Role of the Student

This type of learning puts more pressure on the student. Because there is not one right answer, the students must look at different angles of the problem and come up with the best answer based on the situation. For students who are used to memorizing the teacher’s notes, this causes anxiety. For bored students the challenge is welcome.

Role of the Teacher

The teacher goes from being a lecturer to being a coach (Lynrock, 1999). This is a change for the teacher in that new behavior skills are required. Instead of lecturing to a group of students, the classroom becomes much like a newsroom. Students are involved in different aspects of problem-based learning—researching information online, calling an expert, collaborating in a small group to agree on the final answer. It makes for a messy classroom which is sometimes hard for teachers to accept.

Assessment Tools

Because problem-based learning is different from traditional learning, different assessment tools are needed. Students work in groups, and peer assessment can help determine the contribution of different members to the group project. Oral and written reports of the solution can be used to assess what was learned. Traditional exams can also be used. Since each student will learn different things because of the activities involved, some form of self-assessment will help determine the new skills the student has acquired (Jones, 2000).

PBL Examples

One example of PBL is a webquest (Summerville, 2000). The teacher finds the information on the web and has the students interact with the data to do some kind of project. Many teachers are doing this and examples are on the web (http://cdweb.sdsu.edu/webquest/webquest.html) Problem-based learning has been used successfully in graduate, undergraduate, and K-12 schools. It has also been used in various disciplines in arts and sciences such as criminal justice, political science, public administration, physics, biology, chemistry, and art as well as education and business (http://www.udel.edu/pbl).

Reiman (1998) in Thinking for a Living talks about the skills needed in the future. Problem-based learning helps prepare students for the jobs in their future.

Abstract: This paper seeks to report the findings of a study concerning online course development at a midwestern university. The study examined the use of a cohort model for online course development and the typical individual online course development to support the instructional, technical and psychological aspects of online course development by faculty in higher education. The study sought to answer the question: Can a cohort model provide the technological, instructional, and psychological support needed in the development of online courses in ways different from a faculty member working alone in the development of an online course?

Introduction

The migration of a traditional course to a web-based environment requires a rethinking of the instructional design, grading methods, group-work designs, technology skill level, and the community building that often occurs in a traditional classroom. Faculty members often lack the technical skills necessary to redesign the course materials for the web environment to meet the high standards they desire. This leads to frustration with online delivery and a negative feeling that the course will never "work as it did in the traditional classroom". In reality, this attitude is fact—the course will never work as it did in the traditional classroom—and must be changed to achieve the desired outcomes in this new visually based web environment. However, since course development for higher education faculty typically occurs in isolation, faculty can become frustrated with the development of new materials for the web, especially when they lack an understanding of how to work in this online medium.

The College of Education and College of Music has developed a group of online courses in support of their mission to provide ongoing opportunities to graduate students with a desire to obtain certification or renewed certification for teaching and administration as well as undergraduates often closed out of "high demand" courses. In an effort to meet a rising demand by undergraduates, area teachers, graduate students, superintendents, and international students for more flexible educational services, these colleges have developed online courses for the following students:

1. Graduate students in Computer Education and Technology who must obtain certification to become K-12 Technology Coordinators,
2. Graduate students in Music Education who must obtain certification to become K-12 Music Teachers,
3. K-12 teachers who now must obtain a masters degree in their field to maintain Ohio certification,
4. Superintendents in rural communities who must now be certified by the state of Ohio to hold a superintendent position,
5. Undergraduate students who need required courses for student teaching that are typically in "high demand" each quarter, and
6. Graduate students in African Studies and Instructional Technology as part of the College of Education linkages to the University of Western Cape in South Africa.
In discussions with the Center for Innovation in Technology for Learning (CITL), as the courses were being developed, faculty were concerned with developing the courses to meet the same standards as experienced in the traditional classroom. Often asked was the question, how could technical problems be addressed especially for the “novice technology user” by the faculty and the online student? Another major concern was how the lack of face-to-face contact with students would impact the faculty member as an instructor and on teaching evaluations. Questions were raised about the possibility of working with a team of faculty during the development of individual online courses. These questions lead to the development of a cohort of faculty who worked together to develop their individual online courses.

The Study

The members of the cohort group were College of Music and College of Education faculty presently developing online instruction using Blackboard CourseInfo 3.11. Personal interviews with faculty and a descriptive approach in which written information was used to substantiate the question to be answered was used during data collection. Attention was given to the details of the online course development process and changes as the faculty designed their courses.

The cohort met to establish the group, to identify technological needs and to discuss planned instructional methods for their courses. The cohort had opportunities to view other online courses in which Blackboard CourseInfo had been used and how the various materials were presented. Often the development of online course materials takes a different form than originally planned when faculty see various methods of presenting an idea. Cohort members discussed how small groups and discussion would occur within their course structures. The College of Music faculty had very different instructional problems than the College of Education in that the College of Music needed to be able to place sound files within the Blackboard CourseInfo for their students to evaluate. This posed a unique problem to the music faculty because most were novice users of this application of the technology. Help from the faculty in the College of Communications and WOUB Public Television was enlisted to help the faculty envision the possibilities of presenting the music scores online and to help develop the technical skills needed to accomplish the task. Most of the discussion by the cohort focused on course development, problem solving, technical problems, technological skills and course changes to be made as the course progresses. Discussion by the members of the cohort was recorded. An instructional technology graduate student and the researcher provided technical support to the members of the cohort. Members were asked to reflect upon the process of developing the course and the instructional and psychological hurdles that were encountered in the process. The graduate student and the researcher also maintained a journal of discussion with members, the meetings, and their reflections of the process as an observer.

A group of faculty who have worked alone in the development of their online courses was randomly selected from a list provided to the researcher from the CITL. The faculty were from colleges across the university. Selected faculty were interviewed using the same interview questions as the cohort group but with an emphasis on the individual course development process. Discussion and answers concerning the interview questions were recorded for examination.

All journals, self-assessments, meeting notes, and recordings from the cohort as well as discussions and comments from non-cohort faculty were examined to determine common themes and differences between the two groups in their instructional, technological, and psychological approaches to the development of online courses (Bogdan, R. & Biklen, S., 1998).

Findings

Multimedia and telecommunications technologies continue to evolve and advance with the promises of offering the learner with a richer and more meaningful education relevant for the future workplace and learning. The incredible growth had created challenges for educator to expand educational opportunities beyond University campuses to provide on-demand, anytime, anywhere instruction. However, faculty members often lack the skills necessary to create online courses because technology use was not part of their pre-service education (Cyrs, T. 1997). This study compared the use of a cohort model and the typical individual online course development by faculty with reference to technology, instructional and psychological support.
Solving Technical Problems

Technological problems comprised concerns related to the hardware and software used in online learning environments. These include problems related to bandwidth, speed of communication lines, software applications, and cost. The most prominent technological challenge identified by the study was the frustration associated with lack of knowledge in using the software (Blackboard CourseInfo 3.11) by individual faculty working alone. Individual faculty members working alone on course development adopted different approaches to developing their online courses:

Locate an Expert. The individual faculty members with limited skills and knowledge of developing online course used a paid expert in course development. The expert was typically a former student of the program who was very familiar with the course content. Typically they had no face-to-face interaction and all discussions were conducted via e-mail and the telephone. Using such an approach helped the faculty member to avoid having to be confronted with technology issues associated with the use of the software. The faculty member used the expert as a sounding board for technical problems.

Locate a Helper. Friends with technical knowledge were also identified as sources of help to some individual faculty members building online courses. One faculty member working alone stated, “I posted all the contents and inserted the images and then I gave it to my friend. He kind of made it look nicer by using Photoshop and inserted some graphics”. The faculty member spent some time with the helper, three to four hours, to learn how to use the Blackboard CourseInfo software. The rest was e-mail back and forth, and it was effective. Several faculty stated, “Having a helper gave me the encouragement I needed to do more”.

Locate a Mentor. Some faculty members identified mentoring as being an effective and efficient approach to online course development. Comments often included statements as; “it is faster if someone helped you than trying to figure it out yourself”. The drawback to this approach was the limited number of meetings schedule to work together. Often the mentor and faculty member did not feel obligated to meet due to the independent nature of the course development.

Build a Team with Skills. In another approach a team of faculty members with expertise in different subject areas agreed to develop an online course together. Each member of the team was identified as having specific skills to give to the course. The member with skills and knowledge in technology applications was responsible for any technical setbacks that they encountered in the course development. This approach to “figuring things out” depended on one individual. The longer it took to figure it out, the longer the team had to wait.

Locate Support. Individual faculty members also identified several sources of support, one being the online manual for Blackboard. When confronted with a technical problem the faculty member referred to the online manual or used the “Help” menu. “I would go to the manual to try and figure it out and if I couldn’t then I would call the mentor”, stated an interviewee. Faculty learned to rely on their own ability to problem solve with the help of manuals. Several indicated they had not used online HELP functions in the past but were experts after developing the online course. The CITL was also named as a source of technical support by individual faculty. Periodically, the center organized workshops for faculty members.

The study indicated that in all the above-mentioned approaches there was also very limited interaction and the main channel of communication was through the e-mail. This left many feeling frustrated with the technical problems and slow rate of online course development. Frustrations were sometime due to messages that were not clear and instructions that are difficult to follow.

According to Forsyth (1990), a group is defined as two or more interdependent individuals who influence each other through social interactions. Communication within the cohort was mostly verbal, at any place and anytime. Individual’s technical problems were discussed in offices, hallways, and meetings and at every possible opportunity. Proximity among individuals favored frequent interaction and communication. Individuals’ had their offices in the same building and often next to each other. There were frequent face-to-face interactions that promoted positive interdependence.

Individuals felt supported technically and inspired to develop their online courses. One cohort member admitted his lack of desire to use the technology was altered when he began working with the cohort. He stated, “First it [cohort] has exposed me to the reality of using technology which I have been shying away from. Because I don’t understand the language. But this challenge is helping me to face reality and I like that. I am excited working with a cohort”. Several faculty in the cohort echoed the statement of this cohort member, “I saw how excited she [a cohort faculty member] was about the online course development and how well her course was going and I thought, I want to do this too. And I can with her help!”

843
Cohort members found that each had technical strengths that they could call upon when the technological tasks seemed overwhelming.

**Battling with Instructional design**

The impact of online learning on the learner was of major concern to all faculty members. Both the individual faculty members working alone on their online course development and the cohort faculty members voiced concerns about developing strategies that would empower the learner, encourage cooperative and independent learning as well as active learning in the online environment. A complaint often voiced by learners in the online learning environment is that they feel isolated and unconnected to other members in the class or to coursework.

How to design online instruction to meet the standards, how to stimulate critical thinking, questioning, and discussions, how to ensure effective group work, case study development, inquiry projects, and lectures were the same concerns voiced for the online instructional design as with the traditional instructional design. One individual faculty stated, “All of these things added together make an interesting course and only some of those things are available to you on the online format.” In questioning the individual faculty, the medium seemed to drive the methodology thus challenging individual faculty member’s ability to create online courses with desired instructional goals. In certain disciplines e.g. educational administration, faculty members were confronted with the problem of how to vary the instructional format. “The design was a real challenge and having to re-think teaching strategy was a real challenge”. The designing of the online courses seemed most difficult to the novice faculty member and the amount of time spent in the design and redesign was often at the expense of other duties.

Deciding on the content, materials to include, how much information to provide was a constant question in the instructional design process. An individual faculty member stated, “Working in an environment that is filled with multiple media can lead to feeling of being overwhelmed. In developing the course, it was hard to figure out how much information I needed to put in the course. It took a lot of time and effort, many months of work.” Many indicated that the course must be complete when implemented or the results can be disastrous. Faculty indicated that the changes made after the course is implemented take enough time without working on building the course as you teach.

The study also indicated that some individual faculty members were concerned with students’ reaction to the information provided and choices for students. Several suggested, “There were hundred and hundreds of links. Information to reinforce content, there were quizzes and group projects.” Bringing in a sense of humor and the personality of the instructor online was another concern of all faculty. “In a classroom you can use sense of humor, but in this format, I created some pop-up boxes to bring some other kind of things into the course. It was a little frustrating at times and it took longer hours to get things done”.

Members of the cohort group were supportive of each other as a result of interaction and collaboration throughout the development of their online courses. The cohort members indicated that by working together they had an opportunity to become better acquainted with the courses that the other cohort members taught. They were able to better understand the connections between the courses in the curriculum and offer suggestions for connecting the courses through the instructional design process. One cohort member stated, “We saw that the audio/listening pieces could actually be worked on over a spring and summer rather than in just one course. This made the content of both courses richer for the student.”

The cohort allowed their creative potentials to be combined for a common purpose. “We had a meeting and we talked about what each other is doing, how it has to be done and how to help each other”. “If someone in the cohort was more technologically skilled, that person would help everyone learn how to use the technology and we would in turn help them with developing their content so they were not overwhelmed by doing it all”. This allowed individuals to reveal themselves to one another and to receive feedbacks from the group. This process also helped individuals to develop new skills.

**Psychological Concerns and Support**

The study indicated that individual faculty members were worried about knowledge and skills in using the software (Blackboard CourseInfo 3.11). One faculty member said, “The first time I taught online I got 80 emails from the students the first day, which for some reason I hadn’t anticipated. I thought, how could I ever do this many emails day to day? When I told a group of my colleagues about all the emails, they said, well you
shouldn't have built the online course. I felt rejected by my peers. Here I wanted to be innovative and teach in a different medium and my colleagues didn't support it. I thought, I will never do this again”.

The study also indicated that individual members realized that developing online courses was extremely labor intensive and so having about two people or three on a team, would enable the sharing of work, sharing of ideas and perceptions of what’s going on and shape the activities for better learning. One individual faculty member who had found a helper said, “Availability of immediate help/support is essential for individuals working alone, as it releases stress”.

Other concerns included how to ensure that the assignments were reasonable and the trouble of having to make this decision alone when there was not a clear understanding of the online environment. One member of the cohort concluded, “Working with a team guarantees moral support and this is too much work for one person to do”.

The cohort members had the opportunity to interact and become interdependent emotionally as they worked toward a common success. The cohesiveness within the cohort promoted a sense of trust. Surrounded by a network of support and mutual understanding, members in the cohort had higher self-esteem and experienced lower levels of anxiety. Individuals within the cohort felt free to explore their own potentialities, risk self-revelation and try novice ideas because they felt surrounded by a supportive environment. The cohesive nature of the cohort afforded the opportunity to share thoughts and emotions. Consequently an emotional safety environment was created.

An empirical research on cohorts in university setting conducted by Hill (1992) and Kasten (1992) indicated that students in a cohort reported receiving psychological support from group members, feeling of reduced sense of loneliness, and developing strong affiliations. The study revealed that interaction made them feel connected and not isolated. The also felt emotionally secured. "She was by my side when I am doing all these”.

Several cohort members echoed this research sentiment, “I know that they [other cohort members] will be there if I have problems so it makes this easier and I am sure that I will be successful and our program will be successful.”

Conclusions

To change the world, faculty need reasons to take risks, to incur resistance, hazard failure, and to grasp the opportunities for action that their vision avails them. It is hoped that this research will provide information concerning the processes occurring when faculty develop online courses with respect to the technical, instructional, and psychological changes associated with online course development. While much research has been conducted concerning the learning that occurs online, the differences and similarities of the learning that occurs, little information is available concerning the changes that faculty undergo as they move from the traditional classroom to the online classroom.

With the use of a cohort formed by faculty, the isolation and frustration often felt in the development of online courses can be lessened. The faculty members of the cohort group within a college or program typically have similar experiences in classroom instruction and similar interactions with the students that they will teach. The researcher's own experience and antidotes obtained from faculty who have developed their courses without support indicate that the isolation of developing and teaching online can be detrimental to continued online teaching. Also peer pressure by fellow faculty members does not always support the development of online courses, which leads to further isolation. Members of cohorts often remark that the cohort provides them with needed emotional support during periods of stress. The collegiality of the group supports the successes of each person within the cohort and lays a foundation for intellectual stimulation.

Teachers as Multimedia Authors: A Workshop Developer's Experience

Joseph J. Frantiska, Jr.
University of Massachusetts
School of Education
jfrantiska@aol.com

Abstract: The advent of New Media provides a unique opportunity for teachers to develop their own educational websites. However, learning the necessary techniques and procedures can be difficult. One method for delivery of these skills is to develop a workshop with the objective of learning hypermedia development skills via an integrated project. Using the project as the main teaching tool allows for the learning of the new skills with immediate application to an end product.

Background

Considerable discussion has been made about how best to instruct teachers on designing and developing educational websites. In 1996, a three-hour workshop was given at the Massachusetts Educational Computing Conference on developing such a website. In such a short period of time it is necessary to impart the basic yet important concepts for a successful development process. It was decided to develop the workshop in an integrated lecture / lab format. That is, the participants would be taught a particular concept and then immediately implement it. This gives the participant quick feedback as to their progress in understanding the concepts as well as an appreciation for the practicality of them.

While this format aids the learner, it does create some additional concerns for the instructor / workshop developer. Pedagogically, the workshop was designed and presented in a top-down approach. A top-down approach can be analogized to the construction of a pyramid. The more intricate upper layers are dependent upon the larger, less detailed layers being laid down properly and forming a solid base for construction. The workshop developer must determine what concepts come first and then lay out the remaining sequence of concepts and procedures.

Design and Development

The basic structure of the finished project of the workshop was a main page discussing tornadoes and hurricanes at a high level of detail with links that point to a series of pages that describe each phenomenon in greater detail. Also, an interactive form could be chosen to collect information about the user. A person deciding to follow the tornado path would see text and graphics detailing tornado characteristics as well as a map of a tornado ground track as well as a sound file of an actual tornado. Following the hurricane path will encounter text and graphics describing hurricane behavior and statistics as well as a Quicktime movie of a hurricane from a weather satellite perspective.

The first step was to describe the basic structure of a web page in Hypertext Markup Language (HTML) which was the language used to develop all pages in the site. Drawing on the pyramid analogy, the participants were initially taught the basic structure of an HTML page including how to embed links to point to other pages. They then created the main page with the required text and links to the hurricane and tornado sequence pages. To further complete the skeleton of the site the structure of each of the tornado and hurricane pages were completed.

The hurricane sequence was arbitrarily chosen as the first sequence to be completed. The first page contained links and accompanying text that described Hurricane Luis that hit the Caribbean in 1995, a Quicktime movie of Hurricane Marilyn and text of how hurricanes are formed and categorized. Building upon the basic page structure, participants were instructed in embedding graphic files and then built the Luis page. Next was a
discussion of animation and Quicktime formatted files. The students then added text and a link to the Quicktime file to the Marilyn page. Finally, methods of structuring text lead to an exercise of putting text on the formation / categorization page.

The tornado sequence was then constructed. The main tornado page consisted of a picture of the tornado which struck Wichita, KS in 1991 with some special (blinking) text. Also, a link was provided to view a diagram of the path of the tornado which struck Dimmitt, TX in 1995. Links were also added to point to a page containing a sound file of an actual tornado, a page describing tornado statistics on a state-by-state basis and a page about how to protect oneself in the event of a tornado. As with the hurricane sequence, students were instructed in the required HTML skill and then immediately implemented the necessary procedure(s) to construct the particular page. Along the way, the participants understood how to embed graphics of different types and how each type is appropriate for various instances. They also practiced embedding and understanding sound files, tables and alignment of text portions.

Another important skill that was obtained was the understanding of how all pages in the site can be connected to provide a concise, rich field of knowledge as seen in the figure 1. The dashed lines represent links back to the main pages. The importance of this skill can be seen by the complexity of linkages even in this relatively simple site.

![Figure 1: Final Website Configuration](image)

**Conclusion / Results**

The experience for the instructor and students was a worthwhile one. Students commented on the utility of the skills learned and short time it took to acquire them. They also felt that this "boot camp" approach was an efficient use of their time and many felt a desire to continue learning more and to do some projects of their own. From an instructor's viewpoint, the experience was rewarding and informative. The short course time requires that great care be taken to follow concise but complete instruction immediately with relevant practice and feedback in an efficient manner.
Proactive Faculty Teaching and Learning Initiatives

Abstract: Faculty do not always get the luxury of time or money to attend professional computer training sessions and read computing trade publications cover to cover. Yet, there is an expectation for continued professional development, often beyond their area of expertise. Academic Computing at the University of South Florida will present the current best practices utilized for faculty training, support and professional development. This presentation will also cover an overview of how Academic Computing integrates into the VITAL consortium and the evolution of faculty computing services. IT support professionals, and faculty will leave this presentation with abundant and diverse ideas to make faculty learning tailored, yet quick and effective.

The computer industry's constant evolution requires full time observation and training to stay abreast. For faculty, the constant pressure of infusing technology into the curriculum and classroom requires deft computing skills and current computing knowledge. Since faculty do not always get the luxury of time or money to attend professional computer training sessions and read computing trade publications cover to cover, there needs to be a treasure chest of efficient and effective computing resources. This expectation for continued professional development can often be met with campus computing resources.

At the University of South Florida several collaborative initiatives are addressing this hot topic. On a broad scale, the VITAL (Virtual Instructional Team for the Advancement of Learning) consortium was established in 1997 to provide a support structure for faculty wanting to integrate technology into their teaching and learning models. VITAL is comprised of seven departments joining forces to utilize differing approaches and services. VITAL units offer faculty assistance and support they need. Through VITAL, faculty members are encouraged to seek individual mentoring and assistance as well as attend workshops designed for small groups. Faculty who want individual assistance with technology issues can call upon a "generic" VITAL contact through multiple means. To facilitate access, VITAL has a web site (http://www.usfedulvital), an email list (vital@usfedu), and a central phone number. Academic Computing participates in this consortium of departments. This paper will focus on the proactive measures Academic Computing takes to provide faculty with computing support and instruction.

Academic Computing supports faculty, students and research while providing a wide variety of technical services. Faculty technical development is also explicitly provided in the Academic Computing training center and the faculty computer lab. These areas, known as Faculty Academic Computing Technologies (FACT), were consolidated and devised to fill the need of faculty needing necessary skills and access to technical resources. Services offered by FACT can be categorized into three areas: technology review, training and computing facilities. Each part serves a different facet of faculty needs, but ultimately all three areas intertwine to provide the best possible computing environment in support of instruction and research.
Technology Review: The FACT Review is a means for faculty to learn about new technologies, costs, comparisons and diverse uses. This FACT area also provides electronic access to resources and tools developed within Academic Computing. Basically, computing tools desirable to faculty are reviewed or created and presented. A review database contains details about the products, such as, technical specifications, screen captures, demonstration files, links to relevant websites and reviews for usability and performance. The database is available online for searching, categorizing and comparing reviewed resources. Hands-on demonstration sessions are scheduled in multiple, short time chunks for participants to experiment with and consult with the review staff. Resources are identified by request, as well as by staff keeping pace with the technology industry. The process and database development began fall 2000 after conceptual ideas were gathered from technology trade publications and electronic resources (e.g., PC Computing's A-List). With a student staff of two, more than five products have been examined as of November 2000. The fledgling review process has not yet been fully advertised, but approximately 25 faculty members have participated in three product presentations. The growing clientele of faculty have expressed positive feedback. Most have noted that the service simplifies searching for appropriate tools to utilize in and out of the classroom, and minimizes time spent learning a new product.

Training & Presentation: The Academic Computing Training Center not only presents the review seminars as noted above, but also presents training on integrated environments for hosting web-based courses and basic through advanced computer skills instruction. The classes are known as 'Class Shorts' and are offered on a wide range of current software, hardware and programming topics. Classes are time chunked in 15 minute to 2 hour blocks and are offered at varying times throughout the day, evening and weekends. Approximately 20 classes are offered every week with 10 seats available in the training center. Classes are also organized into beginning, intermediate and advanced task specific levels. The sessions can be taken individually or in series. The goal of this format provides the potential for learning whole applications or just needed tasks. The result of this concept is a flexible type of computer skills training to meet the needs of a wide range of faculty and students. The program, which has been in operation since January 1998, has served approximately 5,500 participants both in the Academic Computing training center or at 'on site' instructional labs on any of USF’s four campuses. The program utilizes training materials developed in house, free resources online and purchased course materials (e.g., ez-ref software). Another growing area of the training center is “training on request.” Faculty request an Academic Computing instructor to come in their classroom (either lecture based or hands-on computing) and teach a computing topic. Most popular topics include: campus-computing services for students, web development and campus email. Faculty have also used the training as an extra credit tool for students in their courses.

Computing Facilities: The FACT Lab contains hardware and software in support of faculty technology development. The student-staffed support lab contains equipment and resources that enable faculty to learn new computing skills while developing class content, or to focus on professional development. This faculty-only lab provides equipment, consulting, instruction and support for tasks such as online course development and image design, CD burning, web development, scanning and digitizing text. In addition, faculty members also receive assistance via email and phone on a wide range of computing related topics and technical troubleshooting. The lab currently operates with six workstations 40 hours a week. In a typical semester, approximately 50 faculty have utilized the lab with more than 200 visits.

All areas are thriving due to a highly skilled staff who enthusiastically embraces developing, working with and presenting new technologies. Currently, one full time staff member and seven part time student employees sustain this area of Academic Computing. It has been our experience, that the abundant and diverse types of output for our resources make faculty learning flexible, tailored, quick and effective. The collaborative efforts of the VITAL consortium also help to increase awareness of these great resources, and offer additional means to reach our faculty audience. As a result, the services provided by Academic Computing are continually evolving to meet the needs of our diverse population and the challenges for improved learning presented by emerging technologies.
Abstract: Teacher staff development implies change. Staff development for teachers to incorporate a new technology into their classroom practice assumes that changes in student and teacher behaviors will occur in the form of teachers and students using technology in the teaching and learning process. Technology training for teachers often falls short of its anticipated outcomes. This paper will describe an instructional design model for teacher staff development to train teachers to integrate the Internet into their classroom routine. It is proposed that a staff development program designed to effect change in a participants' values and beliefs, provide knowledge of skills and strategies for immediate application in the classroom, and acknowledge the stages of development in the adult learning process will result in sustained change in classroom activities. The instructional design for the teacher staff development delivered through Project REFLECT offers such a model.

Introduction

With the emphasis on school reform at the forefront of many discussions regarding American schooling, the imperative for teachers to learn to use technologies for instructional purposes has accelerated. Pressure can be observed from a variety of venues including the government through legislation, accreditation organizations, school administrators and decision-makers, the corporate world, and the general public.

Unfortunately, current technology training for teachers is inadequate. Only one in five teachers report they are comfortable using technology. The U.S. government recommends schools spend 30% of their technology monies on training but in reality only 12 - 18% is used for that purpose. Training is often a one-shot event and frequently is conducted by non-educators. Clearly there exists a need to transform the way we plan for, design, and conduct technology training for teachers.

The focus of this paper is to describe an instructional design for a staff development program for classroom teachers to learn to integrate the Internet into their day-to-day classroom routine. The staff development instructional design is manifested in an inservice course in which teachers learn new skills, explore classroom applications, and reflect on their teaching philosophies and practices. Although the ultimate goal of the course is to enhance the learning experiences of K-12 students, the course is a professional development experience delivered to teachers. The staff development focuses on teachers' acquisition of technology skills, identification and development of classroom pedagogical practices using Internet technologies, and recognition and evolution of participants' values, beliefs, and practices regarding Internet-based instruction in the K-12 classroom.

Theoretical Foundation

Teacher's Developmental Stages

The scope and sequence of the curriculum design follows a model of stages of development. This approach is based on the research on teacher competence and experienced and expert teachers (Berliner 1988; Sternberg and Horvath, 1995), diffusion of innovations models (Rogers, 1995) and the ACOT studies of adoption of technology (Fisher, Dwyer, and Yocam 1996).

Sternberg and Horvath (1995) suggest an Expert Teaching Prototype with three primary features distinguishing the expert from the novice: Knowledge, Efficiency, and Insight. Briefly, the Expert Teaching
prototype suggests that experts bring more knowledge to bear in solving problems and do so more effectively and efficiently than do novices. Further, experts are more likely to arrive at creative solutions to problems than their novice counterparts. Sternberg and Horvath are quick to clarify that not every experienced teacher is expert. The expert teacher, then, is knowledgeable and has extensive accessible knowledge that is organized for use in teaching. The prototypical expert teacher has knowledge of the organizational context of the classroom and is able to adapt to the practical constraints of teaching. The expert teacher, according to Sternberg and Horvath, is able to perform the many activities of teaching with little or no cognitive effort. Finally the expert teacher is planful and self-aware in approaching problems and is able to derive solutions to problems through selective analysis of information (Sternberg and Horvath, 1995).

David Berliner describes his Pedagogical Developmental Stages, which focus on describing teachers within each of his five proposed stages. The stages characterize teachers in terms of their classroom processes, interpretation of classroom events, attention to feedback from classroom activities that affect immediate decision-making, and schema development. The five pedagogical development stages with a sample of defining characteristics are: Novice (deliberate, gaining procedural knowledge), Advanced Beginner (insightful, developing strategic knowledge, still unable to differentiate what is important), Competent (rational, sets priorities based on experiential knowledge, takes personal responsibility for classroom results), Proficient (intuitive, recognizes similarities within differing situations, analytic and deliberative), and Expert (arational and intuitive, non-analytical and non-deliberative, fluid and seamless).

Novice teachers, when confronted with new curricula or pedagogical approaches, begin with the literal, obvious aspects of the lesson or content. Teachers must first comprehend the content and develop a skill base with it before they can begin to apply the material to a learning situation. As teachers gain expertise, they begin to strategize how to teach with the new material and discover and create applications in the classroom for the new material. Later, teachers begin to focus on the interactions of the students with the content and teaching experiences and focus less on the "prescriptive" aspects of the curriculum. As teachers become accomplished with the given content, they re-work it into their personal instructional repertoire, building on it and reshaping it to accommodate their teaching philosophies, beliefs about learning, and student needs and interests. These developmental stages are not limited to beginning teachers. Indeed, experienced teachers, when faced with using or teaching a new curriculum or content also progress through the developmental stages.

This stage-oriented continuum loosely parallels some models for diffusion of innovation. Rogers (1995), for example, suggests five stages in the "innovation-decision process through which an individual passes from first knowledge of an innovation, to forming an attitude toward the innovation, to a decision to adopt or reject, to implementation of the new idea, and to confirmation of this decision" (p. 163). The Apple Classroom of Tomorrow (ACOT) research also proposes stages of development for teachers to embrace technology for use as a routinized part of the curriculum, beginning with acknowledgement of the technology's presence, to using it for traditional teaching tasks, to adapting it to specific elements of the teaching and learning process and enhancing productivity, to using it effortlessly and with minimal cognitive expenditures, to creating new knowledge and learning experiences with the innovation. As teachers consider adoption of a new curriculum or content, they may be observed, over a period of time, moving through the stages of adoption as described by Rogers or the ACOT studies. This is significant for staff development planners. Since the purpose of staff development is to prepare teachers to adopt and embrace a new curriculum or pedagogical practice, understanding and considering the stages for adoption can enhance the staff development experience.

Rogers provides a model for the adoption of an innovation in his fourth edition, Diffusion of Innovations (1995). He purports that an individual's decision about an innovation is not instantaneous, but rather is a process that occurs over time. He suggests that there exist sequential stages in the process of innovation decision-making: Knowledge (awareness of the innovation and how it functions), Persuasion (a positive or negative attitude is formed about the innovation), Decision (decision-maker participates in activities that lead to a choice to either accept or reject the innovation), Implementation (innovation is put into use), and Confirmation (reinforcement for the innovation-decision already made is sought). Rogers' model is one of several that explain diffusion events.

The Apple Classroom of Tomorrow (ACOT) studies (Dwyer, Ringstaff, & Sandholtz, 1990) describe the evolution of teachers' use of technology in their classroom settings. Teachers in the study were provided with "constant access" to technology and were observed and interviewed over a period of time. The results of this early study contribute to our understanding of the process of teachers' integration of technology into their teaching practice. The researchers describe the instructional evolution in technology-intensive
classrooms in five phases: Entry, Adoption, Adaptation, Appropriation, and Invention. At the Entry phase technology existed in the teachers' classrooms. Teachers attempted to fit the technology into the familiar paradigm of textbooks, chalkboards, and workbooks. At this phase experienced teachers were faced with the same problems as novice teachers: discipline, resources management, and personal frustration (Dwyer, Ringstaff, & Sandholtz, 1990). In the Adoption phase, teachers were described as attempting to use the technology resources to supplement and support traditional instruction. During the Adaptation phase the major theme that emerged was productivity. Students and teachers took advantage of their knowledge of the use of technology to become more productive. The Appropriation phase occurred in the second year of the project. This phase is evidenced by teachers demonstrating an understanding of the technology and using it effortlessly to accomplish their work. The final stage, Invention, is described as a "placeholder" in which ACOT teachers can further develop and wherein new learning environments may be created (Dwyer, Ringstaff, & Sandholtz, 1990).

The research on expert teachers development and pedagogical development and that on adoption of innovations informed the instructional design for the curriculum for Project REFLECT. The staff development for technology integration curriculum follows a paradigm similar to the models presented above, starting with basic and familiar topics, providing the learner the opportunity to develop a skill base with Internet technologies. As the learner becomes familiar or proficient with the skills of the innovation, the staff development curriculum guides the learner into exploring and then developing teaching strategies for using the content and skills. The learner begins to develop his/her own applications for use of the innovation for use in the classroom and ultimately embraces the content as a basic element of his or her own teaching. This model recognizes that teachers typically go through stages or processes prior to embracing an innovative curriculum or pedagogical practice and that this process is not instantaneous, but rather, takes time. The curriculum is presented in modules or strands in a developmental fashion. A more expert individual may be comfortable starting later on the developmental continuum. A table (Table 1) summarizing the aforementioned models and the developmental stage elements of the staff development model for Project REFLECT follows.

Motivational, Change, and Adult Learning Theories

The literature on change theory informs us that change in a pattern or practice will occur only after individuals change their normative orientations to old patterns or practices and develop a commitment to new ones (Chin & Benne, 1984, p. 23). "Changes in normative orientations involve changes in attitudes, values, skills, and significant relationships, not just changes in knowledge, information, or intellectual rationales for action and practice" (Chin & Benne, 1984, p.23). This strategy for change is referred to as normative-re-educative. This theory goes on to suggest that acceptance of a new set of values and beliefs usually cannot be brought about in a piecemeal fashion. A value system is a system and therefore must change as a system, not item by item (Chin & Benne, 1984). The theory rests on the assumption that the individual plays an active role in the re-education process, interacting with the stimuli from the environment and making...
decisions about how or whether to incorporate the new value among those existing. Lewin referred to this as life space (Marrow, 1977) in his Field Theory. Field theory is a motivational theory whereby the individual is seen as a system under tension (Patnoe, 1988). Tensions arise when there is a need or a want (Marrow, 1977, p. 34). Life space encompasses the needs, goals, unconscious influences, memories, beliefs, events of a political, economic, and social nature, and anything else that might have a direct effect on one's behavior (Marrow, 1977). Behavior, according to Lewin, is a function of the person and his environment. As a person attends to a tension and accommodates a new belief, value, idea, he begins the re-education process.

Effective re-education must affect the person being re-educated in three ways (Benne, 1984, p. 274). The person's cognitive structure must be altered (modes of perceptions, ways of seeing his physical and social worlds, and facts, concepts, expectations, and beliefs). The individual must modify his valences and values (principles of what he should consider doing and not doing, attractions and aversions to his and other groups and their standards, feelings in regard to status differences and authority, and reaction to different sources of approval and disapproval of himself). Finally, re-education must affect the individual's repertoire of behavioral skills. It takes time and effort in training for a group to learn a method of experimental inquiry where their own feelings, perceptions, commitments, and behavior are the data to be processed in the inquiry (Benne, 1984, p. 227). Extensive hands-on experiences do not automatically create correct concepts or knowledge (Benne, 1984).

The idea that deeply held beliefs can stand in the way of change is not new (Dwyer, 1990, p. 36). Teachers' beliefs about instruction and schooling are important factors that underlie the institution's resistance to change (Dwyer, 1990). Fenstermacher (1979) suggests that normative-re-education can be accomplished by getting teachers to reflect on their beliefs in light of reasonably objective feedback and on their actions and the consequences of their actions. First, however, Dwyer (1990, p. 37) maintains that teachers must see and understand the connection between their beliefs and actions and they must also be aware of alternative belief systems.

Argyris and Schön (1974) suggest that individuals (or systems) may have two sets of belief systems or theories that guide their actions: theories-in-use and espoused theories. Theories-in-use are theories that are acknowledged as such and espoused theories are ideas that individuals say they believe (Young, 1990, p. 132). A problem may occur when the ideology of the organization or system is incongruent with the real motives and goals of its participants (Young, 1990). Advocates of change tell teachers and administrators to abandon their conceptions and the consequences of their actions. First, however, Dwyer (1990, p. 37) maintains that teachers must see and understand the connection between their beliefs and actions and they must also be aware of alternative belief systems.

Argyris and Schön (1974) suggest that individuals (or systems) may have two sets of belief systems or theories that guide their actions: theories-in-use and espoused theories. Theories-in-use are theories that are acknowledged as such and espoused theories are ideas that individuals say they believe (Young, 1990, p. 132). A problem may occur when the ideology of the organization or system is incongruent with the real motives and goals of its participants (Young, 1990). Advocates of change tell teachers and administrators to abandon their conceptions and the consequences of their actions. First, however, Dwyer (1990, p. 37) maintains that teachers must see and understand the connection between their beliefs and actions and they must also be aware of alternative belief systems.

The Instructional Model
Design of the Course
The Internet Classroom Teachers Training Course (ICTTC) offered to teachers through the funded grant, Project REFLECT, is a comprehensive curriculum designed for K-12 classroom teachers to learn to effectively infuse the Internet into their regular curriculum. The staff development model weaves the
technical knowledge and skills a classroom practitioner needs with pedagogical practices, organizational approaches, evaluative strategies, and the aims of the regular curriculum. These cognitive structures and behavioral skills are approached and brought about as each individual reflects on her or his own philosophical perspective and values, beliefs, and practices about teaching and learning. The design of the staff development model is based on the assumption that people learn best and retain more when they actively participate in the teaching and learning experience.

Elements of the Course Design

The course has three primary desired outcomes: 1) the acquisition of Internet technology skills for use in the classroom, 2) the development of pedagogical practices to incorporate the technology innovation, and 3) the identification and evolution of the course participants' values, beliefs and practices regarding the technology innovation. To this end the course content is divided into six modules or strands. The instructional design of the course provides for beginning with basic and familiar topics to develop a skill base and then moves toward the development of teaching strategies with the technology innovation. The course assignments through which the skills and pedagogical practices are developed have direct application for classroom practice. Discussion of issues, concerns, philosophies, and theories that underpin the Internet technology in the classroom are woven throughout.

The scope and sequence of the six modules acknowledges the stages of development of teachers adopting a curricular innovation. It presents the cognitive elements of the course in a simple to complex approach, allowing and encouraging participants to work the new content into their own teaching practices and to ultimately create new ways to use the content. This approach is consistent with and supportive of the Expert Teaching Prototype, developing the knowledge base, accommodating it into the classroom practices, and ultimately applying it fluidly and effortlessly into the teaching act.

Course participants generally work in pairs and are involved in mentoring one another in the Project REFLECT model - in class and through electronic dialogues outside of class - and are responsible for planning and conducting staff development activities for colleagues in their own schools using a "train-the-trainer" approach. Although the teachers generally move through the Pedagogical Development Stages over a long period of time, the experiences of students as teachers and teachers as students support the Pedagogical Development Stages and help to expedite the process. Course participants, informally, through the accomplishment of course activities and assignments, have the opportunity to mentor one another or to conduct mini-lessons for one's peers. It is evident through observation of these spontaneous and planned lessons that participants are tapping into their newly acquired well-organized knowledge base to efficiently solve problems or accomplish learning goals. In a more formalized activity, participants design and implement staff development activities related to the course content for teachers in their schools. Mentoring acknowledges the rich backgrounds that each adult learner brings to the course and also provides the opportunity to try out one's new knowledge and pedagogical practices in a "safe" environment, building content and pedagogical knowledge and assessing the "fit" of the innovation into one's own value system. The breadth and depth of the course curriculum and the manner in which the content is presented are key factors to the success of the ongoing and recurring use and further development of the content by individuals. Learners learn at different rates and bring a myriad of experiences, backgrounds, and beliefs to the instructional setting; therefore, the instructional design of the staff development course must consider these varied learning rates and stages and provide for learning to continue after the formal instruction of the course has ended. Course participants have an opportunity to return to the course resources (website and curriculum guide) long after the course has ended. They still have available all course resources after they individually have had the opportunity to consider the adoption of the curricular innovation or have developed the content or skill base to the degree whereby they can effortlessly accommodate it into their instructional repertoire. Too often staff development programs assume the training (and therefore learning) is ended at the conclusion of the session.

For sustained change to occur or for an individual to consider adopting a change, however, the individual's value system must be affected. Demonstrating knowledge of the innovation or observing a pedagogical practice associated with the innovation is not, in and of itself, sufficient to ensure real and sustained change. The staff development program must effect a change in the participants' value systems or attitudes. As Project REFLECT course participants acquire new knowledge and skills and accommodate these into their own classroom practices, they are provided opportunities to reflect on their new knowledge, ideas, and practices. These reflections occur informally in class and through electronic communications with
classmates as well as individually through a form that is completed on the web by each participant at the end of each module. This reflective activity is one that provides a richness in the staff development experience, providing course participants with an opportunity to examine their values, beliefs, and philosophies and to analyze them for fit with the instructional technology experience. Participants also reflect on their own teaching and learning experiences and often develop strategies to enhance their own teaching and their students' learning.

Conclusion

The staff development model used in Project REFLECT for classroom teachers' Internet instruction considers the literature on teacher stages of development and change, motivation, and adult learning theories. The model begins by presenting basic and familiar topics to develop a skill base, moves toward the development of teaching strategies that have application for classroom practice, and encourages innovative uses of the new knowledge and skills. Discussion of issues, concerns, philosophies, and theories that underpin the technology in the classroom are woven throughout. Teachers are actively engaged in the learning process and build their new knowledge on their existing schema. Teachers reflect on their values, beliefs, and behaviors regarding use of the Internet technology innovation in their classroom practices. Staff development such as this, that affects the entire system, the whole person, can result in sustained change.

Teaching on the Web: A Constructivist Approach to Faculty Development

Dr. Sanford Gold
FDR Station PO Box 1268
New York, NY 10150
Email: sholom_gold@yahoo.com

I. Introduction

One of the affordances of the new online learning movement is the opportunity it presents to reexamine the ways in which some aspects of traditional instruction can be re-conceived to operate effectively in the online asynchronous environment. This technological shift -- from knowledge being fixed to a certain time and place, to knowledge being accessible at anytime and at anyplace -- creates the potential for a change in the way learning is transacted from those who provide information (i.e. teachers or facilitators) to those who receive it (i.e. students).

This article focuses on the training of teachers of higher education by means of a two-week workshop -- “Teaching on the Web: A Nuts and Bolts Approach” -- in online pedagogy and facilitation techniques. This workshop is used as the intervention to examine what the effects are of being an online learner on future online teachers.

Users were notified of the course through online advertising and email. Almost 90% of the students indicated voluntary participation. In the end, the class was well attended with 57 students on the official role; 44 completed the pre and/or post-course survey, a 77% completion rate. This group is the sample examined.

II. Results

This article sets out to answer the question whether or not exposure to the course had an effect on the forty-four sampled participants.

Hypothesis 1 - The extent to which respondents rethought their teaching practices was positively related to the increase in exposure to the course. This hypothesis was tested based on students answer to one survey question. From 0 (not at all) to 10 (very much), please rate the extent to which this class helped you rethink your teaching practices?

Using a linear regression model, comparing the dependent variable (mean= 5.74, SD=3.71) to the three independent variables, the results indicate a highly significant change in the sample’s rethinking their teaching. The results are at the .000 level and the over half the variance (r square=.531) is explained by
these three indicators. This confirms that the two-week intervention was successful in its aims of having teachers reexamine their ways of teaching when faced with the online medium. Total hours of exposure are the strongest indicator (partial p=.007), and more times students exposed themselves to the course and related materials, the stronger the effect.

Comparative changes in teachers’ philosophies are difficult to assess in a two-week intervention, and the author does not claim that the course fundamentally changed teachers approach to instruction. No pre-course data measuring teaching philosophies was gathered. However, qualitative data from the discussion board, students’ posts, and materials generated, and the result of hypothesis 2 indicate that the shift was more in line with constructivist methodology.

**Hypothesis 2** - The extent to which attitudes towards various aspects of online teaching and learning was positively related to the increase in exposure to the course. To study attitudinal change, the investigator devised a 17-item likert scale ranging from strongly disagree to strongly agree. Each attitude indicator, that is the difference between pre and post individual attitude means, was compared. Out of the 17 attitudes, three proved to be significant to the .05 level in a paired sample test.

- Online distance learning courses encourage more student participation than traditional face-to-face courses. (p=.005)
- Online distance learning teachers and students can produce learning outcomes better than traditional face-to-face teachers and students. (p=.013)
- Online distance learning courses have more student-to-student interaction than traditional face-to-face courses. (p=.014)

This finding is interesting and helps define what type of rethinking was taking place. Rethinking may be seen more in the direction of increased student participation and interaction. Students believed that learning outcomes derived from these practices were also efficacious. This finding provides additional validation of the course and its objective.

**Hypothesis 3** - This measure examined whether the frequency of the distribution of pre and post scores of a 15 question multiple-choice exam. Using a paired sample t-test, these results are highly significant (p=.000). The mean difference scores (pre = 4.68, post mean = 8.16) shifted upward signaling an increase in knowledge gained.
This shift is not completely explained by the course intervention. This means that the three measures, total hours, logins, and posts, do not explain the full treatment effects. Perhaps, exposure to the course may not have resulted in all the learning gain. The course was not designed to teach for the test.

**Hypothesis 4** - The question used to investigate this change was: *Should teaching online distance learning courses be a part of regular faculty work?* The difference in mean scores pre and post were compared to produce the dependent variable. Using a chi square test, a significant result was found (Chi Square = .036). The results can also be seen by the means of those who switched from before the course, indicating it was different from regular faculty work, to after the course, indicating it was the same as regular faculty work. The average means of the “different” group is 16 hours of course exposure while the “same” is 24. The six people that switched were exposed over 22 hours, higher than average.

These results point to the integration of the online teaching experience with the traditional one. Teachers who have more training feel as if the online world is an extension of their job, and not something unique or alien. These findings concur nicely with the Taylor and White survey (1991) of an Australian University’s faculty attitudes toward distance learning, and Pierpoint and Hartnett study (1988) of American programs, which concluded that the art of teaching and interpersonal interaction were highly valued in job satisfaction. [1] [2]. Lonsdale indicates current faculty reward structures show an over-reliance on extrinsic rewards and a lack of congruence between the established reward mechanisms and intrinsic motivation. Intrinsic motivation is characterized by the desire to participate in an activity where the reward is the act of participation itself. [3] Constructivist-based teacher training courses may be a vehicle to stimulate the intrinsic motivations of classroom-based faculty members as they go online to teach.

**III. ALN and Constructivism**

As a theoretical approach, the course employed a constructivist philosophy in its design. Constructivist environments start with observations within a world of authentic artifacts rooted in authentic situations. Students, while accessing various materials, construct ongoing interpretations of their observations, and collaborate with their peers. Finally, students serve as coaches and teachers to each other to show their mastery of what they learned. Researchers have pointed out the connections between the online medium and the constructivists’ framework of teaching and learning. [4] [5] [6] They claim that the learning methodology is as important as the instructional technology employed. There also seems to be a
connection between the pedagogical tendency of the teacher and their Internet use and valuation. The more constructivist the orientation, the greater the teachers’ average use of the Internet and the more positively they viewed its incorporation into instruction. [7]

In accordance with this research, the choice of instructional design for the training course was a deliberate decision; all attempts were made not to make an online teacher training course, but to make a constructivist online teacher training course. Instead of outcome, the class facilitator focused all his energies on process and tried to facilitate the students’ own ability to acquire knowledge.

What are the facilities provided by ALN that make implementing the constructivist approach more feasible? To examine this, the instructional principles of a constructivist environment need to be more rigidly defined. Piaget’s processes for knowledge construction are:

I. Assimilation - Associate new events with background knowledge and prior conceptions.

II. Accommodation- Change existing structures to new information.

III. Equilibrium – Balance internal understanding with external “reality” (e.g. other’s understanding).

IV. Disequilibrium – Experience of a new invent without achieving a state of equilibrium. [8]

The table below maps the Piaget’s four processes involved in the construction of knowledge, the principles involved and how they map to an ALN (adapted from Akyalcin, Constructivism – an epistemological journey from Piaget to Papert). [9]

<td>Assimilation</td>
<td>Anchor all learning activities to a larger task or problem. The learner should clearly perceive and accept the relevance of the specific learning activities in relation to the larger task.</td>
<td>Individual Unit activities leading to Team Project</td>
</tr>
</tbody>
</table>
VI. Results

In summary, results indicate that the teachers shifted towards a more constructivist orientation, valuing increased interaction and communication. Along with this change, teachers also gained some knowledge about distance education. This combination of content and experience provides dual reinforcement validating the course experience.

After exposure to the course, the respondents felt that online courses offered more student participation than traditional face-to-face courses, and that online courses have more student-to-student interaction than traditional face-to-face courses. Moreover, teachers saw the online medium as more of an extension of their faculty work. That is, teachers saw teaching is their job and doing it online was now part of their job. This would indicate that the central issue for the future of teachers is more about training and less about the correct reward structures.

Institutions should take note that as their faculty force becomes more empowered using this online medium; they will want to use it. After all, teaching is sometimes referred to as a calling more than a
regular vocation, and strong inner motivations need to be valued and recognized. The workshop's integration of method and medium is, the investigator claims, the primary reason for the positive results in changes in teachers' attitudes and thinking about educational practice. This reexamination of existing practices and adoption of ones more appropriate to the online learning environment is one of the affordances (i.e. change catalyst) of the Internet.

These findings buttress this corporatist, constructivist view of learning as contributing to deeper understanding that may affect behavioral change. From posted messages, activities, and surveys, the data showed that the ability to connect with others knowledge and experiences, as well as, their feedback is essential.

Abstract: The ACTIVE project addresses the need to improve the preparation of preservice teachers through providing instruction that models the integration of technology into classroom delivery. The focus of this project is ACTIVE—Authentic, Competency-based, Technology-enhanced, Integrated, Versatile, and Evaluative—curriculum. This project was funded by a Title II Teacher Quality sub-grant and began in fall 2000. Initial results from the first six months of operation will be shared. The researchers are also seeking information on similar projects.

Introduction

Making use of the Teacher Preparation StaR Chart: A Self-Assessment Tool for Colleges of Education (CEO Forum, 2000) Western New Mexico University (WNMU) has an overall ranking as a Developing Tech institution. The low ranking shows a strong need for a university-wide program to meet the technology needs of the preservice educators attending our institution. At the same time, in an effort to enhance teacher quality, the state of New Mexico (NM) has revised the competencies upon which its teacher preparation programs are designed. The ACTIVE Learning Project was designed to begin meeting both needs.

The Project

At the October 1998 Western Interstate Commission for Higher Education (WICHE), a panel of four university presidents emphasized the necessity of modeling the correct application of teaching strategies that include the integration of technology. Effective preparation of preservice teachers requires a college experience where the use of technology is modeled by professors in all subject areas. Technology infusion, by itself, does not improve student achievement. Desired changes take place only when the technology is correctly used.

Five ACTIVE Teams have been formed to meet the need for a connected learning community. Each team will include a School of Education faculty member, a teaching field faculty member, a preservice teacher, and a clinical faculty advisor from local public schools. Each graduate of the Teacher Education Program at WNMU must declare a “teaching field” which requires a State Department of Education approved 24-36 credit hour sequence of courses, i.e., language arts, math, science, reading, bilingual, social studies, and fine arts. While taking these specific courses, the student also must take a sequence of professional education courses. Field experiences are included at three levels: Exploratory, Curriculum, and Practice Teaching. The students chosen for ACTIVE Teams will be midway through the Teacher Education Program. The connection between the ACTIVE Teams and the Clinical Faculty will make a public school classroom available for university faculty and preservice teachers to use their skills as
they introduce curriculum designed through the project. Virtual connections will be established for team communication (Berg, 1999).

The age of most of the facilities at WNMU and the need for discussion and learning to take place 24 hours a day, and 7 days a week, necessitates the use of portable equipment to provide technology for this modeling (Young, 1997). ACTIVE teams are being provided laptops for this purpose. Chaffee (2000) describes the value of a similar initiative in North Dakota. The computers will remain university property and will be checked out to the faculty members for the duration of their participation in the project. Due to the fact that the majority of students attending WNMU cannot afford home computers, three laptop computers will also be made available to the student members of ACTIVE Teams on a shorter-term checkout basis. Faculty will be required to use WebCT for their courses and all ACTIVE participants will be included in a special WebCT group for collaboration and discussion (Biggs, 2000).

The initial activity of each ACTIVE Team was to set team training goals based upon the twenty NM Technology Competencies. In this way, the personnel of the project are able to design both individual and group sessions that meet the needs of the individual participants and teams. For training to be most effective, it must meet an immediate need of the trainee. The participants are also designing rubrics for the NM competencies (Krueger, Hansen, and Smaldino, 2000; Kemp et al., 2000).

This project is supported through the creation of an Expertise Center for ACTVE Learning. This space will house the personnel hired by this project, along with the technology and resources needed by the ACTIVE participants both for training and curriculum development, and will be fully integrated into the university’s network so participants can access the Internet and printers. The Expertise Center will be available “to train faculty to use technology, show them how to use it effectively in the classroom, and offer just-in-time technical support” (Rogers, 2000).

The funding for the project was received in September 2000, delaying the establishment of the project. Three teams have been created by early November with two more to be created soon. Anecdotal evidence will be shared with conference participants.

Abstract: Professional development that supports teachers as they create constructivist learning environments supported by technology allows them to construct professional knowledge about pedagogy, content, and technology, as well as strategies for managing a changing classroom environment. By providing the very experiences promoted for constructivist learning environments in the classroom, through professional development, it is possible that teachers will confront their “theories in use” to enable them to create learning experiences appropriate for the children of the Information Age. For this purpose, the Technology Assistance Group at the Southwest Educational Development Laboratory created six videos that portray several K-8 classroom teachers as they grew through the process of creating constructivist classrooms supported by technology. Featured in these videos are vignettes of students, teachers, and principals who share their experiences in learning, supporting, and the use technology to change teaching practices.

Creating a Vision With Technology

These two videos were produced in conjunction with a three-year project that involved 150 teachers in six site schools across five states. They were designed to be used as professional experiences for in-service and pre-service educators and These two videos provide several vignettes of students and teachers using technology in rural school districts comprised of low income families. Suggestions for using these videos are included in the various activity modules found in the Active Learning with Technology (ALT) professional development portfolio.

Engaged Discoverers: Kids Constructing Knowledge with Technology. This video depicts K-12 classrooms in sixteen schools throughout the Southwest where a variety of technologies support student-centered approaches in the classroom. Innovative teachers create environments where students collaboratively solve authentic problems using technology as a tool and new roles for students and teachers encourage kids to become “engaged discovers.” This video is used in the Creating a Vision module in the ALT portfolio where teachers watch how other teachers use technology in the classroom. This is also an excellent video for school administrators and interested community members to help them create a vision for technology. Total running time - 28:25 minutes.
Classrooms Under Construction: Integrating Student Centered Learning with Technology. This video portrays students, teachers, and principals from culturally diverse schools across the Southwest in the process of constructing learner-centered classrooms using technology. Students, teachers, and administrators learn as well as teach, sharing and learning new ideas, new technologies, and new strategies for building knowledge that relates to their own experiences and to the world they inhabit. This video can be used in the Examining Our Practice in the ALT portfolio where teachers look at their own classrooms to identify characteristics of learner-centered activities supported by technology. Teachers in this video describe how they have learned to use technology in their classrooms and how they have changed their instructional strategies. Total running time - 24:20

Classroom Episodes

These videos were produced toward the end of the two years of the SEDL project and show individual classrooms with students and teachers actively involved with technology. All of these videos are available by contacting the Southwest Educational Development Laboratory at [www.sedl.org] or by contacting any of the authors.

2nd Grade Classroom Episode: The Desert. This classroom video episode depicts an interdisciplinary unit of study about the desert in a 2nd grade classroom. A variety of technologies are used to support student-centered approaches in this classroom. Total running time: 18:45 minutes.

Reading Buddies: 1st and 2nd Graders Learning Together. This classroom video episode depicts how first grade and fifth grade students learn together as they create an electronic alphabet book for the younger children in their school. Total running time - 18:30 minutes.

6th Grade Classroom Episode: Collaborative Language Arts. This classroom episode depicts students engaged in several collaborative language arts activities, including writing and editing autobiographies, sharing book reviews, creating a myth, and writing free verse poems. A variety of technologies are used to support these activities. Total running time: 17:03 minutes.

9th Grade Classroom Episode: Spanish Travelers. This classroom episode depicts small groups of students working on a project-based learning activity. Their task is to find pertinent information and create a travel brochure for selected Spanish speaking countries. A variety of technologies are used to support their work, including computers, the Internet, digital cameras, and word-processing and database software. Total running time - 14:00 minutes.

Availability

The professional development modules from the Active Learning with Technology portfolio (ALT) mentioned earlier, can be downloaded from the following website: [http://www.sedl.org/tap/profdev.html] and all of these videos are available by contacting either the Southwest Educational Development Laboratory at [www.sedl.org] or any of the authors.
Creating a Culture Shift: Establishing a Technology and Learning Center

Carl Hoagland & Eric Aplyn
Univ. of Missouri-St. Louis
USA

Introduction
A culture shift is a change in the rules of conduct. The College of Education (COE) at the University of Missouri-St. Louis needed a cultural shift. With the university certifying over 500 teachers a year, these students need to be technologically literate. The evidence was that the students were not being adequately prepared to integrate technology into the curriculum. Pressure for technologically literate graduates was coming from the Missouri Department of Elementary and Secondary Education and from school districts. Students at the university also have practicums in technology rich classrooms and they may end up working in a technology rich classroom or MINTS™ classroom. In the 21st Century, students hired from the University of Missouri-St. Louis must know how to integrate technology.

A number of indicators confirm that COE faculty—65 full time and more than twice that number of adjunct faculty need to increase their use of technology. Campus Computing reports that COE faculty made fewer requests than Arts and Science faculty for lab use; they made fewer requests for Internet connections, and they made no requests for use of the Computer on a Stick Classrooms.** Additionally, the computer classrooms available for faculty to use for classes were not fully scheduled.

One of the roles of Campus Computing has been to support the use and operation of technology in the COE. It also made sure that a faculty member’s computer worked. Faculty was expected to take responsibility to learn applications, but they received no guidance for integrating that application into their courses. Additionally, when faculty did use technology in the classroom and a problem with integration arose they received little or no support since no group had been identified to help with the integration of technology in courses. This environment was one in which technology use was not encouraged. The faculty was on its own to find support.

Change
With impetus from the Dean of the College of Education, a culture shift is being undertaken for the use of technology in instruction. The centerpiece of the cultural change is the establishment of a technology and learning center. The proposed shift is both the mission of the center and a question. Can a technology culture change take place through a properly implemented technology and learning center?

With the Dean’s push for change, many faculty were still missing adequate institutional support to develop the knowledge, competence and confidence to integrate technology. Many faculty had expressed a desire to incorporate more technology in their courses, but they needed support. They needed a change in culture so new ideas and approaches could be tried with help and assistance.

Shift
The Dean of the College of Education communicated numerous times his expectation that faculty should use and integrate technology. The Dean also began communicating messages and memos by e-mail only. Networked computers were installed in all faculty offices. Each faculty member was connected to e-mail and the Internet. File space was available for storage of large documents. Printers were connected to the network and many faculty had individual printers.

Through the leadership of the COE Dean and with the support of the Chancellor, funds were secured to establish a technology and learning center, to endow a chair in technology and learning, to hire an additional faculty member,

* Technology rich classrooms or MINTS (Multimedia Interactive Networked Technologies) classrooms are supported by the State of Missouri
** Computer on a Stick are classrooms with an internet connected computer and a projection system
and to reallocate funds within the current COE budget for staff and annual equipment upgrades. The E. Desmond Lee Technology and Learning Center, named and funded by a visionary leader in the St. Louis business community opened its doors on April 7, 2000. The center’s purpose is to bring the college and general education community from limited and rudimentary use of technology in instruction to ubiquitous use.

From the beginning, the center was organized and operated very differently from all other computing facilities on campus. The Center is intended to be a place to “hang out.” An emphasis is placed on having as few rules as possible and having staff that provides a level of assistance that encourages faculty and students to use technology. Staff members greet clients and encourage them to ask for help. The staff has been trained to provide useful service in a pleasant manner. Personnel have been asked and trained to provide a very high level of client service. The room—originally a chapel with a mosaic tile ceiling—is designed for individual and collaborative work. The 70--plus workstations are arranged for a variety of functions. Single stations may be used for individual work. Others are arranged in clusters for group projects. A seminar room is available with a SmartBoard™ with connected workstations. A presentation and discussion area enables faculty and students to give seminars. A “cyber lounge” is set up for informal gatherings. Signposts and friendly barriers direct students and faculty. Wireless computers are available to take in the courtyard or to use anywhere in the center. Digital cameras are available for on and off campus use. Support for faculty is immediate and appropriate. Food and drink are unrestricted.

Staff are instructed to work through a problem until it is solved. If the staff member cannot solve the problem, he or she must find another staff member who can. The first staff member is expected to stay with the problem and learn the solution as well. An example of this is the faculty member who came with a 150-page dissertation that needed to be scanned into a word processing and PDF format. The staff member quickly realized that scanning the documents one page at a time could take many, many hours. By seeking the assistance of a second staff member who knew how to use the DocuCenter, the dissertation was scanned into both formats, stored in a folder and e-mailed in about 30 minutes. The first staff member also learned the procedure. If no one is able to solve a problem, the solution becomes a staff project. In other words, staff is encouraged to look at problems as opportunities. Staff is encouraged to speak in non-technical terms and avoid jargon. The training and discussions at weekly staff meetings focus as much, if not more on serving clients as on learning the technology. Staff is chosen for having an aptitude for teaching themselves technology applications, largely through online tutorials.

The center programs that help faculty integrate technology in the classroom are numerous: workshops for faculty, demonstrations by teachers in the field, faculty work groups, discussions, and individual consultations. One positive result that happened through an individual consultation was a faculty member’s decision to place all of his paper handout materials in digital folders for student access by computer, instead of copying and selling the paper documents in the bookstore. This has allowed him to use the materials differently in class. The faculty member who characterizes himself as a limited user is now instructing professors from other sections of this course on this technology use. This example, we believe, illustrates a cultural shift. The new culture being created intends to support and respect faculty in their use of technology at their individual comfort level.

The center is designed as a technology hothouse. Faculty and students can be nurtured in their growth and experiences with technology, and new ideas can be tried out in a supportive environment. The staff in the center is trying to help faculty see technology as enabling not intimidating.

Challenge

Establishing and sustaining a new of culture for educational technology is a large task. It takes a properly functioning infrastructure, a support system and the expectation that technology can and will be integrated in the curriculum. Through the leadership of the E. Desmond Lee Technology and Learning Center, faculty now have the opportunity to develop the knowledge, the competence and the confidence to integrate technology. The challenge is to build a seamless integration of technology in the college curriculum.
Effective Technology Staff Development: A Grass-Roots Approach

Mark Hofer, Curry School of Education, University of Virginia, USA, mhofer@virginia.edu

Abstract: Training to support the integration of technology into the curriculum can be difficult. Research suggests that on-site, just-in-time instruction is more effective than one-time workshops in facilitating meaningful technology integration into the classroom. The Teacher Technology Leadership Academy in the Archdiocese of Indianapolis is a grass-roots approach to staff development in technology. It is a cost effective, train-the-trainer approach that provides research-based staff development in technology for classroom teachers. This model can be transferred to any school or district.

References

Schools in the United States are currently receiving mixed marks for integrating technology into the classroom. According to the 1998 CEO Forum Study, of 80,000 public schools surveyed nationally, 54% of schools were considered “low tech.” Only 6% of schools were found to be “on target.” The Archdiocese of Indianapolis faces many of the problems of the public schools with respect technology. The archdiocese consists of 71 parish-supported schools with nearly 25,000 students and 1,500 teachers in grades K-12.

It is not difficult to find the source of the problem of integrating technology in schools. Despite the fact that many current teachers are not prepared to use technology in their classes, they do not receive the kind of support they need. An average of $132.57 per student was spent on educational technology in 1999-2000 (Quality Education Data, 2000). Only $6.86 of this amount (5% of the total) was spent on professional development.

There are many different staff development models currently in use to help teachers learn the skills they need to use technology. According to Maurer (1998), there are three main staff development models for technology: the after-school workshop, the all-day, off-site workshop, and conferences. A common type of technology training occurs in after-school workshops. After the teacher has completed a day of work, they attempt to learn a new complex skill which they will not be able to immediately practice. Teachers rarely retain and use what they have learned under these conditions (Maurer, 1998).

Another common method is an all-day, off-site workshop. In Indianapolis, many teachers take advantage of the technology workshops offered at Butler University. While these programs are in-depth and helpful for teachers learning new skills, there is no follow-up or support after the workshop.

Conferences expose teachers to new ideas, but there typically is limited hands-on experience and discussion of ways in which these ideas could be transferred to their own classrooms. While each of these methods can be successful with a limited number of participants, none of them lead to significant, long-term benefits in the classroom (Maurer, 1998). Given the small staff and budget, it was important for the Archdiocese of Indianapolis to develop a program that was both efficient and effective.

To address the technology training needs for the Archdiocese of Indianapolis, the Teacher Technology Leadership Academy (TTLA) was created. This “train-the-trainer” model, based on the work of Malcolm Knowles (1984), has been effective in helping teachers not only enhance their software skills, but also to...
find ways to integrate technology into the curriculum. Each year, the TTLA is comprised of a cohort of 16 classroom teachers chosen based on their willingness to try innovative instructional strategies rather than their computing skills. The group meets six times during the school year. Each session is comprised of instruction in a new software tool (database, spreadsheet, etc.), laboratory time for practicing new skills learned, time to develop a lesson for the classroom using the tool, and time to work with their peers. One key aspect of the work sessions is that each participant works on a project that will be useful to her right away. This philosophy of working on immediately applicable skills (just-in-time learning) makes the learning relevant, practical and draws on teachers’ own experience. By the end of each session, each participant leaves with software help sheets, a lesson plan, and a project created with the software tool.

Most importantly, participants are provided with all the required materials to prepare other teachers to implement technology effectively.

During two years of operation, the participants of the TTLA have met with great success. Findings from pre- and post-tests of both attitudes towards technology in the classroom and skills learned indicated significant improvement (approximately 20% increase each). Twenty-four teachers (8 the first year, 16 the second) have completed the program and are currently implementing technology-infused lessons in their classrooms and training other teachers. As a result of the TTLA program, participants have designed and implemented a total of 142 lessons in the classroom, and seventy-three training sessions were offered by the participants for other teachers in 1999-2000 alone.

TTLA is more successful than many of the models noted above because of its reliance on the adult learning theory (andragogy) developed by Malcolm Knowles (1984). Knowles provides several guidelines for adult learners that were incorporated into the TTLA model. He asserts that instruction for adults should be different from instruction for children (pedagogy). Adults learn for different reasons than children and have far more life experiences to consider when planning instruction. He argues that adults need to learn through real-world experiences rather than textbooks or theory. Adults need to know the practical value of what they are learning. They approach learning more as problem solving. And adults learn best when the knowledge is of immediate practical value to them. The TTLA is designed to incorporate the principles of andragogy directly into the instruction.

Some commercial programs also incorporate many of these principles. While expert consultants from computer training companies and online software training provide an excellent source of teaching content, there are many advantages to creating a grass-roots program like the TTLA. We have found that teachers respond more to other teachers than a technology coordinator or an outside consultant. Teachers have credibility and familiarity with their peers (Maurer, 1998). The participants in TTLA know that the instructor knows what it is like to face the challenges of using technology in the classroom. The peer relationship is also important, not just with the instructor, but between students. Participant evaluations consistently highlight the value of working and talking with other teachers. They value the exchange of ideas and techniques sometimes more than the instruction itself. This cohort group then provides an important support system for participants as they meet with successes and challenges in the classroom. Perhaps most importantly, with a grass-roots system, the innovation can diffuse much more quickly as TTLA graduates work with their own staffs and other schools.

In developing grass-roots technology training programs, additional key items have proven to be helpful. First, it is crucial to recruit the right participants to be effective trainers. Interpersonal skills, enthusiasm, and an ability to explain things well are all important considerations. It is also important to train the trainers to work with other adults. In addition to all the handouts and presentation materials, TTLA participants leave with a good understanding of andragogy. It is equally important to support the trainers as they begin to train other teachers. A discussion board, mailing list, or other mechanism to provide answers to questions and concerns is critical. It is also important to chart and report the progress of the program. This can help to target any shortcomings or opportunities to constantly improve the program.

As teachers, administrators and technology leaders confront the challenge of integrating technology into our schools, the creation of a grass-roots program grounded in the principles of andragogy can meet the challenge. As the community of leadership (Maurer, 1998) works together to support teachers in this worthy endeavor, significant progress has been possible.
Influence of Computer Assisted Teaching on Development of Faculty Staff Members at Atatürk University

Melih Karakuzu
Atatürk University, Faculty of Education
Computer and Instructional Technologies Dept.
Erzurum-Turkey
E-mail: karakuzu@atauni.edu.tr

Abstract: With the intention of determining the attitudes of faculty instructors to Computer Assisted Teaching (CAT) in their own major fields of study I attempted to carry out this survey. This study is based on the collected data via a questionnaire applied on 98 staff members currently teaching at Atatürk University, Erzurum, Turkey. The survey intends to determine and analyze various opinions of the staff members about the effects of Computer Assisted Teaching (CAT) on their development.

Collected data from the replied questionnaire items were analyzed using frequency-percent and a report of the study that investigated the affect of Computer Assisted Teaching (CAT) on the development of the staff members at the university.

In conclusion, evidence based on the staff members’ opinions was found that Computer Assisted Teaching (CAT) has a significant effect on the development of staff members.

Considering the influence of Computer Assisted Teaching on the development of staff members at Atatürk University, Erzurum-Turkey, a questionnaire containing 15 items, two of which were related to individual’s field of study or department where he works and teaching experience at university. Other 13 items were intended to reveal the instructor’s view on whether Computer Assisted Teaching affects the development of the instructor or not. Last item was not a multiple choice item. For that item the participant was expected to write his/her additional view on effects of Computer Assisted Teaching on the development of staff members at Atatürk University.

As stated by (Eley 1995, p.22-26) “it has been argued that computer-assisted learning (CAL) offers the possibility of introducing new teaching and learning styles which can expand the horizons of staff and students alike.”

All the participants are working at 8 different departments of Faculty of Education at Atatürk University, Erzurum. 98 instructor filled in the questionnaire forms. The participants stated that there is not any Computer Assisted Teaching facility at the faculty, so that they couldn’t deal with Computer Assisted Teaching or Learning issues. This is also supported by Eley’s (1995) quotation from McDonough (1992) that:

“there is little evidence of universities having instituted a staff development programme to ensure that there is sufficient expertise to provide the necessary support for the use of computers in teaching and to encourage curriculum development. It is essential that this failure is remedied”

However they are not directly deal with Computer Assisted Teaching they declared their opinions on computer assisted teaching’s influence on staff members’ development. Mean of total points in the questionnaire results (2.71/3 and 32.61/36 points) indicates that a great majority of the instructors who participated agreed that Computer Assisted Teaching has a significant affect on development of instructors. Following questionnaire items indicates the percentage and frequency result tables. In each item frequency and percentage of each choice were given. Choices for 12 items were YES, NO and PARTLY. Points for the choices were as follows: YES=3 points, NO=1 point and PARTLY= 2 points. Overview of results are shown in Table I:

<td>98</td>
<td>2 30 66</td>
<td>2,0 30,6 67,3</td>
<td>2,65</td>
</tr>
</tbody>
</table>
As Computer Assisted Teaching saved the instructor's teaching time, it provides extra time for him to deal with creative issues, such as developing course material or project and so forth.

The instructor spending his time to create course content through Computer Assisted Teaching is in a continuous effort to get new knowledge, so that he develops renewing his knowledge.

As the students attending a computer assisted course can access to information more rapidly than any other way, the instructor adapts himself to this dynamic demands of the students, so that he develops in this way.

Both the instructor and the student develop themselves by discussing vocational/academic topics by being a member of a listserv through the enlightenment of Computer Assisted Teaching.

Computer Assisted Teaching requires the instructor to use available measurement and evaluation techniques. Therefore Computer Assisted Teaching is influential on self development of the instructor.

As the student of a Computer Assisted Teaching course is more active than those of a proper course, the instructor teaches his course actively and enthusiastically.

Table I. Frequencies of items.

Collected data were analyzed through Frequency and One Way ANOVA Test on SPSS v9.01. Table II indicates that there is no significant difference among departments/fields of study (P>0.005) based on the instructors' views on the influence of Computer Assisted Teaching on the development of staff members.

Table II. Variance Analyses of Departments

Also it is found that there is no significant difference among teaching experience periods of staff members considering the effect of Computer Assisted Teaching on instructors' development (P>0.005). See Table III.

Table III. Variance Analyses of Teaching Experience Periods

Some selected opinions of questionnaire participants for the item 15 requires to be written additionally are worth mentioning.

- Computer Assisted Teaching is influential on developing instructor’s skills on selecting and evaluating educational softwares in his field of study.
- Computer Assisted Teaching develops instructor’s skill of effectiveness on participating on Educational software developing activities.
- Computer Assisted Teaching influences positively instructor’s ordering his information compiled from other sources in presenting during his courses.
In conclusion staff members are strongly demanding to take part in Computer Assisted Teaching activities in terms of not only increasing quality of education but also developing teacher training at higher education level. It may be suggested that Computer Assisted Teaching environment at school should be provided according to the recent advanced technological needs for both learners and the teaching staff. Otherwise realization of these invaluable opinions of the instructors cannot go beyond a nice dream.

Characteristics of Support Initiatives to Stimulate Professional Development on ICT

Elisabeth Laga
Jan Elen
University Educational Support Office
University of Leuven
Belgium
Elisabeth.Laga@duo.kuleuven.ac.be
Jan.Elen@duo.kuleuven.ac.be

Abstract: Educational institutions have to support their staff in their professional development on ICT. The innovation and professional development literature suggest some, be it vague, principles to realise this support. In line with these principles a support strategy has been developed at the University of Leuven. In this contribution, an analysis is made of the different initiatives, in order to detect effective and powerful factors. An analysis scheme was developed. Powerful features of professional development initiatives that may guide decisions on elaborating educational support strategies and professional development initiatives are identified.

Educational institutions have to support their staff in their professional development on ICT. The diversity with respect to knowledge, skills and attitudes on ICT, requires a diversity of initiatives for professional development. Traditional professional development training initiatives are to be completed with a systematic support strategy, pointed to different phases of the professional educational development, covering a variety of ICT-issues and addressing a variety of target groups.

Laga, Elen and Waeytens (1999) argued that only 'integrated' support strategies can be successful. This means that various aspects of ICT-employment (hardware, software, education, symbol systems and management) are covered and their interrelationship is clarified. Because the use of ICT is (and should be) instrumental to the realisation of content specific educational goals, a second aspect of integration is that all discussions about the use of ICT are related to the educational approaches or philosophy of the institution. In addition to the integration requirements, the following principles for a global educational support strategy were identified: 1) the strategy covers all aspects and meets the needs of all ICT-users; 2) specific components of the strategy are targeted to specific users, with different questions and needs. Hence, support components of the strategy differ from one another with respect to the amount, intensity and content of support; and 3) support is intended to be self-destructive and oriented towards enhanced independence of ICT-users.

Although vague, these principles can be useful as general guidelines. Bearing them in mind, numerous and diverse initiatives can be part of a professional support strategy. Not all of these initiatives will be equally effective. However, it remains difficult at this stage to assess the (potential) effectiveness of both general support strategies and specific ICT-related professional development activities. This difficulty is related both to the number of influencing factors and the absence of a clear analysis scheme. In this contribution, such an analysis scheme is presented. In order to show its relevance, the scheme is used to analyse the ICT-related support initiatives and the strategy of the University of Leuven. The strategy was gradually developed by considering the above mentioned principles. An analysis of these initiatives, along with some evaluation results, enables to describe important features of specific initiatives for professional development and of the support strategy as a whole.

Analysis Scheme

The analysis scheme (see Table 1) contains elements presumed to be relevant for professional development in general, and professional development on ICT in particular. This scheme allows for a more analytical description of specific support initiatives. Such descriptions enable targeted evaluations and more encompassing comparisons. The following elements are included:

1) Purpose: What purpose do the organisers of this initiative have in mind? Sensitising, informing, training, coaching or a combination? In deciding about the purpose, knowledge, skills and attitudes about ICT of potential participants, have to be considered.
2) **Target group:** Different persons have different responsibilities with respect to the training or the specific course in which ICT could be used. They also have a different task in the realisation and implementation of the ICT-application.

3) **Perspective:** Is the initiative concentrated on an isolated issue (e.g., the use of e-mail), a specific viewpoint on the use of ICT in education (e.g., the educational viewpoint), or does it cover various aspects and viewpoints of ICT-employment (e.g., technology, organisation, …)?

4) **Initiator:** Is the initiative the result of a request from the users (re-active) or has some other organisational body decided (pro-active) that users might benefit from the activity?

5) **Accessibility:** Can the target group get access to the support when they need?

6) **Control:** Who controls the programme and content of the support initiative: the users or the organisers?

7) **Commitment of the participants:** Does one expect active participation from the participants?

8) **Connection to the specific educational context of the participants:** Is the specific educational context of the participants taken into account during the support initiative?

9) **Number of participants:** Is the initiative directed towards individuals or groups?

10) **Instructional methods:** What instructional methods are used by the organisers?

11) **Use of ICT:** Do participants use ICT during the initiative?

**Table 1: Analysis scheme**

**Analysis of the Support Initiatives of the University of Leuven**

The University of Leuven has gradually developed a diverse set of activities to support educational innovation and the use of ICT. Attempts were made to consolidate these activities (see Table 2) and elaborate an integrated ICT support strategy. By using the described analysis scheme, an analysis of these initiatives is made.

1) **Yearly conference about educational innovation.** The purpose of this conference is to sensitise staff and decision-makers for educational innovation. Innovation is emphasised, the use of ICT is only viewed from an educational point. The conference is a fixed annually pro-active initiative. The target group has no control over programme or content, no active participation from the participants is required and there is no direct relation to their specific educational context. In addition to some lectures, staff may participate in discussions about specific subjects and can take a look at some ICT-applications realised by colleagues.

2) **Professional educational training for new teaching staff.** New staff is introduced in the educational philosophy of the institution. They get the opportunity to learn about and reflect upon different aspects of learning environments and their interrelationship. Participants are informed about the potential role of ICT in education in one session. The perspective is only educational. Participants get assignments in order to clarify the relation with their educational context. The extent to which ICT is discussed depends on the participants. They may ask for individual targeted support. This individual support complements the collective training where participants have no control over the programme and content. ICT is used as a means to spread information and assignments.

3) **Workshop for new teaching assistants.** New assistants are invited for a seminar on their educational task. During this seminar they can participate in a collective workshop about the educational use of ICT. The use of ICT is discussed from different points of view, but the educational viewpoint is emphasised. This pro-active workshop is fixed in time. Participants have no control over the programme. Active participation is...
required. The precise content depends to some extent on their questions. The relatedness to the specific educational contexts of the participants is rather vague. The workshop contains exercises and discussions. Participants do not use ICT.

4) **Informative sessions.** Teaching staff and assistants are invited for informative sessions about isolated educational or technological issues on using ICT in education (e.g., 'influence of symbol systems on the learning of students', 'videoconferencing', 'teammwork through the net'). These pro-active sessions are fixed in time and have a fixed programme and content. No active participation is required and there is no direct relation with the specific educational contexts of the participants. During these collective sessions there is place for lecturing and discussion. Sometimes videoconferencing is used, in order to enable participation by staff members at a distant location.

5) **Training sessions.** These sessions are open to all staff members and emphasise an isolated issue of ICT (e.g., the evaluation (what, how and when) of ICT-applications and their use in an educational context). The training is collective, pro-active and fixed in time. Participants have no control over programme and content. During the training session active participation is requested. Lectures, assignments, teamwork and discussions are combined during the training sessions. There is a small relatedness to the specific educational context of the participants during assignments. Participants do not use ICT.

6) **Demonstrations.** Staff, assistants and students are invited for demonstrations of ICT-applications developed by colleagues. Participants are informed about different components of ICT: the development, the role in the learning environment, the structure of the application, the use of the application by the students, technological requirements and problems, software used, evaluation methods and results, etc. The demonstrations are fixed in time, collective and pro-active (although in the future they may be re-active). Participants have no control over programme or content, and no active participation is required. The educational context of participants is not taken into account. During demonstrations lecturing, demonstration and discussion are combined. Until three months after the demonstration, participants can explore the ICT-application and the informative given during the demonstration itself in a dedicated demonstration room. During this re-active and individual support, they use the involved ICT-application.

7) **Intensive training about the use of ICT in education.** Teaching staff and their assistants are intensively trained and coached in using ICT in their education. The training covers different aspects of ICT-employment from different perspectives. The training of 10 days is fixed in time and pro-active. The participants have some control over programme and content. Organisers are flexible enough to go along with questions and interest of the participants. The training is immediately related to the specific educational context of the participants. Being actually involved in a project on the use of ICT in education is an entry requirement. A project means that the participants have a plan to use ICT in their course. The training exists of lectures, assignments for each project team, collective assignments, workshops for hands-on experience, discussions between project teams, demonstrations and project work. Each project team can work with personalised technological and educational coaching on the design and development of the ICT-application of their project. ICT use by the participants is limited.

8) **Training about the use of ICT in education.** During this training teaching assistants are informed and trained in the use of ICT in education. The training covers all viewpoints of ICT-employment. It aims at exchanging experiences and preventing assistants to loose time in finding and trying out a lot of things while designing and developing an application. The training is pro-active and fixed in time (but spread over 8 months). Participants have some control over programme and content. The training is only partly fixed and organisers are flexible to go along with questions and interests of the participants. The relation with the specific context is high. To be actively involved in an educational ICT-related project is an entry requirement. Assistants must be responsible for the design and development of a specific ICT-application for a specific educational setting or course. During collective sessions, lectures, demonstrations, assignments and discussion are used. Between two sessions of the training, the participants get an assignment, directly related to their own project. ICT is used to offer informative materials, and to discuss related topics. Upon request of the participants, they may get individual coaching for completing the assignments or for their own project-related design, development, implementation and/or evaluation activities.

9) **Support path for beginning ICT-users.** Staff members who plan to use ICT in their course can be coached. This implies that they get five assignments on the design, development, implementation and evaluation of a specific ICT-application. The initiative is pro-active as well as re-active. Each assignment is at least one time discussed with an educational expert. On request more guidance regarding this and/or other aspects of the use of ICT can be provided. Participants control the content, the programme and the timing of the initiative. The initiative is partly fixed in time, partly just-in-time. ICT is used to distribute information.

10) **Individual support.** Teaching staff and assistants can raise specific questions about all design, development, implementation and evaluation activities and with respect to any aspect of ICT-employment. Answers to these questions are formulated or coaching with respect to these activities is given by educational, technological and/or media experts. This re-active support is just-in-time and the content is in full control of the participants. The support is directly related to the specific educational context of the participants.
There is no use of ICT to deliver the support. If different people have the same questions (e.g., about a specific software tool), those people are brought together. If appropriate, an informative session or training can be organised.

11) Helpdesk. All decision-makers, staff members and assistants can send questions about using ICT in education via e-mail to a helpdesk. Questions may be informative about a topic (e.g., examples of specific ICT-applications or tools), and be related to any aspect of ICT-employment. The helpdesk answers the question, informs where to find more information, refers to experts on the topic or to specific examples, etc. This initiative is re-active, just-in-time and individual. The relatedness of this content to the specific educational setting depends on the question.

Table 2 gives an overview of this analysis. There are no specific professional development activities for members of the support staff. This alternative of the element ‘target group’ is therefore left out this overview.

Observations of Particular Initiatives

Some of the described and analysed support initiatives are in their conceptual phase. Below are the most important observations, experienced problems and evaluation results of and with the other initiatives.

- Questions on ICT in education of staff members mainly address technological and/or organisational issues. These questions reflect a naive view on the use of ICT in education. One of the consequences is that ICT is mostly added to and not integrated in the learning environment.
- This observation calls for caution with initiatives to sensitising staff. Any solely technological initiative would strengthen such a view. Therefore, sensitising initiatives should always be related to the realisation of student-centred learning environments.
- Informative sessions do not resolve questions about the contextualisation of the information presented. Regularly, participants feel left behind with questions about the meaning of the information for their own settings and what steps they have to take to transfer the informative into their courses.
- Effects of professional development activities on ICT become larger, when the relationship with the specific course or content is more direct and more active participation from the participants is required.
- Some of the participants of the intensive training on ICT testified that training leads to a radical change in their educational behaviour. Remarkable is the observation from the evaluation results, that mainly teaching staff had the feeling to have learned something, while assistants do not report large learning gains. Staff members may be more involved in the teaching task and have more questions about it. This corresponds to the opinion of Korthagen and Kessels (1999), that a learner must have personal concerns about teaching or must have encountered concrete problems in order to benefit from professional development activities.
- After only three sessions of the training for assistants, two of the seven projects asked for individual support with respect to specific educational and/or technological aspects. Four out of 15 projects that participated in the intensive training returned within a year for individual coaching with respect to educational or technological aspects. Training and coaching, fixed in a short time, seems not to be sufficient for those who are really working on an ICT-application.
- A good balance between pro- and re-active initiatives seems to work. Teaching staff and assistants mostly do not know what knowledge and skills they need for effectively using ICT in their courses. So pro-active initiatives are necessary. Otherwise it is not always possible to handle specific and concrete questions of individual staff in these (mostly) collective initiatives.
- The majority of people that asked individual support, were people who previously participated in some training. There are at least three possible explanations for this: 1) these people are aware that for an effective use of ICT in their education, there is a need for expertise they do not have, while others are unaware of this and do not experience problems with it; 2) they know that they can ask for individual support, others do not know this; or 3) other people have the knowledge and skills needed, hence, they do not need any training and/or individual support.
- During individual support it is not always easy to detect what one wants to realise, probably because staff members and assistants do not have an elaborated terminology to discuss educational issues. Another factor is that this ‘counselling’ requires specific skills of the support-giving experts.
- Participants of the intensive training who returned for individual support seemed not always to have changed their subjective educational theories. But in comparison of staff members and assistants who did not participate in any training on ICT, they can clarify what they want to realise and understand more easily questions and suggestions from the experts.

Table 2: Overview of the analysis of the initiatives, part of the global support strategy for professional development on ICT of the University of Leuven. (X = valid; () = valid, but not standard; / = non; * = little or small; ** = a lot or strong; *** = complete or very strong)
- Some of the participants could not combine the intensive training with their daily work and perceived the training as too time-consuming. Others found it worthwhile that they had to free time for training.
- Based on the spontaneous reactions on the evaluation forms of the intensive training, one may conclude that most participants found it very useful to participate in the training in project groups. The discussions between staff members and their assistants seemed to have been very instructive. The same observations can be made for the training of assistants. One assistant who asked individual support came alone the first time. The second time he returned with the responsible staff member.
- People like to see examples of effective ICT-applications, and are very interested in the (positive and negative) experiences of colleagues with the design, development, implementation and evaluation of an ICT-application. This is in harmony with one of the findings from a study of the American Productivity & Quality Centre (APQC) on best practices in faculty instructional development on the use of technology in teaching (Bates, 1999). Faculty members seemed to learn best from peers through show-and-tell demonstrations by colleagues who developed good examples of technology-based teaching.
- Because the use of ICT in education, with all its aspects, is a rather new domain, only few people have (all) the required knowledge. If one wants to organise informative and training initiatives, one needs to appeal to others. Given the lack of widely spread experience, it is not easy to find persons who 1) want to contribute, 2) have the knowledge about the use of ICT in education, and 3) have the skills to develop activities that respond to the purpose of the initiative. Especially for the training activities, the creation of a rich learning environment is not a simple task. A good collaboration and coordination in a multidisciplinary team is therefore essential.

Conclusion: Powerful Features of Professional Development Initiatives

Although there is (at this moment) no empirical evidence about the effectiveness of the different initiatives and the global support strategy, one can identify some powerful features of professional development initiatives. These features may guide decisions while both elaborating an educational support strategy and designing specific professional development initiatives:

- In order to promote transfer the relationship between the educational context and the training elements must be as high as possible. Transfer is also facilitated when participants are active, have specific problems and/or questions.
- Staff members who have no concrete problems and/or questions should be reached by sensitising initiatives, but always in a context of educational innovation or the realisation of student-centred learning environments. Participants with concrete plans to use ICT should be given the opportunity to actively elaborate their plans from different perspectives. These plans are to be continuously challenged.
- One can only require active participation if the relevance of the initiative for their educational context is clear.
- Collaboration between staff members and their assistants benefits to all and should therefore be stimulated.
- Staff members who share their questions and experiences with respect to the design, development, implementation and evaluation of an ICT-application enrich the professional development on ICT of colleagues.
- Professional development on ICT requires time. It is necessary that participants get and make time.
- A good balance between pro- and re-active initiatives is beneficial.
- People need a place where individual questions are answered or individual support is provided just-in-time and upon request. If one wants during training that participants learn to detect the expertise they need for effectively using ICT in education, one also has to make this expertise available. Staff members cannot become experts on the use of ICT in education. They only can obtain more expertise about it.
- Re-active individual support or pro-active coaching initiatives should be flexible enough to deal with any type of questions about ICT-employment.

Abstract: This paper outlines a framework for transforming technology integration within a public school system from isolated success stories to a district-wide movement. This is accomplished in two phases: 1) A district staff development day based on the SITE conference model is used to expose educators to available resources and possibilities for curriculum and technology integration. 2) This day is followed by a yearlong focus on professional development and curriculum support utilizing online, interactive tools. Central to the entire process is encouraging educators to become leaders in their own development by taking advantage of online resources that encourage mentoring and collaboration.

Finding our Catalyst

Solutions can be few and far between in the field of Instructional Technology; however, it is the recurring themes that can be illuminating. After attending SITE for two years, one of these themes seemed to continually catch our attention. It appeared that many districts that had widespread success with technology integration had a catalyst of some sort, something that took integration from the level of dispersed, isolated successes to district-wide acceptance and participation.

Over the last three years, our office has experienced the more isolated successes with curriculum/technology integration. While this can be exciting, it is mostly one-on-one work that is resource intensive and does little to further district-wide progress. We began to look for our catalyst. We wanted something that would raise the district’s technology energy past the activation level required to begin the desired chain reaction of integration throughout the district.

We decided our catalyst would be found in a staff development solution, and the SITE conference model would be an excellent method for delivery. Our commitment would be a year of unprecedented district-wide professional development beginning with a day devoted to curriculum/technology integration. Our proposal to utilize one of two district-wide staff development days was based on the following premise:
1. Staff Development is an important issue that is difficult to effectively address in a district as large and diverse as Framingham, MA (15 schools and 51 languages spoken in homes).

2. Curriculum/Technology Integration in Framingham has progressed slowly over the last two years, and it will continue at the current rate unless new methods of leveraging resources are implemented.

3. It is well documented that Professional Development is one of the vital components to effective Curriculum/Technology integration.

We believed that by pooling the resources of the Office of Technology with those of the Office of Curriculum and Staff Development we could develop a conference-style day based on the free-flowing model of the SITE conference with multiple concurrent presentations, discussion groups, and open rooms for some hands-on experimentation with technology resources.

This staff development day (to be held on October 20, 2000) would have four important components:

1. The presentations and discussions would be by teachers and for teachers. Seventy of our approximately 85 presenters would be Framingham teachers sharing their curriculum/technology integration experiences with 975 staff members.

2. Presentations would be rooted in resources available to teachers throughout the district. The Office of Technology guarantees a “toolbox” of resources for every teacher (e.g., Internet, Inspiration, MSOffice/AppleWorks, Timeliner, Hyperstudio, etc.) This means that staff members could immediately utilize the ideas they acquired from the presentations.

3. The SITE model would allow staff members to tailor the day to meet their individual needs. The intent would be to maximize their exposure to and enthusiasm for curriculum/technology integration.

4. The day would be a kick-off to a yearlong commitment to staff development as it relates to curriculum/technology integration. The day would not be expected to stand-alone. The follow-up instructional support with staff and the encouraging of collaboration would be vital to sustaining our desired “chain reaction.”

Preparations

The details of arranging the professional development day took approximately 4 months to organize. This was the first time that Framingham would bring all of its educators into one location for one subject on a professional development day. Meetings with the Office of Staff Development were useful in arranging logistics of the day due to their experience with previous professional development days.

Presenters were mostly educators from Framingham, as we have mentioned. All presenters were required to use PowerPoint or Apple Works slide shows. No overheads were allowed. Meetings with these presenters were scheduled in order to convey the theme of the day, and to lend assistance in developing presentations. Presenters were provided with templates for slide shows. These templates included questions for the presenters that focused on the theme of the day. Many teachers found these to be quite helpful. These district presenters received $50 per presentation.

A select few presenters from outside of the Framingham Public Schools were invited. These included representatives from Public Broadcasting System (PBS), Apple Computers, Classroom Connect, CyberArts International, and representatives from institutions offering Masters programs in Instructional Technology. One stipulation placed on these presenters was that they focus on resources available to teachers for their classrooms or their own professional development. We were not looking for vendors who would show teachers products they could not afford.

The day was billed as Curriculum and Technology Integration: a Day for Framingham Educators. Every educator received a 6-page program (including a description of each presentation) 3 days prior to the event. This allowed attendees to choose presentations that interested them, as well as choose second and third options in case rooms were full. There was no pre-registration for sessions. Initially, presentations followed a SITE model with ½-hour presentations and some 1-hour discussions. Concern regarding logistics of the day caused us to change all sessions to 45 minutes. Three sessions were offered in the morning and 3 in the afternoon with an average of 22 presentations per session. Rooms dubbed “Follow-up Rooms” were added to
allow attendees to extended discussions initiated by presentations. Attendees also had the option of visiting “Toolbox Rooms.” These were lab setting in which teachers could spend some “play-time” learning about district-wide software and Internet resources.

Results of the Day

The professional development day was very successful. Key to the success of the day was the considerable support available to participants and attendees. The entire technology staff and members of the Office of Staff Development were available for technical and logistical support. Approximately 20 high school students also provided technical assistance and helped to move attendees from the auditorium to the presentation areas and back.

Results from a questionnaire enclosed in the programs suggest that attendees found the SITE conference model refreshing compared to the more traditional professional development day model in which teachers have little or no choice regarding the day’s topics. A total of 181 responses were collected. All questions were measured on a 5-point Lickert scale with a lower score being more favorable. The most favorable responses were to questions regarding the multiple presentation format (mean=1.68) and regarding the realistic connection of presentations to using technology in the classroom (1.77). The least favorable response involved finding adequate choices for specific grade levels (2.34); however, this mean response is still quite favorable.

Other feedback, conversationally and in the form of e-mail, has been most encouraging. One attendee commented, "It was very well done...very professional and energizing...the other thing that made it so great was that everything that was demonstrated, was so do-able." Another comment from a presenter also hit the mark, “As I was leaving, a teacher stopped her car, got out, and said, ‘I just had to tell you thank you - your presentation has given me the courage to try this in my own classroom.’ This quote alone made the effort that went into my presentation worthwhile and speaks to the power of peers teaching peers.”

We are currently collecting information on the impact of this day, but changes have already been noticed. There has been an increase in requests for assistance using technology in the classroom, especially in using Inspiration, WebQuests, Journey North, and other Internet based resources. We have also had more than 40 staff members sign up to use a new online collaboration tool (Taskstream) for developing lesson plans.

Free! to Learn

The staff development day appeared to be challenging enough, but to meet the anticipated flood of interest with yearlong instructional support and only two fulltime Instructional Technology Specialists seemed a task of heroic proportions. It was obvious that we needed to find additional resources that could be leveraged. It was important to find someone that shared our vision and could help maintain the momentum established at the staff development day. School Change Network and their “Free! To Learn” concept fit the bill.

Free! to Learn was originally developed by School Change Network as a newsletter and interactive "manifesto" designed to spread the idea that in today's networked world, educators ought to have the capacity to take charge of their own professional development. Soon after the inception of the Free! to Learn newsletter, School Change Network expanded the scope of the project to provide a suite of services that would help schools and districts shift to a new professional development paradigm – one in which teachers become the leaders of their own professional growth through collaboration, collegiality, and taking advantage of learning opportunities online.

The Free! to Learn approach to professional development dovetailed perfectly with our SITE-modeled staff development concept. In addition, School Change Network could bring the expertise and tools we needed to meet the curriculum/technology integration needs of our staff members. One of the most exciting directions our partnership will be taking is the use of an online, interactive curriculum development tool that encourages professional learning and collaboration through online peer mentoring. Our intention is that this tool, and some additional training, will result in a self-sustaining district-wide network of educators who can more effectively collaborate and take control of their own development.

Mentoring and collaboration are popular topics, and with the wide range of technology skills among
educators, they are topics that can have an impact on teacher learning. We also feel that by using this online tool, we are approaching educators at a local level, instead of sending them to a third party, such as an online course. This tool facilitates professional collaboration within our own district, where teachers are in a comfortable environment with colleagues they know, and not with relatively unfamiliar "outside experts."

Where Do We Go from Here?

School Change Network will also assist in collecting and analyzing data to measure our progress as a district. We recognize that if this is to have a lasting impact on the Framingham Public Schools, it is necessary to show evidence of our success. We believe that data regarding the effect our approach will have on teachers can be readily collected. One area we will monitor is the development of lesson plans using the online mentoring tool. The lesson plans created with this tool will provide technology-integrated products that are connected to state frameworks, and can be used in classrooms. The biggest challenge will be quantifying changes in student learning as a result of our work with teachers.

We also need to be able to quantify progress in the dissemination of technology integration over the next year. As stated previously, this project was initiated by the desire to move from small occurrences of curriculum/technology integration and towards an expanding sphere of interest and activity.

It is our belief that this process will result in a framework that can be replicated for other districts to generate their own chain reaction, and that a presentation at SITE2001 of the project underway will help us to disseminate the framework. It is also our intention to submit a proposal to present our one-year results at SITE2002.
IMPLEMENTATIONS OF VIDEOCONFERENCING IN IN-SERVICE TEACHER TRAINING

Jukka Mäki
Head of Information and Communication Technology
Research and Development Center
The Ziridis Schools, Athens, Greece
ict@ziridis.gr

Abstract: This paper presents the possibilities of VC in staff development and experiences that the Ziridis School has had when teachers took part in interactive lessons instructed via ISDN-videoconference. The results of the experiences are explained and some suggestions for the use of ISDN-videoconferencing are made for in-service training and staff development. The paper is presented with videotaped-material of distance lessons and interviews of staff in Greece and remote teachers in Finland.

1. The Ziridis Schools

The Ziridis Schools is a private leading educational organization in Athens with a 67 years tradition. Today it has nearly 2000 students in Kindergarten, Elementary, Junior High School and Senior High School and a staff of 350.

The mission statement of the Ziridis Schools is: “In the most modern educational environment we create the citizens of the world. The leaders of tomorrow.” Through experimentation and discovery the school promotes the special talents of each child.

The educational philosophy of the school is based on multiple intelligences, cooperative learning, teamteaching and interdisciplinary approaches. A special emphasis is given to ICT and various internet- and email-projects are implemented with schools in Greece, Europe and other countries of the world. The school has four modern computer laboratories, computers in classrooms and own production of CD-ROMs. The school is the first one in Greece using ISDN-videoconference as a tool for teaching and learning.

There is a special Center of Research and Development which works on the implementation innovations and teaching practices. It is divided into three departments: Information and Communication Technology, Teacher Training and New Programs, and Student Care [www.ziridis.gr].

2. In-service training

In order to reach the goals and fulfill the mission the staff must be aware of possibilities of ICT in education. As part of our in-service further education and staff development we have used ISDN-based videoconferencing. The educators have received instruction from the Department of Educational Sciences and Teacher Training of the University of Oulu where there exists a lot of experience of distance learning environments (wwwedu.oulu.fi). The lessons have been delivered using ISDN-videoconference technology from Finland and so the trainees have had authentic experiences as learners. Main focus has been placed on to classroom-based instruction.

Interaction. During the lessons the interaction between the teacher and the distance class is analyzed. The personality and teaching skills of teacher plays a significant role. He must be also familiar with communication using media. He must be like a director of a theatrical play who takes care of visual outlook. He must be a bit of a technician in order to handle the vc-equipment and supportive equipment (like document camera). The critical point is his professionalism and careful lesson planning.

But not only is the interaction between the teacher and the students important, but also the interaction between students is very important. The social atmosphere is a little different from a “normal” classroom situation. There might be even lessons that the remote classroom doesn't have a teacher at all and the pupils take care of technology and discipline. This needs a little training for pupils and a good team-spirit. A suitable group is considered as 8 to 12 students.
Physical environment. During training period is analyzed also the physical environment of distance lesson. Apart from appropriate videoconferencing equipment there also must be a suitable classroom for distance learning. Garish colors must not be used, the lights must be well-directed, proper furniture, sufficient and adequate appendix material for teaching etc. The placement of microphones, loudspeakers, screen or projector and camera are extremely essential, because sound and picture are the most important elements in the successful completion of the learning objectives.

Experiences. Videoconferencing has given challenges to create the contents of in-service training exactly according to the needs of the staff. The technology has facilitated the use of experts from a well-known foreign university which has a long history in videoconferencing and generally in the use of ICT in education. The staff of the Ziridis School has been trained by several professionals without them loosing their valuable time for travelling. And so the costs also have naturally been much lower.

When the teachers have themselves been as "pupils" in videoconference lesson, they understand the learning situation much better, the communication, the interaction, and the limitations with voice and picture. Many small details during a lesson, unintentional noises like cough, the tapping of a pencil, noises of a squeaky chair etc. They have also noticed how important it is to change the picture between two cameras (if it exists), rhythm of lesson like speaking, pausing, asking questions, showing transparencies, giving time to think or answer and so on. Also basic things like
- listening to one another,
- the way of making questions understandable,
- having eye-contact with pupils,
- is the teacher communicating for an individual or a group
- how does a teacher make his instruction interesting

All these points become more emphasized in videoconference lesson than in normal face-to-face situation. But it gives many possibilities for students to practice their skills of cooperative learning and team work, they must be more active and responsible in their own learning and they learn to be more self-disciplined.

3. Suggestions

Very good training for every teacher is to change opinions and to discuss about learning processes with other teachers in other teaching environments. It's advisable to organize special training for different categories of teachers, i.e. elementary school teachers and high school teachers in different groups. It is also very practical to divide teachers in groups according to their areas of specialization, because every teaching subject is different: language teaching differs a great deal from a physics laboratory and so the teaching methods also in VC-environment are different.

The experiences of the teachers of the Ziridis Schools in the use of videoconferencing as the way of in-service training have been very positive. The idea is to create a network of schools and universities in Greece and all over the world that are cooperating through VC. Also technology gives a number of possibilities for extended education of administrational staff. Therefore the persons of management and secretarial staff are able to share the experiences and learn from each other.

Smart Classrooms Led by Technology Using Teacher Educators

Inés Márquez Chisholm
College of Education
Arizona State University West
United States
ines@asu.edu

Keith Wetzel
College of Education
Arizona State University West
United States
ines@asu.edu

Abstract. The College of Education at a western upper division state university has two computer classrooms, called Smart Classrooms, that mirror the configuration found in many local schools where teachers have a limited number of computers. This paper presents the results of a qualitative study in which the authors explored the pedagogical beliefs of five teacher educators who used technology in their teaching. The researchers wished to know their reasons for booking the classroom and their cultural preferences in designing instructional activities. The data consisted of interview transcriptions and responses to written follow up questions. Data analysis indicated that the faculty chose to use a Smart Classroom because it matched their teaching methods. They developed a variety of meaningful technology uses for their students and addressed many elements of multicultural integration. The authors discuss implications for faculty development and raise questions for further study.

Introduction

Teacher education faculty serve as role models for their students; their uses of technology and attitudes towards it directly impact student teachers' implementation of educational technology (Huang, 1994). Equally, they serve as models for teaching in culturally supportive ways. Their attitudes towards and assumptions about diversity manifest themselves in how they use technology to support learning differences, diverse needs and cultural preferences for learning. Unfortunately, many professors do not use technology in their teaching (Parker, 1997) and, therefore, do not effectively model technology use for preservice teachers (Moursund & Bielefeldt, 1999). At the same time, many teacher educators do not intentionally use technology in ways that are supportive of cultural diversity. It is not surprising then that most recent teacher education graduates do not feel prepared to integrate technology in their curriculum (U.S. OTA, 1995) nor in culturally diverse classrooms.

Faculty Modeling

In order to increase the number of teacher educators who model multicultural technology integration, we must first identify those factors which may increase the likelihood of faculty modeling of multicultural technology integration. We speculate that faculty members' world views and teaching approaches may influence their selection and management of technology applications in the classroom. In an exploratory study of 157 technology-using teacher educators, Robin and Harris (1998) found that those surveyed showed a tendency toward learner-centered teaching. Those who preferred learner-centered teaching approaches were more social and indicated a preference for highly participative educational activities.

Similarly, cultural preferences and beliefs play an important part in how technology-using educators organize classroom learning activities. Chisholm (1998) identified six culturally supportive teaching elements for technology integration: cultural awareness, cultural relevance, culturally supportive environment, equitable access, instructional flexibility and instructional integration. A case study by Stafford-Levy and Wiburg (2000)
found that the six elements fit a constructivist instructional approach and foster minority students' learning by creating a culturally supportive, challenging environment.

Facilitating Transfer of Learning

Not only must there be thoughtful planning of faculty instruction for multicultural technology integration, but the physical layout of classrooms also needs careful planning. Transfer of learning is facilitated when the environment in which material is learned is similar to the environment in which the learner will later be expected to demonstrate the learning (Woolfolk, 1995). Preservice teachers should learn about the integration of technology in university classrooms that mimic the K-12 classrooms in which they will teach. Those classrooms typically do not have one computer per student, but rather to four computers that students share. We might assume that institutions preparing new teachers would hold classes in facilities that mirrored the typical placement of computers in K-12 schools. However, in a recent study of four colleges of education considered exemplary for their integration of technology in teaching, Struder & Wetzel (1999) found that they did not have teaching facilities that mirrored the placement of computers in many K-12 classrooms.

By the same token, preservice teachers should learn about multicultural integration of technology through participation in learning activities that model effective instructional practices. The successful integration of technology in culturally diverse settings requires implementation of appropriate multicultural teaching practices, as well as relevant, productive applications of technology. However, many teacher education faculty are unsure of how to integrate multicultural elements into their courses or see it as something more to add to an already full curriculum. Consequently, preservice teachers may not link how faculty model technology use or instructional practices to their application in multicultural settings.

The Study

Purpose

The purpose of this study was to explore the pedagogical beliefs of five teacher educators who use technology in their teaching. These faculty members were early users of one of two computer classrooms, called Smart Classrooms, that in fact mirror the configuration found in many local schools. The researchers wished to know their reasons for booking the classroom and their cultural preferences in designing instructional activities. Teaching approaches that involve cooperative learning, students' learning styles, and individual cultural preferences may influence faculty selection and use of technology. Thus the researchers sought to understand the possible link between the faculty's teaching philosophies and instructional activities with their use of technology in teaching.

Methodology

The researchers created a set of questions to guide interviews with these five subjects. The data consist of interview transcriptions and responses to written follow-up questions. The five interviewed were the only teacher education instructors, aside from those teaching educational technology, who used the Smart Classrooms. The interview protocol included questions such as: a) What is your teaching philosophy? B) In what ways is your course student-centered? c) do you address the teaching of diverse populations? If so, how? and d) Describe some of the instructional activities you have conducted in this room.

Setting and Sample

The College of Education at a western upper division state university has established two computer Smart Classrooms that in fact mirror the configuration found in many local schools where teachers have a limited number of computers in their classrooms. The Smart Classrooms have eight networked computer
student stations and a central area for 25-30 students made up of seating at 24 movable tables. Each student workstation contains one recent model computer and two monitors allowing 3-5 students to work together.

The five faculty interviewed were the only users of these classrooms from the College of Education. They were all female and represented the following programs: Bilingual Education, Educational Administration, Elementary Education, Secondary Education, and Special Education. One is a Full Professor, three are Associate Professors, and one is an Assistant Professor. Their experience in higher education ranged from 31 to 5 years with a mean of 14 years.

Data Analysis

Using the constant comparative method (Strauss, 1987), data analysis began as data were first collected and continued throughout the study. Each researcher independently read the transcripts and identified patterns and questions. Subsequently, they met to discuss patterns they observed in the data and questions that arose after the readings. Together they created follow-up questions and emailed them to the subjects. After collecting this data, the researchers re-read all transcripts and re-categorized the data. The themes that emerged were: beliefs, learning activities, and technology fit, management of technology, student-centered approaches, learning activities, assessment of teaching, and multicultural teaching. One researcher used the interview data and follow-up questions to create mini-cases which each professor read and indicated that it represented them accurately. Member checking was also employed as a draft of the full study was sent to the informants to check for accuracy of data and feedback on our analysis. None of the findings were disputed or questioned.

Findings

The researchers found that the faculty chose to use a Smart Classroom because it matched their teaching methods. They valued collaborative student work groups and the eight computer stations made it easy to arrange projects for their students. Although the faculty studied were not formally aware of the six elements of multicultural technology integration, our analysis showed that the faculty designed some activities and made some choices that were resonant with them. Though four of the five faculty thought they were not technology experts, their expertise was sufficient to give them the confidence to try a new teaching environment. Four of the five faculty booking this classroom had designed their own web pages and although their web pages varied in content and complexity, they often included two or more of the following: course syllabi, discussion lists, online journals, and Internet sites related to course content and classroom activities. Similarly, a critical mass of the students had sufficient levels of technology skills to allow the group work to focus on meaningful course outcomes, not just technology skills. Three of the five faculty members assigned a student computer expert to each group. This structure encouraged learning from peers.

An analysis of the interview transcripts revealed no mention of the issue of technology support by central campus computing. This is important because adequate technology support is a key to inducing faculty to use technology in the classroom (Strudler & Wetzel, 1999). Classroom technology support appears not to be an issue for the faculty studied.

The faculty interviewed had developed a variety of meaningful technology uses for their students. These faculty knew what to do and had the technology expertise to make it happen. In their teaching, they addressed many aspects of the six elements of multicultural integration.

Implications and Questions

The findings from this study have implications for faculty development. Faculty will model multicultural technology integration when they see a direct link to their course content, teaching goals, and instructional style. Hence, faculty development activities should provide examples of technology use in specific courses and offer support in faculty planning to integrate technology. Further, teacher educators may frequently apply multiculturally appropriate strategies to technology integration, but not necessarily with an intent to model multicultural integration. Awareness of the multicultural elements and their relationship to their own teaching may expand their repertoire of culturally supportive strategies.
The current study raises the following questions for further study: Why don't other teacher education faculty choose to use the Smart Classrooms? Do faculty chose not to use the Smart Classrooms because their teaching methods may not match the Smart Classroom design? Do faculty not feel sufficiently confident in their technology skills? Do faculty not have a vision of meaningful and compelling use of technology in their areas? If the obstacle is technology expertise, what level of technology expertise will faculty need to feel comfortable using technology in teaching? If the obstacle is vision, what uses of technology are compelling for faculty in their specific content areas? What experiences will help them develop personally compelling uses of technology in teaching? Perhaps more difficult is the issue of developing culturally appropriate uses of technology in teaching. How do we model the six multicultural technology integration elements in faculty training?

Abstract: The goal of the "Preparing Tomorrow's Teacher to Use Technology" grant awarded to the University of Houston College of Education is to encourage the integration of technology into courses taught by education professors. This modeling of an appropriate use of technology by the university professors is intended to help pre-service teachers acquire proficiency in the use of technology for curricular purposes. To accomplish this goal, many changes had to be implemented, the most challenging of which was to assist professors to move toward pedagogical change through the fusing of technological resources and activities with their curricular objectives. Using an action research model, a collaborative community was developed between professors and the grant project members. The resulting increased interest and excitement of the professors was reflected in their communication with colleagues, their use of electronic communication with their students, and their growing integration of technology into their curriculum.

Introduction

The ultimate goal of a recent "Preparing Tomorrow's Teachers to Use Technology" grant awarded to the University of Houston College of Education is to encourage the use of appropriate technology in the future K-12 population taught by our graduates. Appropriate use of technology is associated with a student's active participation in the learning process and increased approaches to problem solving. To meet this goal, pre-service teachers must gain confidence and proficiency with using and integrating technology into their pedagogy. Providing models of instruction that integrate technology and counter years of traditional classrooms allow students to have alternative models of effective teaching (Duffield, 1997).

Problem

If it is true that beginning teachers teach as they were taught, one hindrance to meeting the goal of appropriate technology use by our pre-service teachers is that higher education faculty prefer to rely on more traditional methods for
delivering instruction (Spotts & Bowman, 1995). Therefore, it is imperative to the success of this project to change the way that many college professors currently teach. Change can be hard for many people, and it can be especially hard in a population of people who are considered experts in their field. Professors need to be guided to recognize and accept that technology is not a replacement for the content of the disciplines that comprise their curriculum, but an extension that can complement that content (Willis, 1997).

Action research involves constant change and therefore is the appropriate methodology to meet the goals of this project (Stringer, 1999). The community-based action research model - look, think, act - is a cyclical set of activities involving observation, reflection, and action. Contact with faculty has paralleled on a lesser scale the action research model of the entire project.

Project Design

The three-year project entitled “Action Communities for Teaching Excellence” is designed to reach the grant’s ultimate goal from several angles including: (1) providing the diverse urban student population with a supportive, consistent environment and convenient computer access, (2) converting the currently required technology course for education majors into a series of lab courses which will more closely address the various needs of education students, (3) bridging campus- and field-based experiences and resources using technological solutions, and (4) helping the faculty gain confidence and proficiency with using and integrating technology into required course instruction. Since number four involves changing the actions of people, it is the most challenging and perhaps the most rewarding of all. It is recognized that teacher educators must first acquire basic technology skills and be able to model effective presentation skills before they can enable future teachers to use technology to provide meaningful learning experiences for their students (Rodriguez, 1996). The key is how to facilitate this change.

The original plan for interacting with the fifteen professors who teach the eight targeted courses included: (1) dividing the courses among the grant project members, based first on matching the content knowledge of the course with the project member’s areas of expertise, and second by the previous relationship, if any, with the specific professor, (2) contacting professors by telephone to set up appointments, and (3) reading the course syllabus before the first meeting. In fact, many of the grant project members had no previous knowledge of the professors with whom they worked. Attempting to contact by telephone often led to completely useless rounds of phone-tag, and project members discovered that many of the course syllabi were unavailable. Project members found that matching professors by course content and personality with the project team and making effective use of e-mail were useful tactics when making the first contact.

The grant project team decided that it would be best not to talk about the role of pedagogical change at the first meeting with the professor for fear of being politely dismissed. Instead, the plan for the first meeting was to (1) meet with the professors one-on-one, (2) explain the ultimate goal of the grant, (3) determine the professor’s current teaching practices, (4) determine if and where instructional technology is used in the course presently, (5) explain the role and availability of technical support from others working on the grant, (6) establish an agenda for the following meeting, and (7) establish a positive relationship with the professor.

Project Implementation

There were some obstacles to overcome in the implementation of the project as originally conceived. Though some meetings did take place on campus in faculty offices, the project team had to be flexible enough to meet with professors at their convenience and at a location which they chose. For some adjunct professors who have full-time positions off campus, that meant meeting at their off-campus office or even in their home at a time convenient for them. At the first meeting, team members had not planned to discuss increasing the use of technology in the actual practice of the professor. However, it was found that many people pushed for an answer to the question, “How does your grant involve me?” This led to answering truthfully about the present use of instructional technology (IT) in their classes and possibilities for increased future use of technology. Rather than obstruct interaction with them, it freed the conversation. Several people expressed that they had little time for this grant project in their busy schedule; therefore, they wanted project members to be brief. Helping professors save time through the use of technology in support of their teaching frequently piqued the interest of a professor who was at first resistant to or skeptical about the project. It was often this hook, the intense desire to make the best use of time, which opened conversations that quickly expanded to other types of technology uses by instructors.

At this initial contact with each professor, one of the tasks of the project team was to attempt to ascertain the level of engagement of the professor. Stringer (personal communication, Aug. 15,2000) proposes that there are four levels of
engagement in persuasive arguments: resistance, apathy, interest, and excitement. The experience of the team as they worked on this project led to the addition of another level, skepticism, which was placed between resistance and apathy.

An informal analysis of the professors’ levels of engagement at onset identified 64 percent at the apathetic, skeptical, or resistant level. Two months later, 100 percent were at the excited or interested level. The professors’ movement through the levels of engagement was reflected in their increased willingness to meet with members of the grant project, their personal initiation of meetings and communication, and the gradual incorporation of technology into their teaching practices and assignments.

Table 1. Professor’s Level of Engagement

The actual method of accomplishing movement through the levels of engagement was a combination of awakening enlightened self-interest on the part of the participants and developing a collaborative relationship between the professors and the members of the grant project team. With the initial purpose of the grant expressed by the grant team members as supporting professors’ use of technology and increasing their efficient use of time, the stage was set for professors (1) to be validated in their curricular choices, (2) to be assisted in the actual technical underpinnings of a basic use of technology, such as an Excel spreadsheet/grade book, and (3) to be primed for their self-actualization as technology users through the availability of on-one assistance.

Professor voices changed with their exposure to team members and with tailored responses to their individual needs. One professor ended a brief meeting by swiveling around in his chair to check his e-mail while commenting, “Well, my classes are set. I don’t know how your program can help me, but come back next week if you want.”

A visit to the professor’s class allowed two team members an opportunity to come to the next meeting with suggestions for making the professor’s lecture more accessible to the 150 students in his class. That professor spent three weeks with a technical assistant developing PowerPoint presentations to facilitate his discussions. He looked forward to each lesson as he quickly saw the benefit of PowerPoint over writing on an overhead. His students, who had expressed difficulty in reading his handwriting, gave him positive feedback on his utilization of PowerPoint for his classes. In his most recent interview, this professor voiced a desire to integrate technology into students’ projects to deepen his students’ use of the computer as a tool for learning and for teaching their future students.

Due to the importance of the collaborative relationship between grant team members and faculty, attention was paid to both the selection of initial contact personnel as well as technical assistants. The technical assistants conducted tutoring sessions, set up grade books, put quizzes on-line, coordinated the creation of listservs, and monitored hardware and software set-ups for various purposes. Just as both curriculum expertise and personality had been factors in the selection of initial contact personnel, technical expertise and personality qualities were also relevant to the pairings of the professors and technical assistants. A professor who felt technologically deficient was paired with an experienced, patient technology assistant who could create lessons personalized to that professor’s needs. Additionally, a professor who already used PowerPoint in lectures was paired with one who could proceed to digitizing video for insertion in these presentations.

One adjunct professor had an entire dissertation stored only on the desktop of a laptop computer, as she did not know how to save a backup to a disk. This same professor is now using an Excel spreadsheet for a gradebook, creating PowerPoint presentations, and looking for ways for students to create required projects by utilizing technology.

One professor who was already a proficient personal user with lectures utilizing PowerPoint, highly developed word processing skills, and e-mail communication with students found that required reflections could be posted to a hypergroup which the grant team set up for her. A hypergroup is a specialized web site where a question or assignment is posted and students may post their replies. It can also be utilized as a listserv if students are required to join.
As the instructor became more familiar with the hypergroup, she began to use its Internet capabilities by having students post the addresses of sites that were applicable to the course so others could access them as well and share the information that had been discovered.

This desire to share their new knowledge extended to their colleagues. Faculty members who generally were isolated from their peers due to schedules, workloads, or habit became curious about their instructional counterparts' use of technology. If the grant project member was working with two different professors who taught the same course and mentioned a resource that had been effectively employed by another, a connection was made between the two professors. If one professor's hypergroup site was shown to another professor as a demonstration of various ways to employ a hypergroup to meet curricular goals, insight into both process and product was possible. Although the grant project members came from outside the community of professors, their contact with the instructors increased the intellectual communication between the professors.

As the interest grew, the grant group offered workshops in beginning PowerPoint that were open to both students and faculty. The participants expressed interest in returning for intermediate and advanced workshops. They also began requesting the use of labs or rooms with projection capability for PowerPoint presentations. In response, the grant team canvassed other departments as to their lab facilities, their use of projection devices, and the number of existing rooms with built-in equipment beyond just an overhead projector.

As more professors began integrating technology into their assignments, the question of student access was ameliorated by the reorganization of the previous course for technology in the classroom. This class was restructured into labs to allow students to address their individual technology levels. These courses provide assistance to the students in completing assignments from their education courses. They become familiar with the use of a hypergroup, are introduced to the most commonly used programs such as PowerPoint, Word, and Excel, and may work on education assignments requiring the use of technology.

Like the metaphorical World Wide Web that expands exponentially by creating connections, the grant project members are becoming links between departments within the university, between computer labs serving various departments, between professors and their colleagues, and between professors and their students. While facilitating adoption of technology into the instructors' individual pedagogy, the grant project members are becoming facilitators of change as they interact with the professors and diverse areas of the university. One surprising discovery of the team is the myriad issues that frequently impact on the education of pre-service teachers and generally have not been addressed by current procedures. This outside view of the "bigger picture" can only lead to a greater understanding of the needs of the pre-service teacher and the resources available to meet these needs.

Conclusion

Pedagogical change is the outgrowth of both the integration of technology and the development of the collaborative community created by the project. The integration of technology that provides for active participation in the learning process encompasses instructors, grant project members, and students in the process of change. Through this collaboration, the grant project members have found that many instructors of future teachers have become eagerly engaged in learning to integrate the appropriate use of technology into their teaching. By modeling technological integration and the concomitant pedagogical change, these professors are helping the future students of these pre-service teachers acquire the technical integration skills critical to success in the 21st century.

Introduction

If Socrates and Plato were alive today, would they still meet in the streets of Athens to probe topics with questions, or would they meet online to do so? Consider another legendary tutor Annie Sullivan, who held Helen Keller's hand under a running faucet to teach the word "water". How would Sullivan promote this type of concrete understanding online? The stories of these legendary tutoring relationships endure because they model two of the most powerful principles of learning: from Socrates, we learn that good instruction teaches students to ask the right questions; from Sullivan, we learn that meaning is constructed through first hand experience. The crescendo of the distance education movement compels us to examine the application of these theories to new, online learning environments. To that end, educators must ask: do our most cherished teaching and tutoring principles transcend the vehicles in which those principles are delivered?

By separating the face-to-face dimension from one-to-one instruction, distance educators wage unprecedented challenges to entrenched assumptions about effective learning relationships. Invoking "the human touch", opponents of distance education remind us that powerful tutoring interactions are founded on face-to-face engagement. Skeptics decry tutoring at a distance, and this skepticism naturally extends to training tutors from a distance. The virtual relationships afforded by the Internet, they argue, are inherently diluted; compromised learning, they conclude, is the logical result. Quite contrary to warnings of dilute experiences, advocates of tutoring at a distance cite inclusiveness, accessibility, personalization, scalability, and, most importantly, opportunities to build powerful learning relationships that, by subtracting the miles that separate two minds, are otherwise impossible.

This presentation focuses on challenges and solutions that emerged in the development of a distance training program for online instructors. We divide the challenges and solutions into three areas -- pedagogy, content, and relationship. We present observations from the analysis of authentic online training interactions. Our observations suggest that cherished learning principles can endure if reinterpreted within a new framework of teaching and learning.

A. Training Context: The Provider and the Technology Platform

This case study focuses on the training program provided by a for-profit organization called SMARTTHINKING, Inc. SMARTTHINKING's primary innovations are (1) 24/7 real-time tutor training service, provided by experts, designed to supplement collegiate-level coursework; and (2) training professors and exemplary graduate students to tutor online (we call these tutor trainees "e-structors").

The technology platform used to conduct training is an interactive whiteboard with web-based materials. An interactive whiteboard is an Internet communication tool that graphically simulates the type of whiteboard one finds in a conference room or classroom. It enables real-time and simultaneous communication via text, color, and drawing tools.

The context for this case study is the experience of training a team of psychology instructors who tutor in a faceless, interactive whiteboard environment. This presentation explores what we observed when we hired experts in the domain of psychology and asked them to use their expertise in a new environment.

B. Three Challenges: Pedagogy, Content & Relationship
Three observations – one, that online, one-to-one pedagogy can lapse into a fact-finding service; two, that experts who tutor in a rapidly evolving domain (like psychology) will know different and sometimes dated content knowledge; and three, that tutor training happens “in relationship” – fuel the skepticism directed toward training tutor trainees at a distance, and engender the three challenges we frame as generative tensions:

- **The Pedagogy Challenge: Training Tutors to be Cyber Librarians or Model Thinkers?**
- **The Content Challenge: Is Providing Consistent Tutoring Possible with Inconsistent Professional Profiles?**
- **The Relationship Challenge: How Can the Affective Dimensions of Face-to-Face Interactions Transfer to One-to-One Interactions?**

D. A Case Study of Solutions: Examining the Development of a Distance Training Program for Psychology E-structors

Our training program has theoretical underpinnings: our pedagogy is informed by research from fields that study how we know (cognitive science) and how we grow (developmental psychology) in educational contexts. Trainees learn by doing through interactive real-time (synchronous) and self-paced (asynchronous) activities. The online tutor trainee training and evaluation processes are comprised of 20 hours of web-based modules. Training involves six hours of real-time practicum exercises with a live trainer, 14 hours of self-paced exercises, and three hours of assessment.

A Pedagogy Solution

Let’s suppose a student is studying neuropsychology. Sophisticated, three-dimensional graphics of virtual brains are mere keystrokes away if one has access to the internet. There is a danger, we believe, that a tutor will become a cyber librarian who searches well, but does not teach well.

To devise a solution to the pedagogy challenge (How will we train tutor trainees to be model thinkers, not cyber librarians?), we asked: How can a training interaction simulate a good tutoring interaction so that it metaphorically gets the trainee’s hand wet, as Annie Sullivan did with Helen Keller?

Thus, we set the expectation that tutor trainee trainees must create, not merely search for pre-packaged information. We predicted that tutors who respond to questions like cyber librarians, i.e. by doing Internet searches in order to help, would not earn intellectual trust from the students. This prediction informed our training protocol, and we developed slides we could load onto the interactive whiteboard that not only presented content, but more importantly modeled how we wanted that content delivered. Consider the following two training exchanges from our archives. Each tutor trainee was shown a training slide with the same task: “Draw synaptic transmission with the following terms: vesicles, synapse, dopamine, axon, dendrite, receptor. No diagram is included here; rely on the tool bar to teach and illustrate.” By asking the tutor trainee to create something from nothing, we eliminate the option of doing a search – being a cyber librarian – and we set high expectations for how tutoring exchanges should ensue.

Archive #1 offers a lens into Tutor trainee MK’s approach to an open-ended task. For this analysis, whether he offers reliable information in this diagram of synaptic transmission is almost irrelevant, for there are a number of visual and verbal representation weaknesses. First, the information is eclipsed by a disorganized approach to the task. To any viewer, the chaotic arrows are abundant and distracting; to the neuropsychology student, the multidirectional arrows obscure the unidirectional flow of electricity that characterizes synaptic transmission. Furthermore, the labels are poorly placed, too far from their referents, and too scattered to show the sequence in which neural functions unfold.

Second, key information represented in the diagram and text is not accurate (i.e. two synapses cited instead of one; receptor not accurate shape; dendrites ignored etc.) Moreover, in terms of modeling good thinking, this tutor trainee does not reveal how to approach this task in an organized sequence of steps. Although he...
is encouraged to ask for help, he feigns knowledge he does not possess. Finally, he does not demonstrate the humility of an "I don't know" that tends to engender trust and risk-taking in students.

Archive 1: Tutor Trainee MK

In Archive #2, by contrast, tutor trainee AG demonstrates her expertise by delivering accurate information in a methodologically sound manner. She begins with a simple picture, not text. The picture, however, is not simplistic; she categorizes and combines labels when appropriate. For example, on the left side, her labels group the terms vesicle, dopamine, and neurotransmitter to demonstrate how the terms relate to and define one another. On the right side, her labels offer a "big picture" by summarizing the sequence of synaptic transmission. The result is a clutter-free visual representation of the components involved in synaptic transmission.

After her picture is complete, she supports this diagram with text. Her clear prose explains the split-second process of synaptic transmission by breaking it into a sequence of steps. By choosing to number the steps, she models how to think sequentially. Finally, she concludes the interaction by summarizing the process with a single sentence. This progression—from picture to text to summary—was AG's intuitive solution to an open-ended task. Unlike the previous archive, she uses her on-command representation skills and knowledge base to create something from nothing (at least nothing more than a few terms), and thus engenders intellectual trust in the student while modeling an organized approach to the task.

Archive 2: Tutor Trainee AG

Thus, to meet the pedagogy challenge, we eschew glitzy images, for training should model what can be easily created while tutoring.

A Content Solution

Since we offer specialized assistance to students struggling through difficult college courses, we hired professional tutors, most of whom have doctorates in the academic subject they tutor. To devise a solution
to the content challenge (How can we provide consistent tutor training despite inconsistent professional profiles?), we asked: given the variation among the education of professionals/academics, how can we compensate for the relative strengths and weaknesses of tutor trainees in subject areas so that the content-related knowledge base of tutors exists at a uniformly high caliber? We achieved this through a two-part solution: (1) top-down assessment, then (2) bottom-up training.

**Top-down Assessment**

In the domain of psychology, being well established professionally tends to also mean being out of graduate school for a long time. We found that a well-published scholar, in spite of an impressive resume and a thorough interview, may not have training that coincides with the revolutionary interdisciplinary changes the field of psychology is experiencing. Thus, part of our training protocol was designed to identify content weaknesses in our psychology tutor trainees.

Archive 3 shows one such interaction. The slide asks a basic brain question: “Where is the hippocampus? Where is it in relation to the amygdala?” Tutor trainee KP gives an incorrect answer in terms of shape (the hippocampus is a small tilted “U”, not a large golf-ball) and location (it is in the temporal lobe, not the occipital lobe/medulla, as the trainer notes in black text). However, Tutor trainee KP prefaced her guess by explicitly identifying her academic weakness: “Neurology is not a strongpoint for me.” The trainer then engages in dialogue that draws the parts correctly, explains the significance of this brain architecture, then and most importantly relates the significance to the tutor trainee’s professional bent and clinical experience. Finally, having assessed the content area in which KP needs more extensive training, the trainer can proceed to the second step of our content solution – bottom-up training.

**Bottom-up Training**

Hiring academic and professional psychologists promotes the development of a cyber think tank; we use this intellectual power to enrich and customize training. In psychology, we made hiring decisions based on a “mapping strategy” so that training, and then tutoring, includes depth and breadth of content.

By mapping well, we engage in bottom-up training in several ways. In this discussion, we look at strategic pairing. Who would be a good match for tutor trainee KP? Let us contrast Archive 3 with Archive 4 below, which was completed by tutor trainee MW. In presenting this slide to tutor trainee MW, she draws both brain shapes quickly and, with accurate shape and location, has created a colorful diagram in seconds. Ostensibly, this demonstrates mere exposure to content and memorization skills. But the trainer pushes the interaction with MW, asking her to explain the significance of these adjacent brain parts,
the hippocampus and the amygdala and (black text): “explain the learning/emotion connection ... very briefly”. Tutor trainee MW (red text) answers accurately, sequentially, and without hesitation. The trainer is confident tutor trainee MW will be a good match for tutor trainee KP, and in this strategic pairing, tutor trainee MW will play the role of tutor trainee when dealing with neuropsychology content, but will play the role of student/learner when dealing with trauma content, which is tutor trainee KP’s area of strength.

In addition to leveling the knowledge base of our tutoring team, **strategic pairing** also builds online dialoguing skills, forges relationships, augments a sense of teamwork, and makes training adaptive.

**Archive 4: Tutor Trainee MW**

**A Relationship Solution**

If learning is emotional, can you create the affective dimensions of the living, breathing space shared by two people in face-to-face learning experiences?

Of the three challenges we explore, this third challenge is the most important because it addresses the conditions that drive the first two challenges — that is, teaching with sound approach (pedagogy) and sound information (content). When we communicate online, we forego the intangibles of traditional tutoring, like limbic messages, gesticulations, facial expressions, cadence, and intonation. Moreover, knowing how to promote student risk-taking without these nonverbal cues and mechanisms makes forging supportive relationships, especially in a new learning environment like a whiteboard, even more difficult. Archive 5, however, shows how this is possible.

**Archive 5: Tutor Trainer FF and Tutor Trainee PC**
Archive 5 shows a training interaction between tutor trainer FF, who has expertise with social science statistics, and tutor trainee PC, who never encountered statistics while earning his Ph.D. Though tutor trainee PC has over twenty-five years of teaching experience and is several decades older than tutor trainee FF, in this training session he is placed in the position of the learner.

This problem-solving dialogue opens with confusion and closes with clarity. How does this happen? When we analyzed this interaction, we realized that the psychology discussions are framed within very personal comments that share background information, feelings, and even fear. For example, PC and FF open the overall tutoring session (which includes eight slides on several topics) with some “cyber humor” as they joke about finicky Internet connections and their tutoring locations:

PC: Frank, my line’s misbehaving. Be patient.
FF: No problem – we’re communicating halfway across the globe after all!

We see this structure occur within the overall session, too. For example, tutor trainee PC prefaces an answer (one which reveals his limited understanding of standard deviation) with a self-deprecating comment: “In my feeble head...” After four sentences about standard deviation, he ends his explanation with a self-effacing joke that reveals his background: “See what happens when you do math with a theologian?”

Tutor trainer FF’s response follows a similar framing structure. Translating emotional reactions and nonverbal actions into text, tutor FF “laughs” at PC’s joke (“[H]a ha”), then pauses for reflection: “I’m thinking, just a moment.” After this pause, he offers a technical diagram and explanation, invites PC’s feedback, but still closes with a personal comment -- one that reinforces his awareness of PC’s home near Australia, site of the summer Olympics: “Have fun watching the [O]lympics!”

The interaction, therefore, does not confine itself to the learning topic – in this case, the technicalities of standard deviations. Self-deprecating remarks, humor, and pauses, then, are not inefficient or tangential; rather, they are essential for establishing rapport and promoting learning.

F. Concluding Remarks

Our analysis of these challenges begins to reveal the complexity of our initial question: Can good teaching principles transcend the vehicles in which those principles are delivered? Although this case study brings us a step closer to understanding the ways in which online interactions can help learners ask good questions and construct meaning through first-hand experience, the analysis provides no definitive answers, and in fact raises more questions. Future research might focus on the following:

- How, during online synchronous interactions, do individuals convey thoughts that are typically internalized in face-to-face environments?
- Does the nature of a dynamic, synchronous interaction change once it is archived? If so, in what ways?
- Are students learning in these online environments? If so, how are they learning, and to what extent is this learning different from traditional face-to-face environments?

While we are not in a position to quantify or qualify the nature of learning that transpires in these new interactive online environments, we can make one distinction – that is, the opportunity to return. The essence of this opportunity is captured in the closing remarks trainee PC to trainer FF (Archive 5): “What I’m going to do is hit the “Save” button under “Session” and I’ll see what happens...I’d like to study this, just to make it sink in deeper.”
Changing with the Times: The Evolution of a Faculty and Staff Web Development Program

Elizabeth Poff
St. Philip's College
San Antonio, Texas U.S.
Email efox@accd.edu

Abstract: Educational institutions have a responsibility to provide faculty and staff adequate training in web development so that faculty, staff and the institutions they represent can communicate their ideas, information, course content and activities over the Internet. The key to successful implementation is to deliver the training in such a way as to make faculty and staff want to participate in the training, as well as to make the training relevant, and to encourage continual development once the training has been given. St. Philip's College has structured its curriculum to facilitate the adult learner in such a way as to remain flexible enough to meet the emerging needs of each individual interested in pursuing web development. Discover how the web development program at St. Philip's College has changed with the times, and has evolved to remain relevant and valuable to those it serves.
TEACHING WITH TECHNOLOGY: STAFF DEVELOPMENT THROUGH A TURNKEY TRAINER MODEL

Dr. Richard Walter, Associate Superintendent
West Babylon School District, West Babylon, New York USA

Mrs. Patricia M. Squicciarini, 5th Grade Teacher
Tooker Avenue Elementary School, West Babylon, New York USA

Ms. Carole L. Polney, English Teacher and Webmaster
West Babylon Senior High School, West Babylon, New York USA
Email: Lv2LearnNY@aol.com

ABSTRACT

Using a PowerPoint presentation, the Associate Superintendent, a fifth grade teacher and a high school English teacher will demonstrate the key ideas and themes of the staff development Turnkey Trainer Model and its applications and benefits within the school district. We will discuss the "administrative" role of the model (budget, implementation of the turnkey trainers—choosing the "Teacher Technologists") and will present the trainers in action. We will explain how the staff development sessions are conducted; how encouraging reluctant staff builds trust and willingness to try and learn; how continuous support and growth enable cooperation among faculty, as well as between buildings. All presenters will discuss obstacles, challenges and strengths of implementing technology into a school district. The discussion will be supported with handouts of successful staff development workshops. A question and answer period will follow the presentation.

DESCRIPTION

Continuous training has been the key to keeping up with the advancements and changes with technology in the education field, especially with the inclusion of the Internet in many of the new learning standards. The needs of the teachers must be met if a district wants to successfully implement the use of technology. The Turnkey Trainer model, which supports the technologies and has continual training, can only lead to successful teaching and learning in the classroom. Staff development can make a powerful difference for students and teachers alike. Although districts may have different demographics, the problems facing districts, in regard to staff development and technology, remain the same. Effective teaching with technology can only be accomplished if districts devote money, time and opportunities for further training of the staff.

OBJECTIVES
The presentation will provide an overview of a staff development model that supported a district wide implementation of technology in our school system. Turnkey Trainer Representatives (K-12) and the Associate Superintendent for Personnel and Technology will explain the model. Issues such as: linkage to curriculum, budget, and variance in teacher technology skills will be addressed. Other issues that will be discussed are: how staff development activities, in-service programs and summer technology academies increased the skills and use of technology in the classroom by integrating the technology, in particular the Internet and intranets, as tools into lessons. This interactive session will allow for discussion among presenters and participants—the best way to learn about implementing technology and teacher training is to discuss various models and methods that have proven effective.

ACKNOWLEDGEMENTS

The presenters wish to thank the following: the West Babylon Board of Education; Superintendent of Schools, Mr. Mel Noble; the West Babylon faculty and administrators, and the West Babylon Community for their support in bringing technology to the children.
The Carrot or the Stick: The Development of Faculty Technology Competencies

Susan M. Powers
School of Education
Indiana State University
powers@indstate.edu

Kenneth Janz
School of Education
Indiana State University
soejanz@isugw.indstate.edu

Abstract: The School of Education at Indiana State University put forth a requirement that all faculty who requested new desktop computers must meet a set of established faculty technology competencies. The goals were to use a velvet glove in order to ensure that faculty can perform the same technology competencies as students, ensure new technologies are used to their fullest, identify those persons who needed training and assistance, and build departmental awareness of potential technology mentors. The competencies are a work in progress that have been ratified by SOE governing bodies, but are still working toward true implementation.

Background on Faculty Competencies

As technology advances, it also advances on the educational community. Reflective in this movement is the development of technology standards for many in education. For example, the International Society for Technology in Education (ISTE) has developed the National Educational Technology Standards for K-12 Students (ISTE 2000a) as well as the National Educational Technology Standards for Teachers (ISTE 2000b). The State of North Carolina has led the way by the creation of a list of basic and advanced technology competencies for professional education faculty and students. Using this core list of competencies, UNC-Charlotte's College of Education developed a set of assessments, formative evaluations, and feedback for their education faculty (Algozzine et al 1999). Given the backing and encouragement of state mandates, this full process worked well for UNC-Charlotte. However, given the pressing demand of standards for our teachers and other students, and a lack of state guidance, Indiana State University's SOE ITAC embarked on a new venture to develop its own faculty competencies.

Creating the Technology Competencies

The reasons for the establishment of faculty technology competencies were fourfold. First, a number of student competencies for undergraduate, masters and doctoral students had been passed by a variety of governing bodies on campus. For pedagogical reasons, it was important to know that faculty could achieve the same level of competency as their students. It is a commonly accepted truth that teachers teach as they themselves have been taught. Therefore, to have graduates that can successfully integrate technology into their classrooms or professional lives, they must first have effective models of technology integration in their faculty.

Despite the best intentions behind the pedagogical reasons for technology competencies, the efficient use of new technology purchases was the reason that "sold" the idea behind the development of faculty competencies. Faculty and staff throughout the SOE were frustrated at seeing high-end technology sit unused on faculty desks, or worse, being used merely as a high-end typewriter or solitaire partner. As technology dollars continue to diminish in relation to need, it seems prudent to assure that technology expenditures go where the needs are the highest and/or individuals are willing to improve skills.
Third, if we truly want to improve skills, then we need to target the deficient skills of individuals. Since the technology competencies are essentially a self-assessment of skills, individuals (in conjunction with their department head) can identify deficiencies in their technology skill set. This information, which is then passed on to ITAC, is crucial in creating targeted training.

Finally, greater awareness of where a department's technology "strengths" might be will encourage individuals within a department to seek peers for assistance. Being able to turn to a colleague for just-in-time assistance lessens the demand upon IT support staff and provides potentially more immediate, and relevant response.

During the Spring of 1999, each department was requested to develop a set of competencies for their faculty and staff. When faculty/staff from that department requested a new computer, the department would need to provide documentation to the technology committee that identified the specific competencies the faculty/staff member had and what specific skills they needed assistance in achieving. Faculty/staff do not need to be fully proficient in order to receive a new machine; rather, the goal was to be able to identify department-specific skills needed to help plan for professional development workshops and training. Documents were created and collected from each department by departmental representatives on the technology committee and forwarded on to the Dean for approval. By the end of the academic year, the Dean approved all departmental documents, and they were placed on the SOE website (http://soe.indstate.edu/itac/).

Reflection on the Process

As stated earlier, the competencies have the power to help bring about true technology literacy by placing standards on faculty similar to those expected of students. The "carrot" of a new computer is merely an incentive to encourage faculty, staff, and department heads to work with technology competencies. When the process is taken seriously, everyone can benefit -- the departments, faculty, the school, students, etc. However, this process is seen by some to be one additional hurdle that must be surmounted, one way or another, in order to achieve the prize of the new desktop computers. To make the process work, and to make it palatable to everyone involved, academic integrity is a key element. Unfortunately, some ITAC members know of instances where faculty competencies were signed off upon without any intention of enforcing the spirit of the competency guidelines. Since little direct evidence exists, ITAC continues to work on this issue to ensure that faculty technology skill continues to increase in order to meet the needs of our students.

Conclusion

This process has been in place in the SOE for only one year. As this paper is being written, the process of certifying technology competencies is about to begin again. Through the lessons learned the first time around, ITAC is working to improve the process. One way is by sharing some of the more efficient, streamlined competency documents with other departments. Another way is by finding better ways to ensure that competencies are met, and ensuring that as the existing and required skills of our students increase so do faculty skills. The SOE is committed to the knowledge that having strong technology skills in our faculty will have ultimate benefits to our greatest asset, our students.

Empowerment of Personnel to Survive in an IT-enabled
Organisation and an e-World. (A South African Perspective)

Mr. CE Pretorius
Manager Client Services
Dept. Information Technology and Management
Potchefstroom University for Christian Higher Education

1 Introduction

In this dynamic decade, a University that is successful in future will be one that has planned for the future early enough to have been able to change its strategies, business and operations according to the demands of the country and the people (clients) at that point in time. It will continuously envision its future in such a way that it will keep adapting its strategies to profit optimally from the technological and learner-related developments of the present and future ages in order to remain a viable institution.

In practical terms it means that the successful University of 2005 will have envisaged the driving forces of the e-world, globalisation and life-long learning. It will have changed its strategies, business and operations in good time, and keep adjusting them in such a way that the University will also prosper in the long term.

One of the most important success factors of the e-enabled University is IT-skilled faculty and staff. IT alone won’t do the job. It needs to be placed in the hands of knowledgeable, skilled and creative people with a clear focus on their job. This applies to both faculty and staff, and not only to IT staff. Personnel need to have general as well as specialised skills, appropriate to their specific roles in the enterprise. Without these skills, technology is often blamed for failures, and the enormous investment in IT will be wasted. Without a paradigm shift in the appreciation and role of technology, it will simply become part of the problem of rising costs, instead of becoming part of the solution.

2 Technology trends

The global trend towards e-business is fuelled by dramatic technological improvements and a shift in business economics. The extremely fast pace of technology development and product evolution is also stimulated by increased competition in the IT industry. The pervasive use of especially the microcomputer for business as well as leisure and entertainment is creating huge markets for the IT industry. Any business that wishes to survive and thrive in this new cyber era will have to take serious cognisance of these developments. Trends like

- the internet and World Wide Web
- affordability and power of the workstation and laptop
- penetration of technology in the everyday life
- the human/computer interface
- real multimedia
- knowledge management
- the dominance of Microsoft
- licensing of application programs
- virtual support
- technology based learning
- collaboration (partners, components, etc.)
- personalization
technology in the library
- electronic journals
- databases
- conglomerates

create lots of opportunities, but without a solid base of IT-skilled personnel, universities will experience these trends as threats.

IT is everywhere - On campus, in the hostel, at home, overseas.
IT is used by everyone - From the gatewatchmen to the Principal
IT can be used anytime all the time - 24*7*365

One of the most important success factors of the e-enabled university is IT-skilled faculty and staff. IT alone won't do the job. It needs to be placed in the hands of knowledgeable, skilled and creative people with a clear focus on their job.

4 Empowerment of personnel

4.1 Scope
To optimally utilise the potential of communication and information technologies, whether primarily on-campus or at a distance, requires high-level relevant skills. Three types of skill sets are necessary for personnel:

- **A sufficient level of technical and manipulative ability** to be efficient and comfortable with the operation of a networked PC and software applications (refer to levels 1 and 2 in the diagram below)
- **High-order pedagogic skills** for faculty (this skills set constitutes level 3 in Figure 1)
- **Skills of university management** which is aimed at heads of departments, deans etc. (level 4 in diagram)

4.2 Objectives
The objective of this project is to enhance the IT skills of all personnel members, but more specifically of faculty, in order to empower them to work effectively in the new flexible learning environment.
4.3 Strategies

4.3.1 The four-level approach (WHAT)

It is very important to start with basic skills. Whenever one wants to develop network based learning material and deliver it in the student support system you have to be able to use Word 97. To be able to use Word 97 one at least has to have keyboard and mouse, basic IT, management of files, stylesheets and PUKNET (University local area network) skills. Depending on the material, you probably need to know how to work with spreadsheets and basic graphics. Just to prepare very simple learning material you need to be skilled in at least 5 areas on level one and at least 2 areas on level 2. To be able to deliver this course in the student support system you need to know how to plan, design, develop and deliver network based learning material, what the student support system offers you and how does it work, how to work with email, the internet, a browser etc. Thus to deliver a course you need basic, advanced and specialised IT skills as well as skills for the new learning environment.

Parallel to this it is very important for personnel to know why they are doing all this. Why is it important to use the intranet and internet to deliver courses, why do I need the skills, how does my profile look, etc. We intend to develop courses in this regard starting from level one.

The fourth level of the model is aimed at heads of departments and deans. It is important for them to have insight on the impact of IT strategies on his/her division.

Other areas we feel it necessary to be skilled in over and above the ones I have mentioned is the following:

- Document management – Just about all documents and therefore learning material are produced using a computer. The knowledge of the university is contained in these documents and it is therefore important to manage it. Documents need to be stored centrally and managed accordingly.

- Research Toolbox – This is a product we use to make sure that a standard basic research process is followed and it is especially used by first time researchers. It also gives a research director easy access to all his/her research projects.

- Business Applications – The student support system will be tightly integrated with the business applications and therefore allow a student to access his/her exam results, financial information etc. through the student support system. Faculty and administrative staff will be faced with questions in this regard.
Academic Information retrieval techniques – there are a wide world of information at your fingertips. You need to know where and how to search for these information.

The actual skill profile of various staffmembers will differ but it is important to mention again that every staffmember, from the gatewatchmen to the Principal, need to be skilled to survive in an e-world and ride this new wave.

4.3.2 Implementation strategy (HOW)

4.3.2.1 Phased implementation

4.3.2.1.1 Phase 1
Implementation of levels 1 and 2 of the model.

4.3.2.1.2 Goals
1) To be learner-centred 2) To start the profiling process 3) To include assessment as part of the learning process 4) To be able to have management information at hand timeously 5) To register the courses with the South African Qualifications Authority.

4.3.2.1.3 Progress made
We have outsourced most of the level 1 and 2 courses to a private company called Boston Business College. We allocated our IT training room and all the equipment in that room for this purpose. In exchange for that Boston Business College offers the courses to university staff and faculty at a very low price.

At first we used a central budget to finance the project but after two or three months we decided to pass on the costs to the departments. Since May 2000 when the project was officially launched, 903 courses have been enrolled for. This is at least three times more than in the past.

The huge success of phase 1 is partly because learners receive a nationally accepted certification after successfully completing the course and because they can learn at their own pace, whenever they want to. At this stage learners still have to physically go to the training room but all the outsourced courses will be available on our intranet in the 2nd quarter of 2001.

4.3.2.1.4 Phase 2
Implement level 3 and the Attitude part of the model.

We are still busy planning this phase and have not really started any structured course. The planning, design, development and delivery of network based learning material is the responsibility of the Bureau of Academic support services and they plan to implement a course 3rd quarter of 2001. At this stage they help faculty on a one on one basis.

The student support system, which we developed ourselves in association with a private company, will be ready for implementation early in 2001 and therefore we will start the course only in 2001.

4.3.2.1.5 Phase 3
Implement level 4 of the model.

We are still busy planning this phase and have not really started any structured course. We are still not sure what the format of this course should be. It will probably be a combination of material, information sessions, discussion groups, etc.

It is important to notice that it is not only the IT department who is involved in the implementation of this model but also Academic Support Services and the HR department.

4.3.2.2 Faculty and Staff Skill Profile

The model focuses on all personnel and not just faculty, but the third level is mainly focused on faculty. We are aiming to have an IT skills profile per post. For example, a faculty secretary will have a profile that will include level 1, certain skills on level 2 and perhaps skills on level 3, whereas a staff secretary won’t need skills on level 3.

It is very important to work closely with the human resources department as well as directors/managers to define these profiles. As the requirements change, so will the profiles.
These profiles will also form part of the appointment process of personnel and the yearly performance evaluation.

![Figure 2: Typical profiles.](image)

Example of a "Secretary profile" who assist faculty to deliver courses in the student support system

Example of a "Dean Profile"

4.3.2.3 Assessment

Assessment and certification is a very important aspect of this model. This is the only way in which one can measure skills. It is not necessary for anyone to attend a course. If the learner thinks he/she has enough knowledge, he/she can write a pre-test or do the formal test without doing the course.

4.3.2.4 SAQA and NQF accreditation

The new South African constitution provides for a structured approach to education and training of employees. Each organisation has to report to the South African Qualifications Authority (SAQA) regarding in-house courses for personnel, courses (in-house and external) personnel has finished over a period of time, cost etc. What is important for us is to register all our courses with SAQA. This is the only way in which the university can claim back a percentage of the funds it has paid over to SAQA.

Although this report back every month is a lengthy process, it force you to evaluate the training of personnel every month. In a certain sense it was much easier for us to implement this IT-Skills model within the broader framework of the NQF (National Qualification Framework) because they have already set the table.

4.3.2.5 The Budget

Although we started off by allowing anyone to register for any course for free, we quickly realised that this was the wrong approach for the longer term. But for a start it was easy to get personnel involved and excited about the project.

There is a central budget approved for 2001 but we will only subsidise departments. In the longer term when the profiling has being done each department will have its own skills development budget because they will know exactly what their needs are.

4.4 Statistics (The past and the present)

In seven months 903 courses have been enrolled for, compared to approximately 400 per year in the past. This is significantly more and can be ascribed to:

- The fact that learners can learn at their own pace, at their own time as long as they want to.
- Assessments and certification
- Good marketing strategy of the outsourced company
- Central budget
Just to repeat what I said in the beginning: The skill development model was not aimed to accommodate just a specific group of people. Although Faculty and Administrative staff make out most of the learner population, top management on the one side and service workers on the other side are also involved.

5 The future
We are planning to give more structure to the project in 2001 by:

- Formalising the profiling in co-operation with the HR department.
- Work out strategies to integrate personnel training and performance evaluation.
- Implement Levels 3 and 4, the attitude courses and the others which we haven't implemented yet.
- A secondary objective of the project was to relieve some pressure off the IT Help Desk. We will evaluate that.
- Adopt the model as time change.
Articulating Technology Needs To Administrators And Policy Makers

Thomas A. Rakes
Glenda C. Rakes
The University of Louisiana at Monroe
United States
rakes@ulm.edu
edgrakes@ulm.edu

Abstract: There is a continuing disconnect among those who recognize the value and growing needs associated with technology-related innovation and campus administrators and policy makers who are in charge of overall budgeting and resource allocation. How does one communicate effectively within the context of the administrative framework of a college or university? When making funding requests to those who may be less familiar with specific aspects of information technology issues, one should 1) make data-based requests, 2) speak from a global perspective, and 3) consider administrators' priorities.

Introduction

There is a continuing disconnect among those who recognize the value and growing needs associated with technology-related innovation and campus administrators and policy makers. These needs may involve instructional and information technologies as well as needs involving personnel, equipment, space, line-item budget support, and numerous other issues that involve communications among technology personnel and administrative and policy leaders who are responsible for the allocation of resources. There are varying levels of technology sophistication among administrators and vastly different levels of economic and priority interests existing on college and university campuses. The following information is provided to assist faculty and staff in preparing funding requests when the technology experts are not necessarily those in charge of overall budgeting and resource allocation.

How does one communicate effectively within the context of the administrative framework of a college or university? As a practical consideration, keep in mind the serious challenges that higher education is now facing. Institutions are in a perpetual financial vice (Selingo, 2000) with tuition rising along with increasing financial needs. Many of these financial needs are technology related (Market Data Retrieval, 1999). Imbedded within economic and quality issues is the need to consider three areas when developing requests for technology resources. When justifying requests requiring new or redistributed resources it is important to 1) make data-based requests, 2) speak from a global perspective, and 3) consider specific priorities of busy administrators.

Make Data-Based Requests

There is a tendency for many administrators to become consumed by details involving accreditation, system reporting, performance and enrollment data, student and faculty concerns, and other daily occurrences. Funding requests that do not provide specific detail are often lost in the daily "shuffle." It is important to approach administrators with meaningful data to explain or support innovative ideas and concepts (Bradford & Duncan, 2000; Hafner & Oblinger, 1998). It is essential to use specific information to support a particular funding request. When appropriate, information from system, state, regional, or national data makes an excellent basis for explanations and comparisons. The constant evolution of instructional technology
guarantees that the pressure to spend will continue to rise. Examples that include references to peer institutional group data will help make particularly compelling arguments in support of specific requests.

One excellent source for such information is provided by the COSTS project (McCollum, 1999). The project provides detailed data from a survey of 100 colleges and universities. The survey gives useful descriptions concerning what peer institutions are doing with technology budgets. This data allows administrators to see technology costs as compared with comparable institutions. This data is useful to administrators who must justify their budgets to supervisors who may not have a clear sense of how much technology should cost. Such data allows administrators to put spending requests into perspective.

Speak From a Global Perspective

Policy makers operate within an environment that usually includes multiple interests that compete for attention, resources, and priority within the institution. In this context, a global perspective may mean considering ideas, plans, and projects that appeal to or address needs across a region or state. However, thinking from a more broad-based perspective is also helpful for campus-wide efforts. Technology needs can easily drift beyond college or departmental boundaries. Focus on ideas that will benefit multiple groups (students, alumni, faculty, staff, other institutional partners, etc.) and future efforts. Requests that have potential benefits for more than one department or college or community agency increases the overall value and appeal of a request. Link requests to university or departmental or college mission statements and technology plans whenever possible.

Consider the Administrator's Priorities

One of the least understood and often overlooked considerations involves numerous, frequently unspoken factors that are generally recognized within administrative ranks, but are not always apparent to faculty, staff, and others who operate outside the administrative circles. Consider the time pressures under which most administrators operate. When meeting in person, use a written agenda and keep within the time scheduled for your meeting. Demonstrate an organized approach that reflects a serious, planned presentation. Be prepared to describe your successful experience with related projects. Frequently, the best predictor of future behavior is past behavior. Give the administrator a reason to believe you will be successful with the proposed project.

When scheduling appointments to discuss funding requests, pay attention to situations that may divert an administrator's attention away from your needs. Time sensitive conditions exist for campus leadership and these can cause delays or less than full consideration of requests. Be sensitive to issues and deadlines that could cause an idea or request to receive less than adequate attention.

Provide an executive summary of your request that provides enough detail without creating an additional time burden. Written material should be as concise as free of jargon as possible. The language of technology can be unclear to those not as familiar with a particular topic. Do not camouflage good ideas among the jargon of the latest innovation. Use bullet points, charts, and graphs to reflect important concepts. Clearly describe the group to be served by the project, the importance of the project, the results you anticipate, and provide a specific breakdown of the funds requested.

Abstract: Faculty development in the college of education has changed and evolved over the last several years. In the beginning, faculty received technical help from the technical support staff, but had little support at the curriculum integration level. In the fall of 1999 the College of Education embarked on a technology training program. This program was offered to all faculty and after completing 16 hours of training, the participating faculty members received a laptop computer. The training program was offered through the central academic computing center, a university-wide agency. This program was deemed a great success and the faculty left happily with their new computers. But, what really happened? We found that the faculty did not learn as much as we thought and they thought. A second program was developed. Similarities and differences between the two programs are discussed. Hopefully the experiences and development in this program will help others in the area of faculty development to better train and educate their faculty in technology and enable faculty to embrace technology in new ways.

Background

Faculty development in the college of education has evolved over the last several years. In the beginning, faculty received technical help from the technical support staff, but had little support at the curriculum integration level. In the fall of 1999 the College of Education embarked on a technology training program. This program was offered to all faculty. The faculty participants, after completing 16 hours of training, received a laptop computer. This training sessions were offered through the central academic computing center, a university-wide agency. This program was deemed a great success and the faculty left happily with their new computers. But, what really happened?

Phase I

For discussion purposes, this program is referred to as Phase I. The major emphasis of Phase 1 of this program was on the skills level. Courses were offered in webpage development, Adobe Photoshop, PowerPoint, etc. Faculty registered for these workshops based, not on knowledge of the capabilities or the relevance of the software, but on the title of the session, and scheduling convenience. Consequently,
although the faculty successfully completed these workshops, they had little understanding of how to apply these skills to their teaching and little connection actual needs in their classroom. At the time of the training, faculty seemed pleased with what they had learned and gave very positive reviews of the program and the sessions. Now, just a few months later, we are questioning what the faculty really learned. A review of Phase I training concluded that:

- Many participants stated that they don’t remember anything that they had learned in the training
- Some participants still need support in areas in which they received more than 12 hours of training.
- More consultations needed to be done with faculty to ensure they were enrolling in a workshop relevant to their skills level, and contextual needs.

These observations and others forced us to rethink our faculty development program, and led to additional questions. Were they using their newly acquired hardware in innovative ways? Did this change the way they teach or at least provide a convenient way for them to use technology for administrative purposes? Not really. Some of the laptops remain in their cartons. Why did this happen when the program seemed so successful? This remainder of this paper describes an alternate program currently being offered and explains the differences and why it has the potential to be more successful. This program is called Phase 2.

**Phase 2**

When trying to understand why a group of people adopt technology at different rates, we look to the research in the field. According to Everett Rogers, in his book Diffusion of Innovations (1983), there are four components of innovation diffusion: the innovation itself, the time-frame for adopting the innovation, the social system within which the innovation is diffused and the communication of the innovation from one individual to another. Rogers defines individuals on a continuum from innovative to laggard, and classifies them into five different adopter groups: innovators, early adopters, early majority, late majority, and laggards. The faculty of the College of Education can be placed in each of these classifications. The innovators and early adopters have been using technology for years before organized training took place. Since the entry-level training workshops probably didn’t meet the needs of these groups, they were given the option of learning something new on their own in order to obtain a laptop. The faculty development programs were primarily targeted at the early majority, late majority, and the laggards. Phase 1 met the needs of the first three groups, the innovators, early adopters, early majority, but the last two groups were left on their own.

According to Hall and Loucks (1978) Staff development can best be facilitated for the individual by use of a client-centered diagnostic/prescriptive model. Too many in-service training activities address the needs of trainers rather than those of the trainees. Based on what we learned from faculty coupled with the research on change, and innovation diffusion we evaluated Phase I and made some necessary changes to the program.

Similarities exist between Phase I of the technology training program and Phase II. For example, faculty completing 16 hours of technology training will receive a laptop computer, all workshops are done in a hands-on environment where faculty sit at the computer and work. Both Phases consisted of workshops that are independent of each other, usually covering one topic at a time and spans either one session or two.

The way in which the workshops differ are many, and profound. First of all, a smaller group of professors participated in Phase 2 and received more individualized attention. Before the training began, each participant had an initial consultation to determine exactly what the professor was interested in learning and how they would like to use technology in their teaching. Their specific needs determined which classes would be taught and in what order. Participant feedback was extremely important in the formation of the program and in workshop development.

Another significant difference between the two is in the instructional delivery mode. Phase 1 consisted of a “watch and then do” model. “Click on File, then open.” Instruction consisted of learning the different menus and how the software worked. Phase 2 is less structured and more hands-on. The participants were given a project or problem that they had to work on and figure out how to use the software for the project. Of course, some guidance was given. The focus was taken away from the specific software application and put on using the software to solve the problem at hand. The goal was to teach the participants how to “tinker” with software and find what they are looking for, instead of every action being dictated to them. This teaches the participant to learn how to use the software instead of learning to follow
a recipe or follow simple instructions. This isn't always an enjoyable way to learn, but in the end the participants did feel like they were learning something.

Every workshop in Phase 2 focuses on creating a meaningful project that is contextual to the needs of the participants. Every participant did not walk away with the same thing. For example, some professors created web pages for their courses, others created a personal web page. This made the workshops more meaningful to them and more applicable to their needs. We believe another significant reason why the content of the workshops is better is that the teachers and developers of Phase 2 are from the College of Education, not a central university agency. This is important because the trainers are more familiar with the type of teaching that occurs in this college.

Conclusions

At this time, Phase 2 is still being implemented, therefore long-term outcomes cannot be measured. However, a follow-up plan has been developed to see how the workshops have changed the way the professors use technology personally and in their teaching over time.

The purpose of this paper is to help others in the area of faculty development to better train and educate their faculty in technology and get the laggards to embrace technology in new ways.

Introducing Tutor Professor to Online Distance Education:

By Online course

Authors
Verónica Salinas Urbina, Virtual University, ITESM. México.
Rosa María Garza, Virtual University, ITESM. México

Abstract
This paper discusses the development of tutoring guidelines for tutor-professors in the Virtual University of Monterrey Institute of Technology (ITESM). The purpose in discussing these guidelines is that they may be relevant to teaching in any online environment. We also developed an online course for tutor professors considering these guidelines.

First, we developed a tutoring guide because our instructors were not used to teaching online. We feel that our experience in designing this guide could be useful for others working in technology-based distributed learning environments. This guide is not a "recipe", but a set of recommendations that we hope tutors will use as a reference and apply appropriately to their educational context.

We created these guidelines and recommendations, so the tutors can use it and perhaps they could save time and resources, and focus their functions in accordance with the institutional philosophy, course learning outcomes, and technology use, etc. because they will be more involved with many ideas suggested here and these ideas could help them to achieve these advantages.

It is important to consider how well prepared new professors are for online teaching when they begin their teaching duties because they may not be familiar with the ITESM context. We need to provide guidance for them to review deeply some premises or assumptions. For instance, are they familiar with our institution and its mission and philosophy? Are they
aware of the different cognitive strategies that can be used to facilitate students’ knowledge acquisition. Do they know how to use Web-CT, Learning Space, etc.? (the web-based course development and delivery environment). We developed these guidelines and recommendations to improve online teaching at ITESM by making it consistent with the institutional philosophy, course learning outcomes and technology use.

In an attempt to improve tutor performance in online teaching we produced an online course where professors could live this experience and also could be prepared in their duties as a tutors in this kind of distance education model. This online course was developed by searching different bibliographic references and through discussions with experienced online tutors.

The course includes topics related with Distance Education, learners in this context and also different Recommendations for Tutor Professors in the Virtual University. It is our hope that after taking this course the tutor professors will achieve the following objectives:

1. Know and understand the Monterrey Institute Technology mission;
2. Review and apply the Virtual University policies;
3. Work collaboratively (with the team who designs and develops the course);
4. Learn how to use technologies (Training);
5. Manage their time effectively as tutor professors;
6. Plan their courses effectively, considering virtual environment conceptualization, satellite sessions/videoconferencing with UBC, learning approaches, online activities, evaluations and special projects;
7. Incorporate instructional strategies in order to follow the ITESM mission;
8. Know how to create a communicative environment with their students;
9. Manage and control the course administrative affairs;
10. Motivate their students by creating affective links, and performance awards;
11. Give meaningful and timely feedback;
12. Know how to moderate online discussion forums;
13. Evaluate the learning-teaching;
14. Stay up to date in their professional field;
15. Foster and develop research projects to enhance distance learning environment.

The online course will be updated regularly with tutors' experiences in order to stay abreast of this rapidly changing field.

On the other hand, we design an online learning environment —training area— so tutor professors can acquire knowledges, but also develop the necessary skills and attitudes. This virtual learning environment was developed considering the guidelines for tutor professors and we would promote interaction amongst tutor professors, and also foster practice. In this way, tutor professors are having a similar learning experience as their students. This online course is offered right now in the Virtual University, ITESM for all the tutor professors and this course belongs to the formal training program for new tutor professors who use technologies in their learning and teaching processes, specifically in the Virtual University.

Abstract: An ethnography of graduate education students in interactive video-based classrooms provided the data for the exploration of student perceptions of the instructor's role in the technologically mediated learning environment that is set forth in this paper. Data suggest students assigned new responsibilities to the instructor and expected the instructor to bridge the distance gap between the classrooms, clarify new rules for classroom behavior, and maintain a focus on course content despite of the instructor's added technology related duties.

Introduction

Traditionally the classroom has been the teacher's domain (Barr & Dreeben, 1983). Students came to the teacher's classroom, took grades home that the teacher gave, and studied what the teacher said to study (Jackson, 1968). The teacher was in place to control social interaction (Borman, 1978; Shultz & Florio, 1979), to direct classroom organization (Dickinson, 1985; Shultz, Florio, & Erickson, 1982), and to guide learning activities. The teacher was the authority that held power in the classroom (hooks, 1994). In most classrooms this is still true today. Students still look to the instructor for guidance in the classroom, accept his/her evaluation of their performance, and expect him/her to carry a level of expertise in the subject matter that far exceeds their own.

However, there is also a longstanding relationship of trust between teachers and students. They "understand each other's behavior as directed to the best interests of what they are trying to do together and how they can hold each other accountable for any breach of the formulated consensus" (McDermott, 1977, p. 199). The form of trust that McDermott (1977) refers to is dependent upon interaction between the learner and the instructor and requires effort on the part of both to maintain it (McDermott & Church, 1976).

Distance education literature establishes the importance of creating classroom environments that provide the connectedness that instructors and learners need in the absence of face-to-face interaction to maintain their trust relationship (Boone, 1996; Garland & Loranger, 1996; Grasha, 1996). In the distance environment, however, more effort is required on the part of the students and instructors to maintain the traditional trust relationship, as well as to accomplish other traditional classroom responsibilities (Moore & Kearsley, 1996).

Our recently completed ethnographic research of interactive video-based classrooms suggests that before students entered their distance learning environment for the first time they were not prepared for the different roles that either they or the instructor would encounter. Their expectations were rooted in their traditional ideas that the physical presence of the instructor would allow that instructor to lead, guide, direct, teach, moderate, and have a particular awareness of students as individuals. When the technological mediation of the classroom interrupted the expected roles and behavioral patterns for classroom participants, students subliminally assigned new roles and expectations to their instructors and felt uncertainty about their own role. The data suggest that the inclination of students was to place the responsibility for the success of the added classroom elements on the instructor.
In this paper we will consider what students said about their expectations of the instructor and how those expectations influenced students' adaptation to their new classroom environment. An examination of student expectations provides insight that can inform distance educators who are in the planning phase about learner needs, can increase veteran distance instructors' sensitivity to students who are new to the environment, and can prepare new distance educators for scenarios they may encounter when they begin their distance teaching experiences.

The Study

The data that served as the basis for this paper was gathered during a one-year ethnographic case study of 13 graduate education classes that took place in an interactive video-based classroom that was officially named the Interactive Distance Learning Studio (IDLS) (Clevenger-Schmertzing, 2000). Students participated in class simultaneously from two different locations. Courses included in the study varied significantly in teaching style, course objectives, course content and student responses. Traditional ethnographic and qualitative research methods facilitated data gathering and analysis (Agar 1996; Maxwell 1996). Data gathering involved more than 400 hours of participant observations in classrooms, formal interviews and informal conversations with students and faculty, weekly e-mail correspondence, open-ended surveys, focus group interviews, and video of all classes. Thematic coding, frequency counts, and frequent debriefings between ethnographers L. and R. Schmertzing contributed to interpretation and ongoing analysis of the data (Spradley & Mann 1975). Throughout the ethnography hundreds of students expressed ideas, concerns, and thoughts on their distance learning experiences. Comments included in this paper are representative of themes that surfaced repeatedly in conversations, interviews, and survey data.

The Students' Voices

During the course of our study, students often voiced concerns that related to style of instruction, content of the course, class management, and learning style preferences. A major theme that emerged from these discussions related to the individuality of instructors and the significant role they played in facilitating positive experiences in both traditional and distance classrooms. A student at the remote site said, “I think the technology works. I think it depends so much on the instructor” (RFt M FG 010.87). Another student, a host site student, said something very similar, “If [my instructor] had been someone else who couldn't do that [keep class discussion going across sites], it [class] would be a flop, I mean, the instructor is the key point in there (HFt F 1-v05.1251). Students were clear that, “The teacher is the most important thing. If the teacher is prepared and excited and cares, [...] then you are getting what you need to get” (HFt M s11.8.1694).

Students depended a great deal on their instructor to make their distance learning class a success, as they would in a traditional classroom. The difference, however, was that as students tried to understand the new technologically mediated environment they also developed new needs and consequently had new expectations of the instructor. Our data suggest that the inclination of students was to place the responsibility for the success of the added classroom elements on the instructor. As students adapted to their distance-learning environment, they made assumptions that the instructor would guide them through the uncomfortable spaces in their distance education experience. They expected the instructor to provide guidelines for adjusting to that experience. Many students assumed that the instructors would offer new rules for classroom behavior, that they would build a bridge that eliminated the distance between the two sites, and that they would have the ability to maintain a focus on content rather than on technology. The way the instructor handled these matters alongside his/her traditional classroom responsibilities had significant impact on the ways in which students adapted to the environment and changed the way they interpreted their own role in the classroom.

On Providing Rules

As a result of the absence of the instructor at one site and the breakdown in the rule system associated with traditional classrooms, researchers witnessed adult students reverting to immature classroom behaviors similar to those that one might expect to find in grade school. One student said it was because, “the feeling of someone being
there of authority [was missing]" (RFt F I s10.4.153). Some adult graduate students actually admitted the need for instructors to control the class and to remind them of the rules. Marybeth was one such student.

Like don't talk when someone else is talking. You have to revert back to the first and second grades because we act that way with the [instructor at the other site]. I just think a lot of people don't realize that when the instructor is at the other site you think that they don't hear you or see you. So, I think that a lot of people just need to be aware of that. If you [the instructor] have to tell them or write it up on the board, I think you need to do that. (RFt F I s10.4.1051)

Students feelings of personal disconnectedness lead them to forget that they were visually and audibly linked to people at another site and consequently to behave inappropriately. Marybeth knew the behavior was inappropriate and felt that it happened because students had not come to a clear understanding of what was going on with the technology in the classroom. Her inclination was to expect the instructor to do what was necessary to get the situation under control.

Some graduate students wanted the instructor to propose other types of rules. Maylee felt it was the responsibility of the instructor to force the student's use of the technology.

For some people it would take a little longer, but I think once you [the instructor] put your foot down and say, "Okay, let's go back to elementary school here. These are the rules. And to be a part of this class, this is what I need you to do to make it work." So, yes, there it is, "I need your participation [beyond] your comments or your working in this group. I need your participation in ringing this bell because those people over there are a part of this group, as well. So I need your participation, to help me as a professor make them feel like they are really a part of this group, because that's important to me as a professor. Those people over there need to feel just as important and that they are as much a part of this group as you are." (HP F I p4.28.1050)

Maylee had classes in the distance classroom every semester during the course of this research and her suggestion is actually based on a clearer understanding than most students had of the importance of connecting across campuses and what it took to accomplish that. For instance it meant using microphone controls to participate in class and Maylee firmly believed students needed to do it whether they wanted to or not. She also believed it was the instructor's responsibility to make that happen.

In the traditional graduate classroom it is not the norm to verbalize the traditionally unwritten classroom rules that address social structure and classroom interaction. However, knowing the rules of engagement in an environment like distance learning classrooms has been shown to enhance learners' use of the technology and, in turn, improve interactions between students in the classroom (Herrington & Rehn, 1993; Martin & Bramble, 1996; McCabe, 1998). The point remains that many students want to rely on the instructor to not only make the rules, but also to make other students follow the rules.

On Bridging the Gap

In addition to the uncertainty students experienced in relation to the unwritten rules of the classroom and how the instructor handled those rules, students also spoke of uncertainty related to bridging the distance across sites. In general, students did not initially take on the burden of connecting the two sites themselves, rather they expected the instructor to make the connection. "Somehow that instructor is going to have to pull both groups together" (RFt F I v811.1694).

In the classroom where everyone shares the same physical space, classroom participants learn to read body language (Barr & Dreeben, 1983; Mehan, 1980). Instructors and students alike fuel their understanding of situations and each other, not just with what is said, but to a great extent through issues of immediacy; things like behaviors, gestures, and subtleties of space and time that signal connection (Comstock, Rowell, & Bowers, 1995; Shultz et al., 1982). This physical proximity adds a dimension to the way students understand their instructors that is difficult, but not impossible to achieve in the distance environment.

Minnie, a remote student noticed her instructor's body language and how it functioned as a communication tool.

I think that she [the instructor] encourages us. I just think that she has open body language and she's got a way of communicating. I don't know if she has practiced this because I could see where it would be real easy for a professor to focus in only on the class that she is in and kind of ignore the people that are in the other area that are the distant learners. And, I think that she has been able to bridge that, I've been real impressed. (RFt F I v104.491)
For Minnie, the instructor’s overall demeanor, openness, and the apparent ease with which she traversed the separate sites through the technology allowed Minnie to feel connected to the instructor. Students looked to the instructor to help them understand what was going on in the classroom and how to deal with being separated. The modeled behavior of the instructor influenced the way the student herself approached the distance between the sites (Ben-Peretz & Halkes, 1987; Comeaux, 1995).

Even when students thought the instructor was doing a good job, they often had suggestions for how she could do better. Molly shared one of her suggestions with me.

I think that she does a good job with what she is doing. The only suggestion I think I would do, is to call on people that are being quiet, and just get them started saying anything, even if it is one sentence. That would bring those people in. It would help those people to see that they are not being ignored. That, we know they are there. And I think it would be better if some of the people who speak a lot were not necessarily called on because they want to speak. (HFt F I v111.737)

Essentially, Molly clarified her understanding of some of the instructor’s role by adding the expectation that the instructor should know and watch out for the students who may hide behind the technology and not get engaged in the class. Madge stated her support for the same idea. “I think the professors are going to have to be very well aware of coming back and forth between the two [sites] and not letting somebody get left out there, like the forgotten child and that could easily happen. For if they [the classes] get too big you could just sit there and well, you can sit quietly in the corner and do your reading” (HFt F I v14.1693).

Once again, the student placed the responsibility on the instructor to draw students into the class. It is worth noting that students might say things that sound similar to things that they say about the instructor’s responsibilities in a traditional class, like “call on people that are being quiet,” but in this research data show that the situation is magnified and the statements are made with more urgency. Not all students in the environment placed so much responsibility on the instructor. Many did however, especially students who were in their first course in the distance environment and/or early in the courses for their graduate programs.

The traditional expectation that the instructor be attune to most of what is happening in the classroom does not seem unreasonable to students, yet it is something that appeared to be quite difficult to achieve. I asked Mel about it.

Intrvr: Did you feel like she was aware of the atmosphere in your classroom?
Mel: Uh uh, no. And I don’t think that was any fault of her own, I think that we were just so far away from her that she didn’t realize what was going on in that room. She didn’t realize, you know, that some people never did any of the work, they just asked to copy it. You know, I don’t think, she had no way of knowing it. There was just no way. (RFt F I v8)

Though Mel might have felt that the instructor needed to be more aware of things that were going on in the remote site, she did not blame the instructor for not knowing. She excused the instructor because of the distance classroom. Heimlich and Norland (1994) report that adult students inherently want to cling to the traditional ways of respecting the teacher. This may partially explain why many students in the IDLS gave the instructor latitude and blamed the distance environment when things seemed difficult for the instructor. “They are trying to watch two classrooms and that’s kind of hard” (RFt F I s10.4.60.a). A host student had the same type feelings, “Well, I’d say I am in here, and if she’s here teaching us, you could read, or she could read your facial expression. But if she’s in the TV, it’s hard, oh she cannot read what your facial expression is” (HP F I p201.317). Students varied significantly in the degree of tolerance and understanding they showed for the instructor as the instructor attempted to adjust to the technology in the IDLS.

On Focus

The preconceptions with which adult students entered the classroom were based, in part, on the pedagogical experiences of their past which generate the image that the instructor is the embodiment of what they are to learn (Heimlich & Norland, 1994). The instructor then becomes the visual focal point upon which the student centers his/her thoughts on the course content. In the IDLS, when the attention of instructors was divided between their traditional responsibilities and the technology, students like Melody expressed concern, not simply because of the time it took, but also because it disrupted their thinking and learning processes.

[The instructor] is there and she is worrying about the cameras and getting the tape recorders going and getting this going and getting that going. She is busy focusing on setting up the classroom rather than on kind of interacting with us. At the time when she would walk in and put her notebook up and say,
whatever, you know, that time of interacting. Instead she is putting on her microphone and adjusting the cameras and making sure they are all up and running. I think that is a big difference. (RfI F I v14.1393)

Melody sensed that the technological demands of the IDLS kept her instructor from “interacting” with students at a time that was traditionally time “for interactions with us.”

The perception that the technology required a piece of the instructor’s attention, which students were not accustomed to sharing, varied among students. Malcomb, one of the military men who was a student in the IDLS at the time, had an interesting way of expressing the complications that instructors had to handle to keep class running smoothly.

A professor can’t do it all by himself. As a pilot for 24 years, I flew fighter type aircraft, F-4’s, A-10’s and that sort of thing, but I spent some years as an instructor pilot as well. […] I can remember writing, scripting and doing everything for a formation video, […] and I’m sitting there, and I’m flying the airplane. […] and I’m coming in on the re-join, I’m talking about the procedures, and then I’ll click another button so that I could talk to the guy who is sitting next to me with the camera and direct his view, and the point is, I guess what I’m getting at is, you in fact, you can do all that but you can’t do it the first time. (HP M I v12.20.827)

This student put the instructor task into perspective by equating it to his own experience of trying to teach, direct, and manipulate technology all at the same time. He, like many of his peers, was empathetic in his recognition of the complexity that had been added to the instructor’s job.

The impressions other students had of the same complexity caused more personal complications for them in relation to their focus in class. Misty was significantly bothered by the instructor attending to technological glitches. The instructor has got enough to do, they’ve got to teach a class and that requires full attention, especially at this level. It is not something that you can just do. […] If the instructor is even the slightest bit distracted with something technical going on, both sides, the one where the instructor is and the other side starts to resent the fact that they are in a distance learning lab and they have to deal with this technology garbage because we don’t really like it to begin with and if any little thing happens that demands our instructor’s time and attention, we get, I get, very resentful of that. And it makes you remember that you are in a distance learning lab. You might have forgotten for a second and lost yourself in the moment of the class and you’re engaged in the subject matter and you’re forgetting that you’re watching a monitor but then, all of a sudden, when the instructor is fumbling with microphones or needs to deal with something that a facilitator could handle, himself or herself, it’s a problem. (RfI F I v107.835)

Misty used the instructor as a guide to keep her own attention focused. When the technology demanded the time and attention of the instructor, Misty had difficulty staying focused. She also raised another issue that went beyond her difficulty with focusing on course content. She got “resentful” of the technology and the methods used in the IDLS. Her resentment disrupted her attempt to adapt to the classroom and actually jarred her thinking, causing her to think about the “technology garbage” that was interfering with her learning experience.

Although the instructor may not have held the same physical position in the IDLS that she did in the traditional classroom, she still was to be the focal point for many students. In the traditional classroom when focus is interrupted, students may get distracted or even irritated, but the problem that caused the interruption is usually removed and does not recur. In the IDLS, not only can the interruption be recurring, but the thing that students sensed was causing the problem, the technology itself, continues to be something that students need to feel comfortable with and positive toward in order to get the most out of their learning experience. The way students adapt to these interruptions is vital for their overall well-being in the IDLS.

Conclusion

The instructor in the IDLS had a different physical presence from an instructor in a traditional classroom setting. In the home site she was encumbered by technology and at the remote site she was on TV. Nevertheless she was still the focal point for many students. Moreover most students, following the pattern of traditional classroom culture where they expect the teacher to be responsible for resolving issues and controlling interaction, expected her to do the same in the distance classroom. Thus the instructor’s role, in the distance classroom is complicated and compounded. On the one hand she must be aware and reflexive about the way technology is changing her performance and the way students perceive her. On the other hand she must take on the added burden of resolving not only those crisis issues that would occur in any classroom but also the additional ones related to establishing new classroom rules, bridging the distance between sites, and maintaining a content focus in spite of the technological mediation.

Abstract: As educational institutions envelop technologies to include online course components from the distributed model to complete anywhere/anytime online programs, faculty and student mental models of teaching/learning must change. The change can be slow as the face-to-face model of teaching/learning evolves into with the new model. How can institutional professional developments programs provide the new teaching model for faculty with no experience using online technologies? Faculty need to know both how these new technologies work and how they might implement these technologies to facilitate learning. How does the institution ensure that its professional development programs are not individually targeted but rather grow individual learning into organizational learning?

Daniel Kim, of the Senge Learning Organization, has provided a model for linking individual change to organization change. This paper will present the rationale and the model to effectively link individual learning to organizational learning. In addition, two case studies will be provided during the face to face presentation.

Introduction

In a fashion likened to the internal combustion engine, information technologies are “shaping the transformation of higher education” (Matthews 1998). Higher education seems to be rallying some of its forces to respond to this change, yet in many instances, the response is merely surface response to just the technology and the infrastructure. However, the Peter Senge learning organization philosophy is catching on at least in theory in many campus strategic planning sessions offering the hopes of facilitating change from the top down and the bottom up. Organizational learning, according to Zederayko and Ward (1999), takes deliberate and ongoing effort.

Institutional strategic planning may help produce new institutional mental models, yet changing the mental models in regard to teaching and learning will not be easy, for in the traditional model of education, “learning” has not been the primary mission of universities. According to O’Banion (“A Learning College”). “Ask any educators what the purpose or mission of a university is and they respond: research, teaching, and service.” “No one ever . . . asked me for information regarding my teaching ability, much less data about the kind or quality of learning I had helped my students achieve” (“A Learning College”). Stigler and Hiebert (1997) addressed teaching itself in this new model and stated that the “biggest long-term problem is not how we teach but that we have no way of getting better. We have no mechanism built into the teaching profession that allows us to improve gradually over time.”

In addition to lack of mechanism for improvement, Cravener (1998) reported that A proposal to a professional educator that he or she needs to adopt new media for teaching is a potential threat: the implicit assumption is that the old way was somehow inadequate, insufficient, or not optimal. Feeling even marginally incompetent is anxiety-provoking; people continually defend themselves against the experience. These affective factors often raise active resistance to distance
learning paradigms and the faculty development programs associated with them, predisposing faculty to avoid or reject learning to use educational technologies.

The lack of time and incentives for professional learning are significant impediments for developing a learning organization. It is difficult for teachers to be members of learning communities or learning organizations without time for regular reflection, research, collaboration, and innovation. Dr. Terry O'Banion contended that unless faculty are trained in non-traditional teaching styles, environments, and pedagogies and unless learning institutions become learning organizations, information technologies "have great potential to expand really bad teaching and really bad educational models. . . . " ("A Learning College," 1998).

What appears evident then is that untrained and unsupported faculty could be considered the weakest link in new teaching and learning environments, i.e., in potentially successful online learning programs. Strengthening that link requires well-developed professional development programs with appropriate faculty incentives for moving into the new mental model of teaching and learning.

If teachers need to be lifelong learners, if our teaching focus needs to shift to a learning focus, and if learning institutions need to become learning organizations, education faces many challenges. Perhaps the first challenge is to disconfirm the “fragmented learning styles of individuals and spread the learning throughout the organization” (Kim 1993). This educational paradigm shift for learners inherently includes how the organization that facilitates the learning, i.e., the learning institution, shifts its practices and policies regarding how it constructs, encourages, and applies its own learning.

**Learning Organization**

How do learning institutions become learning organizations – or communities with an enhanced capacity to learn, adapt, and change? Senge (1990) presented a model for the learning organization and included five new “component technologies” that “provide a vital dimension in building organizations that can truly ‘learn,’ . . . and enhance their capacity to realize their highest aspirations”; systems thinking, personal mastery, mental models, building shared vision, and team learning. The institution of higher learning that facilitates learning must itself become a learning institution [organization]. In a “learning college,” learning is the mission, the purpose, and the core value for administration, faculty, staff, as well as students.

Daniel H. Kim (1993) from the Centre for Organizational Learning at MIT Sloan School of Management presented the OADI-IMM model for individual learning that included: Observe, Assess, Design, Implement --- a process that would develop an Individual Mental Model (IMM). Senge (1990) described mental models as deeply held internal images of how the world works and stated that our individual mental models have a powerful influence on what we do because they also affect what we see. It would seem that if the new technologies draw teaching/learning into the constructivist mode, then faculty steeped in the traditional teaching model need to create a new individual mental model of “learning space” and “learning process.” The movement from sage-on-the-stage to guide-on-the-side needs to be observed (experienced) and assessed (considered for incorporation into the individual’s mental model). The observation and assessment of Information Technology’s impact on learning must come first in order to shape personal mastery and a new mental model.

Hierarchical constraints run contrary to shared mental models and organizational learning. O’Banion articulated the Fordist hierarchical model of promotion in a university stating the highest reward is the distinguished research chair with promotion through professional ranks based on juried articles and books published. The notorious tenure track system of job security and status that rewards research and publication and does not recognize or reward the development of new teaching styles prevents many faculty from aligning themselves with innovative teaching/learning strategies. Coupled with the research/publication requirement is
the need for community service and campus committee obligations that further that tenure process.¹ Once tenured faculty have become part of the guard, they have vested interest in the notion that research, scholarship, and publication are the gatekeepers to the attainment of that academic security blanket. The system replicates itself and the loop closes to the recognition of innovative teaching/learning environments. Gatekeeping controls access with the word control fundamental here.

Higher education is synonymous with hierarchy: president, vice presidents, deans, division chairs, department chairs, faculty (full professor, assistant professor, associate professor, instructor, adjunct, teaching assistant). We have a classical system of management with the attendant values of continuity, certainty, and control. Fitzgerald ("Living on the Edge") stated that education "remains mesmerized by the Newtonian promise of certainty that has taught us to do nothing until we are absolutely certain we know what will happen in detail if we do anything." Nobody likes to be in error, least of all people in positions of influence who "for their entire careers have claimed to know it all, to be ‘learned’ rather than a learner" (Fitzgerald, "Mindful Chaos").

Kim’s OADI-IMM model that links individual learning to organization learning echoes Fitzgerald’s theory. Organizations learn through individual members and thus are directly or indirectly affected by individual learning. The cycles of individual learning affect learning at organizational level because individual mental models influence the organization’s shared mental model. Organizations can learn only through their members but are not dependent upon any specific members. This understanding led Kim to link individual learning to organizational learning by moving OADI – IMM to OADI-SMM (shared mental model). Why put so much attention on mental models? “Because the mental models in individuals’ heads are where a vast majority of an organization’s knowledge (both know-how and know-why) lies” (Kim 1993).

Into his organizational learning model, Kim incorporated the Argyris and Schon concept of double loop learning which involves individual mental models challenging deep-rooted assumptions and norms of an organization to affect organization action. Kim indirectly incorporated Senge’s five disciplines: a shared vision, personal mastery, team building, mental models, and systems thinking. The facilitation of personal mastery shapes an individual’s mental model that with team building becomes a shared mental model. If individual mental models are created, and if those individual personal mastery skills in the new arenas are honed, then self-organizing systems evolve that shape the shared vision and lead to systems thinking.

Three levels or orientations of learning are identified: individual, team or group, and organizational. A learning organization’s vision, strategy, leaders, values, structures, systems, processes, and practices all work to foster people’s learning and development and to accelerate systems-level learning. Organizational learning occurs in increments or as transformation with skill development focus on individuals and/or groups (Gephart, et al., 1996) in learning organizations, leaders and managers at all levels provide critical support to the learning and development of individuals and teams by

- modeling learning behavior
- providing systems that facilitate learning
- encouraging people to contribute new ideas
- ensuring the dissemination of knowledge and learning
- freeing resources in order to signal the organization’s commitment to learning
- sharing leadership

Leaders and managers who lead with knowledge of the learning organization and chaos and complexity theory recognize that they have considerable power to create an effective learning environment by providing the systems that encourage learning. They enable the development of employees’ knowledge, skills, and abilities through personal development plans and cross training. Learning organization managers encourage the exchange of ideas, creativity, and suggestions while leaving room for the making of mistakes.

¹ A. W. Bates, Director of Distance Education and Technology, Continuing Studies at the University of British Columbia, presented the June 199, 1999, keynote address at the First Annual WebCT-ULT conference in Vancouver, British Columbia, “The Impact of WebCT on the Design of Teaching in Higher Education.”
A professional development plan must revolve around a gradual increase in faculty skill and confidence with online technologies and pedagogy while at the same time assist with the immediate implementation of these skills in traditional courses with subsequent implementation into online components. Empowering the faculty will empower the students and amount to no less than restructuring the university.

In order to transform individual mental models and subsequently the institutional mental model, the professional development plan needs to be grounded in the most powerful process in complexity theory: the micro level - the people relationship dimension. In 1978, James MacGregor Burns introduced the concepts of transactional and transformational leadership highlighting three characteristics of transformational leaders:

- Set high standards of conduct and become a role model gaining trust, respect, and confidence from others
- Articulate the future desired state and a plan to achieve it
- Question the status quo and continuously innovate, even at the peak of success; energize people to develop and achieve their full potential and performance (http://cls.binghamton.edu/mission.html)

Regine (as cited in Santosus, 1999) articulated similar leadership characteristics for success in a complex environment:

- Be accessible
- Respond immediately to others
- Acknowledge and value people’s contributions at all levels
- Create opportunities for people
- Take time to build trusting relationships and to walk the talk

Kim (1993) defined individual learning as “increasing one’s capacity to take effective action.” The Kim OADI model relates to individual learning and stands for observe, assess, design, and implement. Kim turned to Argyris and Schon (1978) to understand how individual learning can affect organizational learning. “Organizational learning is not merely individual learning, yet organizations learn only through the experience and actions of individuals.” Based on Argyris and Schon observations, Kim noted that an organization learns through its individual members and therefore is affected neither directly or indirectly by individual learning. Argyris and Schon argued that organizational learning takes place through “individual actors whose actions are based on a set of shared models.” With this understanding, Kim added SMM (shared mental model) to the OADI model (OADI-SMM) linking individual learning to organizational learning and thus effecting the change in the organizational mental model that is required for organizational learning. Let’s look at the OADI-SMM model as it applies to the strategic plan to embed online technologies into the traditional campus.

<table>
<thead>
<tr>
<th>Observe</th>
<th>Faculty will participate in an online course that teaches about online technologies and pedagogy and promotes participant interaction on topics of online learning through the use of an electronic bulletin board and chat sessions.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Assess</td>
<td>Participants will assess a traditional class’s adaptability to online environments. Participants will write the purpose of the class, the global objectives, and assess which online environments would work for the course. Participants will share assignments in the online bulletin board moving individual models closer to the shared model concept.</td>
</tr>
<tr>
<td>Design</td>
<td>After assessing a traditional class for adaptability to online technologies, participants will design one lesson as the lesson structure framework for the entire course. This lesson, created in a web editor and uploaded into the online bulletin board, will be shared with others.</td>
</tr>
</tbody>
</table>
The last lesson will ask participants to post a mail message to the online instructor detailing which environments they would like to build into their traditional course and determine a time when the instructor can visit their office to assist them with required technology. The lesson will include the assurance that the instructional design staff will assist with the first lessons in the computer lab and provide assistance with design and will be available for participation in the course’s introductory hands-on lessons using the technologies.

Instructional design staff will provide online and face-to-face group activities to promote the shared mental models. Individuals building confidence and competence with online technologies will self-organize and begin to share mental models.

According to Kim, as individuals learn, the individual mental models (IMM) affect learning at the organizational level and become shared mental models (SMM). Organizational learning is dependent on individuals improving their mental models, and emphasis is placed on mental models because the “mental models in individuals’ heads are where a vast majority of an organization’s knowledge lies.” Kim’s OADI-SMM model incorporates Argyris and Schon’s concept of single and double-loop learning where double-loop learning involves challenging deep-rooted assumptions and norms of an organization.

Two case studies of the OADI-SMM model include the professional development program at a small four year liberal arts university in the Midwest and the other the model for online course management trainer certification through WebCT. Both models place participants into an online learning course (observe) that requests participants submit assignments that involve assessing and sharing of their learning and its application to online learning in a variety of forms (assess). In both models participants design an online learning lesson and share it with other participants in the online environment (design) while they are encouraged, nurtured, and supported in both an online and a face-to-face format as they grow in confidence and ability with their new mental models (implement). In both models, participants are then brought into a face-to-face environment where they share their new mental models and support and encourage each other in the continued development and implementation of this new model. Both models have been effective as reported in qualitative feedback via online surveys. A formal study has not occurred.

Conclusion

Traditional mental models of teaching and learning have existed for decades. Most educators tend to facilitate teaching and learning in the same model in which they learned, even if they may have found that teaching and learning to have been ineffective for them. Peter Senge’s learning organization philosophy discusses changing mental models for new paradigms; Daniel Kim presents the model for linking individual mental models to institutional mental models. Higher education institutions would be enriched by consideration of the Kim OADI-SMM as the foundation for their professional development initiative.

Summer Technology Institutes:
Overcoming Barriers to Technology Integration in Higher Education

Dr. Denise Staudt
Director of Teacher Education
University of the Incarnate Word
USA
staudt@universe.uiwtx.edu

Abstract
As the century begins, the need for K-12 students to be technologically literate grows more urgent every day because of the rapid expansion of information. If the potential benefits of this information revolution are to be realized in schools, the teachers of today must be prepared to use modern technology as educational tools. Today’s classrooms demand that beginning teachers possess the necessary skills to integrate technology into the curriculum. As the first step in the change process, the teacher educators needed to be retooled and retrained. In the summer of 2000, three Summer Technology Institutes for faculty at the University of the Incarnate Word were developed and implemented. The purpose of these institutes was to help faculty develop technology skills to aid in the improvement of their classroom teaching.

Need for Faculty Development

In 1996, President Clinton launched a national mission to make every person technologically literate by the 21st century. He recognized that technology can help expand opportunities for American children to improve their skills, maximize their potential, and ready them for the 21st century. As the century begins, the need for K-12 students to be technologically literate grows more urgent every day because of the rapid expansion of information. If the potential benefits of this information revolution are to be realized in schools, the teachers of today must be prepared to use modern technology as educational tools. Today’s classrooms demand that beginning teachers possess the necessary skills to integrate technology into the curriculum (Marker and Ehman, 1989).

In recent years, there has been growing recognition that teacher preparation programs must prepare their preservice teachers to teach in tomorrow’s classrooms. However, there is also recognition that while many teacher preparation programs provide some computer training for preservice education, many of the university faculty, both inside and outside of the School of Education, do not have the technology expertise needed to develop well-prepared technology-proficient teachers. The concerns about preservice teacher education and faculty development in technology is well documented in the research (Persky, 1990, Bruder, 1993, White, 1994). This daring challenge for universities requires a realistic evaluation of where teacher preparation programs are today, where they are headed, and how they intend to get there.

Hoadley, M.R., Engelking, J. L. & Bright, L.K. (1995) maintain that in order for teacher preparation programs to be successful, it must be recognized that faculty need training, support, and time for reflection to integrate technology into the curriculum. The Summer Technology Institutes, developed as part of faculty development at the University of the Incarnate Word, provided the teacher preparation faculty as well as other university faculty with the needed training, support, and time for reflection that was needed.

Vision

The vision of faculty involved in teacher preparation at the University of the Incarnate Word is to produce quality teachers who are well-versed in innovative instruction, skilled in technology and prepared to serve the multicultural and diverse student populations of South Texas. We believe that future teachers should learn with modern technologies integrated into the postsecondary curriculum by faculty who are
modeling technology-proficient instruction, particularly in courses where they acquire subject area expertise.

However, in a realistic evaluation of the effectiveness of the technology component of the University of the Incarnate Word's teacher preparation program, most faculty are neither modeling the use of technology nor requiring students to use technology. The results of an Instructional Technology Needs Assessment survey of the UIW faculty in 1998 reveal that 51% of the faculty use technology in their instruction only once or twice a semester and 47% of the faculty require students to use computers only once or twice a semester. Most of the instruction in technology at UIW involves teaching about technology as a separate subject, not teaching with technology by integrating it into other coursework to provide a model for instructional use. The lack of modeling, a very powerful teaching strategy, creates major gaps in regards to technology of our future teachers.

In order to make the vision of our faculty in teacher preparation become a reality and to adequately train future teachers to use technology, we realized that technology must be integrated into all aspects of the teacher preparation program. Genuinely integrating technology into the preservice teacher preparation program at the University of the Incarnate Word would require system-wide change, initiative, and time.

As the first step in the change process, the teacher educators needed to be retooled and retrained. In the summer of 2000, three Summer Technology Institutes for faculty at the University of the Incarnate Word were developed and implemented. The purpose of these institutes was to help faculty develop technology skills to aid in the improvement of their classroom teaching. The content of the institutes included study of the instructional design process and the principles of graphic design, hands-on practice with multimedia presentation and web editing packages. Participants in the institutions learned to use digital imaging tools and worked with digital sound.

During the Institute, faculty developed a project relevant to courses that they taught. Some faculty developed PowerPoint presentations while other faculty, at higher levels of technology proficiency, developed web pages for their courses. At the end of the two-week session, each faculty had their projects placed on the STI Web site for others to view. Upon completion of the training, each faculty received a stipend of $1000 as well as gifts of hardware and software.

In addition, all fulltime university faculty who participated in the Summer Technology Institute program were eligible to submit a proposal to become a Technology Fellow during the next school year. This unique program enables three faculty members to become technology resources for other faculty at the university. The proposals submitted by the faculty outlined a project that integrates technology into their classroom instruction. The Technology Fellows will receive one course release time for the fall or spring semester to work on the project. The fellows will also be asked to do two presentations of their final project to the university community.

As is true with many institutions, University of the Incarnate Word is embracing new technologies to fulfill preservice teacher's changing needs. The Technology Summer Institute project is an example of professional development in technological literacy that focuses on individual faculty needs and levels of expertise. Clearly, a major priority for the university is to impacted teaching and learning in the university classroom through the Summer Technology Institutes.

Abstract: This paper is a report on a study done at the Center for Excellence in Education at Northern Arizona University. In 1984, the Center was created on a concept of moving away from the typical hierarchical structure of a college of education toward a matrix. The matrix was designed to help create a community of people in a diverse organization and move away from the "turf" concept of departmentalization. A concept that was to be verbalized by Peter Senge (1990) in his book on learning organizations. By the fall of 2000, the Center has deteriorated back to a hierarchical, departmentalized college of education. Senge (1990) identifies 7 organizational learning disabilities that are typical in organizations that are not learning organizations. This study was a survey of the faculty of the Center to help gain a better understanding of where we are in terms of suffering from these 7 learning disabilities.

Introduction

We, especially those who are the product of the Western logical scientific mind-set, are taught to break complexity and complicated subjects into manageable tasks. But in doing so we pay a hidden, enormous price. We lose our intrinsic sense of connection to a larger whole and can no longer see the consequences of our actions. When we try to reassemble the fragments to see the "big picture" it is similar to trying to reassemble the fragments of a broken mirror in order to see our true reflection. What all too often happens is that we develop mental models of the world that it is composed of separate, unrelated forces. In 1990, Peter M. Senge published The Fifth Discipline: The Art and Practice of The Learning Organization. Senge states the tools and ideas presented in the book are for the purpose of destroying this illusion that the world is created of separate, unrelated forces. He contends that when an organization gives up this illusion that what can result is a learning organization where the people of the organization continually expand their capacity to create the results they truly desire. He goes on to state that it is no accident that most organizations learn poorly. "The way they are designed and managed, the way peoples' jobs are defined, and, most importantly, the way we have been taught to think and interact (not only in organizations but more broadly) create fundamental learning disabilities," (Senge, 1990, p. 18). Within an organization, these disabilities operate despite our best efforts and what learning that does occur within an organization takes place despite these learning disabilities. The reason is that they permeate all organizations to some degree. Senge (1990) identifies seven organizational learning disabilities.

The first learning disability is, "I Am My Position." As members of an organization we are conditioned to be loyal to our jobs, so much so that we confuse them with our own identities. Most people see themselves within a "system" over which they have little or no control. Thusly, they tend to concentrate their "work energies" within self-defined limited boundaries of their position. When asked what they do for a living, they will
respond by giving the task they perform every day, not the purpose of the greater enterprise in which they take part.

The second learning disability Senge calls, “The Enemy is Out There.” In all human beings, there is this self protection mechanism that entices us to find someone or something outside ourselves to blame when things go wrong. Within an organization this “Thou shalt always find an external agent to blame,” is often raised to a commandment level. This syndrome is a by-product of “I Am My Position.” When we focus only on our position, we do not see how our own actions extend beyond the boundary of that position. When those actions have consequences that come back to hurt us, we misperceive these new problems as externally caused.

The third organizational learning disability is “The Illusion of Taking Charge.” Leaders within an organization frequently proclaim the need to take charge in facing difficult problems. They proclaim it is time to stop waiting for someone else to do something, they then roll out the latest program that they have designed to face up to difficult issues and solve the problems. All to often, this “proactiveness” is reactiveness in disguise. These “programs” are in reality a more aggressive way of fighting the “enemy out there.” They are a form of reacting – regardless of what it is called. “True proactiveness comes from seeing how we contribute to our own problems. It is a product of our way of thinking, not our emotional state” (Senge, 1990, p. 21).

The next organizational learning disability is called, “The Fixation On Events.” We are conditioned to see life as a series of events, and we believe that for every event there is one obvious cause. Focusing on events leads to what is called “event” explanations. Such explanations may be true as far as they go, but the reality of the situation is that they distract us from seeing the long-term patterns of change that lie behind the events and from understanding the causes of those patterns. Senge (1990) states that the irony is that in today’s society the primary threat to our survival, both as organizations and as societies, come not from sudden events but from slow, gradual process like the arms race, environmental decay and the erosion of a society’s public school system.

The fifth learning disability is “The Parable of the Boiled Frog.” If you place a frog in room temperature water and gradually begin to heat the water the frog will do nothing and will eventually sit there and boil. Why? Because the frog’s internal apparatus for sensing threats to survival is geared to sudden changes in his environment, not slow, gradual changes. We as human beings have the same problem. We will not avoid the same fate of the frog until we learn to slow down and see the gradual processes that often pose the greatest threats. Learning to see slow, gradual processes requires slowing down our frenetic pace and paying attention to the subtle as well as the dramatic.

The sixth learning disability is “The Delusion of Learning from Experience.” When our actions have consequences beyond our learning horizon, it becomes impossible to learn from direct experience. Herein lies the core learning dilemma that confronts organizations. We learn best from experience but we never directly experience the consequences of many of our most important decisions. Cycles are particularly hard to learn from, especially if the cycles last for several years. Traditionally, organizations attempt to deal with this problem by breaking the decision making process up into components. They institute functional hierarchies that are easier for people to manage. What nearly always happens is that the hierarchies grow into fiefdoms which eventually cut off contact between functions and separate the decision makers even farther from the full impacts of their decisions.

This brings us to the last organizational learning disability identified by Senge (1990), “The Myth of the Management Team.” Standing forward to do battle with the dilemmas and disabilities of an organization is the management or administrative team. Together, they are supposed to sort out the complex cross-functional issues that are critical to the organization. All to often these teams tend to spend their time fighting for turf, avoiding anything that will make them look bad personally, and pretending that everyone is behind the team’s collective strategy – maintaining the appearance of a cohesive team. If there is disagreement, its usually expressed in a manner that lays blame, polarizes opinion, and fails to reveal the underlying differences in assumptions and experience in a way that the team as a whole could learn. Historically, most management or
administrative teams function quite well with routine issues but break down under pressure. Only to be replaced by another team

**Brief History of The Center for Excellence in Education**

In January of 1984, the then Governor of Arizona, Bruce Babbitt, recommended that the Arizona Board of Regents and the state Board of Education begin to explore alternatives to colleges of education. Responding to that pressure, in the fall of 1984 the traditional College of Education at Northern Arizona University was disbanded and the Center for Excellence in Education was created. The concepts of departments were done away with and a non-hierarchical matrix was put into place. A Director and Associate Director replaced the traditional Dean and Associate Dean. This was far more than just a name change. Within the matrix concept, the directors became part of a team that oversaw the day-to-day operations of the Center. The other members of this team were the Director of Research, Director of Educational Services, Director of School Services and Director of Professional Programs. Each Director handled specific tasks within the Center, but were responsive to the Center as a whole. The faculty then became a single unit that had direct contact with all of the Directors and their expertise was then channeled to where it was the most effective. There was open communication between all the faculty and the faculty had direct access to all the directors. This allowed a creative energy to appear that lead to some of the most innovative programs that had ever been developed in Arizona.

The diversity of programs created a problem of coordination. To assist in the coordination of these programs and to help open channels of communication between programs, in 1987 the matrix was adapted to include the concept of areas with area chairs. Each faculty member was assigned to an area, but both the area chair and the faculty through negotiations was still free to apply their expertise where they felt it was needed most. Most important was that the budget was not under the direction of the area chair. Budget allocations were made public and the distribution of those funds was determined by input from the team of directors, area chairs, and faculty committees. The primary function of the area chairs was to help coordinate the many different programs.

In 1997, a new Director was hired by the Center. This director immediately began to disassemble the concept of the matrix and reinstate the hierarchical university concept of a college. The name of the office was changed from Director back to Dean. All budgetary matters were placed the direct control of the Dean. All Associate Directors were removed and Associate Deans put in their place. By the Spring of 2000, departmentalization was reestablished with department chairs. Faculty governance was isolated to trivial matters and faculty had no input on budget items. By the Fall of 2000, the Center for Excellence in Education was for all practical purposes a typical college of education.

Faculty who had experienced the concept of the matrix and shared governance appear to be very discouraged. Airs of negativism and dissatisfactions seem to be growing within the faculty. Disputes and “turf” battles appear where little or no conflict had occurred before. To quote a senior faculty, “I was astonished when I was chewed out by a department chair for ‘stealing her faculty’ when I asked another faculty member from her department if they would be interested in teaching a course in our department. This never occurred before.”

**The Study**

Several faculty members were very aware of the work of Peter Senge (1990, 1994, 1999, 2000). The Educational Technology Faculty had received a grant to conduct professional development with a local school district based upon systems thinking and the *Fifth Discipline* (Senge, 1990). Also, through a National Science Foundation grant, the Northern Arizona Leadership Institute was created within the Center. This Institute began working with the superintendents of several Phoenix area school districts. Much of this work had as its foundation the five disciplines. Due to this understanding, combined with the changes that had occurred within the Center for Excellence in Education it was decided to see how the faculty related to the seven organizational learning disabilities identified by Senge (1990). Questions were designed based upon the seven
disabilities. The questions were placed on the web so that faculty and staff could take the survey anonymously from their office or home computers.

Findings

Within the Center for Excellence there are 93 full time and part time faculty members. The number that responded to the survey was 24 which represents a 24% response rate.

The first learning disability is, “I Am My Position.” When members of an organization are asked what they do for a living, they will respond by giving the task they perform every day, not the purpose of the greater enterprise in which they take part. The people of the Center were asked to classify themselves as an (assistant, associate, or full) professor, or a staff member, or an administrator. This would be considered as an indicator of “I Am My Position.” They were also given the choice to classify themselves as a member of a Department or as part of the Center for Excellence in Education. This would be indicators that they viewed themselves more in terms of the greater enterprise.

| Viewed themselves as professor, staff or administrator | 92% |
| Viewed themselves as a member of a department or CEE | 18% |

Another indicator of the “I Am My Position.” is that the individuals see themselves within a “system” over which they have little or no control. The survey gave them a series of tasks that most are involved in and asked them to rate the tasks as: 1. Any effort in that area would be useless, 2. I have control in a few areas so I work in those areas and don’t bother with the rest, 3. In that area I can make changes but within the Center what I do has little or no effect, 4. Somewhere between 3 and 5, and 5. I can make changes and those changes can result in changes within the Center. Below are the results:

| Modifications in a syllabus | 1: 0% | 2: 0% | 3: 17% | 4: 25% | 5: 58% |
| Modifications in programs | 1: 8% | 2: 25% | 3: 13% | 4: 42% | 5: 12% |
| Creating changes in structure of the Center | 1: 33% | 2: 33% | 3: 8% | 4: 25% | 5: 0% |
| Creating changes in operations of the Center | 1: 38% | 2: 29% | 3: 17% | 4: 17% | 5: 0% |
| Creating changes in their area | 1: 0% | 2: 41% | 3: 13% | 4: 33% | 5: 13% |
| Creating changes through committee work | 1: 17% | 2: 29% | 3: 29% | 4: 17% | 5: 8% |
| Creating changes how courses are taught | 1: 4% | 2: 8% | 3: 8% | 4: 29% | 5: 50% |
| Creating changes in what courses are taught | 1: 13% | 2: 20% | 3: 25% | 4: 21% | 5: 21% |
| Having input on administrative changes | 1: 57% | 2: 22% | 3: 4% | 4: 13% | 5: 4% |
| Helping facilitate the Center mission | 1: 13% | 2: 29% | 3: 13% | 4: 20% | 5: 25% |
| Providing quality learning environments | 1: 4% | 2: 4% | 3: 25% | 4: 25% | 5: 42% |

The second learning disability is “The Enemy is Out There.” When people focus only on their position, we do not see how our own actions extend beyond the boundary of that position and when those actions have consequences that come back to hurt us, we misperceive these new problems as externally caused. What is not perceived is that “out there” and “in here” are part of a single system. The faculty was to use the following rubric to react to some issues that face us: 1: I am not sure what the cause is, but I feel that change can happen, 2. There is a cause, I just don’t know how to create change, 3. I know the cause and if I can just work harder and smarter I can create change, 4. The primary cause is the leadership of the Center, 5. The primary cause is outside the Center caused by pressure from the university, state and/or national political structures. Below are the results:

| Most teacher prep programs have little effect | 1: 29% | 2: 8% | 3: 41% | 4: 8% | 5: 13% |
| Morale in the Center is low | 1: 8% | 2: 4% | 3: 16% | 4: 66% | 5: 4% |
| State tests keep students from being teachers | 1: 29% | 2: 0% | 3: 33% | 4: 0% | 5: 38% |
| Successful faculty in the Center are leaving | 1: 21% | 2: 8% | 3: 16% | 4: 50% | 5: 4% |
Why the Center is where it is

1: 13%  
2: 30%  
3: 17%  
4: 8%  
5: 30%

People in the Center feel powerless

1: 21%  
2: 13%  
3: 13%  
4: 50%  
5: 4%

People of the Center do not express concerns

1: 26%  
2: 9%  
3: 13%  
4: 52%  
5: 0%

Ten percent of the participants believe that this action is the solution, 2. This action maybe part of the solution, but other actions will be necessary, 3. I might prefer or not prefer this action, but it will create no lasting change until I change, 4. I believe that this action will have no effect on the problem or make the situation worse, 5. I have no thoughts on this action. Below are the results:

Remove the Center’s Administrative Team

1: 17%  
2: 49%  
3: 4%  
4: 17%  
5: 13%

Remove State’s Education officials

1: 4%  
2: 52%  
3: 4%  
4: 26%  
5: 13%

Create change in The University Administration

1: 8%  
2: 49%  
3: 13%  
4: 22%  
5: 8%

Create more effective faculty governance

1: 13%  
2: 65%  
3: 8%  
4: 13%  
5: 0%

The third organizational learning disability is “The Illusion of Taking Charge.” All too often, this “proactiveness” is reactiveness in disguise. True proactiveness is a product of our way of thinking and comes from seeing how we contribute to our own problems. In the survey the participants were given some possible changes that concerned faculty satisfaction. They were asked to rate the change using the following rubric: 1: I believe that this action is the solution, 2. This action maybe part of the solution, but other actions will be necessary, 3. I might prefer or not prefer this action, but it will create no lasting change until I change, 4. I believe that this action will have no effect on the problem or make the situation worse, 5. I have no thoughts on this action. Below are the results:

Best describes how you feel about the event

1: 10%  
2: 10%  
3: 29%  
4: 38%  
5: 14%

The next organizational learning disability is called, “The Fixation On Events.” We are conditioned to see life as a series of events, and we believe that for every event there is one obvious cause. Focusing on events leads to what is called “event” explanations. The participants were asked to think of something that recently happened in the Center that directly affected them. They were then asked to use the following rubric to describe how they felt about that event: 1. I know exactly what caused the event, 2. I have a basic understanding of the cause, 3. There were complex causes, but I understand them fairly well, 4. There were complex causes and I understood a few of them, 5. I have no clue to the real cause. Below are the results:

Why the Center is where it is

1: 13%  
2: 30%  
3: 17%  
4: 8%  
5: 30%

The sixth learning disability is “The Delusion of Learning from Experience.” When our actions have consequences beyond our learning horizon, it becomes impossible to learn from direct experience. Herein lies the core learning dilemma that confronts organizations. The participants were given the following statement: Having experienced the changes that have occurred in the Center in the past few years, which statement best describes how you feel. They were then given the following rubric: 1. I certainly learned from these experiences and now I know what to and not to do, 2. I now have a better understanding of the consequences of my decisions and have a basic understanding of what to and not to do, 3. The whole situation is so overwhelming I really don’t care anymore, 4. I want to do something, but the organization of the Center is so complex that I am not sure I understand what to do or not to do, 5. I have not been part of the Center long enough to have an opinion. Below are the results:

How do you feel about the changes

1: 5%  
2: 36%  
3: 5%  
4: 27%  
5: 27%

The fifth learning disability is “The Parable of the Boiled Frog.” We as human beings will not avoid the same fate of the frog until we learn to slow down and see the gradual processes that often pose the greatest threats. The participants were asked to view the changes that have occurred in the Center over the past few years and asked to use the following rubric to describe their feelings: 1. I am not sure how the Center got where it is today, 2. I can identify certain changes in our organization that have resulted in the Center being where it is today, 3. I can identify two or three specific decisions that were made that resulted in the Center being where it is today, 4. I can pinpoint the exact decision that resulted in the Center being where it is today, 5. I have not been at the Center long enough to accurately answer this question. Below are the results:

The last organizational learning disability identified by Senge (1990) is “The Myth of the Management Team.” This team is supposed to sort out the complex cross-functional issues that are critical to the
organization. The participants were given the lead statement: I feel that if we can ever get the proper
administrative team in place. They were given the following choices: 1. They will begin to solve the problems
of the Center, 2. They will create new plans that will begin improving the situation, 3. They will not solve the
Center's problems because we are replacing one system of control with another, 4. The only way that they can
begin to solve some of the issues of the Center is by listening to faculty, 5. The only way solutions can be
found to the problems I see is for me to work closely with this Team. Below are the results:

| Getting the proper administrative team in place | 1: 4% | 2: 4% | 3: 17% | 4: 40% | 5. 35% |

Summary

When asked to define themselves 92% of those surveyed defined themselves in terms of their position, not as a
member of the Center. One of the symptoms of the learning disability “I am my position” is that individuals
see themselves in a system over which they have little control. When the responses were analyzed it showed
that the participants viewed themselves having a high degree of control over those things that involved directly
the classroom. However, 48% felt they had little or no control over things that affected the Center as a whole.
When it came to administrative decisions, 79% felt that they had little or no influence. A polarization of the
faculty appeared when it came to the higher aspirations of the Center. This was shown when 45% felt that they
did have the potential to influence achieving the Center mission, but 45% felt that they had little or no control.
When evaluating the perception of the participants concerning “The enemy is out there,” the results indicate
when examining issues outside of the Center only 30% had the attitude that there was a external cause over
which they had little influence. However, when it came to issues within the Center, 58% of the responses
indicated that there was a perceived “enemy” that caused the problem. Concerning the disability of taking
action against a perceived enemy, 57% of the participants believed that taking a proactive stance against issues
outside the Center was a good idea. Within the Center, 72% felt like taking charge and being proactive against
the perceived “enemy” was something that should happen. When it came to fixation on events, I am not sure
the way the survey was written really addressed this issue. When the responses were tabulated, 49% gave
responses that might indicate they were fixating on events, and 52% saw issues to be so complex that they
could not fix on any particular event. Due to the gradual changes of the Center from a matrix system to a
typical hierarchical college of education, faculty were more perceptive to the fact that slow changes are the
biggest threat. Those that were aware that slow change is the biggest threat to an organization was 41%.
Also, 41% thought that they could learn from experience and make better decisions in the future. The
encouraging result centered around the myth of the administrative team. Only 8% felt that getting the right
administrative team in place would solve many of the problems of the Center. A large majority, 75%, felt that
the only way positive change was going to occur was if they themselves were involved in the solution. It is our
feeling that this is the result of being involved in a system where each member of the faculty was a vital part
Having experienced that capability, they have an insight that others who have not had that experience may not
have.

The Center for Excellence in Education is a typical college of education today. This came about after having
experiencing an organization that is very different. What we are observing is that we as an organization are
moving farther and farther away from the concepts of a Learning Organization as described by Senge (1990).
Everyone Who Cares About Education, states that “It is becoming clear that schools can be re-created, made
vital, and sustainably renewed by fiat or command, and not by regulation, but by taking a learning
orientation,” (p. 5). The Center for Excellence in Education at one time was moving toward this learning
orientation, but lost sight of its vision. What this study indicates is that we as an organization are more and
more moving into a organizational learning disability mindset. It also indicates, that we have to potential to
stop this deterioration if we only will.

Abstract: Explore innovative methods to advance your program's technology initiative and staff development for all faculty—full-time and adjunct, on-campus and on-line.

One effective way to advance your program's technology initiative and enhance team building is through the use of a one-day faculty retreat. Most programs have several sections of its introductory courses, with a narrowing enrollment in upper level courses. It is important that there be uniformity in the standards and content of course offerings and that the National Educational Technology Standards for Students be incorporated into all courses, from the elementary to the advanced.

In advance of the retreat, participants are expected to read a great deal of material and come fully prepared, so that the time at the retreat can be used to maximum advantage. Also, select a location where small groups can break out and use technology, yet easily come together to share results.

Expected outcomes of the faculty retreat can include updated courses, new approaches to student assessment; a list of skill sets that each student should have when entering and exiting each course; and creating an on-line student tutorial. Working from the perspective of Standards and Goals, using NETS as a guide, participants work in small groups on updating each course.

Keeping courses updated is a primary concern for all technology programs and a key project to be accomplished at the retreat should course updating, especially if courses were designed before NETS. Participants should be grouped by the course they teach and, at the end of their session, share ways of up-dating and improving that course. A second key element should be to create a list of skills sets students need when entering and leaving courses. Third, a program should have standardized assessment techniques, especially when courses are offered in different teaching modes—on-campus, on-line, and off-campus. A sharing of these techniques helps faculty look at different ways of assessing student performance and enables the chair to set standards.
As far as team building, it is important that all the faculty—especially the adjuncts—understand the policies and procedures of the program, have access to all of the resources that are available to full-time faculty, and feel part of the team. Guest speakers should include those people who support and enhance the program, such as the directors of the library, academic computing, graduate study, and evening student services; deans; and, if possible, invite the president of the university to attend as well.

Minutes should be taken and shared with the participants. A program book is an excellent reinforcement tool, not only for those faculty who attend the workshop but also for those who teach on-line courses and live far distances. In addition, the program books serves as a readily available orientation tool when new faculty are hired.

Including adjuncts, especially those who teach on-line and off-campus, in faculty meetings is not a common occurrence, but it is a critical element in developing a department that is well-motivated and delivers a standard level of service.

During this presentation the audience will have an opportunity to plan a faculty retreat and write the agenda for the meeting.
TECHNOLOGY STAFF DEVELOPMENT AT AN URBAN PUBLIC UNIVERSITY

Abstract: The Instruction and Technology Initiative at New Jersey City University, an Hispanic Serving Institution, was designed to increase the capacity of faculty to foster instructional innovation via educational technology, both within the University and to reach teachers on the local and the statewide level. The Initiative is designed to fuse technology education with the specific learning needs of students through one-to-one and small group faculty training, and that full-time personnel staff the Center, serving as in-house consultants to the faculty.

The Center, designed to give faculty a central place to work and share ideas with colleagues, consists of a centrally located lab complemented by smaller labs at two other sites on campus and houses state-of-the-art instructional technology for faculty use. In addition to computer/multimedia workstations, the Center has interactive media equipment such as CD-ROMs, audio/video editing tools, CD-ROM writers, laser printers, presentation technology, scanners, laser discs, and digital photographic technology.

Key elements in this initiative that make it different from many others are that the Center is designed to fuse technology education with the specific learning needs of the NJCU student population through one-to-one and small group faculty training, and that full-time personnel staff the Center, serving as in-house consultants to the faculty. The Center curriculum has three components. The first is technology training, which includes Creating Multimedia-based Presentations for Classroom Instruction and Multimedia Equipment Training. Because most NJCU faculty, like those at so many other universities, were never formally trained in the field of education, yet are involved in teacher preparation, the second component is The National Educational Technology Standards and Its Integration into the NJ Core Curriculum. The third module is specialized workshops on The Cultural Aspects of Teaching/Learning Styles and The Learning Styles of Older Returning Students.

Faculty have the ability to create multimedia materials using a variety of delivery modes including CD-ROM media that students can view at home or in a lab. For both students who are using the campus data network as well as the students who access the resources from anywhere in the world via the Internet, faculty are able to utilize several methods of delivering interactive material via the World Wide Web and the Internet. Examples include: full motion video.
segments, interactive quizzes that can be either practice or timed, live chat sessions with faculty
to discuss problems without traveling to the campus, and the ability for the instructor to really
see what the student is doing via collaborative technologies.

To insure that the technology is utilized to maximum advantage, the Instructional
Technology Committee, made up of faculty selected from each of the three divisions,
coordinates activities. Two full-time people are available support the faculty: the Multimedia
Curriculum Specialist and the Multimedia Technician. The Multimedia Curriculum Specialist is
responsible for training faculty in the "translation" of curriculum from traditional formats to
multimedia format; evaluating currently available multimedia curricular materials and training
faculty to conduct such evaluations; and facilitating faculty use of distance learning methods to
deliver multimedia instruction. The Multimedia Technician is charged with ensuring that
equipment operates properly and that faculty are trained on the equipment. The technician also
oversees equipment installation, preventive maintenance, vendor liaison, software installations,
and upgrades.

The Curriculum Specialist routinely conducts seminars on the integration of learning and
technology as well as the needs and abilities of diverse and remote learners. These workshops
illustrate to faculty how non-traditional, student-focused, interactive instruction helps
multicultural students successfully learn and take an active interest in their education. In
addition, the Center conducts small group and departmental work sessions to provide specific
assistance to faculty to incorporate successful strategies into their courses.

As one of the original nine public colleges, New Jersey City University is the only
institution that has remained in a densely populated urban setting. It serves students who,
overwhelmingly, are the first generation of the family to seek a college education. It represents a
path toward opportunity for an economically poor constituency, most of who are highly
motivated, academically underprepared, and upwardly mobile.

During this presentation the audience will explore a range of alternative methods of using
educational technology that have proven to be successful with diverse and under-prepared
learners.
Faculty Training - Lessons in a "Flash"

Michael Uttendorfer
Center for Teaching and Learning with Technology
New York Institute of Technology
United States
muttendo@nyit.edu

Abstract: This paper is an examination of current literature identifying factors affecting faculty use of technology for instruction. One of the key research findings identifies training as an essential element in the success of faculty use of technology. This paper describes one solution being evaluated by the faculty development center that has shown great potential for providing training to numerous full-time and adjunct faculty members who are widely dispersed on multiple campuses by delivering the training online.

Introduction

With ever-increasing demand from college administrators and students, faculty members are being encouraged to embrace technology as a way to increase the number of students served, improve the quality of their instruction, better prepare students for the workplace and reach students not previously served by traditional classroom instruction. This paper will examine factors reported in the literature as causes of college faculty reluctance to use technology as well as factors that help promote its increased use. The types of technology used by faculty for instructional purposes will also be reviewed.

While the use of technology is rapidly increasing in the business world, the use of technology in academia is still not widely accepted (Okpala & Okpala, 1997; Spotts & Bowman, 1995). With the need to expand the use of technology increasing, it is important for colleges and universities to recognize the critical issues that impede growth in the use of technology by instructors and address them if their goals are to be met. Identifying incentives and motivational factors that will help expand the use of technology by college faculty will be beneficial to institutions of higher education. Understanding the need for support systems will assist colleges and universities in planning for the infusion of technology in teaching.

This paper is not an exhaustive review of the literature but was prepared to establish a foundation for planning and implementing faculty and staff development programs in the use of technology as a tool for instruction. Understanding how faculty use technology, their concerns about technology and factors that help produce positive acceptance by faculty members are keys to successful instructional technology implementation and expansion projects.

Factors Negatively Affecting Use of Technology by Faculty

Several contributing factors were identified in the literature as causes of faculty reluctance to adopt technology. Among the most common reasons cited in these studies were factors related to deficiencies including lack of training, lack of support, lack of equipment, limited access to hardware and lack of funds (Spotts & Bowman, 1993; Roberts & Ferris, 1994; Okpala & Okpala, 1997; Novek, 1999; Dickson, 1999; Quick, 1999).

Other difficulties such as time requirements and availability of equipment were also identified as usage barriers. Spotts and Bowman (1993) found that over 50% of their 306 survey respondents reported that the time required to learn and use technology was the major contributing factor to its low level of acceptance by faculty. Quick (1999) also reported lack of time available to learn how to use technology as a major impediment to faculty use.

Novek (1999) reported that faculty in her study had several fears about the use of instructional technology. The first fear was about the devaluation of their role as instructors and possibly the loss of employment as technology use increased. A second concern expressed by the respondents was their fear that expanded use of technology in teaching would dehumanize the instructional experience for students and result in their alienation. Although most of their fears were related to the use of distance education technologies, the
faculty saw the increased use of technology as a threat to their livelihood. This perception of technology would certainly have a negative effect on their willingness to participate in its usage. College administrators must be sensitive to these concerns when considering the use of technology for distance education.

A faculty's attitude about the importance of technology in their instruction was another factor that seemed to determine the extent to which technology was used. Okpala & Okpala (1997) took a random sample of faculty members from three Historically Black Colleges and University Institutions in the South. Their study found that 38% of the respondents indicated that they felt technology was not important to their instruction. Most of the instructors in this group also indicated that they did not use instructional technology in their courses.

Positive Factors Influencing Use of Technology

Several of the studies identified important factors that influenced the faculty's positive attitude towards instructional technology. Equipment availability ranked highest in importance (Spotts & Bowman, 1993; Nantz & Lundgren, 1998; Groves & Zemel, 2000). Improved student learning was also ranked highly in importance. (Spotts & Bowman, 1993; Groves & Zemel, 2000).

Several other positive factors reported include funds to purchase materials, advantages over traditional methods of teaching, ease of use, compatibility with subject matter, release time to learn technology, and availability of training. These studies suggest that for a program designed to increase faculty use of technology to be successful, program developers must be sure that the technology is readily accessible. Time must be made available for faculty to experiment with the technology and training must be provided to support them in their efforts.

Dusick & Yildirim (2000) found a high positive correlation between ownership of a home computer and computer competency. The study also found that computer competency was a predictor of instructional use of computers. The researchers concluded that use of a computer by faculty at home has a positive effect on their use of computer technology for instructional purposes.

Faculty Use of Technology for Instruction

Several studies (Okpala & Okpala, 1997; Inman & Mayes, 1998; Taber, 1998; Groves & Zemel, 2000) reported on the types of technology used by college faculty. Understanding existing faculty use of technology is extremely important in planning training and staff development programs (Inman & Mayes, 1998). All of the studies reviewed found faculty use of word processing and e-mail was common. Most also indicated that the use of multimedia and distance learning technologies was very low. Mitra, Steffendmeier, Lensmeier & Massoni (1999) found that the traditional use of computers for programming and data processing has shifted to the use of computers for communication.

Taber (1999) found the use of presentation software ranked very high (90% or higher) among the technologies used. Groves & Zemel (2000) also reported high (70%) usage of presentation software. This conflicts with the findings of Okpala & Okpala (1997) who reported low (12%) usage for presentation software. These differences, from data reported in different yet well designed research studies, illustrate the importance of understanding the distinct characteristics of the faculty needs in each college or university before embarking on development of technology training workshops.

Use of the Internet for instructional purposes ranked high in a number of the more recent studies (Inman & Mayes, 1998; Taber, 1999; Groves & Zemel, 2000). Older studies did not report such findings. Recent widespread expansions in Internet access at colleges and universities is the mostly explanation for the differences in the findings.

Inman & Mayes (1998) and Taber (1998) found frequent usage of computer-based instruction reported by their respondents while Groves & Zemel (2000) and Okpala & Okpala (1997) reported low usage of those technologies. These apparent conflicts in reported information reinforce the notion that a local needs analysis is critical to meaningful staff development planning.

Incentives for Faculty to Encourage Use of Technology

Learning to use new technology clearly takes time. Many of the studies found it was extremely important to provide incentives to faculty to make appropriate use of the available technologies for instruction
As one might expect, monetary rewards, stipends, tenure and promotion credits, and release time were commonly reported incentives. Spotts & Bowman (1993) found that the most frequently reported incentive for expanding the use of technology was evidence of improved student learning. Miller & Husmann (1999) found it was not external rewards such as merit pay or release time but internal rewards such as self-fulfillment and enjoyment of teaching that motivated faculty to participate in technology use. Respondents reported that observing increases in student motivation and student performance were more important incentives to increase the use of technology than were financial rewards to the faculty for participating in the use of technology.

The Role of Training

Faculty training is a critical component to successful integration of technology in higher education. The critical role of teachers in effective learning means that all must have training, preparation, and institutional support to successfully teach with technology. Few teachers have had either teacher education or field experiences that enable them to be effective distance education teachers or successfully use technology in their own classroom. (Office of Technology Assessment, 1989, p.17)

Although the quote above is more than ten years old, the essence of its message has not significantly changed. In a recent survey of community colleges, Milliron and Leach (1997) reported that the training structures for developing the technology skills of faculty members are still not in place and yet training is viewed as an essential ingredient in keeping their faculty current. The importance of understanding technology use and faculty needs in training is an extremely important issue in staff development planning.

Assisting faculty in developing the skills and knowledge to make use of this technology will become a critical issue in program and faculty development. However, without research to determine what kinds of training and technology are in use and are needed at a particular college, university, or system, efforts to train faculty will not reach their full potential. (Inman & Mayes, 1999, p. 20)

For a staff development program to meet the needs of the faculty, it is critical that the trainers understand the specific type of technology being used by the faculty and what new technologies may also be useful. Inman & Mayes (1999) suggest that training programs must be designed to allow for multiple training experiences. They found that as faculty become more familiar with technology, their need for additional training in other technologies is likely to increase.

Inman & Mayes (1999) also suggested that there should be a distinct separation of general education and hardware training from advanced training in more sophisticated technologies. Dusick & Yildirim (2000) also found the need for separation of users and nonusers in training. Experienced users were focused on improving their existing skills through specific training. Nonusers preferred short personal training sessions or in small groups.

Dusick & Yildirim (2000) found that computer competency and prior computer instruction were significant predictors of the use of computers for instructional purposes by faculty. It is evident from the study that training is an important positive factor in expanding faculty use of computer technology.

Candiotti & Clarke (1998) and Dusick & Yildirim (2000) also found that support for faculty while they are learning new technology is critical. Both studies suggested that a modest investment in support staff yields far higher returns in increased faculty use.

The Problem

A major problem faced by the Center for Teaching and Learning with Technology was how do you train countless numbers of faculty members who are geographically dispersed on three main campuses and numerous remote satellite locations and all have conflicting time schedules. Several options were considered. The most obvious was to schedule training sessions at varying times and locations to try to accommodate the variety of needs of our faculty. This, of course, is time-consuming and expensive.

A Solution
Since one of the major goals of the Center is to encourage the use of technology by faculty to enhance teaching and learning and provide them with the support to make that happen, it was logical for the Center to investigate the use of technology to help solve this problem. The College already had its own web servers and internet connections to the majority of faculty offices as well as to numerous locations throughout our campuses. So instead of bringing the faculty to a single location for training, it was decided to try to bring the training to the faculty through the internet wherever they are.

The first task was to identify what media elements would be necessary to do the most common types of training that faculty requested. Interactive video would certainly be helpful but production is expensive and time-consuming and was not really necessary for most applications. Video over the web is greatly improved but still problematic for most low-bandwidth users. Screen captures of program screens for demonstration purposes were useful in traditional instructor-led training sessions and certainly seemed appropriate for online delivery. Audio instructions also proved effective to support instruction. Animating illustrations of items such as pulldown menus, button selections, and other features was also desirable if they would not take a long time to develop.

Macromedia's Flash was selected as a primary online training development tool. It supported the media elements required by the Center for producing effective training tutorials online. Flash's built-in tutorials made learning to create media-rich, interactive instruction on the web fast and easy. Files sizes were lower than comparable HTML pages would have been so there are no long delays waiting for new images to appear. Audio tracks stream well even over low bandwidth connections. Reusable models were created to cut development time for new training projects. The latest version of Macromedia Flash even comes with a library of learning interactions that speed up the process of creating online training for faculty. Flash is supported by most of the common browsers.

Although at the time of this writing no significant data collection has taken place, anecdotal reports from faculty members who have used the online tutorials found them helpful and much more convenient than traditional instructor-led training sessions. A more formal evaluation is planned for the end of the semester.

Conclusions

Increasing college faculty use of instructional technology takes careful planning and ongoing support. Before a college or university undertakes a program to increase the use of technology, it is critical that factors which may cause faculty resistance to technology are identified. The research suggested that many of these negative factors are due to deficiencies that can often be overcome by careful advance planning and preparation. Conditions that encourage faculty acceptance and use of technology must be in place for programs aimed at increasing technology integration to be successful. Availability and easy access to hardware and software are vital components of a successful technology expansion.

Ongoing training and support for faculty also plays a critical role in the expansion of technology use. Trainers must be aware of the types of technology that are available and those currently in use in order to create training programs that will be beneficial and relevant to faculty.

The use of the internet to provide training to faculty any time, in virtually any location, shows potential for solving a number of faculty training issues. A rapid development tool such as Macromedia Flash makes it possible to create web-based training applications without a prohibitive expenditure of time and effort.

Abstract: Technology teacher training is one of the most preferred methods in schools and other educational institutions to close the gap between teachers' expected level and current level of technology use in the classroom. The purpose of this paper is to investigate, based on Mager and Pipe’s (1997) performance analysis model, if technology teacher training is the only solution to improve teachers' performance in using technology in the classroom. First, a literature review on technology teacher training will be provided and then the performance analysis model will be used to evaluate the necessity of the training.

Introduction

The literature has much information about different views on technology teacher training programs designed to improve teachers’ performance in integrating computers into the classroom. However, human performance specialists advocate that training is not always the solution to tackle with low human performance. Non-instructional or management solutions would be applicable to certain situations (Rothwell & Kazanas, 1998).

The purpose of this paper is to investigate, based on Mager and Pipe’s (1997) performance analysis model, if technology teacher training is the solution to improve teachers' performance in using technology in the classroom. First, a literature review on technology teacher training will be provided and then the performance analysis model will be used to evaluate the necessity of the training.

Literature Review

The literature indicates that lack of educational technology training prevents teachers from the use of computers in schools (Scheffler, 1997) and an appropriate training increases teachers' comfort level, enthusiasm, confidence and skills to use technology (McNamara, 1995). Hardy (1998) says that seven-year continuous training and experience are necessary to become a comfortable and confident user of educational technology. Of the seven years, teachers need five years to get used to the technology and then they start expending the use by adapting some computer applications, such as tutorial programs and drill and practice software.

Several training programs have been tried out and discussed by researchers. McNamara (1995) depicts a training program that is composed of three levels: Awareness, development of skills and applications of knowledge. In the awareness stage, the training focuses on basic knowledge about computers. After that, equipment operation and the use of computer applications should be taught. In the last stage, applications of knowledge, the main theme should be integrating computers into the curriculum and using the computer for classroom management.
In another approach, the training is designed such a way that teachers consecutively become technology assistant, technology teacher and technology leader. The technology assistant is capable of manipulating computer hardware and running computer applications at least with the help of the manuals. Technology teachers are able to evaluate educational software and integrate them into the curriculum without supervision. Technology leaders can use the technology with different pedagogical approaches, such as cooperative learning and constructivism, and use advanced multimedia and Internet applications (Guffey, 1998).

Siegel (1995) proposes a three-level teacher-training program. At the end of the first level, teachers become familiar to some specific hardware and software. During the second level, teachers learn evaluating educational software to implement in the classroom. In the last level, teachers become capable of producing ideas on the technology integration.

After training, teachers should gain several competencies important for the technology adaptation in education. Teachers should be a competent computer user (McNamara, 1995; Guffey, 1998; Siegel, 1995; Hardy, 1998; Walters, 1992, Willis, 1994). That includes understanding and operating of major computer parts such as monitor, modem and sound card as well as major computer peripherals including printer, scanner, cameras etc. Software competencies are installing and running operating systems, educational software and tool software, such as word-processing, spreadsheets, presentation and database (Guffey, 1998; Siegel, 1995; Willis, 1994).

Besides computer and software skills, teachers should be trained on the pedagogical issues and classroom management. Teachers have to be knowledgeable about instructional design models, integrating computers into the curriculum, computer assisted instruction and evaluating educational software to use in the classroom (McNamara, 1995; Forcheri, 1986, Siegel, 1995; Walters, 1992). Also, teachers are able to use the computer as a classroom management tool, such as keeping journals and reports about students and taking attendance (Hardy, 1998). Programming and Internet are other important competencies for teachers to learn (Becker, 1994).

The literature proposes the following tips and strategies to improve the effectiveness of a teacher training program: The training priority should be given to volunteer teachers; the training should be given by experienced classroom teachers or teacher trainers; the training should provide teachers with practical examples and extensive hands-on experiences with computers; the teachers should instantly use new technology skills in their classes; and teachers should be provided follow-up support after the training. (Heidi, 1999; McNamara, 1995; Wetze and et al, 1996; Siegel, 1995; Gilmore, 1995; Tally, 1995)

Technology Training and Teacher Performance

Are teachers really employing computers effectively in the classroom? Is there a difference between how they should utilize computers and how they are currently using them in the classroom? Those questions are concerning about teachers' performance to adapt computers into curriculum. Human performance technologists employ systematic models to identify deficits in human performance, investigate their causes and bring solutions.

Mager and Pipe's performance analysis flow chart can be used to investigate if training is necessary for teachers to successfully implement computer-based activities in classroom. The performance analysis flow diagram focuses on three issues: Identifying performance discrepancies and determining their importance, considering alternative solutions for those discrepancies and considering training solutions.

Teachers' Performance Discrepancy in the Use of Educational Technology

In the last 20 years, the numbers of computers have increased significantly in schools. However, significant percentage of new teachers has not used computers for instructional purposes (Wild, 1996; Hardy, 1998). On the other hand, even though some teachers try to adapt the computer in their lessons they are not able to achieve an appropriate integration (Dunn & Ridgway, 1991). Most of the time computers are employed in an unproductive manner and isolated from the classroom. For instance, they are substituted for paper-and-pencil individual worksheet activities and used as a tool to reward and punish students due to their behaviors (Becker, 1992). In high schools only 31 percent of the student computer time is devoted to
the support of academic subjects (Fostering the use of educational technology). So, “computers should be further integrated into the actual curriculum” (Heidi, 1999).

As can be seen from the information above, teachers do not utilize computers at the expected level. What are the consequences of teachers’ performance gap in using technology in classroom? This is a controversial issue among educators. Some believe computers are not able to provide a significant improvement in students’ learning (Cormack, 1995). On the contrary, it is advocated that well designed technology supported lessons are able to improve students’ learning performance and decreases the learning time. Students’ attitude towards learning is increased, as well (Dusic, 1998). Looking at the issue from educational system change perspective, Branson (1998) assigns an important role to technology to carry out the transition from current teaching-centered educational system, which is considered to reach its final efficiency limits and does not become better, to new learning-centered education system.

Training Solutions to Close the Gap

According to the Mager and Pipe’s performance model training can be considered as an appropriate solution for low performance if one does not have enough job related knowledge and skills. In connection with this, if teachers have lack of the knowledge and skills to adapt technology in the classroom training can be helpful. So the question is “do deficits in the technology knowledge and skills prevent teachers from employing technology to teach?”

Walters (1992) indicates that only 20 percent of new teachers believe that they were prepared to use computers in instruction. Even though having positive attitude towards technology, very high percentage of teachers, around 90%, even is not confident about their computer literacy skills and knowledge (Dupagne, 1992). Moreover, student teachers do not know the basic computer skills and designing computer-supported lesson plans (Cormack, 1995). Usually, they have not been educated about and exposed to systematic ways to integrate technology during their educations because colleges of education have not fully adapted technology courses into their programs, not met student-teachers’ computer education need (Pugalee, 1998) and the faculties in those colleges lack the expertise in both technical and pedagogical skills in educational technology. (Hardy, 1998; Wild, 1996). This limits the prospective teachers’ competencies and knowledge of integrating technology in the curriculum.

The information above coming from the technology teacher training literature apparently says teachers often lack the skills and knowledge in using technology. There is a considerable need to provide teachers with training in how to appropriately design and deliver instruction that incorporates technology (Pugalee, 1998). Usually exemplary computer using teachers work in school districts that heavily invest in staff development program and they have more formal training in using and teaching with the computer (Becker, 1994). Supporting this judgment, many technology experts agree that an ongoing barrier to implementing technology in schools continuous to be the lack of appropriate training for teachers (Hardy, 1998). If they are provided with time and support for in-service training they may gain positive attitudes towards technology and easily learn planning and using the computers, so that technology integration can be successfully achieved in school (Dupagne, 1992; Sheingold & Hadley, 1990).

Alternative Solutions

Technology teacher training, alone, is not capable of solving the multidimensional problems related to technology integration in education. Besides the training need there are several other obstacles preventing teachers from successfully using technology to teach. Mager and Pipe in their performance analysis flowchart first systematically examine alternative solutions to training. They consider four factors that may cause low performance: Unclear performance expectations, inadequate resources and feedback, punishing desired performance and rewarding poor performance.

As far as clear expectations are concerned, the technology integration is still a vague concept. Having done many studies about technology and education, researchers have failed to put out common, concrete and practical criteria with regard to the best ways of using computers in classroom and teachers are not provided with clear-cut expectations to successfully implement the technology.

In spite of big investment in purchasing hardware and software in schools, even more than the amount spent for the staff training and professional development, teachers complain about inadequacy of
technology equipment and resources. There might be several reasons of that. The current average computer/student ratio (even though increased significantly in the recent years to 1/9) might be still a low proportion; many broken and malfunctioning computers are sitting in classrooms or computer labs due to lack of technical support; and the compatibility between new and old technologies is lost due to the rapid growth in the computer technology. Old computers do not support new versions of software and hardware. The last two reasons may indicate that, even though significant number of computers appears in the inventories of schools they are practically not useable. (Wetzel and et al, 1996)

Feedback is an important mechanism to improve human performance. Behaviorist psychologists have done significant number of research on feedback and how to provide it and when. However, the educational technology literature lacks information about how effective feedbacks should be provided with teachers upon their technology integration practices in the classroom and who should do it. Technology coordinators would do that but few schools have fulltime technology coordinators and they are overloaded with many different tasks including teaching computer literacy, maintaining computer lab etc. Basically, they are not able to allocate time to observe and provide feedback for the teachers.

One of the most controversial issues in education is student evaluation. In many states, students are required to take standardized performance tests and teachers are held accountable for the students’ scores. Researchers indicate that different learning processes require different evaluation procedures. For instance, standardized tests are usually associated with instructivist/behaviorist type of teaching. Yet, the literature shows that teachers prefer to use technology in a more student-centered/constructivist way that is not properly evaluated by performance tests. So, evaluating computer-supported instruction through an inappropriate means and holding computer-using teachers accountable for students’ low scores based on an inappropriate evaluation technique would be punishing the computer-using teachers as well as rewording the non-computer using teachers because their students have a greater chance to show better performance on standardized tests.

Conclusion

According to the literature, teachers do not have enough competencies to integrate computers in the classroom and they do not get sufficient in-service training. Pre-service teachers also graduate from colleges of education with a very little exposure to and knowledge about educational technology. There is a substantial need to provide teachers with educational technology training.

However, the training should not be considered alone. Teachers have to be provided with additional assistants such as job aids and EPSS supporting the training. Moreover, there is a need to develop a school/district (or broader) level system or policy that coordinate and manage the technology integration and implementations in schools. This system or policy should define what is expected from educational technology and how it will be judged, how teachers have to employ technology in classroom, what technology and non-technology resources will be available for teachers and what incentives will be given to them.

Increasing the Use of Computers in Early Childhood Teacher Education: Psychological Factors and Developmental Appropriateness

Karl F. Wheatley, Ph.D.
Department of Specialized Instructional Programs
Cleveland State University
U.S.A.
k.wheatley@csuohio.edu

Abstract: This paper examines the case of one urban early childhood teacher educator's increasing use of computers in early childhood (PK-3) curriculum courses, over a period of one year. The paper describes the both the obstacles to such increased computer use and the factors related to this increasing integration of computers. The case is analyzed from the perspective of the early childhood concept of developmental appropriateness, and with respect to the motivation and learning required of the teacher educator.

Data

Data for the case included the teacher educators' reflective journal entries, and descriptions of the integration of computers into class activities and student assignments. Data also included reflections on the course activities in which computers, early childhood software, and net searches were integrated into the course.

Obstacles to Increasing Computer Use

There were numerous obstacles to either any increased utilization of computers for instruction, or increased attention in the courses to issues of computer use in early childhood education. These included obstacles often found in teacher education—the teacher educator's modest computer skills and lack of knowledge of current uses of computers in schools. One more area-specific obstacle was the teacher educator's set of concerns about the developmental appropriateness of computer use in early childhood education. However, the most significant obstacles seem to have been psychological—the teacher educator's ambivalence about increased use of computers, related to various psychological and technical obstacles to using computers in his urban teacher education setting.

Factors Underlying Increased Computer Use

The factors underlying success in increasing computer use included the availability of a second grade teacher who modeled successful use of computers in her classroom. Important in this case was the fact that this teacher's utilization of technology was not overly complex in nature, and seemed within reach of the teacher educator's own level of computer skill. Another factor was the public expectation that the teacher educator would at least give increased computer use a chance, as part of his involvement in a technology grant. An important aspect of this motivating influence was the degree of flexibility afforded the
teacher educator in terms of how computers or other technology were expected to be used. A third factor was adequate technical support at the university. However, the most significant factors seem to have been psychological. These included the teacher educators' reinterpretation of three things--his modest use of computers in instruction, his own relationship to technology, and his feelings of teacher efficacy regarding using computers in his teaching.

Analysis and Discussion

From the perspective of early childhood teacher education, this case reveals in greater depth some of the concerns about the developmental appropriateness of computers in classrooms for very young children. However, it balances these concerns with the teacher educator's discovery of evidence of some of the developmental benefits of such computer use.

The case was analyzed using three important aspects of motivation theory--teacher efficacy, self-regulation, and achievement goal theory. In particular, the adoption of a particular alternative perspective on teacher effectiveness helped the teacher educator persist in attempts at increased computer use. This alternative conception, which differs from traditional conceptions of teacher efficacy, was used by the teacher educator for self-regulation of his own motivation and learning. In turn, this alternative perspective of teacher efficacy was only possible by adopting the kind of "learning orientation" discussed in goal theory.

The case study presented here does not represent a case of exemplary computer use in teacher education. Indeed, the discussion of the case stresses the importance that less-than-exemplary models have for the success of any changes in schools and teacher education--whether that change is integration of technology or any other reforms. These points are discussed in light of the research by Zimmerman, Bandura and others on mastery models versus coping models.

Educational Significance

This case is significant because it is one example of what is necessary for widespread increases in the integration of computers and technology into teacher education. That is, it represents one pathway for gradual, incremental increases in computer use among somewhat skeptical teacher educators with only modest technology skills. In doing so, it highlights crucial psychological processes for supporting teacher educators' learning about and use of computers in instruction, especially for teacher educators who are not at the cutting edge of technology use.

From Theory to Practice - Practical Use of Classroom Technology

Sue Burch, Grand Island Public Schools Technology Coordinator, Grand Island NE sburch@esu10.org

Dr. Rob Ziegler, Superintendent Madison Public Schools, Madison NE, rziegler@esu8.org

Dr. Woody Ziegler, Assistant Professor in Educational Leadership, Doane College Lincoln, NE, wziegler@nebraska.com

Abstract: The 21st Century is here. This brings new opportunities and challenges as businesses seek more technology skills for their future labor force. At the same time groups are looking at the welfare young child and call for reductions of computer time. Teachers find themselves in the middle of the 21st century needs and the issues around standards, assessment and developmental levels of children. This is often interpreted as a need to do an either or approach. The technology pyramid, multi-media planning guide and rubrics demonstrate ways for the teacher to provide for the needs of all of the groups with a balanced approach thus meeting the needs of all learners.

Introduction

In October of 2000 the Alliance for Childhood presented a report called, “Fool’s Gold: A Critical Look at Computers in Childhood” (Cordes, 2000). The report takes educators, curriculum developers, and technology advocates to task concerning the use of technology at the elementary school level. The authors mention their concern for the health of our children, the lack of positive personal connections between children and adults, the lack of physical play and activity to which technology contribute, and the lack of stimulation brought about by using technology in the classroom (Cordes, 2000).

Advocates of student use of technology might find these concerns over reactive (Vaille, J., 2000) (Thornburg, 2000). Technology supportive educators would talk about the child’s motivation to learn using computers. Educators would answer that if kids are sitting in front of computers six hours a day this report should be focusing on parenting and not on the educational system. (Schmidt, 2000) “Fool’s Gold” poses questions which educators, must examine thoroughly if we are to make the educational experience of our students one in which the whole child grows in a proper developmental manner.

Early childhood educators, parents, and technology advocates can meet learning needs and help the young child grow in an appropriate developmental manner while using technology. If that is to happen, however, the adults must continue their learning and understanding in applying the concepts of learning theory to the proper use of technology in the classroom. Learning theories brought to educators by Piaget, Hunter, Bloom, and McCarthy need to be explored and applied if we hope to use technology in a manner that is conducive to constructivist education.

Learners of all ages need experiences that will prepare them for their future. This means different activities and opportunities based on student readiness and abilities. Learning theories developed to assist teachers in the delivery of a curriculum. In 1956, Benjamin Bloom first shared one theory still quoted by educators today. Bloom’s Taxonomy of Critical Thinking and Problem Solving focused on the cognitive domain (Allen, 1998). Bloom’s Taxonomy placed a ranking on the types of questions and learning opportunities asked of the learner. The lowest level considered factual recall. The difficulty rises with each of the six levels ending with evaluation. To assist the educator in identifying the level or developing questions for a specific level of difficulty collections of verbs provide assistance (Lane, 2000).
The pyramid represents Bloom's Taxonomy (Burch, Ziegler & Ziegler, 2000). Common practice in schools places the most time to the lowest levels with decreasing time spent on each of the higher levels. The B & Z² pyramid adds another level onto the taxonomy. The "Connections and Integrity" level seeks to identify the thinking needed to understand self and to work with diverse groups.

Madeline Hunter presented a Direct Instruction Model in 1967. Hunter's work eventually became known as ITIP - Instructional Theory Into Practice. Hunter's first model identified 9 steps that may be included in an effective lesson (Allen, 1998). The Hunter Model continues to be identified as a planning tool for developing lesson plans and supervision of instruction (Wolf, 1987).

Efforts such as Bernice McCarthy's 4Mat (Butler et al., 1997) and the Cooperative Teaching Model (Johnson, D., Johnson, R., 2000) are additional educational models seeking to improve learning opportunities for students.
These models, in combination with other education research seek to enhance delivery of instruction with the purpose of providing more effective learning experiences for students. With the advent of the personal computer in 1978, educators faced new opportunities and challenges. Computers continue to accelerate in speed and memory capacity while the cost continues to decline (Yang, 2000). Software continues to change at an alarming rate. Students and teachers can now edit full motion video on a desktop computer with titles and special affects galore (Steinberg, 2000). The Internet moved from a system of connecting through e-mail into a World Wide Web full of information that once only the most learned in the largest cities could access. These factors bring are changing learning opportunities.

Studies are show advances in student learning. Katie Herrick summarizes nine articles and reinforces the importance of using word processing constructively (Herrick, 2000). Experiences such as Australia Quest are taking students across the world to experience and problem solve issues that previously were only viewed by a handful of explores and researchers (Buettner, 2000). The world is expanding for learners of all ages.

Unfortunately, the benefits of these advancements are not enjoyed by all. A “digital divide” exists (Milken, 1998 & Lemke, 1999) that is preventing students from accessing these experiences. The present divide results from lack of access to the technology and the mindset of the teachers in the classroom. The department of labor observed this concern in 1991. The Secretary's Commission on Achieving Necessary Skills (SCANS) called on the American educational system, from pre-school through post-graduate, to attend to the responsibilities graduates assume as workers, parents, and citizens. Asserting that there is more to life than earning a living, SCANS also insisted that the following set of foundation skills and competencies are essential for all in the modern world. (United States Department of Labor, 1992)

Two additional models help show where the students are functioning as they use technology. The Technology Hierarchy, developed by Nancy Sculla, (Sculla, 1999) shows levels of technology use and complexity. The NETS project by International Society for Technology Education (ISTE) identifies levels of competency for students. A Nebraska Department of Education task force aligned Nebraska competencies with the NETS project. Both of these models can be adapted and applied to Blooms taxonomy. Again, the B & Z2 pyramid adds another level onto the taxonomy. The “Connections and Integrity” level seeks to identify the thinking needed to understand self and to work with diverse groups.

Figure 2. Technology standards for students as developed in 1998 with the Nebraska Student Essential Learnings & Technology (1999) matched to the six levels of Bloom’s Taxonomy. At the top of the pyramid is the B & Z 2 level for Connections and Integrity.

In a time when groups are concerned about lack of interaction with other children and/or meaningful adults, the Connections and Integrity level becomes of crucial importance. When a person knows who they are, they are more willing to reach out and meet or work with someone else. Integrity is knowing personal values and matching behavior to those values. Integrity is important for students to allow them the understanding that they have something to offer to others and to gain from others. Thus the effort to identify their multiple intelligences and provide them with life skills in the form of a value system such as the Eight Keys of Excellence (DePorter, Reardon, & Singer-Nourie, 1999).
Connections can occur using technology. E-mail, video-conferencing, web pages and cooperative projects using programs such as iMovie and HyperStudio allow for connections and interactions to occur. Consider one such technology opportunity. Under the direction of Nancy Bellows, Judy Brumbaugh, Tricia Hirschfeld and Kym Lucas, fifth students from York Elementary School, York, Nebraska, created connections each week as the fifth grade students, School News 2000. This 15 minute broadcast featured school events, classes, books, staff members and numerous topics of interest. Along with learning and applying basic skills, the fifth graders problem solved, worked in cooperative groups and extended themselves to apply traditional classroom skills to a real world activity of broadcasting. (Bellows, Brumbaugh, Hirschfeld and Lucas, 2000). Students of all grade levels looked forward to the production and airing of these weekly shows. This simple multimedia activity generated connections and a feeling of community for the entire school. While the computer, VCR, TVs, digital camera and iMovie made this possible, the real success of this activity came from the students identifying and using their skills while connecting with students throughout the school. These types of opportunities empower the learner and prepare them for life in their future.

Activities such as School News 2000 are possible in many schools. Lacking for many teachers are tools to help them plan and manage the development of the multi-media activity and an effective way to assess the final product. Tools such as the multi-media planning guide divide the project into manageable steps for the student, teacher and parent (Burch, Ziegler & Ziegler, 2000). With dates and check off boxes to track progress. Along with the planning guide are age appropriate rubrics to help the students know what they can strive to accomplish and their product will be measured.
Opportunities to prepare students for their future are a necessity. Congress recently authorized the 21st Century Workforce Commission. In June of 2000, this commission released their findings. Their conclusions began with, "The current and future health of America's 21st Century Economy depends directly on how broadly and how deeply Americans reach a new level of literacy - "21st Century Literacy" - that includes strong academic skills, thinking, reasoning, teamwork skills and proficiency in using technology. Educators have a challenge to move beyond TTWWADI (That's the way we've always done it) syndrome (Jukes, 2000). It is time to prepare students for their future rather than our past. We must look to the developmental needs of the learner. Determine ways appropriate use and selection of technology that move the students up the levels of Bloom's Taxonomy for Critical Thinking and Problem Solving. Finally, we must provide teachers with resources to help them access how they are teaching and what they can do to become a more affective teacher in this 21st century world.

The appropriate integration of technology into today’s learning environment remains a predominant area of importance within the areas of graduate and inservice. Research focused upon face-to-face, Internet-assisted and Internet-based learning environments has expanded imperative theoretical and application-based discussions. The appropriate and successful integration of technology within the learning environment is the focus of the outstanding articles within this section. The authors offer the latest research and theoretical issues through which the future of face-to-face and distributed learning environments will emerge. For ease of discernment, the following research paper summaries are presented in alphabetical order by the author’s surname.

Arango-Montero, Asse, Aughey, Betancourt, Goller, Naranjo, Olmedo, Sanchez and Thirunarayanan examine the initial year of the Master of Science in Urban Education degree program with a specialization in Learning Technologies. A discussion surrounding an overview of the program and student comments is presented.

Braboy and Trivette offer a discussion of a project that aids educational endeavors related to analysisation techniques. This specific project focuses upon analyzing historical documents while focusing upon emotional and intellectual Socratic questioning methods.

Brownell and Brownell present the experiences and reflections associated with the design and development of a graduate-level course entitled EDTL 630 Media Literacy Across the Curriculum. Discussion surrounds the design and development of the scope and sequence for the course, equipment viability and availability and future development of the course.

Burnett, Bonnici, Dresang and Thomas provide information concerning the Web-based opportunities for contextual learning. Their efforts are focused upon school library media specialists.

Cakula focuses upon the Latvian need for inservice professional development opportunities for educators. An examination of the design, development and implementation of an interactive course with Swedish and Latvian educators is presented.

Cheeks presented a summary of program evaluation research surrounding a graduate School Library Media Program. Radical changes in school library media services necessitated the evaluation, which focused upon the elimination of the disparity between job competencies required by the specialists and job competencies within the School Library Media Program.

Civletti and da Silva analyzed data pertaining to a social-international and constructivist emphasis within the attitudes and pedagogic practices of educators. The Brazilian “Computer Course Applied to Education” was the focus of the study.

Coombs examines the International Society for Technology in Education (ISTE) five-step curriculum standards outline that is focused upon all advanced programs in educational computing and technology. A discussion of each of the five steps suggested by ISTE includes a suggestion for future graduate-level course interpretation.

Cooper and Hirtle call for a reprieve from the disparities between the learning and the technology integration in the K-12 environments. A focus upon the curricular scope and sequence, as well as the course instructional design, is emphasized.

Dailey, McNelis, Struck and Wall address the shortage of secondary special education professional development schools (PDSs) within the professional education of teacher candidates and inservice teachers. A case study of Townsend University is presented.

Engel and Sparrow focus upon the online Educational Technology Master’s degree program at Florida Gulf Coast University. Further, rationales for decisions made within the program structure, students and program evaluation techniques are discussed.

Ertmer, Johnson and Lane reflect upon a teacher development tool that is designed for scaffolding technology integration within a learning environment. The engagement of educators as well as the inclusive reflective
activities facilitates the expansion of the teacher’s ability to integrate technology within a learning environment.

Figarella presents a case study of technology integration within elementary-level learning environments. The initial semester of the case study is the focus of the paper.

Fourie explores the world of distance education as it relates to the education of graduate-level teachers who are focused upon electronic information research skills. The author notes that considerable success was achieved for all students, even those who dismissively labeled themselves as “computer illiterate”.

Franklin, Duran and Kariuki examine the collaborative use of graduate Instructional Technology students as mentors for inservice elementary educators. A discussion surrounding just-in-time (JIT) learning, professional development opportunities and possible alternative assessment methods are discussed.

Gibson presents a discussion surrounding the impact and results associated with the integration of the ISTE foundation standards within the teacher candidate education program at Wichita State University. An examination of the resulting benefits to the involved entities is also presented.

Goss, Kinslow and Welsh describe the development of a graduate-level teacher certification program for “Teaching and Learning with Technology”. The program matrix with NETS-T performance indicators is clearly articulated.

Grandy, Strickland, Sammons and Strickland focuses this study upon the planning, administration and follow-up of a junior high Earth Science Program that focused upon the appropriate and successful integration of technology. Findings from attitude surveys are included.

Gunter presents a study that focused upon the integration of technology within specific classroom curriculum while taking an online graduate-level educational technology course that was focused upon K-12 educators. Quantitative as well as qualitative data were obtained and presented.

Heath, Dimock and Burniske reflect upon a program that provides focused professional development opportunities and information services to teachers and administrators. The focus is to support and focus upon learner success.

Hornung and Bronack describe a partnership that focuses upon the appropriate and successful integration of technology within learning environments for preservice and inservice educators. A discussion surrounding the successful scope, sequence and scheduling of professional development opportunities is emphasized.

Hughes and Walker discuss a United Kingdom-based professional development scheme that attempts a university response to K-12 educators’ needs. The integration of technology as educational aids within the online environment is discussed.

Hung, So and Pow offer an exploration of a project-based approach towards the development of a learner’s conceptual framework through a multimedia teaching resource bank. The rationale, concept, description of the four stages of development, outcomes and limitations are presented.

Iran-Nejad, Xu and Venugopalan present a study concerning whole theme learning through an Internet-based community. The results of the initial aspects of the study are positive and encouraging.

Irvine, Larkin-Hein and Prejean focus upon middle school science classrooms and the learner’s construction of knowledge networks. The integration of technology, curricular developments and questionnaire results are shared.

Jenson, Lewis and Smith offer innovative models of professional development opportunities for inservice educators, focused specifically upon instructional technology. The authors move beyond the workshop environment to examine an often-overlooked implementation strategy.

Kennedy presents a framework through which to design professional development course opportunities within the specialization area of Instructional Technology. The focus is on meeting the needs of individual educators.

Kibben, McDonald, Tangney and Holmes explore the first-year teacher candidate’s attitudes concerning the role of technology within a classroom environment. Two graduate-level students were focused upon as the case study reviewed the attitudinal shifts over their initial year.

Kitchenham outlines a professional development model concerning the implementation and integration of technology within an educational environment. The preliminary results of an analysis are presented.

Klein-Wohl describes the design of an Internet-based methodology course for inservice educators. The perspective of the paper is from the designer’s point of view and includes discussions surrounding the learning potential of the instructional model within the distributed learning environment.

Kortecamp examines qualitative data concerning teacher’s perceptions of himself or herself as they proceeded to learn new technologies for implementation within the classroom environment. The emergence of common themes is fully discussed.

Kylama and Silander emphasize the pedagogical revolution that is afoot. The emphasis upon shifting pedagogical practices must begin with the whole school community.
Lambert provides a report of a pilot study findings related to the understanding, conceptual understanding and integration of technology into a teacher's classroom environment. Several strategies that may support the teacher's learning curve are discussed.

Lare offers a qualitative study on the impact of Internet-based learning environments on teacher candidates. The interesting results obtained from the study are discussed.

Lee and Lo present the findings of a study focused upon the integration of instructional technology within a Taiwan Junior High School's English classroom environment. Three major findings are presented.

Lehman, Ertmer, Keck and Steele report on the professional development opportunities focused upon inservice educators. The subject matter of the professional development opportunities is the support towards the problem-based integration of technology within a classroom environment.

McCaulley, Porter, Tuinmann and Donkers describe a technology-focused online professional development opportunity program for teachers. This program meets international standards and focuses its efforts on addressing key aspects in ITC training.

Marcovitz describes a pilot project's results concerning teachers who were enrolled in the Multimedia Design in the Classroom course at Loyola College in Maryland. The use of multimedia software applications and Visual Basic for Applications (VBA) were emphasized.

Mullick and Sarner document a two-year period surrounding technology-integrative professional development opportunities. The results indicated that one-year and two-year longitudinal results were positive.

Norton and Farrell reflect upon the question of attitude and classroom practice shifts surrounding the integration of technology within a learning environment. A summary of data is examined from the 1999-2000 time period.

Norton and Schell offer an introspective question associated with many facets of the educational process and then offer results from a research study comparing teacher certification and graduate degree options for teacher educators. Questions surrounding what is the impact of technology, and how many classes must a teacher candidate or inservice teacher encounter to impact the appropriate and successful integration of technology into the classroom environment, are explored.

Papdopoulos, Karamanis, Ioannou and Houssou document the Hellenic Pedagogical Institute's implementation of a teacher-focused professional development opportunity project. The design principles and implementation processes of the project are described.

Reynolds and Morgan explore the inservice teacher's attitudes towards professional development opportunity.

Numerous positive and opportunities for further delineation of professional development opportunities are offered.

Sammons reflects upon online asynchronous experiences, as associated with personal cooperative videos. A multimodal distance learning experience is documented.

Shih and McLaughlin present the curricular scope and sequence of the Web-based Masters of Science in Agronomy program at Iowa State University. A discussion of formative evaluations and a summative evaluation of the course content is also presented.

Tamashiro, Reitinger and Lewis provide a discussion surrounding the innovative aspects associated with online teacher education. Program design and instructional methods implemented within the online environment are examined.

Tu and McIsaac offer an innovative analysis of strategies associated with communities of practice that are focused upon the enhancement of mentoring situations. Mentoring models associated with doctoral students are discussed, as well as the Communities of Practice (CoP) model is presented.

Whipp and Schweizer explore strategies that students implement and foster to succeed within an online educational environment. The metacognitive, motivational and social strategies that the students implement towards a successful online course experience are examined.

Williams, Burns and Oostenink describe initiatives surrounding professional development opportunities in which teachers, curriculum specialists and administrators focus upon aspects of an engaging learning environment. Further, the impact of technology is discussed.

Yildirim, Kocak and Kirazci document a Turkish study that focuses upon the teachers' competency associated with technological aspects of the learning environment. Further, recommendations towards successful and effective technology-related professional development opportunities are offered.

Graduate and inservice theoretical discussions and research that impact the learning environment are imperative to the ever-expanding conceptual framework. Pertinent theoretical issues surrounding graduate level and inservice teacher professional development must be carefully considered and are imperative as technologies become more available within learning environments. The authors within this section have presented rigorous research, contemplative theoretical discussions and thoughtful reflections that exemplify the cutting edge of the world of instructional technology.

Abstract: The use of electronic primary sources provides authentic pieces of the past for students and teachers alike, but these primary sources pose a new challenge for teachers. Teachers need to be trained in techniques for analyzing historical documents and strategies for raising the intellectual and emotional questions that will draw the students' interest. Misuse of electronic primary sources can create a greater distance between students and learning if the teacher is not prepared in both technology, primary source evaluation, and their integration into the curriculum. The "An Adventure of the American Mind" project is the first to meet this challenge head on.

Introduction: In Experience and Education (1938), Dewey defined education as the process of continuous reconstruction of experience with the purpose of widening and deepening its social content while helping the individual to gain control of the methods involved. Dewey used terms like democracy, interest, and growth without giving them precise meanings. Former North Carolina governor, James Hunt, reflected his opinion of education by arguing that the real function of schooling is to make technologically literate citizens. While many philosophies of education disagree with Hunt, the current demand for technology literacy in the classroom requires teachers to teach beyond the basic skills. Teachers and students must master the three C's: communication, collaboration, and creative problem solving. Education's challenge is to transform all formal institutions of learning, from pre-K through college, to insure that we are preparing students for their future not our past.

The Project Initiative: A major USA initiative in our field, "An Adventure of the American Mind" continues in rural western North Carolina. In October 1999, the project began recruitment of local area in-service teachers to participate in a graduate-level course in Spring 2000. Collaborating with Mars Hill and Brevard College, Montreat recruited 48 teachers to be the pilot group for the program. The graduate course began in January 2000 with 28 teachers traveling to Montreat College and 20 traveling to Mars Hill College. Laptops were given to each teacher to provide them with the basic technology resources they would need. The teachers were introduced to the Library of Congress' website American Memory, which contains over three million digitized items from the Library’s collection, and built interactive lessons using these primary sources and Microsoft PowerPoint and FrontPage.

After completing the course in May, 20 teachers applied for and attended an intensive four-day summer institute at the Library of Congress in June. They were given tours of the rare books, maps, and photograph collection areas, and the archivist met with the teachers and explained the collecting and digitizing process. Those teachers who were unable to attend the institute in Washington, D.C. attended a three-day summer institute at Montreat, Mars Hill, or
Brevard College. The local institute also was made available to teachers not participating in the program and the response was incredible. Sixty-four in-service teachers attended.

The laptops have proven to be a beneficial asset to the project. Most schools in rural western North Carolina are without funding for technology; in some cases, the laptop is the only computer in the school. The graduate course provides the time teachers need to search for online materials and build lessons integrating the highly demanded technology. The project provides technical and curriculum support up to one year for the teachers participating in the project.

Findings: Issues did arise in the first year of the project. Some of the schools had limited Internet access and some had none. To combat this issue, the teachers were introduced to Juno, a free email and Internet access provider, and shown how to use a phone jack to dial in. Another issue was Internet filters. Some schools could not access American Memory due to some of the primary source materials contain politically incorrect terms. This proved to be the most difficult issue to resolve due to this being out of the scope of the project. The project could only suggest to the schools' network administrators that the American Memory site be allowed through or a different filter be used. Most schools were able to gain access to American Memory.

Conclusions: In its second year, the project will be reaching over 300 in-service teachers in 15 counties covering the western part of the state. The pilot group of 48 teachers is in phase two of their participation and are mentoring other teachers from their schools, which is doubling the number of teachers being trained. Two universities, Western Carolina and Furman, have been added to the project; thus, the area being reached has been enlarged to include western South Carolina. The initiative has brought much excitement to students as the teachers involved have “brought to life” historical, primary resource documents and photos. Teachers and students of all ages have found working with and manipulating these primary resource documents a valuable, authentic learning tool. Through the integration of the laptop with the primary resources, students are making personal connections with their own learning.

Introduction

Media literacy is well established as a curriculum component in every major English-speaking country in the world, except for the United States. Fortunately, in the last several years, that has begun to change in the U.S. (Tyner, 1998; McBrien, 1999). Media Literacy, defined as the ability to access, analyze, evaluate and produce communication in a variety of forms (Aufderheide & Firestone, 1993) has begun to be addressed in state standards, the K-12 classroom, and teacher education. (Kubey and Baker, 1999; Hobbs, 1998).

In an earlier paper (Brownell & Brownell, 2000) we discussed the development of a master’s level graduate course, Media Literacy Across the Curriculum. This paper reports on experiences in teaching three pilot offerings of the course to two different populations.

Two pilot offerings were taught to students enrolled in a Master’s of Education in Classroom Technology program. This program, which follows national guidelines developed by the International Society for Technology in Education and adopted by the National Council for Accreditation of Teacher Education, offers teachers the opportunity to gain in-depth knowledge and experience with technology as applied to K-12 education. It also prepares graduates to serve as technology integration specialists in their building or district.

One pilot offering was taught to students in a Master’s of Education program in Teaching and Learning. This program is designed to offer teachers an opportunity to gain in-depth understanding of the teaching and learning process, including relevant aspects of modern curriculum studies as well as aspects of various instructional techniques. Students apply this understanding, on a practical basis, to their professional experience in their chosen area of education.

Basic Principles

There are several basic principles and ideas that form the basis for this course. First, regarding media messages, key concepts of media literacy have been identified as follows: 1) All messages are constructions; 2) Messages are representations of social reality; 3) Individuals negotiate meaning by interacting with messages; 4) Messages have economic, political, social and aesthetic purposes; and, 5) Each form of communication has
unique characteristics (Hobbs, 1997). Second, the course is taught using the acquisition model of media literacy, wherein media are viewed as opportunities to explore and gain skills to process such constructions in a mindful way, rather than as products that manipulate individuals and groups (Desmond, 1997). Third, a hands-on component to the course is essential so that media literacy concepts can be better understood. By producing media, we can gain a better understanding of the sea of media in which we swim daily. Additionally, producing media is beneficial in that it is a powerful, empowering experience. Fourth, media literacy is viewed as a set of concepts and techniques that are integrated into the existing curriculum - media literacy is not taught as a separate subject. Fifth, such a course offers an important opportunity to view technology beyond just the computer - for example, still cameras, camcorders, stand-alone DVD players, audio recording devices in various formats, etc. Sixth, media literacy allows people to begin to understand the many literacies we actually need to develop to fully function in modern society (Tyner, 1998; Considine and Haley, 1999). Such literacies include alphabetic literacy, visual literacy, technological literacy, and so on. These literacies do not exist, or function, in isolation. Multiliteracies are prevalent and powerful in our society and attention needs to be paid toward developing all aspects of the various literacies needed to function in our society. Seventh, and most important, media literacy offers a new way to see the world. Media, especially in our society, are everywhere, to the point of being such a part of our lives that we rarely notice them, let alone break them apart and analyze them as constructions. This is important also because as increasingly powerful technologies such as the web and digital, interactive TV become more widespread, they need to be understood as the powerful constructions they are. This is essential if they, and other media, are to be useful and used by society, rather than allowing such media to be used for the manipulation of individuals and groups. As participants start to see media as constructions they gain a new view of their daily experiences. This can be a truly amazing, transformative experience.

Since the principles and concepts above include some production experience, the practical issue of equipment must be addressed. Ideally, each participant will have his or her own set of equipment including, but not limited to, a computer and appropriate desktop video software, a digital camcorder with an assortment of associated external microphones, necessary blank media, an instant, film-processing still-camera, and a minidisc or cassette portable recorder. In our case, we were able to obtain five sets of equipment which we use in-class and which are signed out to self-selected groups of students to use outside of class. Fortunately, the learning curve for the iMovie software is not steep and students can readily learn the skills needed with the software in order to apply the concepts covered in class. In the future we intend to both increase the number of sets of equipment available to students for check-out as well as upgrade the computer labs and camcorders, etc., available on-campus.

Experiences: M.Ed. in Classroom Technology Groups

Experiences in the pilot courses offered to students in the M.Ed. in Classroom Technology program have been insightful. Comments such as the following are common from participants: "I now see the news and TV in a new way and see why my students need this content and these skills," and, "I never considered the amount of media I'm exposed to everyday and that they are constructions that can have a wide variety of purposes."

It is obvious to us that participants see the need for the course and for media literacy across the K-12 curriculum. Participants have said, "This is exactly what this program needed!" In one of the two pilots cited here, and in another currently being taught, a number of students who completed the M.Ed. program and graduated, have returned to take this course immediately after graduation. It is also obvious that, especially because of participants' interest and background in technology, the technical skills required are easily learned with little direct instruction in-class. Once the background technical skills and relevant concepts are operative, a process of production, group analysis, and more practice takes the students a long way into successful work with video as stand-alone movies on tape, via the web, and as clips within presentation software. Further, this production aspect complements the other content in the course and opens ever increasing doors to integrating media literacy into the curriculum.

Experiences: M.Ed. in the Teaching and Learning Group

The M.Ed. in Teaching and Learning group provided insights for which we were not prepared. First, albeit they were a self-selected group, their ability and previous experience with technology was at a much
higher level than expected. This made the hands-on portion of the course flow effortlessly. They were fluent with technology and applied that fluency to those aspects of the course. Second, their understanding of the scholarship and intellectual underpinnings for media literacy was exemplary, as was their facility (and excitement) in finding ways to integrate media literacy into the curriculum. Upon reflection, given the focus of their M.Ed. in Teaching and Learning program this should have been expected. (Their program is designed to offer an opportunity to gain in-depth understanding of the teaching and learning process, including relevant aspects of modern curriculum studies and various instructional techniques.) In any event, it helped to make the course a success for all concerned. The course is now regularly offered as an elective for the M.Ed. in Teaching and Learning program.

Sample Tasks

The following are tasks that are part of the course. Each is briefly annotated to give a sense of the activity. Obviously, students receive written and verbal instruction and clarification for each task prior to commencing work on the given activity. Also, activities are sequenced to occur after relevant content has been covered in the course and all tasks are approached from a media literacy perspective.

Discussion Sheet I & Discussion Sheet II - Each student, per specified criteria, prepares one discussion sheet for each of two chapters in the main text used in the class (currently, Tyner (1998), and then leads (along with a partner if so assigned) a discussion on the content in that chapter. A variation of this activity is sometimes used to conduct the discussion via the group's listserv as either a structured or an unstructured discussion.

TV ad assignment - Each student tapes and presents a current TV ad which is analyzed by the group.

TV analysis assignment - Each student, per specified criteria, analyzes and presents that analysis of a TV show of any type (sitcom, drama, talk show, news, documentary, etc.)

In-camera edited Video/Curriculum Creation - After learning and practicing in-camera editing techniques, participants design an assignment integrated into some area of their current curriculum that incorporates the camcorder and in-camera edited techniques.

iMovie creation #1 and iMovie creation #2 - After a tutorial on iMovie, for #1 students create a movie on a topic of their choice that is shared with and analyzed by the group. For #2, students create an ad using iMovie that is shared with and analyzed by the group.

Web-site analysis - Participants 1) identify and provide an annotated list of web resources on media literacy; and, 2) choose either a self-promotion site, an advocacy site or a city site and analyze the site per media literacy concepts.

Major Project - Students choose an area of the curriculum and devise ways to integrate media literacy concepts and techniques into that area of the curriculum and either: 1) present a product demonstrating such potential integration in the future, with an explanation regarding media literacy concepts; or, 2) present material as in number one, plus present student products from implementation of the integration of media literacy into the existing curriculum.

Sample Schedule

Two of the three pilots have been taught using an alternate week format. In this format, students meet in the evening for five hours once every two weeks throughout the semester (including a brief dinner break). The following detailed schedule is offered to give a feeling for the flow of the course. (Time for each activity is approximate.) It is offered with the usual qualifications: 1) the course is always changing (materials, currency of topics; etc., 2) "flexible purposing," is readily employed, i.e., if something of great educational benefit develops during a session, it is explored and exploited. For example, during the 2000 presidential election, unforeseen but beneficial experiences regarding media literacy were readily followed as they appropriately arose. Also, note that each section had the video equipment available for one-half of the course. Since the course is designed to be approximately 30% hands-on, this presented no problem.

Meeting #1

1. Course Introduction -
Syllabus and Introduce Discussion Sheets/Sign-up for two chapters (30 minutes)
Intro to Media Literacy (70 minutes) - Brief Slide Show plus Renee Hobbs tape
II. In Camera Editing
Terminology/Concepts - slide show (30 minutes)
In-Camera Editing Activity (60 min. - planning/shooting)
In-Camera Editing Activity - Share/discuss/analyze and Equipment Check-out (80 minutes)
Assignment for next class in two weeks - Read Chapters 1 & 2 of Tyner. Locate a place in the curriculum to integrate an in-camera edited assignment - write-up a 1 - 1.5 page description/debriefing questions, shoot the video as if you were the student. Submit in VHS format!

Meeting #2

I. Discussion of Tyner Chapter 1 (30 min.) and Tyner Chapter 2 (30 min.)
II. Submit in-camera edited video assignment/share/analyze/discuss (60 min.)
III. Video Editing on the Computer and Equipment Check-out (2.5 hours)
Assignment for next class in two weeks - Read Chapters 3 & 4 of Tyner. Play with the digital camcorder and the iMovie software and prepare a brief product (your choice) and a 1 - 2 paragraph description of your product. (May be done in pairs and/or one triplet.) Bring your product for the next meeting, on VHS tape!

Meeting #3

I. Discussion of Tyner Chapter 3 (30 min.) Tyner Chapter 4 (30 min.)
II. Share/analyze/discuss iMovie product (60 minutes).
III. Photography -
Still Images - Concepts for Analysis (10 minutes)
Tell a story in images (Use Polaroids) (50 minutes)
Share photographic story/Photography in the Classroom Ideas and Resources (Brainstorm) (30 minutes)
Photography in America - Depth and Perspective (1 hour video)
Assignment - Read Chapters 5 & 6 of Tyner. Create a video ad using iMovie. Generate a shot list, shoot and edit the video. Bring your product for next meeting, on VHS tape!

Meeting #4

I. Discussion of Tyner Chapter 5 (30 min.) Tyner Chapter 6 (30 min.)
II. Share/analyze/discuss iMovie ad creation (45 minutes)
III. Equipment Check-in! (15 min.)
IV. TV in the culture and the classroom
TV viewing survey (30 min.)
TV as Curriculum (Video, handouts and discussion/ resources/activities re/ TV in the classroom - 90 minutes)
Introduce final project assignment (30 minutes)
Assignment for next class in two weeks - Read Chapters 7 & 8 of Tyner. Watch one TV show of one of the following types - sitcom, drama, talk show, news, documentary, or other of your choice, and answer the relevant (supplied) media literacy questions (and others you may generate) and devise one strategy for integrating the show you watched into the curriculum. (Note: Center for Media Literacy, and medial listserv.)

Meeting #5

I. Discussion of Tyner Chapter 7 (30 min.) Tyner Chapter 8 (30 min.)
II. Share TV show assignment (60 min.)
III. Ads and advertising
"The Ad and the Ego" video/discussion (90 min.)
"Production Notes"/discuss OR Analyze current ads activity (60 minutes)
Assignment for next class in two weeks - Read Chapters 9 & 10 of Tyner. Tape one TV ad you either love or hate. Bring the tape (VHS format) to class next week and be prepared to discuss: 1) why you love/hate the ad; and, 2) how you might integrate it into the curriculum. (You may want to look at the “AdCritic” web site or a similar resource for background.)

Meeting #6

I. Discussion of Tyner Chapter 9 (30 min.) Tyner Chapter 10 (30 min.)
II. Share/analyze TV ads (45 minutes)
III. Introduce web site analysis assignment (15 minutes)
IV. "Reading the Movies" Concepts/Activity (150 minutes)

Assignment for next class in two weeks - Complete the web site analysis (from a media literacy perspective) assignment.

Meeting #7

I. Share and discuss the web site analysis (from a media literacy perspective) assignment. (60 minutes)
II. "Reading" the News activity (30 min.)
III. "Reading" the News - video, discussion (90 minutes)
IV. Music Videos and Messages (90 minutes)

Meeting #8

Final Project Presentations/Closure

Conclusion

In consulting with a national figure in media literacy during course development, we were warned that very quickly we would see the need for additional courses in this area. That has been our experience, exactly. In this one particular offering there is always a feeling that more time is needed. (Not uncommon for any instructor in any course!) However, given the positive student response across both programs, the wide range of media literacy topics, the many appropriate opportunities to integrate media literacy into the K-12 curriculum, and the exciting possibilities with digital camcorders, especially when paired with desktop video, we are now investigating the development of a second course in this area. In the current course, with a mix of 70% concepts and 30% hands-on experiences, students gain a firm grasp of the scholarly issues and research supporting media literacy, solid technical skills, and awareness of various opportunities for the practical application of media literacy in the curriculum. One possibility we are considering is flipping course content in a second course to yield a mix of 70% hands-on experiences (developing increased, inDdepth facility with desktop video) and a 30% concepts portion developing an increased understanding of issues, research, scholarship, and applications in the curriculum. Whatever happens next, we are off to a good start and look forward to more positive experiences with future participants in the existing course.

Florida State University
School of Information Studies

Abstract: The purpose of this institutional session is to acquaint the audience with the opportunities for contextual learning through web-based instruction for school library media specialists by the Florida State University School of Information Studies. It includes a justification of need and an overview of the certificate and degree programs that meet these needs. The web-based interface and tools employed are demonstrated and their pedagogical framework is discussed. Finally, specific examples of the ways that contextual learning principles are incorporated into a sampling of four of the courses included in the program is provided.

Introduction

Contextual learning through web-based instruction for school library media specialists has been a goal of the Florida State University School of Information studies for four years. In this paper, we provide a justification of the need for such an approach, and an overview of the certificate and degree programs that meet this need. The web-based interface and tools used by the School to deliver all of its degree programs are introduced and the pedagogical framework is discussed. Finally, specific examples of the ways that contextual learning principles are incorporated into a sampling of four of the courses included in the program is provided. These courses include the Instructional Role of the Information Specialist, Information Needs of Young Adults, School Media Collection Development and Management, and Design and Production of Network Multimedia. Each course demonstrates a unique approach to incorporating context into pedagogy and learning.

Justification of Need & Overview of Certificates and Degrees

In many areas in the state of Florida, as well as in other parts of the United States, there has been a critical shortage of school media specialists for a number of years. In addition, school media specialists who have been successfully working for years find themselves faced with new opportunities and responsibilities related to the rapidly changing information landscape of the past decade. One solution to meeting the needs of both these groups is to provide learning in context. Recent developments in web-based Internet technology make it possible to support learning about information technology and its use through information technology.

Preparation of the school library media specialist is normally accomplished through the completion of the forty-two hour master's degree in library and information studies. Students may opt for a certificate that requires just thirty credit hours, but do not receive the monetary rewards that many districts provide for those who complete graduate degrees. For those students who currently hold a master's degree
in another area, the post-master's specialist in education degree, also thirty credit hours, is an option for preparation that often brings with it the monetary rewards that accompany the completion of an advanced graduate degree.

The Florida State University School of Information Studies has developed web-based distributed learning degree programs to serve certificate, master's and specialist students regardless of their physical location.

The delivery interface has been custom designed and the support tools carefully selected to support contextual learning principles. Students learn about information technology both formally in the two production courses required by the state, and informally through using the technology to support their own learning.

**Interface and Support Tools**

The interface used to deliver all courses was developed in-house and has been widely recognized both nationally and internationally. The development of the interface included a conscious application of contextual learning principles. At each stage of development, focus group interviews and usability testing were conducted. Informal feedback, in the form of unsolicited email messages, "Tell the Dean" sessions and exit interviews, was also collected. There have been four major revision cycles that have occurred based on the analysis of the formal and informal data.

The current version of the course website makes use of a database backend and ColdFusion technology to power its operations. The interface incorporates HTML frames to create a consistent "window frame" through which students view the course. This window frame includes a set of navigational buttons that enable the student to move easily through the different elements of the course, including the calendar, syllabus, resources, discussions, assignments, announcements, communication, help and home. When the student first logs on to the website, and until s/he acknowledges that the syllabus has been read, the syllabus appears in the main window. Once this acknowledgement has been recorded, the student's primary view of the course is through the course calendar.

Custom-designed support tools support both the students' learning and the faculty's teaching needs. Tools to support two formats of communication—synchronous and asynchronous—are included in the course websites. Synchronous communication is handled through the incorporation of a commercial product known as ichat, while asynchronous communication is handled through a home-grown threaded discussion tool originally written in PERL. Discussion boards are organized into three major functional groupings: The Faculty Office, The Technical Discussion Area, General Discussion Area, and Special or Small Group Discussion Areas.

Also integrated into the course websites are tools to support learning assessment. These include the capability to compose, deliver, provide feedback, and automatically grade multiple-choice and true/false tests; track attendance and participation in the synchronous communication sessions; deliver, submit, and grade assignments online; as well as an electronic gradebook that may be maintained throughout the course and enables the student and the instructor to receive both interim and final grade reports. The assessment tools are fully customizable to suit pedagogical styles and objectives.

The most recent developments in the interface relate to support for research. The interface was modified to conduct a delphi study on leadership characteristics in the library and information studies field in 2000. Logging of interaction files, including synchronous and asynchronous communication, has provided the basis for a pilot study on interaction in distance learning that was conducted in 2000. A coding scheme for analyzing the content of these interactions was developed during the pilot and will be incorporated into the website in 2001.

**Integration of Contextual Learning in Four Selected Courses**

**Teaching Information Literacy by Becoming Information Literate: The Instructional Role Context of the Information Specialist**

Paul Zurkowski, the president of the Information Industry Association, first used the term "information literacy" in 1974 (in Loertscher and Woolis, 1999, p. 1). He described information literates as 'people trained in the application of information resources to their work...They have learned techniques
and skills for utilizing the wide range of information tools as well as primary sources in molding information-solutions to their problems.” (Zurkowski, 1974, p. 6). The American Association of School Librarians, in Information Power: Building Partnerships for Learning (AASL, 1998) identifies four roles for the school library media information professional: teacher; instructional partner; information specialist; and program specialist. In addition, the organization promotes nine information literacy standards for student learning, with attendant indicators for each standard. By incorporating the use of computer, telecommunication, and graphic technology along with standards for information literacy into each assignment, students learn contextually or by application.

The Instructional Role of the Information Specialist is a course designed to promote the use of a process approach to teaching and learning. The course website directs student attention immediately to the textual course introduction, as well as the Asynchronous Activity Real Audio/Power Point presentation. Using Information Power as a course text, and information literacy standards as a theoretical basis for teaching and learning, students are guided through the completion of seven assignments that reflect information literacy standards. All assignments may be submitted electronically directly to the course website, depending upon the presentation format selected by the student as being appropriate to the individual assignment.

In the first assignment, for instance, students are required to complete a survey form in which they provide information relating to previous, current, and hoped for career employment and interest areas. This brief assignment is designed to assist in meeting the instructor’s need for information – i.e., the various levels of experience, background, and career direction of class members, in order that course work and assignments can be individualized to the greatest extent possible. Two other assignments direct students to locate, examine and analyze information from a variety of sources and in a variety of formats as a prelude to assignments that follow. Students are directed to web locations, electronic databases, and print resources at which teaching models, instructional models and lesson plans can be found. Students select eight plans or models that are pertinent to their area of interest, and document their selection by means of an annotated bibliography or webography, which is submitted electronically to the course website.

After defining the need for information, determining possible sources for that information, locating and evaluating the information, students then begin to use the information they have located by designing their own teaching unit or instructional model, incorporating information literacy skills into that unit. The completed unit is submitted electronically to the course website. After the unit is evaluated and approved by the instructor, the student then proceeds to deliver or present the teaching unit or model, documenting the delivery either by video taping the presentation and mailing the video tape to the instructor (students are permitted to “send” the video tape via the course website if they have the appropriate technology available) or by creating a Real Audio/Power Point presentation, submitted electronically via the course website. Two additional assignments require that students prepare and present a lecture/demonstration of an electronic database, computer program or other instructional technology, and a lecture/demonstration or written material promoting or publicizing an event or service offered by their institution or organization, using appropriate technology to deliver their presentation to the instructor. Students generally prefer either video tape or Real Audio/Power Point as delivery mechanisms.

By integrating information literacy and technological literacy skills into each assignment, students become adept at locating, preparing and organizing information from a variety of sources for presentation to others. They are encouraged to work collaboratively with subject area specialists (classroom teachers) in the preparation and delivery of the teaching unit or lesson. While assignments are designed for individual student completion, class discussion, or IChats, are frequently organized in small group format to enable students to more easily synthesize, analyze and assess or evaluate the discussion topics (information).

Understanding the Information Needs of Students: The Young Adult Context

Information Needs of Young Adults is a course required for all school media candidates, but the course enrollment includes a variety of others students, including those intending to become library administrators or public library children’s specialists. A few students enroll out of personal interest. The course is an overview of the characteristics and the information needs of young adults and the resources and strategies that may assist adults and youth in meeting these needs. Five developmental stages of young adults are taken into consideration in understanding their information needs: intimacy, intellect, independence, identity, and integrity. The course starts with a historical overview of resources, after which four weeks are spent identifying the information needs of young adults ages 12 – 18. The remainder of the
course explores resources categorized by both genre and developmental stage to meet the identified needs. Numerous strategies and employed in the course to assist the students to advance their skill in employing technology in the context of learning. Assignments and discussions capitalize on web resources.

Students are asked to read articles about the information needs and resources for young adults. A number of these students are available through a virtual library—consisting of either article for which permission has been sought and granted or links to articles from the reading list that appear in various places on the web. The advantage of reading the articles on the web is that links to other related articles are embedded. The content of the article is greatly enriched because of other sites. For example, a web-based article on graphic novels for teens might link to other bibliographies, conventions, essays, news groups, and reviews; to information on legal issues in graphics publishing; or to critical information on both the art and the business of comics publishing for more than 20 years, all within easy reach of the reader. Numerous young adult novels and non-fiction books are assigned for reading during the semester. Students submit a read and react on a web-based form that is available for other students to read. Links to these reactions are posted in the windows in the synchronous discussions “rooms,” and serve as the basis for group analysis of the readings. Each week there are both small group and large group discussions of the week’s readings in chat rooms. To supplement this photos of young adults and interviews with them are posted on the web site, and teens are invited to participate in at least one online session with class members. Interviews by experts in the field of young adult resources are interviewed and visit live chats also. These exercises emphasize using the web as a communication tool.

The mid-term consists of a booktalk by students. Two methods are given for submitting the audio portion of the booktalk. Students may record it on an audiotape and mail it to me or they can send it as an audiofile. Other students are required either to read a written form of the book talk submitted via the web (required of all regardless of the audio format) or to listen to the audio file if it is posted on the web. They meet in groups to discuss and critique the booktalks submitted by others in their group and in the class as a whole. Once again the submissions are posted in the iChat windows (and in the assignment index) for others to read. The web technology allows students to easily see what their classmates have done without endless (and really impossible) paper duplication. The web technology extends the efforts of each class member and makes the teaching of critical evaluation skills easier and more authentic.

The final assignment is to read five books written a winner of the Margaret A. Edwards Award for Young Adult Literature given annually by the Young Adult Library Services Association of the American Library Association and to read literary critiques of their works and to relate biographical information about the authors to their writings. This leads the students into research using the web, as they turn first to web resources for the listing of the award winners and their books, for the availability of the books in online catalogs to which they have access, for the critical reviews of their books, and for biographical information on their authors. In the course of doing the assignment they hone their searching techniques and their evaluation of resources on the web. Each student writes a summary of his or her paper that is posted for other students to read and discuss during the last night of class. Students are allowed to request electronic copies of their classmates’ papers.

School Media Collections in the Information Age: The Collection Development and Management Context

School Collection Development and Management is required for all students seeking school media certification. Many of the class are working either as classroom teachers are in school media centers with out-of-field certification. Occasional other students, particularly those who will work with youth in public libraries or those focusing on collection development and management take the course. The course is an introduction to the principles, policies and applications of collaborative school media management, including the national, state, community and school contexts that affect a media specialist's selection, evaluation, acquisition, access to, and maintenance of resources in a school media program. The assignments in this course are particularly conducive to contextual learning.

The students are asked to sign up for three electronic discussion and news groups during the first month of the course, to monitor them, participate in them only if they have professional questions or items to add (not as a student assignment), and then to prepare an analysis of their experience, including the usefulness to a practicing school media specialists. The first of the three groups is AASLNews. This is a read only and only moderately active news sources that comes from the American Association of School Librarians. It is particularly useful for information regarding legislation, grants, conferences, and
publications relating to school media center resources. The second is LM_Net, a listserv that has more than 12,000 participants involved in school media work. It is available in digest form which I advise the students to use because of the overwhelming nature of the information, much of which relates to collection development and management issues. This is the electronic resource that the students find most useful because of the vast array of professional knowledge on virtually any related topic that is available to them. Most say they plan to continue their subscription. The last source is Education Week which using push technology sends a summary of the week’s news in education to those who sign up with links to the full text publication and articles of interest. This provides context for the students as they student the many issues affecting collection development in media centers. I also ask the students to explore the AASL site as it has links to curriculum connections and numerous other types of resources.

The other two major assignments relate to the collection development and management policy of the Bellingham Washington Public Schools, an exemplary but not perfect district policy in a state that also offers important guidelines. In one of the assignments, the students focus in on the Instructional Materials Selection Policy of Bellingham and compare it to the American Library Association guidelines, also online at the ALA site, critiquing its inclusion and omission, based on what they have learned in class and from their textbooks, readings, and lectures. The second assignment asks them to look at the extensive collection management document (more than sixty pages if printed) and to analyze it from a number of different angles. Between the time I taught this course in the summer 2000 and in the fall 2000, the Bellingham Public Schools had updated their document, so it is a “living resource” that again brings authentic learning through the web to the students and alerts them to the vast resources available.

Because many students in this class are already somewhat knowledgeable in their topics and many have school experience, asynchronous discussions using a web board feature on the class site allows in depth sharing of professional knowledge. One such assignment asks the students to discuss experiences with or questions about censorship. Part of the discussion has them analyze two of six censorship cases studies in an interactive mode. The second asynchronous assignment asks them to read one research article from School Library Media Research, an online research journal, and from Knowledge Quest or School Library Journal (more practitioner oriented journals) and to discuss them on the web board. There are specific guidelines for the expected form and amount of participation and both discussions last a week and require a culminating “what I learned” statement from the students. Students identify this as one of the most valuable activities of the course. It allows them to capitalize upon the expertise within the class with guidance from what they have learned through the course work. This emphasizes the web as both a source of information and an extraordinary medium for communication. Synchronous discussions are held also.

Mirror to Glass: Reflections the Web as an Information Context

Logging into the Design and Production of Network Multimedia course website, Florida State University, School of Information Studies students are automatically directed to the course calendar. New to the world of designing and developing products for the Web, the students’ conceptual understanding is limited to what they see within a web-page document. Thus, their understanding of a web-based multimedia document is surface-level. Unfamiliar with the intricacies of technology such as HTML, Metadata, CGI, graphic and audio files, the webpage at the students’ current level of understanding is like a mirror reflecting back an image of the information presented.

Using the web as a teaching medium, enhanced with synchronous and asynchronous communication formats, the students and instructor work in a collaborative fashion to learn web-based multimedia technologies. Two assignments are submitted with students working individually to produce a product. Simultaneous to the learning of the specific technologies presented in the course, students are introduced to the methods of group work processes. Assigned to groups, students work in collaborative teams to design and develop a prototype product for a specific client.

The course commences with HTML as the primary topic. Using visual presentation format such as PowerPoint slides in conjunction with the National Center for Supercomputing Application’s Beginner’s Guide to HTML website, students embark on an adventure in learning to create web-based documents. Using the hand-tagging method, by the end of the third class session each student has created a simple yet complete webpage. The product is a resume contributing to the development of their professional portfolio.

Building on the foundation of knowledge in HTML, students continue learning technologies that enhance the basic website. Students are introduced to Unix, metadata, CGI, graphics and audio allowing for the incorporation of interactive components that enhance the transfer of information via a web-based
document. Particularly interesting is that the teaching of these technologies utilizes the media as a tool of instruction. For example, the audio portion is taught by presenting a webpage produced by the instructor. Students are directed to this website from the Ichat room. Once at the site the students will find a brief textual introduction followed by a button labeled “sound byte.” Students proceed to listen to a brief audio lecture of the instructor explaining how to incorporate a sound file into a web document. At the end of the sound byte students are directed to view the code for the webpage and note the HTML code used to present the sound file. Essentially, the instructor is using network multimedia as a vehicle of instruction and as a teaching tool to demonstrate to students how to create network multimedia products.

Figure 1: Utilizing the Media as an Instructional Tool

<td>Incorporate audio component</td>
<td>Audio component</td>
</tr>
</tbody>
</table>

As a result of the instructional process outlined above, the students’ understanding of the technologies used to present information on the web is raised to a level where they know how a webpage is produced. Thus, students move from viewing a webpage as a reflection of content to seeing through the page to the intricacies of multimedia used to present information. In a sense, the webpage becomes transparent allowing for a better understanding of the best methods to use in the provision of information via the Internet.

Conclusions

Each of the four courses examined in this paper: Instructional Role of the Information Specialist, Information Needs of Young Adults, School Media Collection Development & Management, and Design & Production of Network Multimedia, provides an important role in the successful web-based delivery of contextual learning to school media library specialists. Through participation in this program, potential school media library specialists learn to teach information literacy while becoming information literate themselves; expand their understanding of the information needs of different populations while learning about the information needs of young adults; learn the principles of collection development and management in the dynamic and sometimes volatile context of the World Wide Web; and are empowered to see through the mirrors of information contexts through participating in the process of designing and building information contexts themselves. School media library specialists are empowered to lead their schools into the 21st century through contextual learning on the World Wide Web.

Information Technologies in Teacher Education

Sarma Cakula
Vidzeme University College
Latvia
sarma@valmiera.lanet.lv

Abstract: Despite of immense and positive changes in schools in Latvia over the past years, the school situation is still characterized by various difficulties. There is clearly a need for in-service training in a modern, non-soviet and democratic way for teachers in the region. Our idea is making an interactive course including combination of Computer Science Didactics, attitudes – Values and Teaching methods. We have international group of Swedish and Latvian teachers who finished first part of this course.

Introduction

European scientists as one of the general targets in higher education for 21st century set that education should be more elastic to divide resources and reshuffle potential accordingly requisition which related with enlarge area of using new technologies (Teichler, 1996). Social function of education is to organize all-rounded personality development with recent knowledge in determined profession. At that moment exist some objective contradictions:

1) between individual intellectual and physical potential from one side and limited time and economical facilities from other side,

2) between tendency to independence in selection of knowledge and existing professional forms and methods of processing new specialists now,

3) between quantum of information and superficial knowledge from one side and quality of practical acquirement in teacher profession from other side.

Perpetual problem of existing teaching system in former soviet countries is expeditious and factual moral aging of acquired knowledge apropos of dynamic technological and organizational process oriented to west countries. In process of acquiring education go awry combination of values and norms with knowledge, skills and mind development in whole which could ensure harmonic and humane development of personality. The dominant of education content is far from function unity (Karpova, 1994). Many psychologists and educationalists have a view that the information technologies (IT) is the beginning of radical upturn in the education. There is a way for free education and we need to talk about social dimension in learning process using IT.

An information system of Latvian education is currently being implemented in Latvia which will be a substantial input in the improvement of the technical facilities of the school, and training the teachers to work with the new information technologies (IT). As the majority of the presently working teachers have never worked with the computers and on the Internet before, this will be a crucial turning point in the development of education in Latvia. However, short courses for teachers are not effective to implement IT into practice, neither will they help to solve many other problems arising in the schools in connection with IT.

Pedagogical practice constitutes a complex web of relationships between teachers and pupils and the social contexts that they represent. It is through the pedagogical action of teachers and pupils that knowledge development in a wider sense - the development of knowledge, attitudes and values - can come about in these social contexts. Today, there is general agreement in pedagogical research that pedagogical action essentially consists of communication. While many appreciate pedagogical action as an influential process centered on individual knowledge development directed towards a defined goal, others see pedagogical action as
communicative. To take a double societal perspective as a starting point means that pedagogical practice can be understood in both perspectives.

The study.

Before starting teacher international in-service course we research the situation in Latvia and Sweden and select general aspects and necessities for both countries. The present situation can be characterized in the following way:

- shortage of teachers in certain subjects;
- incompetence of teachers in using IT;
- lack of new practical teaching methods;
- unequal professional level of teachers in social sciences;
- shortage of teachers with professional pedagogical education.

What knowledge would be most necessary for teachers?

- Psychology (contact, empathy, self-evaluation) because there is a big routine in every day school life.
- Sociology, how society developments are interlinked for evaluating school programs.
- Pedagogics and didactics for teachers with special subject education.
- Teaching methods using new informatic technologies.
- Integrated teaching subjects and selection of useful material which supplement several subjects.
- Interactive teaching, group work and project as a method.
- Analytical and research skills, foreign languages (especially English), computer Science basic skills and work with the Internet, use of special computer programs in certain subjects, awareness and use of possibilities.
- Distance education, life long learning through IT, skills and knowledge to non-stop improve one's life quality (physical, mental, moral, material).
- Value orientation (I – the environment – the world), health education (dependence from various drugs, violence, rest).

A teacher in-service course had been developed. Main theories connecting with this course are democratic principles of education (Dewey 1994), philosophical action theory (Kagan 1974, Kvetnoj 1974, Leontjev 1977) and learning theory as a cognitive approach which connected to meaning and content significance of the information, logical arrangement of learning materials – construction theory (Bruner 1961, 1990, Piaget 1964, 1976).

Many changing processes are going in our society and in the result the goal of education becomes not to get a large base of knowledge but more important how to get knowledge. It changes learning process from illustrative and demonstrative (give knowledge in complete form) to problem oriented process (to get knowledge in incomplete form). When knowledge is incomplete, experimentation takes place to discover new knowledge about a particular domain. It means to develop research method in studying process. Research method contains identification of the problem, imagine the solution, realizing the research, evaluating the result and modification it in praxis (McNiff, 1993). This is the purposing process and studying at all is purpose oriented action (Eric de Corte, 1996).

Knowledge become more deeper and developing of skills more larger as a result of group work because students take part in studying process more dynamic. “Collaborative learning makes public our own learning, learning of others and learning of the group” (Manjanovic, 1999, p.130). It is also social and democratic process. Popular is face-to-face group work but it has some failings. Students who want to dominate enchain others to their ideas. International groups better exchange with ideas but they have more problems with language. It is possible to involve students in learning process more productively using the new information technologies and problem solving. The course is focused to using information technologies and problem solving in teacher in-service education.

It is famous to use the computer in learning process as a tool. One of most effective tasks in learning process are research task. It could be used in individual work searching for information, making papers, using practice programs to developing special knowledge and skills. Recent interest to learning suggests the possibility of integrating sociological and psychological approaches around a notion of learning as activity.
Lave and Wenger, 1991). IT here could be not only as information source but also to make interactive collaboration computer – student or student – computer – student (Light, Light, 1999). When students solve a problem together in pairs or small groups they think more effectively than when they work alone (Kruger, 1993). In group work in place to write an essays computer could be use as a tool for produce multi – media presentations involving graphics, sound and text, for produce a resource (as example data file) to be used by other students or for produce a learning pack for their peers. These new goals are too great for any one student to meet, but cooperative work is essential if we are to take opportunities on offer with classroom computers (Underwood, 1999).

Sometimes IT is seen as threatening to cut learning off from the interpersonal context which give it meaning and utility. A counter-argument that might be offered is that the community practices of student life are actually more threatened from other directions. Some of more interesting applications of information technology in education are those involving computer – mediated communication. This technology affords a possible means of providing for interaction between tutors and students and between students themselves (Light, 1999). The term 'co-operate learning' refers to learning environments in which small groups of students work together to achieve a common goal. It can be differ in two ways. The members of the group may choose to take responsibility for sub-tasks and work co-operatively or they may collaborate by working together on all parts of the problem. If the learners collaborate and share in the decision-making process the level of social interaction is necessarily high but it is not so necessary for co-operative workers. There are some positive effects in group work can be that learning under positive contact conditions can facilitate interpersonal relationships which may in turn have positive effects: on student motivation, self-esteem, academic learning. Some collaborative groups may be efficient because of conflict based mechanisms as Piagetian model (Piaget, 1985) and others due to co-constructive processes (Vygotsky, 1978). Howe develops Piagetian model, that when pairs of students differ not only in their predictions about problem outcomes but also in their underlying conceptual understanding then collaboration facilitates learning. O'Malley (O'Malley 1992) has shown that when a computer program makes different predictions then the human learner is more likely to show evidence of conceptual change than they do when that program either makes similar predictions or show similar conceptions. Learning in groups and with peers may be a more effective way of achieving some educational goals that individualize instruction especially in work with computers but here the important role play discussion. There are some researches which explore whether individual learning is facilitated in computer environments by interaction between students whose conceptions differ and whether the benefits are directly attributable to interaction. (Howe et al.,1992, Howe et al., 1995). There are also some concepts that the computer may facilitate productive interaction in a way that other media cannot, by dint of its capacity to maintain a clear task structure and to provide feedback. However, the studies also showed that in some contexts interaction may be of marginal significance, with shared action being crucial instead. It would appear that such context may be defined by a variety of factors, not all of which are readily controllable. It is though that the computer may still have a central role to play. Main factors which determine productivity of learning process are individual differences (gender, ability, thinking and practice skills, needs) and differ of the environment (group size, kind of task and organization, working room and environment, direction of study). Unified model of productive group work might need to establish how to promote shared action in more positive fashion and how to integrate it with interaction. It need to take both social or contextual factors and individual processes of cognition. Social exchange and joint action are crucial to group performance and individual learning, but at the same time individual perceptions, reflections and knowledge are key determinants of how interaction proceeded and what results it has.

In Latvia we have some problems in pedagogical work. Many teachers don't have an updated pedagogical education. There are many teachers that are incompetent in using IT. In some schools there is a negative atmosphere and attitudes between teachers and pupils are not very sound. Several schools have shortage of teachers in certain subjects. There is a lack of new and practically oriented teaching methods. The professional level of schools and teachers is very uneven, especially when it comes to social sciences. Vidzeme University College in serving as the main institution of higher education in the region of Vidzeme in close cooperation with Växjö University (Sweden) and Educator Training Support Center at the Ministry of Education and Science of the Republic of Latvia have decided to build up teacher education at Vidzeme University College. The emphasis is put on in-service training. The best solution for our courses we find the problem-based learning using IT.
Outcomes.

The main target group of students are teachers in primary and secondary schools in the region of Vidzeme and Vaxjo that have a need for updating their skills and knowledge. Each school makes a team of 4 teachers who works together on one problem. In first turn there are 8 Latvian and 5 Sweden schools with their small teams. The teaching staff will be made up of teachers already employed at Vidzeme University College and Växjö University. The first course started in November, 1999. The courses offered at Vidzeme University College was in the initial phase be taught jointly by Latvian and Swedish teachers. That is; during each class there are 1-2 Latvian teacher(s) from each part (values - attitudes, teaching methods, computer didactics) and 1 Swedish teacher in the classroom assisting each other. Such an approach secure an open dialog giving the teachers a very practically oriented way of learning from each other as well as comment on each other’s performance following the lectures. The Latvian and Swedish teachers do not teach only groups in Latvia. They do jointly teach groups of Swedish students (teachers wanting to upgrade their skills and knowledge) in the same subjects as taught in Latvia. That is; 1 Swedish teacher and 1 - 2 Latvian teacher(s) assists each other in teaching in classrooms at Växjö University. Such an approach opens up new and more practically oriented ways of educational cooperation based on comparative thinking.

The selection of study programs have been based on several factors:
- written recommendations made by teachers and school directors from schools in all parts of the region of Vidzeme;
- conversations between representatives of Vidzeme University College and Växjö University on the one hand and teachers and school directors at schools in Vidzeme on the other hand made during visits to schools in Vidzemes augstskola;
- observations made by representatives from Vidzeme University College and Växjö University;
- questionnaire conducted among teachers at schools in Vidzeme by teachers at Vidzeme University College.

The language of teaching during the courses in Latvia will be Latvian and English. The language of teaching during the courses in Sweden will be Swedish and English.

The course have the following content:
- **Computer Science and Computer Science Didactics** develops basic skills using computers and work with Internet, awareness of use of possibilities (use of special computer program in certain subjects, distance education, life long learning through IT).
- **Attitudes - Values** have orientation on values in the society, dilemmas of marked orientation, child and their development, gender equality, democracy, comparative analyses of equal/elite schools, attitudes towards drugs, alcohol and smoking, integration of pupils with social/mental and physical handicaps.
- **Teaching methods** deals with integrated teaching subjects, interactive teaching, subjects methods, selection of material, project as a method and group work, teaching with integration of pupils with social, mental and physical handicaps (dyslexia). These three courses are linked towards each other.

There are 4 face-to-face two-days sessions for each group Latvian and Sweden when students have some lectures, practical works and group work. Two sessions are together for all participants (1 session in Vaxjo and 1 session in Valmiera) when students work in more larger groups - one or two schools from Latvia side and 1 school from Sweden side. All the time teachers organize and help the student learning. During the time behind sessions students cooperate using e-mails and small group work inside the school. Each session have been finished with a questionnaire about course evaluating, problems and benefits. One of the benefit is
rising teacher's skills using IT.

Table 1: Evaluation of student's skills using IT before the course starting point and after last session.

Conclusion.

As a result of questionaires we found some general inferences which can divide in two groups: student and teacher perspectives.

Student perspectives: 1)positive experience (learning becomes engrossing), 2)develops problem solving skills, critical thinking and cooperative learning, 3)in international groups language problem becomes inconsiderable, 4)if students take part in preparing process then cooperative tools and communication becomes clearer, 5)students emphasize other learning tools not only books, 6)increase studying quality and versatility.

Teacher perspectives: 1)learning process is going in both directions, teacher can teach and learn in the same time, 2)in preparing process all should be planned more detailed, 3)cooperating using IT should be test in various directions.

Vidzeme University College and Växjö University are open for cooperation with other universities; especially with existing universities and colleges involved in the two institutions' Nordplus and other European networks.

REFORM IN GRADUATE SCHOOL TECHNOLOGY PROGRAMS

Cellestine Cheeks, Ph.D.
Department of Reading, special Education & Technology
Towson University
United States
ccheeks@towson.edu

Abstract: This paper presented a summary of research that was collected over a two-year period for the purpose of evaluating a graduate School Library Media Program. Reform in professional education programs that train school library media specialists provides opportunities to eliminate the disparity between job competencies taught and job competencies required by school library media specialists in their jobs. Because school library media services radically changed its emphasis at the end of the second millennium, from focusing on resources to students to creating a community of lifelong learners, it is essential that professional programs that train school library media specialists keep pace with current job demands. Program evaluation that lead to a redesign model which prepares graduate students for their roles as leaders and directors in today's technology-centered schools was needed.

Introduction

The changes that have occurred in society and the pervasiveness of technology during the past decade have resulted in massive changes in education and school library media programs. The functions of school library media specialists have been influenced by an emphasis on students and their learning. K-12 students look to their school for the content of knowledge and ways of accessing it made possible by advances in information technology. The American Association of School Librarians and the Association of Educational Communications and Technology advocated the creation of a community of lifelong learners that utilizes information literacy—understanding how to access and use information—as the core element for achieving lifelong learners. Their model, Information Power, identifies three elements needed in library media programs: 1) learning and teaching; 2) information access and delivery; and 3) program administration (1998).

In a 1995 study (Karp), competencies needed by media specialists in media centers were summarized. Curriculum reform involved a systematic process of evaluation and redesign, which included an examination of the catalyst for change, an instructional model used to collect information on the existing program, data analysis and curriculum construction. The standards recognized nationally for school library media programs are Information Power. The current edition of Information Power (1998) identifies three major elements of the library media program reflective in the library media specialist’s role: learning and teaching, information access and delivery and program administration. Included in Information Power is the Information Literacy Standards for Student Learning and serves as the foundation for effective library media programs. These Standards firmly establish the library media specialist as an essential partner in fostering student learning. The role of the professional is one involving collaboration, leadership and technology—the unifying themes for partnerships in the information age (Maney, 1998).

The question that we asked ourselves was to what extent was our professional program preparing our graduates to assume the partnership roles in learning that Information Power: Building Partnerships for Learning identified? Woodruff (1994) suggested that school library media specialists who had been out of school for longer periods of time than recent graduates needed more up-to-date competencies on the job more often. Were we producing graduates who could fulfill the role of partner in teaching and learning, information access and delivery and program administration? Where in our program could we document authentic experiences that would allow students to observe and model the necessary knowledge, skills and abilities?
The research described in this paper sets out to evaluate our current program using a collaborative perspective. It further details the methods used to collect and analyze data from our major stakeholders throughout the state. And finally it presents a curriculum design model for our school library media program that will support our national and state standards, and therefore provide the foundation for building and sustaining partnerships for learning.

Background of the Study

The Graduate Program in School Library Media is currently the largest provider of certified school library media specialists in the state. The program attracted excellent student graduates who now serve as leaders in their schools, districts, and in the state. Because the program began in 1974 and had not undergone systematic revision, this evaluation was warranted. New courses have been however, instructional design principles have not been applied across the board. A total redesign was needed to meet the needs of school library media leaders for the 21st century. The program needs to provide the foundational, technical and instructional knowledge that graduates will need to continue to be leaders across the state. Based upon the model recommended, graduates will be able to effectively shape schools for the next generation of students in K-12 settings.

The goal of this project was to evaluate the current graduate program in School Library Media and to revise it based upon evidence from the data collected. To accomplish this goal several steps had to be undertaken: 1) an analysis of the current program; 2) data collection from the primary stakeholders reflecting their job performance of SLM specialists; 3) an analysis of the data; 4) a re-evaluation of the program in light of the data analysis; 5) implementation of recommendations as a redesign of the curriculum.

Research Methods

There are early indications that establishing collaborative teams can have great potential for affecting change in the way we introduce innovation to the system (Wagner, 1998). To begin the process of evaluation of the program, faculty in the Instructional Technology Program examined the objectives of each course and identified The Information Literacy Standards for Student Learning, which were evident. These standards were promoted in course syllabi, official documents and the faculty/college web sites, along with the core standards of other departments (Wolcott, et al. 2000). This process was completed during our preparation for NCATE 2000 accreditation.

The next step was to seek the expertise assistance of an instructional developer who provided guidance in instrument development and selection, data collection samples, and data analysis. The instructional designer tested and validated the Holland Priorities Model (HPM) Instrument (Holland, 1996) to identify specific workplace abilities performed by school library media specialists.

Three major stakeholder groups who benefit from the knowledge, skills and abilities of job competencies performed by school library media specialists were identified as samples for administering our instrument. They included: principals from school systems who hire our graduates, school library media supervisors who train, manage and evaluate our graduates, and our graduates themselves who have studied, graduated and have accepted professional positions as school library media specialists across the state.

The first sample consisted of school library supervisors who have the primary responsibility of providing leadership for school libraries across the state. Their expertise and reputation within the field made them primary candidates to serve as panel members of the School Library Media program design advisory committee.

They were informed that our goal was to totally redesign our program. The instructional designer served as facilitator for the sessions because she was not known to any of the panel members and could be less subjective in her presentation.

They were invited to our campus to spend a day meeting with our team of investigators. The first task assigned to these experts was identifying workplace abilities and skills exhibited by current employees in school library media centers. This was an individual activity performed by each participant. This activity
was followed by a briefing provided by each panel member based upon his or her responses on the HPM Workplace Abilities Instrument (1996). This activity was followed by the identification of topics and issues that are apparent in school library media programs and services. Two other surveys were administered and generated data: a Workplace Attributes Survey and a Grass Roots Panel Identification Survey. These surveys allowed the panel to list attributes they had observed performed by media specialists as well as to identify outstanding administrators who have collaborated with school media specialists and could provide another perspective on the job competencies performed by media specialists. All of these instruments provided qualitative data that was analyzed in the study.

The second sample included graduates of the program (alumni) who are now practicing school library media specialists in K-12 settings across the state. This sample provided an insider’s perspective on the program that reflected knowledge, skills and abilities gained while in the program. The same data collection format that was used for the first panel was also used here.

The final sample was made up of superintendents, principals, assistant principals and supervisors from across the state. The results of a study reported by Wolcott (1999) concluded that pre-service teachers place more emphasis on those functions associated with information access and delivery than those related to learning and teaching. Veltze (1992) suggested that programs that prepare principals should include information on school library media programs in order to change negative attitudes of principals concerning libraries. This sample was selected because of their participation in the Maryland Technology Academy, Summer 2000 program, and their support and interest in technology in schools and libraries. The same procedure used on the two previous samples was used here.

At the conclusion of the session each panel member provided an evaluation of the session. They were asked the following questions: 1) How would you rate the value and quality of the session? 2) What are your ideas on how the session could have been of higher value/quality? 3) What was the most valuable or important aspect of the session? 4) What would you say was the least valuable or important aspect of the session? 5) What are your ideas on how we could better match students’ abilities with workplace needs? 6) Would you want to be involved in future initiatives with our institution?

Discussion

The responses from the HMP Workplace Abilities Instrument are currently being analyzed using Microsoft Excel software to determine the abilities, which had the highest priority among all panel members. The topics and issues are being analyzed to determine commonalities that may suggest priority competencies, which should be included in the program. These topics and issues may also suggest units of instruction that should be added to courses or new courses that will need to be designed to meet workplace demands and/or national standards.

Based upon the analysis of this data, the current program will be evaluated to determine what abilities and skills are evident in current course offerings. Courses, which are not currently providing these abilities and skills, will be targeted for deletion and revision. Topics and issues will be identified as a method of determining what new topics should be included in the curriculum as well as those that were not identified as relevant. From this evaluation a new program model will be recommended, developed and implemented.

Abstract: The current study aimed to evaluate the ‘Computer Course Applied to Education’ addressed to teachers from Brazilian public schools and offered by PROINFO (National Computer Program for Education). The analysis was developed through a case study model and the used research technique was ‘Illuminative Evaluation’ (Parlett, 1990). Three categories (Cooperative work, Autonomy and Suitability) and their indicators were separately observed and evaluated throughout the three stages of the course. The analysis of frequency evolution throughout the course demonstrated a progressive rise of category occurrence. “Cooperative work” was identified in 75% initial observations and 91.6%, towards the end. The same happened to “Autonomy”, increasing from 59% to 91.6%, and “Course suitability”, from 70.3% to 94.4%. Through the analyzed data, it was attested that the educational computer course offered by PROINFO in NTE II/RJ could stimulate the adoption of a social-interactional and constructivist attitude by the teachers, concerning their pedagogic practice.

Introduction

The current study aimed to evaluate the ‘Computer Course Applied to Education’ addressed to teachers from public schools and offered by PROINFO (National Computer Program for Education), attempting to promote a social/interactional and constructivist teaching-learning attitude.

PROINFO intends to begin a process of generalizing the use of technology in the Brazilian public school system. In order to assure that the significant sum invested will be efficiently applied, it is necessary to emphasize human training that comes before hardware installation. Demanding physical structure and technical support for running the equipment are also required.

The training of public school teachers in Brazil has happened through NETs (Educational Technology Nucleus), which are decentralized structures to support the process of computer implementation with their basic functions described in the principles of PROINFO.

A profile of how a teacher, trained by the NETs, should be was defined as: autonomous; cooperative; creative and critical; committed to constant learning; more concerned in teaching the students how to learn than merely taking care of didactic matters; engaged in forming individuals prepared to deal with the complexity of taking decisions and the consequent responsibility; able to establish a pleasant relationship with interchange practice (Ministério da Educação e do Desporto/ Secretaria de Educação a Distância , 1997, p.12). These goals are based on theoretical constructivist and social-interactional preconceptions, assuming that if a teacher can experience these concepts during his/her formation, it will enable him/her to incorporate them in education praxis.

According to Piaget, knowledge cannot be conceived as a predetermined matter since birth (innatism), neither as the result of simple records of perceptions and information (empiricism). It results from actions and the interplay between the subject and the surrounding environment. Knowledge is a construction that begins...
during childhood, through the interactions between the subject and what he/she wonders about, both from the physical and cultural world.

Therefore, knowledge is never a passive copy of reality. Intelligence develops through action and the teacher should promote and nourish this progress by the creation of suitable opportunities, and not by teaching methods that tells you what to do and learn. Knowledge results from an inter-relation between the subject that knows and what is been investigated (Macedo, 1994).

There is an active subject, during all ages of life, who searches to know and comprehend the surroundings. Nevertheless it does not happen immediately, through simple contact with the objects. Its possibilities come from what Piaget called of assimilation or action (agitate, suck or rock) schemes; or even mental operations (gather, separate, classify, establish relations), which are actions as well but take place in the mental plane.

Piaget classified as accommodation the mechanism of rising or modifying of an assimilation scheme. The assimilation and accommodation contents will vary during the process of cognitive development, however the intelligent activity is always an active and organized process of adding what is new to what have been already built up, and vice-versa.

On the other hand, the adapting process is completed by successive approaches, connecting assimilations and accommodations. After each adaptation, the new assimilated scheme becomes structured and available for the subject to accomplish other accommodations and, so on.

The central concept of constructivist theory, called the "balancing process", is what promotes this movement.

Facing a challenge, an incentive, a lack in the knowledge, the subject becomes intellectually uneven, gets curious, motivated and, through assimilations and accommodations, tries to establish a dynamic balance for it is achieved by physical and/or mental actions (Piaget, 1990).

According to Vygotsky, we are able to identify three central ideas: (a) the psychological processes have their origin in social processes; (b) the mental process may only be understood through the comprehension of the used mediators; (c) the belief in the genetic or evolutionary method.

It is important to remark that the author does not study the human development separated from its social-interaction's environment. Therefore he integrates social, semiotics and psychological phenomena in one concept. Besides, he accomplishes the analysis of the origins and the process that leads to a determined subject state, which is always dynamic.

Vygotsky remarks the complex transformations that structure human development such as appropriation and transformation of culture and defines the individual ontogenesis as a sequence of important events that happen simultaneously and as a result of social life. Throughout the process, the main concern is to explain the psychological phenomenons as consequences of genetic changes during child development, and therefore considering social environment and culture as foundations. According to the social-interaction's perspective, child development process is placed on the interface (border, boundaries) and convergence of cultural and maturing processes existent in this development, as the subject psychological system becomes the environment where biological adaptations turn to social relations. The individual is born in a cultural context historically structured, with artificially incentive meanings and complex social relations that mediate the active development during interactions. Vygotsky states that subject development is the product of social institutions and educational systems, such as family, school, church, which help to elaborate his/her ideas/thoughts and discover the meaning of somebody's actions and his/her own.

People generally adopt the rule that learning should be even with the evolutionary level of the child, and in order to do so, several stages are established, for reading, writing, etc. There is also the supposition that the child's capacity does not go beyond of what he/she is able of doing by him/herself. However, Vygotsky says that, if we want to check the relations between the evolutionary process and the learning abilities, we must define at least two evolutionary levels: the "real development level", or the "development level of child mental functions, established as the result of determined finished evolutionary cycles" (Vygotsky, 1998, p.131), or in other words, what the child can do all by him/herself; and a second evolutionary level, the "potential development level", which is formed by the activities that the child can achieve only if helped.

Generally, tests that indicate child mental age relate to the real level, while Vygotsky affirms that what children are able of doing with the help of others may be more significant to their mental development than what they can do by themselves.

After establishing the two evolutionary levels, Vygotsky defines the "proximal development zone" as the distance between the real development level and the potential development level (determined by solving a problem helped by an adult or a more capable classmate).
While the real development level defines functions that are already mature, or the final products of development, the proximal development zone defines the “unripe” ones, the functions that are becoming mature and that will be completely structured in the future.

According to Vygotsky’s theory, the mental development level of a person can only be determined if the two development levels are considered and cleared up: the real and the potential. Consequently, both the conception of comparing the development level and the learning process, and the idea that only what the child is able of doing by him/herself is indicative of mental capacity are denied.

The concept of proximal development zone must be highlighted as a significant intellectual tool, which allows the comprehension of personal inner development and also predictions of some functions that will be mature in the future. It is a conception capable of improving the use of diagnosis of mental development in educational problems.

We have arrived to the conclusion that, to Vygotsky, the good learning process is the one that precedes the development (Vygotsky, 1998, p.92), meaning that, evolutionary processes are not similar to learning processes, but the evolutionary process is stimulated by the learning one, which turns gradually into development. That is why internalization is the key-concept in Vygotsky’s theory, which means that for a person to achieve his/her individual goals, it is necessary to go through a learning process that must be internalized. Therefore, the instruction on the proximal development zone stimulates the child’s activity, prompting the whole development processes, which, after internalized, change the functions that the child is able to do by his/herself.

Based on the theoretical conceptions of these two authors, it is assumed that the students learn and develop as they elaborate suitable meanings about the contents of the school subjects. This construction includes the student active contribution; his/her availability and previous knowledge, taking place in an interactive context, in which the teacher acts as a guide, a mediator between the child and the culture. The success of the learning process will strongly depend on this mediation. The learning process is focused on relevant contents and also related to the student context and routine, considering that he/she has a previous knowledge, result of one’s experience, which will be enriched with new contents.

The pedagogic praxis should then stimulate the student to product and think about his productions. Instead of answers, the teacher should propose questions that promote the student construction of his/her knowledge, experimenting and registering the results. The role of the teacher should be of a challenger and stimulator of new discovers instead of mere knowledge provider. It is not expected from the teacher to know all the answers, but to suggest ways to find them.

The challenge of rethinking the role of the teacher is related to redefining the computer role as a pedagogic device/tool, as an addition to create an environment that provides knowledge construction and creative activity of students and teachers.

Based on these indicators, we can state that changing the pedagogic practice depends on continued schooling (academic qualification), as well as on an interdisciplinary perspective in qualification services offered to educators. Through this new profile, the teacher will help the students to be creator agents, capable of abandoning passivity, not acting like simple knowledge receivers.

The academic qualification of the teacher should provide conditions for him/her to construct his/her own knowledge about computer techniques, to understand why and how integrate these methods to education practice and to overcome administrative and pedagogic matters. This practice promotes a transition from a fragmented school system to an integrationist approach of the contents, focused to finding solutions to specific problems relevant to the students, raising their interest. Finally, there should be conditions for the teacher to know how to contextually situate what was learned and experienced during his/her academic qualification to classroom reality, making the student demands and the pedagogic objectives of the teacher more compatible.

Considering how relevant and widespread PROINFO has become, it is really eminent to evaluate its results, verifying the attitude of the trained teachers.

Method

The simple consisted of eight public school teachers from the city of Rio de Janeiro, selected to be trained by the 'Computer Course Applied to Education', offered by NET II/RJ. There were teachers of different subjects in the class, promoting interdisciplinary.

The analysis was developed through a case study model and the used research technique was 'Illuminative Evaluation' (Parlett, 1990).

The procedure had the following stages: (1) “Immersion”: the initial part, when the observer-analyzer
immerses in the environment to be evaluated with two objectives: (a) acknowledge the different aspects and (b) obtain initial data for future indicators of changes that the program might promote; (II) "Dive": the collected indicators are now analyzed and verified their occurrence through behavior manifestations, called "impact evidences"; (III) “Triangulating”: the information data, collected differently by the observers are then confronted.

Results

The data gathering and its organization occurred as it follows: (a) all indicators were registered; (b) indicators were grouped according to their nature (cooperative work, autonomy, course viability); (c) specification of "impact evidences"; (d) a table demonstrating the students performance; (e) analysis and discussion of the results.

The three categories and their indicators were separately observed and evaluated throughout the three stages of the course (40 hour length each).

Category I - Cooperative Work

It was detected when the group became united and active through sharing and participation. A few indicators were evaluated: (a) appreciation of group work; (b) student/student relationship; (c) appreciation of work in pairs.

Concerning "appreciation of group work", some small problems were observed right in the beginning but they were overcome and replaced by cooperation, respect and participation.

The "student/student relationship" showed that the pairs were quickly drawn. However, these pairs became stable which made the interchange of elements more difficult. Trading partners would allow a better interplay, although the stable pairs did not prevent the occurrence of interpersonal relationship involving the entire group.

A positive aspect of the indicator "appreciation of work in pairs" was the acceptance of challenges proposed by the other partner. Even if an element knew more than the other, it did not promote competition. On the contrary, it improved, enriched their work, acting on their 'Proximal Development Zone' (Vygotsky, 1998).

Category II - Autonomy

The indicators were (a) solving problems individually; (b) solving problems in pairs; (c) critical ability; (d) creation through Logo; (e) construction of texts.

Relating to the two first indicators, the group was able to solve their problems, both individually and with a partner, creating alternatives to figure out some questions, gather and analyze information, besides discussing suggestions brought up by the instructors.

According to Piaget (1977), in order to overcome heteronomy, which means acting or judging something without questioning its values and principles, a person needs to be encouraged to develop his/her own values. Concerning critical ability, it was observed that the teachers had the chance to gather, organize and evaluate relevant information, struggling to reach autonomy.

The indicator "creation through Logo" demonstrated that the childlike atmosphere, involved in this kind of activity, promoted some creative moments. Playing with the turtle, for instance, eased the learning process and the project construction, turning the natural fear to make mistakes into a feeling of challenge. The students' growth may be verified through the recorded programs, in which they were gradually able to create sophisticated drawings from rough sketches. The whole creative process that preceded the final product was even more pertinent to the project. According to Piaget, the main focus should be the action of discovering and thus the process much more valuable than the product.

"Text construction" showed that, through the discussions of different material, the students could relate what was being read to their pedagogic practice, improving the texts written by the group.
Category III - Course Viability

Three indicators were drawn: (a) suitability to constructivist principles; (b) acceptance of course proposal by the student-teachers; (c) gradual learning of the material.

In relation to "suitability to constructivist principles", the course allowed the students to evaluate the role of "errors" in the teaching-learning dynamics. It seems that a teacher's profile generally follows a pattern of strict responsibility, not admitting "attempts" or "mistakes". As errors were diagnosed and new tracks to the right answer were revealed, the belief of an autonomous and active subject was then adopted.

The indicator "acceptance of course proposal by the student-teachers" had a rather satisfactory response. Despite their initial ignorance of the course proposal, the students got really engaged in the activities, making suggestions and enriching their work.

Through "gradual learning of the material", it was observed that there was a substantial knowledge acquisition by the students, considering that most of them had never dealt with computers. Nevertheless, by the end of the course, they were able to understand the new language and could develop computer activities in a much more autonomous way.

During each stage of the course, eight teachers were observed through eleven indicators previously described (three from "Cooperative work" category, five from "Autonomy" and three from "Course Suitability"). The indicators were then evaluated according to their frequency: "often" (3), "not often" (1) and "never" (0). The performance of the teachers was calculated through pondered sum of each indicator which could reach a maximum of 24 scores, if all teachers received "often". Categories such as "Cooperative work" and "Course suitability" could have a maximum of 72 (24 x 3) scores and "Autonomy", a maximum of 120 (24 x 5). The following step was to calculate the percentage of the group for each category.

The analysis of frequency evolution throughout the course demonstrated a progressive rise of category occurrence. "Cooperative work" was identified in 75% initial observations and 91.6%, towards the end. The same happened to "Autonomy", increasing from 59% to 91.6%, and "Course suitability", from 70.3% to 94.4%.

<td>94.4%</td>
</tr>
</tbody>
</table>

Table 1: Percentile evolution of the categories throughout the course

Conclusion

Through the analyzed data, which indicated a rise of some categories such as "Autonomy", "Cooperative Work" and "Suitability", it was attested that the educational computer course offered by PROINFO in NTE II/RJ could stimulate the adoption of a social-interactional and constructivist attitude by the teachers, concerning their pedagogical practice.

Concluding so, we recommend the promotion and extension of similar training programs; the maintenance of training services for teachers; an annual diagnosis of how the professionals are adapting to new working proposals and the development of researches about inserting new technology in the school environment.

Integrating ISTE & NCATE Standards into Educational Technology Masters Programs

Steven Coombs
School of Education
Sonoma State University
United States
steven.coombs@sonoma.edu

Abstract

Abstract: Educational Technology Masters programs are coming of age! The International Society for Technology in Education (ISTE) has published a five-step blueprint outlining the curriculum standards requirement for all advanced programs in educational computing and technology (ECT) leadership. This paper briefly examines these standards and explains how they’ve been recently interpreted for all future Ed. Tech.-related Masters courses at Sonoma State University (SSU).

The ISTE & NCATE Advanced Programs Standards

The National Council for the Accreditation of Teacher Education (NCATE) is a powerful body, which is influencing the design of most teacher preparation and professional development programs across the US. Many departments of education in individual States – including California – across the US have signed voluntary agreements with NCATE to recognize reform of their current programs’ in-line with NCATE’s standards. Within this framework NCATE has included a set of specific program standards for all educational computing and technology courses. These have been defined by the ISTE and adopted by NCATE for all courses intended for the initial and advanced preparation of teachers.

For advanced in-service teacher training leadership courses at the Masters level within the field of educational computing and technology literacy (ECTL) these standards have been summarized and abridged in Table 1. A good example of how these ECTL standards are manifested into the school curriculum and employed by students is given in the joint ISTE and Milken Exchange publication entitled: National Educational Technology Standards (NETS) for students. Both this document and another entitled National Educational Technology Standards (NETS-T) for teachers are available as PDF download files from the ISTE and NCATE Websites, which are given in the reference section at the end of this paper.

The ISTE advanced leadership standards for Ed. Tech. require completion of a five section syllabus. Sections 1 to 3 of this ISTE standards syllabus represent prior learning Ed. Tech. skills and experiences that need to be accredited before a candidate can proceed to sections 4 & 5. Sections 1 to 3 describe Ed. Tech. field practices that closely relate to the ECTL standards required by teachers achieving the NETS-T accreditation. Thus, sections 1 to 3 of ISTE’s Ed. Tech. leadership curriculum could be satisfied by a pre-requisite qualification based upon the jointly accredited (ISTE/NCATE) NETS-T program. Ed Tech leadership Masters courses could then be designed upon sections 4 and 5 and the next section of this paper describes the current proposals being considered for implementation at Sonoma State University (SSU).

1) Foundations – ECTL matrix
Prerequisite ECTL skills and knowledge must be both audited and provided for as a prior learning course.

2) ECTL Specific Content
Can also be audited against the ECTL matrix with coursework evidence demonstrating the use of technology to support other curriculum content areas.

3) Professional Preparation in ECTL
This requires candidates to be able to practically integrate ECTL pedagogic methodologies into the school curriculum.

4) ECT Leadership studies
Requires candidates to summarize ECTL-related pedagogic research and contemporary trends in schools. Candidates must also design an authentic research project that evaluates a specific technology used in a PK-12 environment. Candidates must also be involved in instructional design and courseware development using appropriate authoring and graphical software environments. Information and Communications Technology (ICT) environments are also to be explored, i.e. using the transmission of multimedia systems via institutional networks as a presentational tool. In addition to this, candidates are required to be conversant with stand-alone and networked operating systems and be able to identify/manage/troubleshoot suitable software and hardware procurements for both the classroom and administrative environments.

5) Professional preparation for ECT Leadership
Candidates require studies of and experiences with leadership, staff development and supervisory concepts and skills as they relate to the use of technology-based systems in PK-12 education. This will include the unique design of curriculum Ed. Tech. master plans and policy documents based on national/state/local guidelines along with policies related to resource management. Integration of technology tools into teaching must be demonstrated both personally and through the design of staff development action plans to achieve the same. A research project related to achieving and managing change within the school district is also required, as are field experiences that document the change-management process of unique ECTL reform programs.

| Table 1: Interpretation of the ISTE advanced leadership standards for the educational computing and technology literacy (ECTL) matrix. |

**Interpretation of the ISTE standards for Ed Tech Masters Courses at SSU**

At Sonoma State University it has been my task to interpret the ISTE standards and propose four new courses that can be offered as a 12-unit major, or emphasis, within the regular educational MA program in curriculum, teaching and learning (CT&L). The two key problematic issues identified that would affect the design of any Ed. Tech. Program at the Masters level were:

1. Prerequisite evidences and ECTL accreditation;
2. The clinical practice and community-based supervision and assessment requirements.

The ISTE organization requires that “As a prerequisite to the advanced program, candidates must document knowledge and competencies contained in the Educational Computing and Technology Literacy matrix.” (see the advanced leadership guidelines on the Website reference given in this paper). The solution proposed at SSU in order to satisfy these prerequisite ECTL evidences cited in problem (1) was to develop the ISTE standards as a set of curriculum planning learning objectives within our own version of the ECTL matrix. From this matrix we can determine the prior learning entry-level qualifications of all candidates entering the Ed. Tech. Masters program. Previous Ed. Tech. related in-service training courses can be assessed and accredited against the matrix, with any identified deficits accounted for with specific top-up programs. Work is currently under way in developing a common-access transcript that automatically accredits all existing and new Ed. Tech. related staff development in-service training courses.
within the SSU district. Other Ed. Tech. related courses offered at the pre-service qualification level can also be accredited with the same standards. Indeed, the eventual goal is that all teacher trainees graduating from SSU meet the ISTE's ECTL matrix. A flowchart describing these various Ed. Tech. training routes for both pre-service and in-service teachers is given in figure 1 below.

Pre-service NETS-T accredited teachers at the end of first year of teaching.

In-service NETS-T accredited teachers, e.g. Intel courses.

In-service non-accredited teachers.

A 4-profile NETS-T transcript implies a waiver of the ISTE pre-qualification matrix, i.e. prior learning satisfied for parts 1 to 3 and a fixed ISTE pre-qualification matrix can be generated for all the NETS-T courses.

NETS-T equivalent service learning certificate needs to be completed as an Ed Tech Masters pre-requisite. A unique ISTE pre-qualification matrix needs to be generated for each candidate. Praxis-based accreditation needs to be coupled with instructional technology foundation courses except where waived by in-service equivalent experiences.

Access into an ISTE accredited Ed Tech Leadership Program at the Masters or Doctoral level.

A 5-part ISTE syllabus requires all program courses to be audited against the following areas:

1. Foundations in Educational Computing & Technology Literacy (ECTL) [NETS-T].
2. Specialty content preparation in ECTL (i.e. Ed Tech concepts & skills) [NETS-T].
3. Professional preparation in ECTL (i.e. Ed Tech praxis integration, lesson plans) [NETS-T].
4. Specialty Leadership content for ECTL (research & pedagogic theories, instructional design & product development, information access & delivery, operating systems, evaluation and management of hardware & software.
5. Change-management practice (i.e. an Ed Tech action research field project).

Figure 1: Flowchart for Ed Tech leadership courses with ISTE accreditation

The second big issue identified in problem (2) is to meet ISTE's practice standard, which envisages participants' engaging in technology-based educational research and curriculum development leadership programs within, say, a teacher's local school district. One way to deliver Ed. Tech. related clinical practice of this complexity is to go down the route of accrediting Ed. Tech. curriculum reform...
projects within an action research cycle and have these form the basis of a Masters dissertation project. Action research project management methods are considered to be a well-suited tool and approach for enabling authentic curriculum reform practice. Stenhouse (1975) argued that a curriculum was an attempt to communicate the essential principles and features of an educational proposal into a form that is open to critical scrutiny while being integrated into practice. Indeed, Elliot (1991) corroborates with this view and tells us that action research is a good tool for professional personal development as it encourages us to reflect on our actions. Elliot interprets action research pedagogy as a set of practical steps that can guide teachers in transforming educational aims into classroom practice. The action research praxis and pedagogy appear to be in-tune with the ISTE aims for advanced leadership Ed. Tech. programs. In particular, the ISTE Ed. Tech. Leadership matrix in section 5 (See document on ISTE’s Website) requires candidates to be involved in an assessment project that constitutes as part of an Ed. Tech. change-management process within an educational and/or training institution. The ISTE standard 5.6.3 requires all candidates to be involved in a practical Ed. Tech. field study evaluation project:

5.6.3 Document and assess a significant field-based activity involving experiences in instructional program development, staff development, facilities and resource management, or managing change related to technology use in schools.

Given the above ISTE provisos and the criteria interpreted in Table 1, we are now developing the following range of ISTE-related courses as a special track within the Ed Tech major of the CT&L Masters program at SSU and these are summarized in Table 2 below.

Table 2: The proposed ISTE-related Ed Tech Masters courses at Sonoma State University

The first three courses will operate as traditional university-based courses; however, the aim is to develop the final course “project management methods for Ed Tech professional development” as both part-course and part of an action research field study dissertation project.

Conclusion

In conclusion I would recommend that all Ed. Tech. Masters program developers that wish to incorporate the five ISTE leadership standards from the ECTL matrix adopt similar pedagogic strategies to those being proposed at SSU with particular emphasis on the following:
1) An ISTE pre-requisite based upon the current NETS-T standards, which can be accredited against actual Ed Tech field practice and other relevant previous Ed Tech in-service training experiences.

2) A practical field-based work project and/or study based upon action research evaluation methods.

Recommendation 1 is targeted at all applicants wishing to join an ISTE accredited Ed Tech Masters program. An innovative service learning 3-unit accreditation course is being developed at SSU that aims to achieve the following goals:

⇒ accredit and validate all existing on-the-job (field-based) Ed Tech praxis and relevant in-service training experiences;
⇒ top-up any identified skill shortfall from the ISTE pre-qualification matrix (sections 1 to 3) with a tailor-made Ed Tech service learning program to be located within the candidates own place of work, i.e. school or any other training establishment deemed pertinent to developing leadership skills; and,
⇒ provide an interim SSU certificate granting completion of the ISTE matrix preparation areas, i.e. an official transcript accrediting the ISTE syllabus sections 1 to 3 in Table 1.

Recommendation 2 aims to give Masters thesis accreditation to Ed. Tech. management projects that stimulate change-management curriculum reform practice from within the candidate’s field of work. This Masters program real-life design issue was also raised by Tom (1999), who reported that: “Teachers dislike these (Educational Masters) programs. They view them as detached from the daily practice of schooling” (p. 245). This suggests the potential professional merit of implementing a practice-based Master of Education and/or Arts Ed. Tech. program that addresses professional teacher development needs through accreditation of field-based action research curriculum projects.

Abstract: Teachers are faced with implementing technology provided without consultation, often without consideration of the infrastructure, much less the technical or curricular training necessary to make full use of it. Too often we focus our attention on the Mountains of Technology forgetting that landscape is more than just the one prominent feature; it encompasses the Streams of Curricular Change, the Evergreens of Knowledge, the High Plains of Critical Thinking, the Safe Arbors of the Community. Through all this rich environment blow winds of administrative, political and social change that can make barren former gardens of thought and pile rich soil in new areas. Should we as teacher educators help them scale the mountain to obtain a different perspective or encourage them to skirt around, treating the intruder as a stumbling block to their journey and as eyesore that hides and overshadows part of the landscape? What follows is a descriptive case study that examines one university program's attempt to resolve apparent disparities between the learning and integration of technology into K-12 environments.

Genesis

Teachers are faced with a mounting dilemma in this rapidly evolving Age of Information. They are urged, cajoled, pleaded with and threatened to include technology into their curricula. Administrators, politicians, curriculum experts, scientists and corporate America rally around a range of beliefs that locate technology as a central piece in curing the ails of what-is-touted to be an intellectually and near economically bankrupt public education system. School districts open their curricular arms to embrace comprehensive programs of technology—often to the bewilderment and bemusement of in-service teachers who must integrate this technology into an existing curriculum that in some cases is already held together with string and sealing wax. Teachers know, because they live in a world becoming filled with ubiquitous technology, that technology is here to stay—it is changing the way the world communicates, transacts business, socializes, and expresses itself artistically. However, teachers are faced with implementing technology provided without consultation, often without consideration of the infrastructure, much less the technical or curricular training necessary to make full use of it.

Too often we focus our attention on the Mountains of Technology forgetting that landscape is more than just the one prominent feature; it encompasses the Streams of Curricular Change, the Evergreens of Knowledge, the High Plains of Critical Thinking, the Safe Arbors of the Community. Through all this rich environment blow winds of administrative, political and social change that can make barren former gardens of thought and pile rich soil in new areas. What we often perceive as static, unchanging and permanent is in actuality, constantly changing.

What value then teaching current technology skills for their own sake, in isolation, with no thought of need or purpose? How can in-service teachers learn current technology skills and the principles of their implementation, and how can those skills and principles enhance and expand and evolve public school curriculum. As teachers and students work together in growing a learning landscape how do they react to the
sudden appearance of a mountain from without? Do they scale the mountain to obtain a different perspective or do they go around, treating the intruder as a stumbling block to their journey and as eyesore that hides and overshadows part of the landscape?

In a better model learners are in the center of a systemic developmental process in which they, their knowledge and knowledge of processes interact through the community—classroom, local and exponentially more global, informed through continuous ongoing feedback to provide a more organic experience. This model serves as a weathervane, informing principles upon which we can design, construct, and adjust to the changing environment of economic, social and political influences. They form, in a mutable world, constants. The guiding question is how do higher educators, who work with a pre and post service teacher population, provides an environment that exemplifies, illuminates and encourages transfer of this organic process?

Geology

In 1998, Sam Houston State University had in place an M.Ed. degree program with an emphasis in instructional technology. Several characteristics of the program conspired to keep the number of active interested graduate students lower than it could otherwise be including the course sequence, the dispersion of the graduate population through the program and the reliance on independent study with already overloaded faculty. In consequence those graduates enrolled in the program were subject to a particular instructional experience in which they functioned semi-independently of both the supervising faculty member and of other students in the program. With many graduate students also managing home, family and work responsibilities, the experience tended to be a lonely and isolated one with little opportunity for social and academic support.

In an attempt to manage the enrolment situation, the researchers decided to implement a cohort system for the program. The students would start the program together and progress through a predefined sequence as a closed community. Of course cohort members could still take courses through independent study if the need arose. Having made significant changes to the structure and sequencing of the program it became obvious that the nature of the student experience was going to radically change. This gave the researchers the opportunity to proactively engineer the student experience to enhance student performance, the education process, and the support system.

Geography

People learn by using existing schemas to construct new understandings by assimilating new ideas into existing schemas or accommodating existing schema to encompass concepts that completely alter their current conceptions. (Piaget) It becomes important for educators in the university environment to come to know the population they teach—their beliefs and the context of community and cultural values which encompasses those beliefs, so that they can illuminate existing student schema in order to build on students' strengths, shore up their misconceptions or weaknesses in order that they may construct new understandings. These understanding while examined in the relative isolation of the college classroom must be able to go into the schools and communities of the teachers and become part of an organic process of knowing theory, enacting theory into practice, reflecting on that practice, and reformulating theories are principles—praxis.

With a sense of praxis existing within teachers, they can not only extend what has been learned in one context to new contexts (Byrnes, 1996, p.74) but they have the ability to not only contribute to the practice that replicates the transfer of this knowledge, but to contribute to and or extend the theoretical principles which underpin it. It becomes imperative that pre and in-service teacher instruction in technology integration be learner centered, knowledge centered, supported by authentic assessment, and grounded in the context of the communities which it will be practiced.

This research is a descriptive case study that examines one university program's attempt to resolve apparent disparities between the learning and integration of technology into K-12 environments. Data sources which inform the researchers' understandings are: course syllabi, interviews with students and professors, threaded message boards from course work, class debriefings, and student projects and products and interviews with building principals from the informants' schools. The informants in this study include two university professors, eleven K-12 classroom teachers enrolled in the cohort masters in educational technology program, the university students' classrooms from the fall of 1998 through the spring of 2001.

Working from a problem-centered, real-world perspective integrating multiple forms of knowledge and knowing, the study attempted to use technology transparently, focusing on its value as a tool in the problem solving process rather than on technology as a body of extant knowledge.
This data, while purely descriptive, is analyzed for recurring patterns examining the organic process of how students assimilated/accommodated theory, enacted theory to practice inside the college classroom and then transferred or extended it into their own classrooms in communities. Information gleaned from examination of this descriptive analysis is meant to inform the professors in this study, and is brought to the larger academic community for further discussion.

Surveying the Terrain

Traditionally education has been representative of its geographic social, political and cultural environs. Also traditionally education has assumed there is a fixed body of knowledge that can be transmitted from educators to learners. More recent views [Vygotsky, Foucault, Berenfield] recognize that knowledge is transmitted, analyzed, and in many cases, transmuted so quickly that it is continually evolving. No longer, can knowledge be thought to be a static entity dispensed by educators. Instead now, many educators believe that thinking "takes place in communication, in an act of knowing in which the learner assumes the role of knowing subject in dialogue with the educator" (Freire, 1988, p.403-404). Learning is collaboration between students, educators, and professionals in a variety of discipline utilizing a wealth of informational resources, many of which are not limited by geographical time/space boundaries. Educators who use language to mediate problem solving through Berenfield's *Infosphere* have the ability to not only supply information through technological means but also the potential to impact the culture-- the values, ideologies and social context of the populations they serve.

Building the Team

The cohort system is more than a gathering of individuals. To be most effective we believe a community has to emerge from the process, one in which the group members can rely on each other for support, but one also where the individual makes a commitment to group maintenance.

As part of an instructional web site design process in the “Designing Instructional Materials for the Web” course, the cohort members were responsible for engineering the “look and feel” and the structural organization of a word processing site. Over a period of two three-hour brainstorming sessions, each of the students were responsible for managing the sessions, providing the ideas, identifying problems, areas of needed research and mapping the ideas to an instructional model. Cohort members were rotated through roles and responsibilities to limit the potential for monopoly and their contributions and self imposed assignments were tracked. It became clear early on that the task was too big for one individual and that a cooperative effort was required. Cries of “Help me out here, Guys" and "Who's going to take this on" were the order of the day. Often one person could not complete his or her task without a finished product from someone else. Waiting on someone else was not an opportunity to relax, but an opportunity to pitch in and help. Not everyone picked up all the skills but all the skills were mastered. Not everyone completed their tasks but all the tasks were completed.

Mapping the Journey

We as instructors set the goals and or objectives

In the Spring of 2000, I “instructed” this technology cohort in Advanced Methods of Instruction. Since, the teachers in this cohort had, on average 12 years of experience, each, and because they had been together as a cohort for a semester, I eagerly took this opportunity to open the boundaries of their learning landscape by inviting them to “map their terrain.” Together we defined the broad goals for the course juxtaposed against the landscape of their experience and the road of their teaching and learning needs. We identified three questions for the course, which would guide our inquiry:

- How do people learn?
- What are the pedagogical implications for brain research-based learning?
- How do those implications translate into a cyber-learning environment?

Each lesson that I then created was based on those guiding questions had been based on their input. In order that our learning community be able to think metacognitively about those questions, I posted an open threaded message board which would serve as an ongoing forum to express our thinking as we worked through each lesson.

Next, in my instructional decision making process was to choose texts. Because I wanted to model effective “advanced methods of instruction” and I felt this included the way we utilized technology to support our
learning, I used a "cutting edge", theoretically, and delivery-system, online text, How People Learn: Brain, Mind, Experience, and School (Bransford, Brown, Cocking, 1999). In addition to this we used many web-based articles and research including but not limited to: Eric Chudler’s Neuroscience for Kids (http://faculty.washington.edu/chudler/neurok.html); an overview of music and learning by Don Campbell and Chris Brewer (http://www.zephyrpress.com/). My thinking was that in order to think deeply about what advanced methods of instruction should look and be like, we needed to understand the latest theory that supported learning, and that we would simultaneously review literature on cutting edge technology and together as a class we process this thinking through five mechanisms:

- Reading
- Reflecting and responding in writing online to and with our learning community
- Taking a stance in writing-by-writing and publishing online short position papers.
- Contacting an expert.
- Taking an action.

Together we took these actions to process the text and online readings I assigned. Then each individual within our learning community began to focus on some specific aspect of brain research, pedagogy and cyber implementation. They read, identified focus topics and then began to construct a web-based project that integrated their findings about brain research, pedagogy, and cyber implementation. This project had to be able to be utilized by teachers or school-aged children. The students in our learning community used their experience, interests and curricular needs which were particular to their teaching experience to identify the topic of their inquiry and to guide them as the developed their learning project. Underlying these actions were the three guiding questions that formed the objective of their study as well as the framework of their assessment:

- How do people learn?
- What are the pedagogical implications for brain research-based learning?
- How do those implications translate into a cyber-learning environment?

However they get there is part of their journey, is part of their learning.

Notes from the Diary

The cohort experience was a positive experience, not only in terms of their coming to terms with both theoretical content and practical skills but most especially in terms of their application of those concepts and skills to their classroom and a wider context.

Student Empowerment:

Students took control over their learning environment by not only establishing their goals and objectives, and choosing the focus of their projects but by taking turns guiding, responding, and nurturing their learning community through their roles as weekly on-line facilitators. Students worked in pairs taking the leadership in this online responsibility. They monitored the boards to see who was responding and wrote and encouraged those who had not yet responded to begin to respond or to ascertain if they were having any technological or other problems which would keep them from responding. They at all times were polite and respectful in these areas and indeed many times did uncover areas in which they could support their colleagues. In this respect our learning community became a sustained support system empowering its members to rely on themselves and each other as they charted this territory.

Sense of Worth and Usefulness

Our learning community indeed began to understand the current state of their knowledge and to build on it, improve it, and make decisions in the face of uncertainty (Talbert and McLaughlin, 1993). With their experience, or as Dewey (1916) states, "records of previous cultural accomplishments" and with the "engagement in active processes, a tremendous sense of worth and usefulness developed as a result of engagement in this course.

Students were actively processing theory and juxtaposing it against their prior knowledge and current experience. Becky Harmon chose to read in Neuroscience for Kids and article about the full moon’s effect on learning. She relates this to current experience:
A lunar eclipse with a full moon all at the same time! I don't know about your students, but students at my elementary school were horrific yesterday and today. The hall outside the principal's/assistant principal's offices was lined with students who had been sent due to bad behavior. This afternoon, I had to stop an almost knock down drag out fight between two second graders while waiting for their day care bus. I've never had problems with them in the past. So when I saw this article, I just had to read what it said on the topic. Boy was I disappointed with their opinion. Read on to find out why.

The article examined the results of studies done on the influence of the full moon on behavior. Most of the reported findings indicate that there is no direct correlation between the full moon and behavior. Only a few studies reported a positive relationship. The article went on to state that the results of the studies were very inconsistent as "some studies show that a particular behavior will occur more often during the full moon and other studies show no relationship between behavior and the full moon." The article stated that the inconsistent findings were, in part, due to inconsistent test situations. Some included behavior only on the day prior to a full moon, while others included behavior on days prior and following a full moon.

I was so interested in the topic I read two related articles. One, "Human Aggression and the Lunar Synodic Cycle", used computer technology to study five aggressive behaviors as reported by emergency rooms in Dade County, Florida. The results indicated a "statistically significant clustering of cases around the full moon." The other article, "Lunar Cycles and Violent Behavior", studies the behavior of hospitalized psychiatric patients during a full moon. The results of this study indicated that there was "no significant relationship." Even the related articles were hard pressed to agree with one another.

Regardless, my own experience in the teaching profession has led me to believe you ought to be prepared to deal with behaviors on or around full moons.

This student used her choice of reading, reading and processing to help resolve learning and teaching question she had. Her choice of topic and quantity of material to read did not limit her, but rather guided her toward meaningful instructional decision-making. Another student, Dennis Huff, wrote this response and took the following actions after reading:

I was very excited about some of the resources I found on Dr. Chudler's web site! I was so impressed that while I was looking it over I contacted my nephews here in Texas and my second cousins up in Maine and recommended that they take a look at this web site! I've also informed my brother who teaches at Eisenhower in Aldine ISD and my coworkers down at Conroe H.S. Although this is primarily a "science" web site, the applications across the curriculum are tremendous and limited only by a teacher's imagination (and I feel I have a very fertile imagination!) I have downloaded the "Web Page Evaluation" form, the "Brain Metaphor" and the "Brain vs. Computer" pages for use in my Introduction to Computers lesson. This way I can make analogies between the brain and a computer to help the students in activating their schema so they can better assimilate my lesson. I'm so happy!

Engagement with a larger learning community

Since part of our weekly assignment was to contact an expert, many of our students used e-mail to do this thus engaging in a dialogue with experts from the larger learning community. Dr. Eric Chudler was kind enough and responsive to answer several e-mails from our students. The following is an example of one of his responses:

Brenda: Certainly helmets will protect the brain whenever there is an impact to the skull. However, Phineas Gage was subjected to an iron rod that pierced his brain...a different type of trauma than those students will ever experience (I hope!). However, here are some other ways to motivate students to wear helmets and to promote good "brain health":

Engagement with this and other expert gave our students a sense of taking part in larger, meaningful discussions from a learning community actively engaged in and disseminating research on learning. Our
students felt their voices, questions, concerns, and responses became part of this ongoing body of evolving knowledge.

**Modeling what we believe about teaching and learning.**

We strongly felt, and my students came to feel that there are not set answers and strategies that make methods and instructions “advanced” but rather there in an understanding that learner-centered environments include teachers who are aware that learners construct their own meanings, beginning with the beliefs, understandings, and cultural practices they bring to the classroom. If teaching is conceived as constructing a bridge between the subject matter and the student, learner-centered teachers keep a constant eye on both ends of the bridge. The teachers attempt to get a sense of what students know and can do as well as their interests and passions—what each student knows, cares about, is able to do, and wants to do. Accomplished teachers “give learners reason,” by respecting and understanding learners’ prior experiences and understandings, assuming that these can serve as a foundation on which to build bridges to new understandings (Duckworth, 1987).

Designing Professional Development Schools at the Secondary Level: An Integrated Model

Evelyn M. Dailey, Department of Reading Special Education & Instructional Technology, Towson University, Towson, Maryland USA, edailey@towson.edu; Sally McNelis, Department of Secondary Education, Towson University, Towson, Maryland USA, smcnelis@towson.edu; Miriam Struck, Department of Occupational Therapy, Towson University, Towson, Maryland USA, mstruck@towson; Robert Wall, Department of Reading Special Education & Instructional Technology, Towson University, Towson, Maryland USA, rewall@towson.edu.

Background

This paper addresses the critical shortage area of secondary special education by focusing on the development of the first secondary special education Professional Development School (PDS) model for Towson University. Specifically, this proposed PDS model will be used as a recruitment tool for the newly approved Bachelor of Science in secondary special education major at Towson University which was granted in July 1999. The creation of a PDS model in secondary special education will enhance the newly approved major in Secondary Special Education and further the Redesign of Teacher Education in Maryland by offering a year long internship in special education. The proposal is aligned with the Maryland State Department of Education (MSDE) recommendation that teacher candidates have a year long internship in specially designed professional development schools. Moreover, this model will include collaboration with the occupational therapy registered (OTR) program --- the only OTR program in Maryland. This proposed model will be the first of its kind within Maryland and possibly the country.

Towson University is well qualified to carry out such a project based on its recognition by the Association of Teacher Education (ATE) as the 1998 Distinguished Program in Teacher Education. This project would complement Towson's already acknowledged award winning status as an outstanding teacher education institution. Yet most importantly the creation and implementation of a secondary special education PDS model would fulfill a critical shortage need by preparing secondary special educators; this need is indicated in the Maryland Teacher Staffing Report for 1999-2001 which identifies the special education area of generic certification grades 6 -adult as a critical shortage area for FY 1999 and FY 2000 (see attachment C). Equally as important, this proposal addresses the chronic shortage of OTRs in Maryland's public schools. In conclusion, the PDS described in the proposal directly supports the Redesign of Teacher Education. It will provide school based professional training, give teacher candidates a chance to work with children from diverse backgrounds in diverse settings, and link teacher education redesign to school improvement efforts. Quite simply, it is win-win situation for all concerned.

Goals and Outcomes of the Project

- To develop and implement a secondary special education PDS model that provides coordinated, continuing professional development for all members of the school community which is targeted to the specific needs identified by each school
- To develop the internship in secondary special education to be part of the Bachelor of Science degree
- To provide a school-based setting for a collaborative internship experience for OTRs and secondary special education interns

Plan
Building upon the existing secondary education PDS model, we will adapt this PDS model to meet the needs of secondary special education majors. A unique feature of the proposed PDS model is the inclusion of OTR and secondary special education interns. This collaboration is congruent with best practice in the OT literature, but as yet has not been done. The internship experience builds upon knowledge, reflection, performance, and analysis, the four key learning domains of the Essential Dimensions of Teaching. Specifically, the secondary special education PDS experience will focus on classroom management & discipline, inclusion, collaboration, multicultural perspectives, reflection & program portfolio, and planning for teaching. Performance based indicators for student outcomes will be developed. This proposal will enhance preservice and inservice teacher development by providing a clinical laboratory experience or preservice teachers aligned with the recommendations of the Redesign of Teacher Education.

Project Timeline

In the fall, faculty in special education will shadow secondary education faculty at Wilde Lake High School and Harper’s Choice Middle School in Howard County (This has been underway since September 1, 1999). During this period, we will observe and collect data and become familiar with the secondary PDS model. Simultaneously, we will modify the secondary PDS model for special educators, thus designing the special education internship. A course proposal for the internship will be written during January and undergo the curriculum review process during the spring semester 2000. The internship could begin as early as the fall 2000.

In the spring semester, special education and occupational therapy faculty will shadow secondary education faculty at Perry Hall Middle School and Owings Mills High School. The observational period will allow us to establish contacts within the schools in Baltimore and Howard County and elicit letters of support for the expansion of the PDS model at the schools to include special education. It should be noted that all of the above schools have ethnically diverse student populations. Baltimore County Public Schools is the fourth largest school system in Maryland serving over 105,000 students in 161 schools; it was also declared in the Maryland Teaching Staff Report 1999-2001 as one of the jurisdictions which will experience a shortage of certified special education teachers, as was Howard County. Specific goals, milestones, outcomes and their expected dates of completion follow.

Evaluation Plan

The project, as a planning and developmental activity, will require formative evaluation of the process of model development as well as summative evaluation of its outcomes. Time logs, field notes, agendas of meetings, and notes of meetings will be collect by the project evaluator in order to monitor the process. Progress of the process will be monitored by the completion of the milestones. The primary goal of the project will be the development of the collaborative special education and OT internship. Status reports will be provided to the project team in the fall of 1999 and the spring of 2000. A final report in June will be issued in June 2000. Evaluation will include the performance outcome indicators completed by students in the internship and student evaluations of the internship experience. Interview data will be collected from students recruited into the secondary special education major. A survey of student and their supervising teachers’ perceptions regarding the effectiveness of the internship in preparing them for student teaching will be conducted upon implementation.

An independent evaluator will monitor the progress. He will provide formative data to the project team during the fall and spring semesters. Evaluation instruments will be developed to accompany activities conducted in the schools. Consumer groups participating in the activities (Parents, students teachers, TU interns, students and staff) will be queried as to whether activities have accomplished their stated objectives and have met consumer needs. Baseline observations will be used within professional development experiences to determine acquisition of content. Formative data will be used to report and modify the model. Qualitative data will include observations, interviews with PDS Site Coordinators, field notes, debriefing notes after meetings, notes from work sessions and curriculum development work sessions.
Impact

As part of its continuing efforts to help all students reach Maryland State content and student performance standards, Towson University continues to develop and disseminate innovative school-based professional development models and support school improvement and career-long professional development for all members of the school community. The PDS model emphasis the Essential Dimension of Teaching specifically dimensions 6, 9, and 10 "to organize and manage a classroom using approaches supported by student learning needs, research, best practice and expert opinion, to collaborate with the broad educational community including parents, businesses and social service agencies and to engage in careful analysis, problem solving, and reflection in all aspects of teaching.”

In addition, many of the interns will engage in service learning projects which may involve tutoring students for Maryland Functional Testing, SAT & PSAT Preparation, Maryland Core Learning Goals, etc. Another of the benefits of this program will be using the portfolio assessment process for student interns as they are trained to master the Essential Dimensions of Teaching. All participants will be involved in a developmental process for assessing professional preparation practice, and progress. This proposal specifically proposes to implement the Redesign of Teacher Education which calls for reform in teacher education, Maryland’s Core Learning goals. Towson University continues to develop and disseminate innovative school-based professional development models.

Abstract: The professional development model proposed here builds on and extends the use of VisionQuest©, a CD-ROM teacher development tool designed to help teachers envision and achieve technology integration. The VisionQuest© model is based on the assumption that teachers are more likely to embrace pedagogical and classroom change if these changes address real issues they face in practice. Teachers are challenged to reflect on their current knowledge and classroom practices, relative to technology integration, and then, after observing exemplary models included on VisionQuest©, develop and pilot their own solutions to relevant classroom issues. By engaging teachers in reflective activities that nurture and sustain their professional development, VisionQuest© facilitates the growth of teachers' visions for teaching and learning with technology.

Introduction

Despite the fact that technologies have achieved substantial presence in schools (Education Development Center, EDC, 1996), teachers all over the country continue to grapple with both practical and philosophical problems posed by the integration process (Hadley & Sheingold, 1993). Currently, K-12 teachers are experiencing mounting pressures, both from within and outside the educational system, to demonstrate that the huge investments being made in technology are not being wasted. Yet, according to the National Center for Education Statistics (NCES, 1997), "relatively few teachers (20%) report feeling well prepared to integrate educational technology into classroom instruction" (p. 8). Although most teachers report that professional development activities are available to them and that they frequently participate in them (NCES, 2000), teachers continue to face significant barriers as they begin integrating technology within their classrooms.

Traditionally, technology courses for in-service teachers have focused on increasing teachers' technical skills and competencies for using specific software applications. Yet clearly, an increase in teachers' technical skills is insufficient to guarantee the effective use of technology in the classroom. Through previous research efforts (Ertmer, 1999; Ertmer, Addison, Lane, Ross, & Woods, 1999; Ertmer & Hruskocy, 1999; Hruskocy, Cennamo, Ertmer, & Johnson, 2000) we have identified a number of challenges that teachers face as they begin to integrate technology within their curricula. Besides a host of
technical and logistical questions (e.g., How does this software package work? Where and when should we use computers?), more subtle issues, related to teachers' pedagogical visions and beliefs, as well as their perceived confidence for using technology, are also known to impede meaningful classroom use.

The VisionQuest© professional development model emphasizes building on teachers' current beliefs and practices. By starting with teachers' prevailing classroom needs, and acknowledging their current levels of self-efficacy, VisionQuest scaffolds teachers' development by meeting teachers where they are. In addition, this model emphasizes the role that teachers' beliefs play in the adoption and change process and specifically outlines how those beliefs might be addressed through teacher development efforts. While traditional staff development models have been aimed at eliminating first-order barriers (barriers that are external to teachers and include skills training and equipment needs), the VisionQuest© model focuses primarily on challenges presented by second-order barriers (barriers that are intrinsic to teachers and that challenge fundamental beliefs about current practice).

Teacher Beliefs

In summarizing research on teachers' beliefs, Pajares (1992) noted that "there is a strong relationship between teachers' educational beliefs and their planning, instructional decisions, and classroom practices" (p. 326). In particular, teachers' beliefs about their ability to use computers in instruction may be key, given the role self-efficacy is proposed to play in determining behavior. In a recent study by McKinney, Sexton, and Meyerson (1999), participants with lower efficacy beliefs expressed concerns typical of those in an early stage of change (self-concerns) while those with higher self-efficacy had concerns that were more characteristic of later stages of change (impact-concerns).

Self-efficacy refers to personal beliefs about one's capability to learn or perform actions at designated levels (Bandura, 1997). According to Bandura, self-efficacy is based, not solely on the level of skill possessed by an individual, but on judgments about what can be done with current skills. As such, self-efficacy is thought to mediate the relationship between skill and action. Simply put, without skill, performance isn't possible; yet without self-efficacy, performance may not be attempted. According to Bandura, "beliefs of personal efficacy constitute the key factor of human agency" (p. 3). Thus, teachers who have high levels of efficacy for teaching with technology are more likely to participate more eagerly, expend more effort, and persist longer on technology-related tasks than teachers who have low levels of efficacy.

So what does this mean to designers and others who are responsible for teacher development? How can we design professional development experiences that address teachers' second-order barriers, or more specifically, that build teachers' efficacy for using computers in instruction?

Given the long-term nature of the integration/adoptions process, we recommend that staff developers/instructional designers meet implementation needs in a responsive fashion—that is, through "iterative interventions" (Frame, 1991) that meet and challenge individual teachers at their current levels of use. As teachers face changing needs, the strategies designed to meet them must also change. In addition, training strategies should be varied to meet the needs of teachers at different levels of technology use. Different strategies are likely to be more or less effective for teachers with different levels of confidence and skill (Snoeyink, 2000). For example, it is important not to discourage those who have low levels of confidence by surrounding them with others who are much more experienced and confident. By designing staff development programs that start with the real concerns that teachers have, and helping them experience success in solving their own problems, we have a better chance of making headway in the technology integration process.

The VisionQuest© Professional Development Model

VisionQuest© is designed to address teachers' second-order barriers, specifically their visions for, beliefs about, and confidence for teaching and learning with technology. This model (adapted from
NCREL, 1997) builds on, and extends, the use of the VisionQuest© CD-ROM teacher development tool, designed to help teachers envision and achieve technology integration.

VisionQuest© features the classroom practices and technology integration visions of six teachers and is designed to support users' reflections on both the underlying beliefs and classroom strategies that enable exemplary technology use in ordinary settings. Teachers, featured on the CD-ROM, share their ideas for classroom technology use and demonstrate how technology supports their fundamental beliefs about teaching and learning.

The VisionQuest© professional development model, which serves as the underlying framework for the CD-ROM, facilitates the growth of teachers' visions for teaching and learning with technology by engaging them in reflective and collaborative activities that nurture and sustain their professional development. The six-step model (Fig.1) facilitates reflection on, and the transformation of, classroom practice. Teachers are challenged to reflect on their current knowledge and classroom practices, relative to technology integration, and then, after observing exemplary models included on VisionQuest©, develop and pilot personal solutions to relevant classroom issues. Through a collaborative and reflective process, teachers gradually develop their own understandings about how to integrate technology in ways that address relevant curricular and pedagogical issues within their classrooms. Each step in the model is described below.

Figure 1: VisionQuest© Professional Development: Scaffolding Technology Integration

Reflect on Current Knowledge

In the first step of the model, teachers are encouraged to reveal the goals they want to accomplish in their classrooms, the barriers that hinder their work, and the instructional and/or administrative concerns they have, related to specific aspects of classroom practice (e.g., classroom organization, assessment practices). Teachers also are asked to reveal their beliefs about teaching as well as the incentives that motivate them to teach. At these early stages of technology adoption and use, the focus is not on specific technology skills or needs. Teachers are encouraged to consider their needs as both teachers and learners prior to considering their needs as technology users. Teachers and trainers work collaboratively to develop an individual teacher profile, followed by the development of an individual teaching/technology plan (ITP) in the next step. Thus, an individual teacher profile might include information about teachers' 1) classroom practices, 2) classroom context, 3) perceived issues and barriers, 4) beliefs about teaching, 5) motivation for teaching, as well as 6) preferred ways of learning and teaching. By beginning with teachers' perceived needs, we remove the focus from the innovation and place it instead on teaching practices and the important issues teachers face.
Observe Models and Cases

One of the most effective ways to help teachers move forward on their technology integration journeys is through the use of peer and exemplary models (Gilmore, 1995; Pintrich & Schunk, 1996) which are believed to lead to increased confidence and competence. During this step, pre- and in-service teachers observe teachers who use technology in their teaching. Web sites, videos, text materials, and the VisionQuest© CD-ROM are used to examine both the pedagogical beliefs and classroom practices of exemplary technology-using teachers. The CD-ROM is organized around the metaphor of a journey and is divided into three sections: Roadmap, Path, and Destination. Within these three sections key themes are addressed: Guiding Vision, Getting Started, Incentives and Barriers, Teacher and Student Roles, Classroom Organization, Curricular Emphases, Assessment Checkpoints, and Sample Student Products and Assessment Tools.

Reflect on Practice

During this step, teachers and staff developers co-develop an individual teaching/technology plan by considering various means for meeting specific needs identified in the teacher profile. That is, after reviewing the issues teachers face, staff developers help translate these important questions into technology-based learning opportunities. For example, if a teacher indicates that she would like to revise her assessment practices, staff developers might help her consider any of the following technology solutions: creating a grade book, determining weighted scores using a spreadsheet, or developing a rubric based on Internet samples. Depending on the type of support teachers request or require, different types of support should be offered (one-on-one consulting, just-in-time training, formal classroom training, peer collaboration and observation, etc.). Some strategies will work more readily and be more appealing than others, depending, at least to some extent, on the barriers teachers describe. Different barriers (e.g., lack of confidence vs. lack of support) typically suggest the use of different strategies. For example, if teachers mention not yet feeling comfortable with technology, they probably are not ready to begin using technology in the classroom. Instead, they need to increase their personal comfort through increased individual and personal use. By acknowledging and helping teachers work through specific first- and second-order barriers, we help them identify strategies that work for them and simultaneously build confidence in their ability to address future barriers.

Initiate Changes

As teachers test their ideas in their classrooms, they experience first-hand what works and what doesn't. As Maddin (1997) emphasized, "the real learning begins back in the classroom" (p. 56). Information obtained through direct experience is one of the most powerful means to shape future practice. Because teacher self-efficacy is a fluid construct, it changes with new experiences. While early success can raise efficacy, early failures may lower it. For this reason, it is probably important that reluctant teachers experience as much success as possible during their first attempts to use technology within the classroom. Additionally, teachers should set realistic goals for themselves since they will measure their success by how closely they meet the goals they have set (Pintrich & Schunk, 1996). It is not critical that reluctant teachers implement a highly sophisticated lesson with lots of bells and whistles. What's most important is that they are successful. Risk and surprise need to be eliminated, or at least greatly controlled.

Reflect on Changes

Kagan (1992) explained that changes in teachers' beliefs are rarely the result of reading and
applying research findings. Teachers base most of their ideas on their own and others' experiences. In order to promote professional growth, Kagan recommended that teachers' awareness of their own beliefs be raised, followed by experiences that challenge those beliefs and promote integration of new ideas into current belief systems. Such reflection initiates the revision process. After implementing new ideas or tools in the classroom, the teacher takes time, with or without others, to reflect on the teaching/learning processes and outcomes achieved. Teachers consider how the teaching and learning that occurred compared to what was expected. As teachers realize that their "ability to successfully utilize technology has increased, they are motivated to attempt to learn more about technology, its uses, and benefits" (George & Camarata, 1996, p. 51). However, as with most teaching experiences, there are usually many opportunities for improvement. Teachers should be encouraged to focus their reflections primarily on what the students did or did not do in response to the lesson. Based on this information, teachers can consider what changes need to be made to facilitate the types of student performances or levels of thinking desired.

Modify and Extend Understanding

In this final step, teachers are encouraged to discuss their instructional changes with others and consider the overall usefulness and effectiveness of the changes they have initiated. Based on conversations with others, teachers are encouraged to outline their next steps for development. This may include implementing a revised version of the lesson, adding one more idea to the lesson, or reading relevant literature to examine what others have done. Revisions made after each iteration are not likely to be substantial; however, continual refinements, over time, can add up to noticeable differences. As teachers continue to converse with others about how they addressed a relevant issue in their classrooms, as well as the results they obtained, they initiate, in effect, new cycles of development.

Educational Implications

According to Fisher, Dwyer, and Yocam (1996), "The major challenge to supporting school learning with technology lies not with technology but with the professional development of educators" (p. 7). The success of our technology integration efforts will depend, ultimately, on the focus and effectiveness of our staff development efforts.

Traditional approaches to teacher development have typically employed a one-size-fits-all mentality. Responsive professional development, as represented by the VisionQuest© model, meets teachers where they are, yet moves them continually forward by engaging them in activities that explicate both their own and their students' evolving understandings. Recognizing that even "expert" teachers continue to evolve (and that expertise is emulated in a variety of ways), early professional development activities impel teachers to reveal, test, and refine current beliefs about classroom practice. As teachers engage in iterative classroom tryouts and collaboratively reflect on changes in students' thinking, they become more sophisticated at recognizing and assessing their own understandings and abilities. Through this ongoing examination of practice, teachers begin to construct deep understandings of how to translate reform-based pedagogy into practice. As initial questions (e.g., What makes a "good" activity?) lead to additional questions (e.g., How can technology support this activity? How do I assess students' work?), the VisionQuest© model has the potential to engender simultaneous changes in instruction, assessment, and teacher and program development.

A Case Study of a Project to Promote the Integration of Technology in the Classroom at the Elementary Level

Frances Figarella
University of Puerto Rico
Elementary School
francesv@caribe.net

"Abstract": This article examines a professional development project to promote the integration of technology into the classroom with teachers at the University of Puerto Rico Elementary School (UPRES). The purpose of this study is to learn how UPRES teachers learn about technology and on how to integrate this technology into their classroom. This report focuses on the first semester of the special project. In the study a qualitative approach was used for the collection and interpretation of data. The major source of data was the opinion of participants gathered through questionnaires, evaluation forms, and interviews. New practices to integrate technology into the classroom were evidenced and analyzed through participants’ lesson plans. The study describes the stages of teacher learning computer technology, their learning needs and how teachers are integrating technology.

The University of Puerto Rico Elementary School (UPRES) is working on a technology plan to promote the integration of technology into the teaching and learning process. One of the components of the Technology Plan is the Professional Development Program (PDP) for the teachers. This component is considered to be the most important one because it could determine the effective integration of the technology in the classroom. Roblyer (2000) and other authors state that properly trained teachers make the difference between the success or failure of an integration effort. The UPRES started a special project to train the teachers in computers and to promote the integration of technology as a learning tool in the teaching and learning process in the classroom. The special project started in August, 2000 and will be completed in May, 2001. The project consists of workshops sessions, the design and implementation of lessons, and the publication and dissemination of the lessons implemented. The purpose of studying the first semester of the Project is to learn how UPRES teachers learn about computers and integrate them in their classroom. The study documents outcomes of the project and to understand more about the adult learning process. The study also revealed knowledge on the process of integrating technology in schools. The findings of this study are expected to be relevant for others schools involved in the similar initiatives.

The study consists of collecting data about the process and outcomes of the technology special project implementation during a four month period. The data was collected before, during and after the teachers participated in the Technology Professional Development Program of the technology special project in the UPRES. A qualitative approach for collecting and interpreting data was followed. The major source of data was the opinion of participants gathered through questionnaires, evaluation forms and interviews. New practices of participants as they integrate technology into the classroom evidenced with the lesson plans were also analyzed. The participants in the study are twelve elementary school teachers and two student teachers. To collect the data, the researcher used various instruments at different phases of the study. For the very beginning, the researcher used an adaptation of the instrument The Stages in Learning New Technology (SLNT) developed by Russell (1995). This instrument describes the stages through which teachers learning computers at the starting point of the project. A need’s assessment survey was developed to understand the concerns of each teacher and to guide the design of the training sessions. For each workshop, evaluation forms were designed and interviews were carried out as the major sources for identifying the fundamental characteristics of an effective technology learning process and how participants are changing their perspectives on the integration process. The evaluation form measures four criteria: Utility of the software, user-friendly characteristics, effectiveness of the workshop and participants interest to use the software in the teaching-learning process. Also, lesson plans generated by teachers were analyzed to describe how teachers transfer learning to their teaching practice.
Findings: The results of SLNT instrument revealed that 35% of participants are at the basic stage, 24% are at a middle stage, and 41% are at an advanced stage. The need assessment shows that 100% of the teachers in basic level want to learn to use the computer. This information was used to decide to start with two basic sessions for the teachers who are in the basic level. Forty five percent (45%) of the middle and advanced stage teachers need to learn how to use only one computer in the classroom (at the UPRES there is one computer per classroom), and 64% of the teachers need ideas and programs to integrate computers in the classroom. For the first phase of the study, the researcher analyzed data of three workshops offered: Basic computer skills, Inspiration (graphics organizer) and “Erase una vez” (story maker). The participants (100%) who completed the evaluation form agree that the software and the workshops fulfilled the four evaluation criteria. The evaluation form includes questions about their ideas on integrating the software and how they are changing their perspective towards the integration of technology. Figure 3 shows the variety of ideas they expressed. It was interesting to find that all teachers identified different ideas of how to integrate the software.

</table>

The twelve participants of the special project demonstrated they are using the technology for personal productivity. Samples of the kind of work they are doing are: writing/sending letters to parents, creating materials for the students, organizing and planning lessons, obtaining reference material, organizing information and preparing presentations.

Of the twelve teachers, only four teachers evidenced the integration of technology during the first semester of the project through nine lesson plans, which are classified as follows: Promoting writing skills (4); Finding information ; To learn vocabulary; To analyze and organize ideas and; To represent concepts with drawings and diagrams. The four teachers integrating the technology at this phase have between 12 and 15 years of teaching experience. Three of them are at the advanced level.

Discussions: The observations and data collected during the first semester of implementation helped to identify patterns that can be useful to enhance the project and the school technology plan. The next paragraph explains the found patterns. First, those who demonstrate interest in the technology project were at different stages in learning computer technology and have different learning needs. Having determined the stage in learning technology in which they are, and their learning needs, facilitates decision-making to respond to the different developmental stages of the teachers. There are seven (7/12= 58%) enthusiastic teachers that demonstrate motivations to learn more and apply what they have learned about technology. They are consistent in their attendance to workshops. There are five of the teachers (5/12= 42%) who participate in an inconsistent manner and do not demonstrate initiative to integrate the technology in the teaching-learning process. Few teachers aren’t interested or had others priority. Second, the data of the evaluation form allows to conclude the following about the workshops: 1) The software selected for the workshops are teacher friendly (Inspiration and “Erase una vez”), 2) The software can be applied in the classroom, 3) The structure of workshops was very effective in teaching participants how to use the software; and 4) Teachers discovered different creative ways for using the software.

Teaching Electronic Information Research Skills to Teachers

Ina Fourie
Department of Information Science
University of South Africa
South Africa
fourii@unisa.ac.za

Abstract: The University of South Africa offers a distance teaching module in electronic information research skills to teachers doing a master's degree. The module is highly practical and caters for different levels of computer skills. It involves the completion of a literature search, the design of a personal database, and the compilation of a bibliography. The study material includes a study guide, a tutorial letter with portfolio activities, CAI tutorials, and a web-site. Students attend a week-long workshop, or master the practical skills on their own. Portfolio assessment enables them to monitor their mastery of the practical skills and to reflect on their weaknesses and progress. Considerable success has been achieved, even with students who are computer illiterate. However, if students do not obtain access to computers and the internet they do not retain the information research skills, and also forfeit the lifelong skills benefits.

Introduction

In South Africa, as in many other countries, there is a growing interest in electronic information, access to the internet and information literacy. The ability to find, evaluate, analyse and use information is strongly associated with progress, prosperity and gaining a competitive edge. Bruce (1995, p.158) for example proclaims: “Effective research, learning, communication, decision-making and problem-solving, require individuals to be able to locate, manage, evaluate and use appropriate information from a wide range of formal and informal sources”. The need for tertiary students to be introduced to research information skills can be summarised in Sayed’s words (1998, p. x): “Information literacy is thus a “key skill” similar to other foundation skills such as mathematics, statistics, language and communication. The electronic world-brain of the twenty-first century will make information discrimination and handling skills more and more valuable.”

Librarians have developed information handling and retrieval skills over many decades, but for many people information skills can open up a new world — especially if they have never even touched a computer before. It is therefore time for librarians to share their skills with people from other disciplines, such as teachers. The condition, however, is that information research skills should be linked to the students’ curriculum content (Barry 1997; Oberman, Lindauer & Wilson 1998) and their immediate information needs and topics of interest. Since 1998 the Department of Information Science in collaboration with the Library Services at the University of South Africa (Unisa) has been offering a postgraduate module in Research Information Skills. The module is currently offered to students doing master’s degrees in Chemistry Education and Environmental Education. The students are thus all teachers or lecturers — who are in excellent positions to share their newly gained knowledge and skills. Since the content of the module is generic, it can easily be offered to different target groups by simply changing the topics covered in the practical exercises and adjusting the level of assessment. It is thus potentially possible for teachers to share their knowledge with their pupils and colleagues without putting in considerable effort.

Unisa is a distance teaching university. Most of our students are therefore employed adults. They have fulltime jobs, families to take care of and community responsibilities. Furthermore they come from all over the country, from neighbouring countries, and even from Mauritius, the USA and Switzerland. At Unisa we follow a distance teaching model which relies mostly on printed tutorial matter, with no (or very little) compulsory class attendance. For the module in Research Information Skills we do, however, offer an optional one week workshop. Students who are not in a position to attend the workshop are expected to master the skills in their own time by using a variety of resources which are available from the module’s web-site. Access to computers and the internet is then a prerequisite. The rationale behind the module is dealt within detail by Fourie and Ten Krooden (1999).
Purpose and Structure of the Module

The module aims at enabling students to do their own literature searches for the dissertation of limited scope which they complete as part of their studies, and to evaluate and organise the search results to support their research. Apart from clearly formulating a research topic and resulting information need(s), the students are expected to select suitable sources for finding information (eg bibliographies, printed indexes, databases, the library catalogue or an internet resource), formulate a search strategy, use various systems to find information (eg the library catalogue, the ERIC database or an internet search engine), evaluate the information sources, add relevant sources to a personal database and compile a bibliography as a starting point for their research project. The overall aim of the module is therefore for each student to develop the necessary skills for effective retrieval, evaluation, organization and use of information for research.

The expected outcomes for the module include understanding: the link between research and literature searching; the information industry and information infrastructure; computerized databases; the structure and nature of databases in order to apply this knowledge to information retrieval; how to formulate and adapt search strategies in order to retrieve the most relevant search results; the creation and maintenance of a personal database; what the internet is and how to find information through the different internet resources; and the importance of publishing.

It is therefore an extremely practical module, aimed at teaching a lifelong skill to enable students to keep up in a highly technological and information literate society. Since critical reflection and progressive improvement is a critical component of effective and efficient electronic information searching (also called online searching), the emphasis is strongly on practice, critical reflection, and the ability to spot problem areas and to suggest solutions to overcome these.

Content

Although students are introduced to the total information infrastructure, including printed resources, the emphasis is on the use of electronic information resources such as the library catalogue available via the internet, databases via the internet or on CD-ROM (eg ERIC), and other internet resources. The content is set out in a study guide. All students receive a printed copy of the study guide but can, however, also download an electronic version from the internet. The topics covered in the study guide include research and information, information sources, computerized information retrieval, database structures, search strategies, organization and maintenance of information in a personal database, internet navigation, and the use and publishing of information.

Student Population

The module has been designed to cater for the needs of Unisa students. Some of the teachers doing the module are highly computer literate; others have never touched a computer before. Some work in highly technological environments, while others come from rural areas or disadvantaged communities — often without electricity or telephone lines. In the end, however, they are all expected to use electronic information resources to search for literature to complete their dissertations. Additional arrangements therefore have to be made to cater for the needs of computer illiterate students, as well as for those who are highly computer literate and may be held back by an average workshop class. (More about this in a following section.)

It is important to bear in mind that the students are adults, and although they may be ignorant about information research skills, they are experienced teachers and often leaders in their communities. We found, for example, that the students in Environmental Education especially are very active in their communities. They initiate projects for environmental protection or informing the community on environmental hazards. They publish poems, organise prayer groups and offer social comment in their local newspapers. It is therefore essential to value their input as adults, to acknowledge their expectations of the module, and to have empathy with the difficulties they experience in a learning situation that demands computer skills. Some of them admit to being so nervous of using a computer for the first time that they actually shake! In addition to the normal burden (or challenge) of learning a new skill (information searching), they have to use a new tool (a computer) — and save face in the presence of their lecturers and fellow students. (In a separate section I shall deal with how we approach this challenge.) At this
stage it is sufficient to acknowledge the truth in Malcom Knowles' (1990) theory of adult learners and andragogics. Most of the teachers take their studies very seriously. They set high expectations for their mastery of the skills involved. Some admit that it is their responsibility to put in the extra effort to gain computer skills; they are not satisfied with just following our guidelines in a workshop, but want to complete the information searches all on their own. Some are even prepared to voluntarily repeat the module to ensure that they meet with the standards they have set for themselves.

In general the students are prepared to make huge sacrifices to gain research information skills. They consider it as an important life skill, and are prepared to incur travel and accommodation expenses to attend the workshop, and to travel to the computer laboratories in the regional centres. In 1999 two Namibian students travelled over 2500 kilometres to attend the workshop! It is of course then our duty to ensure that we offer the best possible learning opportunities.

Teaching Methods and Learning Events

The module is based on a study guide which includes the learning material, self-assessment activities and references to the portfolio activities. Students also receive a tutorial letter with the portfolio activities that need to be completed for assessment. This also contains the guidelines for compiling portfolios and the checklist with assessment criteria. It is important for students to have the latter before embarking on their portfolios.

Two computer assisted (CAI) tutorials are prescribed. They can be purchased from Unisa Press at very reasonable prices (between $4 and $7). One of the CAI tutorials covers the formulation of search strategies (including the selection of search terms, the combination of search terms, searching on word stems, and searching in selected fields only). It also includes numerous examples and questions for self assessment. The other tutorial covers the structure of databases, such as the fields that are included, how to use the fields to search for information, and how to use the information obtained from database records to design a personal database, or compile a bibliography. Students can work through these tutorials in their own time and at their own pace. This is, however, considered essential preparation for the workshop. Students who do not have access to computers therefore have to attend a training session prior to the workshop, or make use of the computer laboratories at the Unisa regional centres.

A module web-site offers links to additional resources and online training material (e.g., on how to search the library catalogue and how to use the internet). The web-site links to electronic versions of the study material that can be downloaded. It also offers links to supportive material such as selected search engines, information on discussion groups, relevant electronic journals, databases that are freely available, guidelines on evaluating and citing internet resources and the library catalogue.

The learning events also include a week long practical workshop during which students get to use a variety of electronic information resources, and to design their own databases. Since the course is offered through distance teaching, it is not compulsory for students to attend the workshop. If they do not attend the workshop, however, they are expected to use the module’s web-site to learn more about the electronic resources that are covered during the workshop. Training manuals and access to the information resources are available from the web-site of the Unisa Library. As part of the workshop an additional session is offered for students who have not previously worked with computers. During the workshop students are taught how to search the library catalogue, a selection of databases such as ERIC, and how to use internet search engines and directories. They are also taught how to design their own personal databases. We use either a word processing program such as WordPerfect or MS Word to design the personal databases, or we use a commercial database programme, DB/TextWorks. We have permission to provide students with demonstration disks of DB/TextWorks. They can then use these to create a database that can store up to fifty records. Each student’s database should be different, and based on the information they will require to write their dissertation.

Finally, students are also advised to view videos on online searching. These can be ordered from the Unisa Library.

Computer Skills

As mentioned earlier, we have students who are highly computer literate (especially the Chemistry
A large number of students doing Environmental Education have, however, never touched a computer before. It therefore takes considerable effort and a special atmosphere to get them up to standard so that they can keep up with the rest of the group during the workshop.

Training sessions in computer literacy are arranged prior to the workshop. Students are given the opportunity to work through a CAI tutorial on computer literacy. The emphasis is on the mastery of keyboard skills. We feel that for the immediate purpose of the workshop this is sufficient. During the workshop they are then introduced to navigating the internet, and specific database programs — although they may work very slowly, they at least know where to find the appropriate keys. Students cope fairly well if given sufficient time. We can unfortunately not spend more than two days (eg the Friday and Saturday prior to the workshop) on this angle. Although we found that these students can manage, their slow typing speed frustrates the students who are highly computer literate. The fact that they are already anxious and very aware that they are holding up the group, also impedes their progress.

The ideal situation would be to assess students' computer skills and knowledge of information resources before they attend the workshop. They could then be organised in two groups so that the students with no prior computer skills can progress at a slower, less stressful pace. With sufficient practice and attention they could then master the required skills. We are thinking of developing an assessment instrument to allow students to test their own computer skills to ensure that they meet with our requirements for the workshop. We could also include advice on aspects that they still need to master (eg using the navigation buttons of a typical internet browser or menu driven database). The advantage of such a tutorial would be that it can be made available on the internet, and that students could assess their computer skills in their own time and without embarrassment. They could then work on their skills until they meet our entry requirements.

For a number of computer illiterate students, the workshop provided the impetus to make an effort to gain access to a computer or to purchase one. Since they have the opportunity to reinforce their skills, the module in Research Information Skills really opened a whole new world for them. Although students who do not have access to computers at their places of employment can pass the module based on what they learn at the workshop, they would soon forget the skills they mastered.

A separate workshop for computer literate students would be shorter and at a faster pace and include more advanced activities, such as designing a personal web-site.

**Portfolio Assessment**

Portfolios were selected as the assessment method since they are highly suitable for Information Research Skills and the reflective and critical thinking skills required by information searching and the design of databases. The reflective nature of search skills is also stressed by Barry (1997) and Fidel (1994). The students have to submit two assignments based on portfolio activities. The assignments are assessed according to a checklist with criteria, and guidelines are provided for improvement of the answers to the activities. For the first assignment we include a personalized letter, because we found that students make many mistakes since they are not familiar with electronic information retrieval. If we were to use the checklist at this stage, it would be too discouraging for them to be confronted with an average or below average rating.

The whole idea behind portfolio assessment is to allow students to make mistakes, to guide them in correcting their mistakes, and to encourage them to reflect on their own shortcomings and come up with suggestions for improvement. The assessment criteria therefore cover the students' learning experiences, the course outcomes, the presentation of the portfolio, the final product (which is the information search, internet search and personal database), and the completion of the self assessment activities. The examination portfolio is basically the improved versions of the two assignments and the final product. To ensure high standards, it is also examined by an external examiner.

**Students’ experiences**

We have gathered data on students' experiences with portfolio assessment and their experiences of the module and workshop through focus group interviews, personal observations and the comments in their portfolios. We have established that the learning content and the portfolio activities must be formulated very clearly and
completely unambiguously. Since the field is new to most of the students, they can easily be side-tracked, and they can also become very frustrated if they have to waste time on poorly formulated activities. The reason for including the activities must be explicitly spelled out so that students can link it to the end products they have to complete. (It should be remembered that the teachers are not librarians, and therefore the purpose and value of the activities will not always be obvious to them.) Students must also receive brief but very clear and explicit guidelines on how to compile their portfolios. It does not take much to get the teachers totally involved in portfolios per se, instead of focusing on search skills. A number of students mentioned that they learned a lot from portfolios that they can apply to their own teaching situations.

Portfolios are a new method of assessment to our students. It requires a complete change of mind-set and a very supportive and understanding atmosphere to convince them that they are allowed to make mistakes, that they will have the opportunity to correct their mistakes and that they may criticize the lecturer and course content (of course with the necessary substantiation). One student said: "The portfolio experience taught me that I can immediately give the answers, because I can always come back and improve or correct my answers".

Students need to learn that they can trust the lecturer to keep the promises of portfolio assessment. The need for such trust is clear from the following remark by a student: "Although I felt very uncertain in the beginning, I had enough trust in the lecturer to realize that she will not set unrealistic demands. She will not expect us to do something that is impossible". Portfolio assessment also requires a change of mind-set on the part of the lecturer, who needs to learn that the students have higher expectations and that they require more time and attention. Lecturers especially need to learn how to deal with criticism — which is actually invited by portfolio assessment. Fourie and Van Niekerk (1999) and Van Niekerk offer more detail on portfolio assessment (1998).

What Students Gained

The approach we follow in teaching Research Information Skills helps students to realize how they learn — it is not just about the end product: "I was concerned only about the end product, without considering the fact that the actual doing of something can also be a learning experience. We are too set on the end product, which can often cause our work to become very boring." Students also feel that they can apply the skills they have learned outside the immediate situation. They view Research Information Skills as a lifelong skill to share with their pupils, colleagues, and even family members. "I have really enjoyed this course and found that I can apply and share so much of the information and skills that I acquired. I think students need to have a paradigm shift to cope with this course especially with regard to reflective practice." Students felt that they can share their experiences with their fellow students and the lecturer: "The kind of learning that takes place in Research Information Skills, caters for sharing of the processing of constructing ideas instead of simply laboring individually. So everyone, both learners and lecturers, are viewed as resources." Another student proclaimed: "I have also developed as a person and understand that in life nothing is impossible. If you keep on practising and ask for help, you are bound to succeed".

Recommendations

Even though the module is presented through distance learning, students seem to manage well. They are also willing to attend the workshop. A web-site with more support, student interaction and interactive tutorial matter would, however, be of additional benefit. A lack of computer skills impedes students' progress, and since they are adults they may experience even more anxiety due to the need to save face. An electronic assessment instrument available through the web would support them in ensuring that their computer skills meet with our expectations. If not, they could put in more practice through the use of the CAI tutorials before attending the workshop. It should be explained to students that we can support them in mastering the basic information research skills even if they have no prior knowledge of computers. If, however, they cannot gain access to computers and the Internet to reinforce their skills, the module would have little more effect than making them aware of the power and use of electronic information resources.

Students should also be provided with more direction on the variety of resources they can consult. This could be done by mapping the information infrastructure for the particular discipline (e.g., Environmental Education or Chemistry Education), or even building this into a subject portal. The emphasis would be on searching for information from these resources and evaluating the results. Furthermore, it would also be necessary to consider
differentiated learning events for students who are highly computer literate, and who have access to the internet. This could include the development of personal web-sites to organise the results of their literature searches, and to offer links to their discussion groups and journals they need to consult regularly. It could also include links to the numerous current awareness services offered via the internet, and to an electronic portfolio. In future the main emphasis should be on developing opportunities for students who come from different communities: to offer sufficient support as well as sufficient challenges.

Once students from disadvantaged communities have mastered the basic skills, they should have the opportunity to work on more challenging tasks. Since students have to complete the module in one year, this is currently not possible.

Abstract: This paper examines the use of Instructional Technology graduate students as mentors to K-6 elementary teachers in a rural community in the use of technology and the integration of technology into the daily curriculum. Mentors were able to support the elementary teachers in overcoming the barriers to technology use by modeling a vision for integration, just in time learning, access to equipment, professional development opportunities and methods for assessing student work involving technology use.

Introduction

As educational institutions acquire more sophisticated hardware and software, an overwhelming need arises for teachers to obtain the necessary skills to implement these tools into the classroom curriculum. To make effective use of these tools, teachers must redesign lessons around technology resources, solve logistical problems of how to teach a class of students with a small number of computers, and transform the role of teacher in the technologically transformed classroom (Maddux, 1997). While teachers indicate they see value in students using computers, some are not able to make the connection to how the computer fits into the daily classroom. Common barriers to the use of technology by teachers include the vision, access, time, assessment, and professional development (Office of Technology Assessment, 1995). This study describes a mentoring relationship among elementary teachers in a rural school district and graduate students in Instructional Technology at a midwestern university in a College of Education.

The Study

This study investigates one-on-one mentoring as a means of professional development strategy for in-service teachers in using technology in the teaching and learning process. An elementary school in Southeastern Ohio was selected as the study site. The study included eight in-service teachers and eight doctoral students of instructional technology participating for 20 weeks. The participating teachers (called mentees in this process) were teachers in grades K-6. The mentors were 2nd or 3rd year instructional technology graduate students.

Data was gathered from multiple sources using multiple measures including a need assessment survey for teacher mentees, the journals of both teacher mentees and graduate student mentors, and focus group interviews with teacher mentees. Additional data was gathered via a review of print and digital documents and field notes taken by the researchers. The researchers conducted data analysis concurrent with data collection, in a cycle beginning with data collection, continuing through reflection and analysis and then looping back through more data collection. The number of data sources helped to triangulate the data during the research process.

Findings

With respect to the barriers to technology use, the mentoring process provided a model for overcoming these barriers. The barriers are provided below with examples of how mentoring transformed the barriers:
Vision. Mentors modeled integration of the technology in the teacher's classroom providing opportunities for the teacher to observe how technology can be used and managed in their own setting. Often it is not that teachers do not want to use technology but that they lack the ability to "see" and "manage" how technology can be used in the teaching and learning processes of the everyday classroom. Mentee elementary teachers indicated that the process of modeling the use of technology in real settings afforded them the opportunity to "see how it works" and that it is indeed manageable.

Access. Teachers needed help with technical support. Mentors provided the teachers with the needed support by showing teachers how to repair machines, load software, navigate printing problems, and locate needed hardware. This provided teachers with more access to the technology in their classrooms.

Time. Teacher schedules are very difficult to manage. The mentoring allowed the mentor and teacher mentee “just in time” learning. Teachers met in their own classroom, used their own equipment at the time the teacher wanted to work. In a focus group discussion, teachers echoed these sentiments stating, “I want to learn how to use the technology myself, but having the mentor gave me the opportunity to learn it in my time frame and with the students.”

Assessment. Teachers had an opportunity to use the experiences of the mentor to determine ways of designing and evaluating projects. Mentors provided lesson design opportunities to teachers in instances in which the evaluation of technology skills were desired by mentee teachers.

Professional Development. Mentoring allowed the teacher to examine ways of using computers within the curriculum and learning new skills. Mentoring helped the teacher to develop strategies for overcoming the barriers of vision, time, access, and assessment.

In general, the mentors often presented the elementary teacher with models for integration. It was observed that teachers used these models to redesign their lesson to incorporate the use of technology into the lesson that was being taught at the time. Teachers did not create artificial lessons but instead followed their planned lesson and incorporated the technology to enhance the learning process. Some of the examples included following: 1) Native Americans – used a lesson plan on Native Americans to help students create a HyperStudio stack about Native Americans and to quiz the students on knowledge gained in the Native American Unit; 2) Solar Systems and US Constitution – worked with students to create two HyperStudio stacks, one on the solar system and the other on the US constitution; 3) Class Homepage using Communicator – with the help of the mentor worked with her students to create a class homepage; and 4) Student Album – worked with students to create a HyperStudio stack with pages for each student.

Conclusions

The mentoring involving the university instructional technology graduates and elementary teachers overcame many of the time and access barriers to technology integration in elementary classrooms. The mentoring provided vision to the teacher for designing lessons around technology-rich resources, the solving of technical support problems and motivation to use technology in the teaching and learning process. Comments from the teachers at the end of the 20-week period support the continuation of such projects in this elementary school and with others in the area.

The mentoring strategy is a promising means for obtaining professional development in schools for technology integration. Mentorship provides models of computer use to the classroom teacher and help in lesson plan design. This university/K-6 mentoring partnership supported the professional development of the graduate student mentor as well. Finally, in rural school districts that often have a difficult time obtaining substitute teachers, it provides a cost effective means for obtaining technical support and professional development in the use of technology.

Integration or Inoculation?: Selected Large-Scale Professional Development Studies

Abigail Garthwait, abigail@umit.maine.edu
College of Education & Human Development, University of Maine, USA

Abstract: This paper highlights a selection of research studies on multi-district professional development projects producing a clear call for more long-term involvement on the part of administrators and the intellectual, social and philosophical benefits for educators when using a mentoring system.

Teacher training theorists such as Darling-Hammond (1997) stress that traditional models of in-service training are simply not effective. While the literature abounds with research centered on the delivery of professional development (PD) in technology at the building or the district level, the same is not true regarding larger-scale (e.g. multi-district or statewide) research where descriptive models and suggested projects are most prevalent. The paucity of research in this area begs for aggregation. This preliminary literature review highlights a selection of studies that present a clear message to anyone undertaking a multi-district plan.

“Teacher expertise is the most important factor in determining student achievement,” writes Linda Darling-Hammond (Darling-Hammond & Ball 97). Yet requisite technology training is not as widespread as such a strong statement would imply. A 1999 survey reported that only 29% of teachers had more than five hours of PD in technology curriculum integration in the past year (Fatemi 99). For various reasons, PD has not been the answer that educators seek; a national survey of teachers’ technology use found that 93% of teachers cited independent learning as their preferred mode of preparation, compared to professional development activities (88%) and colleagues (87%) (National Center for Education Statistics 00). Nor can we expect the passing of time (and subsequent retirement of untrained teachers) to be the panacea. Fatemi notes that “teachers who have been in the classroom five years or fewer are no more likely to use digital content than those who have been teaching for more than 20 years” (1999).

Griffin (91) defines professional development as “a serious and systematic effort to engage a group of professional educators who work together, a staff, in activities designed specifically to increase the power and authority of their shared work” (p. 244). For many individuals, the effective curricular integration of computers is predicated on a fundamental change in philosophy and pedagogy that must often unfold in the absence of a formalized, supportive culture. Further complicating the PD mix is the multitude of concurrent reforms in education. One pilot project and four peer-to-peer initiatives illustrate the search to extend skill and understanding of computer use for K-12 educators into technological praxis.

In search of formative data, a Louisiana collaborative targeted PD and curriculum integration as part of a statewide pilot study. The teachers involved in the university-run course and the 3-day workshop certainly offered a multitude of suggestions for future iterations but it was noted that they were impressively committed to the project and overwhelmingly enthusiastic about its potential (Whelan et.al. 97). The researchers found two vital characteristics of successful schools. First, these sites exhibited strong management teams with “a commitment to collaboration among partners within the district, including those at the local university and... others outside of education. Additionally the evaluation team found a high degree of commitment to ongoing staff development in successful projects and schools” (p. 418).

A highly successful mentoring project resulted from the collaboration between a technical college and educators from 14 school districts in New Jersey. For three years, monthly meetings and two-week summer institutes resulted in over 150 contact hours between mentors and mentees. By contrasting the most and least successful schools, Holahan and colleagues (00) found the most striking difference was “the extent to which administrators supported the mentor teachers in learning to use computers, developing curricular materials, and providing peer mentoring, as well as the extent to which administrators supported...”
the mentee teachers" (p. 344). A similar program, Regional Educational Technology Assistance in New Mexico began in 1995 and continues today, thus proving the initiative's sustainability. Researchers Norton, & Gonzales (98) noted the acute need to involve administrators, and that the most useful aspect for participants was "the ability to network and share with colleagues... and the opportunity to learn and think about new curriculum and instructional ideas" (p. 44).

Mentor type programs are not only a phenomenon of the United States. As the capacity for large-scale PD emanating from Australia's Department of Education began to diminish, Williams (97) noted that professional organizations stepped in to support teachers as they assumed responsibility for their continuing education. She chronicles one such distance education project delivered that purposefully included face-to-face interactions. The planners negotiated two release days per month for each teacher to attend conferences, study or visit a mentor's classroom. A significant discovery in this research was that immersion within the technology also provided the conduit to professional relations with other educators. This reflective collegiality was a critical factor in deeper philosophical engagement for these educators. Although modest in scale (15 teachers per year) New Zealand sponsored two cycles of Facilitator Training. They handpicked teachers nationally for diversity in teaching experience, fluency with technology and geography (Compton & Jones 98). These teacher facilitators interacted with 355 others. Among the key findings was the value on embedded opportunities to network with colleagues.

These large-scale PD initiatives embody two consistent and key factors. The long-term commitment of administrators in the PD process leads to sustainable integration of technology. A "pre-packaged" inoculation fix solely mandated from above did not appear in this research; the capacity for customization based on the schools' needs, curriculum, existing expertise of teachers is absolutely essential. Furthermore, these successful programs manifested the recognition that learning takes time, practice and meaningful interaction with colleagues.

Ensuring Technology Leaders in Classrooms and Beyond: Technology Training in a Graduate Teacher Education Program

Kay L. Gibson
Department of Curriculum and Instruction
Wichita State University
United States of America
kgibson@twsu.edu

Abstract: This paper discusses the integration of the ISTE foundation standards into the Master of Education in Curriculum and Instruction teacher education program and the resulting impact on the teachers' acquisition of technology knowledge and skills, their classroom teaching, their students' learning, and in a broader sense their schools and districts. The program is described with particular attention given to the way in which students acquired and demonstrated technology knowledge and competencies. Successful integration of the ISTE standards into the program is viewed in terms of the quality and variety of products/assessment pieces using technology that have been generated by the students. Finally, the paper examines the resulting benefits to school districts that employ the teachers participating in this master of education program.

Introduction

The integration of technology into both undergraduate and graduate teacher education programs is one of the most critical issues in higher education today (Rogers 2000). Technology has become central to life in the second millennium. Research has shown that teaching and learning is enhanced by effective use of technology (Kauchak & Eggen 1998). Technology allows a more flexible, interactive, and creative educational setting that brings an immediacy to learning. It enables students to explore areas of interest and deal with real-life problems and issues (Knapp & Glenn 1996). Thus, technology knowledge and skills empowers teachers as well as students.

Undergraduate teacher education programs have embraced the demand for inclusion of technology into curriculum and instruction, with the result that students now are graduating from programs with the knowledge and skills delineated in the technology foundation standards developed by the International Society for Technology in Education (ISTE) (1997), and adopted by the National Council for Accreditation of Teacher Education (NCATE). However, many educators in classrooms gained their initial degree before technology became a component in undergraduate teacher education programs. Many have not participated in district staff development or college courses related to technology in education (McCannon & Crews 2000). Therefore, it is imperative that graduate programs provide opportunities for teachers to develop and enhance their technology competencies.

Background

The Master of Education (M.Ed.) in Curriculum and Instruction was designed to develop dynamic, reflective teachers with the abilities to develop, implement, analyze, evaluate and improve their own practices. The six program goals state that graduates of the program should be able:
#1 to identify, analyze, and explain (a) successful curricular models and instructional strategies and explore the basis for their success, and (b) curricular and instructional problems impeding the improvement of learning and teaching in classrooms and schools, and propose sound solutions.
#2 to monitor, evaluate, and suggest means to improve instructional practice, including the evaluation of educational outcomes and programs.
#3 to assume responsibilities for the development, implementation, evaluation, and revision of curricula or programs of study in particular disciplines and/or for particular populations.
#4 to locate, evaluate, interpret, and apply appropriate research and scholarship to the study and solution of practical educational problems in curriculum and instruction.
#5 to plan and conduct action research, using sound theory and appropriate research designs, to investigate educational questions related to the improvement of curriculum and instruction.
To demonstrate professional leadership skills and continued professional growth in curriculum and instruction.

To achieve these goals the student must demonstrate the knowledge and effective use of skills including (a) communicating with students, colleagues, parents and the public; (b) making decisions; (c) solving problems; (d) collecting, analyzing, and interpreting data; (e) selecting and using appropriate technology; (f) working to resolve diversity issues; and (g) striving to continually improve instruction. The program uses the ISTE foundation standards to guide the development of the students' technology understandings and competencies. There are eighteen standards grouped into the three categories of basic computer/technology operations and concepts; personal and professional use of technology; and application of technology in instruction.

Master of Education students enroll in a two year core of 24 semester credit hours with a cohort of between 30 and 40 students. Now in the sixth year of operation, the site-based M.Ed. program has been made available to 18 different cohorts at 12 off-campus sites with 399 graduates as of the end of the Spring semester, 2000. Another 182 students are currently in the program with 90 scheduled to graduate by the end of Summer 2001.

Each site-based program is taught by three facilitators; one from the university, one from the host site and a third person from the field who complements the expertise of the other two facilitators. A major focus of the program is reflection on practice and action research.

Students work on projects for curriculum and instruction improvement at the classroom, school and district levels. Projects may be conducted by an individual, by small groups from the cohort, or by a collaborative group comprised of one or more M.Ed. Curriculum and Instruction student along with parents and colleagues such as teachers, principals, curriculum advisors, and school curriculum and instruction teams. Student-generated project topics focus on appropriate and effective ways to address needs, concerns and questions about personal classroom practice, school organizational patterns and school-community issues.

This paper examines ways in which the ISTE foundation standards have been integrated into the Master of Education in Curriculum and Instruction graduate teacher education program; and the impact of technology integration on the teachers' acquisition of technology knowledge and skills, their classroom teaching, their students' learning, and in a broader sense their schools and districts.

**Technology integration into the Master of Education program**

The Master of Education in Curriculum and Instruction program's constructivist approach to learning (Fisher, Dwyer & Yocam 1996; Kauchak & Eggen 1998) creates a number of opportunities in which students can acquire technology knowledge and competencies; and then requires their use to successfully complete assignments. In the first semester of the program, the instructional coordinator from the host district provides technology training as the students require it for the completion of research and presentations. During regular class time, students select labs to learn to use e-mail, the Internet, Microsoft Word, Excel, Access, PowerPoint, and HyperStudio. These lab training opportunities continue throughout the two year core program in addition to individual tutoring sessions as needed.

Students also go on campus to receive training in conducting electronic searches. The training is facilitated by library personnel at the main library at Wichita State University. The following week after this training, another class period is spent in the library where students research a self-selected topic for a literature review project. It is expected that they will put into practice the skills gained in the previous week to use available electronic search resources. Students continue to use these skills throughout their M.Ed. program, to complete electronic searches for other projects. After learning how to use the automated library system and gaining the skills of electronically accessing information, students research curriculum and instruction topics and issues relevant to their classroom practice.

The use of software such as Microsoft Word, Excel, and Access, is integrated into the students' action research projects as well. Students use these software programs to analyze, organize and report the data they have collected. With the software, students are able to make professional quality tables and graphs that are used for poster presentations, in research papers, or in multimedia presentations that they develop to share research findings.

Technology is integrated also into the communication procedures of the program. E-mail is used on a regular basis to communicate general course and program information to all students. An electronic newsletter is produced by the site facilitators approximately three times a semester and sent via e-mail.
between class meetings, students communicate by e-mail with course facilitators concerning course and program requirements; and with other students about projects being completed collaboratively.

**Effects of technology integration on student products**

Successful integration of the ISTE standards into the program is viewed in terms of the quality and variety of products/assessment pieces using technology that have been generated by the students. These products include poster projects, PowerPoint presentations, web site development, the use of BlackBoard for course communication, statistical analyses, and electronic portfolios.

Technology is viewed by teachers as a viable method to enhance the learning and teaching in their classrooms (Kauchak & Eggen 1998). In this program, teachers’ action research projects focus largely on ways to better the education process for the students in their classrooms. Improving curriculum and instruction in any content area and at any grade level, often includes the integration of technology into existing curriculum (Knapp & Glenn 1996). Students conduct action research on technology integration topics such as using computer generated graphic organizers for reviewing and testing with elementary students; creating a Web site for the school district and community; and using the Internet to benefit students’ learning. Research is also conducted on the use of technology to enhance home-to-school communication such as in the investigation of the use of BlackBoard to keep in daily contact with parents of high school chemistry students.

Technology has been integrated into student assessment in the program. Students are required to complete 3 projects in each of the four core semesters of the program. The presentation of all of these projects requires the use of various technologies, thus creating the context of performance assessment for every project.

Projects are reported in four different ways. Following the more traditional manner of presenting research, one project per semester is written as a paper. This requires the use of computer software such as Microsoft Word and Endnote to write and format the paper; and Excel and Access to organize data into graphs and tables for insertion into the paper.

A second way in which projects may be reported is through a poster presentation. Students use software to make graphs, tables, titles and labels for their poster. Some students use a digital camera to record events relevant to the project, and then print the photos to display on their poster. A requirement for the poster presentation is that a handout of some type with a summary of the information be available with the poster. This handout often takes the form of a brochure created with software such as Publisher98.

Students also present their projects orally. Many students use technology to create visual aids similar to what might be used in a poster presentation. Additionally, video clips, filmed and edited by the student, have been used to enhance oral presentations.

Finally, at least one multi-media presentation of a project is required during the four semesters of the program core. This requirement is usually completed during the third or fourth semester when students have acquired advanced technology skills. A student’s ability to successfully complete a technology presentation depends to a great extent on his/her acquisition of the competencies set out in the ISTE teacher technology standards. To receive a satisfactory rating for the presentation, the student must (a) use two or more types of media in the presentation; (b) use the Internet as a resource and appropriately cite the information; (c) use the technology to complement not distract from the presentation; and (d) demonstrate organizational skills, such as the use of storyboards, in the planning of the presentation.

**Benefits to school districts**

As teachers have completed the program, a number of general benefits to school districts employing these teachers have become evident. The program has provided the opportunities for teachers to develop exceptional leadership skills in such areas as curriculum development, instructional strategies, educational research, student assessment, strategic planning, team building, facility planning, school improvement models, material selection, and staff development. These skills have resulted largely from the action research projects that the teachers have conducted and presented in the two years of their core course work.
Although expertise in these areas is impressive to employers, the technology-related benefits have been remarkable and gone beyond the districts' initial expectations. Teachers gain the knowledge to make informed decisions in the selection of hardware and software. Technology integration into the curriculum has been by way of various software packages, use of the Internet, and computer clusters. Teachers have set aside their overhead projectors and replaced them with laptops, LCD projectors and PowerPoint or HyperStudio presentations. Smart Boards, scanners, digital cameras, audio and video clips and CDs are used frequently in these teachers' classrooms. The impact of the program partnership between the host site districts and the university has provided technology competent teachers for the district as anticipated. What has been a surprise is the extent to which the teachers have integrated technology into their own classrooms and then, confidently led other teachers to do the same.

But the integration of technology has not been confined to classroom practice. Program graduates have demonstrated their abilities to use technology for school level and district level activities such as the presentation of Quality Performance Accreditation (QPA) reports; curriculum development presentations to school boards and communities; and in the production of school informational brochures, videos and PowerPoint presentations for parents.

Additionally, it has allowed the host district to create technology leader positions in each school. Technology leaders are paid a stipend to provide guidance to the building staff on successful integration of technology into the curriculum. They model teaching that uses technology and they conduct in-service training to increase staff technology knowledge and skills. Teachers wanting to serve in the position, complete an application and then demonstrate technology skills through various technology products. The products are often from assignments that have been completed by the teacher as part of the master of education program. The district has noted an increase in the number of teachers applying and qualifying as technology leaders, and attribute this increase to the teachers' participation in the Master of Education, Curriculum and Instruction program.

Conclusions

The successful integration of the ISTE foundation standards into the Master of Education in Curriculum and Instruction teacher education program has made a substantial impact on the teachers' acquisition of technology knowledge and skills. It has encouraged the integration of technology into their classroom practice, enhanced their students' learning, and contributed to greater technology integration in their schools. Benefits to the school districts that employ the teachers participating in this master of education program have also been noted. Districts benefit in that the teachers are more technology competent. Additionally, the program has allowed districts to create technology leaders in the district.

The West Chester University Teaching and Learning with Technology Program: Aligning Graduate Credit Courses with NETS-T Standards

Marlene K. Goss, John A. Kinslow, Lesley A. Welsh
Professional and Secondary Education
West Chester University
United States
mgoss@wcupa.edu; jkinslow@wcupa.edu; lwelsh@wcupa.edu

Abstract: This paper describes the development of a graduate certificate program for teaching and learning with technology. Program development is a complex process that has numerous accrediting, policy-setting, and political bodies to satisfy requiring the integration of convergent ideologies, all focused on the improvement of teaching and learning. Use of the National Educational Technology Standards for Teachers (NETS-T) enhanced our ability to articulate and expand our vision for technology integration in education. Rather than make this program disparate, the attempt to meet these standards and frameworks resulted in a rich and comprehensive program that will have real value for the teachers and students it serves. This presentation will highlight the development and some of the early results of this program as it is implemented at West Chester University in January 2001.

Background

In 1998 the International Society for Technology in Education (ISTE), in cooperation with the US Department of Education, developed and published National K-12 Educational Technology Standards for students. Subsequently, the standards were connected to curriculum and technology (ISTE, 2000). In April 2000 the National Educational Technology Standards for Teachers (NETS-T) were established through an initiative funded by the US Department of Education's Preparing Tomorrow's Teachers to Use Technology (PT3) program. These NETS-T standards were approved and adopted by National Council for Accreditation of Teacher Education (NCATE), the accrediting body for West Chester University (WCU). They were the guiding principles as we structured and developed a graduate program at our university, created for educators to learn the dynamic relationship among teaching, learning, and technology integration.

It is important to note that our program encourages teaching with technology rather than teaching about technology and is directly linked to classrooms in K-12 schools. Consistent with a Professional Development School initiative, and/or the teacher-scholar model, our graduate program will be offered through alternative delivery mechanisms such as use of the web, 2-way video and on-site classes in participating school sites.

Process

The development and writing process of this graduate program has been shared so that others can benefit from the lessons we learned. We created three graduate courses for our program: a survey course covering the breadth necessary for understanding educational technology integration; an in-depth curriculum and instruction design, and development course; and an application course called seminar and field study. Through focus groups held in Spring 2000 the development of the graduate program was informed by educators from area K-12 school districts, as well as business and community representatives. This process helped us to focus directly on the needs of our clients and the students they serve.

In addition to meeting academic standards of university curriculum committees, this program also is designed to reflect the conceptual framework that drives our teacher preparation program here at WCU. The components of the WCU Conceptual Framework addressed are: content knowledge, knowledge of learner, knowledge of self, reflection, and professionalism.

As we learned and digested the NETS Standards we created a matrix that referenced the 6 standards identified by NETS-T that all classroom teachers should be prepared to meet (see Table 1) and listed the
objectives we intended our graduate students to meet under each of the categories. We adopted the 21 indicators of the NETS-T performance profile for practicing teachers (see Table 2).

I. Technology Operations and Concepts
II. Planning and Designing Learning Environments and Experiences
III. Teaching, Learning, and the Curriculum
IV. Assessment and Evaluation
V. Productivity and Professional Practice
VI. Social, Ethical, Legal, and Human Issues

Table 1: Six NETS-T standards for all classroom teachers.

The matrix is comprised of 21 performance indicators identified by NETS-T for practicing teachers. Each indicator is associated with the relevant NET-S standard (see Table 1) by Roman Numerals. The specific courses that focus on the performance indicator are listed. The program has used multiple methods of assessing whether the teachers have demonstrated competence in each of the standards. The type of assessment is indicated in the last column of Table 2.

provide technological and discipline-specific expertise. (III)

9. teach students methods and strategies to assess the validity and reliability of information gathered through technological means. (II, IV)

10. recognize students' talents in the use of technology and provide them with opportunities to share their expertise with their teachers, peers, and others. (II, III, V)

11. guide students in applying self- and peer-assessment tools to critique student-created technology products and the process used to create those products. (IV)

12. facilitate students' use of technology that addresses their social needs and cultural identity and promotes their interaction with the global community. (III, VI)

13. use results from assessment measures (e.g., learner profiles, computer-based testing, electronic portfolios) to improve instructional planning, management, and implementation of learning strategies. (II, IV)

14. use technology tools to collect, analyze, interpret, represent, & communicate data (student performance & other information) for the purpose of instructional planning & school improvement. (IV)

15. use technology resources to facilitate communications with parents or guardians of students. (V)

16. identify capabilities & limitations of current and emerging technology resources & assess the potential of these systems & services to address personal, lifelong learning, & workplace needs. (I, IV, V)

17. participate in technology-based collaboration as part of continual and comprehensive professional growth to stay abreast of new and emerging technology resources that support enhanced learning for PK-12 students. (V)

18. demonstrate and advocate for legal and ethical behaviors among students, colleagues, and community members regarding the use of technology and information. (V, VI)

19. enforce classroom procedures that guide students' safe and healthy use of technology and that comply with legal and professional responsibilities for students needing assistive technologies. (VI)

20. advocate for equal access to technology for all students in their schools, communities, and homes. (VI)

21. implement procedures consistent with district and school policies that protect the privacy and security of student data and information. (VI)

Table 2: Program matrix with NETS-T performance indicators.
Outcomes

Use of the NETS-T standards has given validity and focus to the development of this program. The program shows the impact of this work with a focus that concentrates on technology use for the improvement of teaching and learning in K-12 schools. The presentation of this paper will include the products that were created through the process. These include a Power Point™ presentation, Teaching and Learning with Technology brochures, and data from our evaluation report.

Conclusion

Working on the development of this program through the use of the NETS-T standards enhanced our ability to articulate and expand our vision for technology integration in education. We are confident that the design of the program meets current needs and expectations for teaching and learning with technology.

This program was created through the integration of convergent ideologies, all focused on the improvement of teaching and learning. Rather than make this program disparate, the attempt to meet these standards and frameworks resulted in a rich and comprehensive program that will have real value for the teachers and students it serves.

This paper presentation will highlight the development and some of the early results of this program as it is implemented at WCU in January 2001.

Subject-Specific Technology Integration Training: Lessons in Planning, Administering, and Follow-Up

Regan Grandy, College of Education, Idaho State University, USA. granreg@isu.edu
Jane Strickland, College of Education, Idaho State University, USA. strijane@isu.edu
Dorthy Sammons, College of Education, Idaho State University, USA. sammdott@isu.edu
Al Strickland, College of Education, Idaho State University, USA. strialbe@isu.edu

Abstract: Strickland (1999) reported the results of a Teacher Technology Mentor program in southeastern Idaho, which strongly indicated that the school mentors were not transferring their technology knowledge into classroom practice. Strickland recommended that subject-specific technology integration programs be developed to insure better integration of technology in the classroom. Based upon this recommendation, Idaho State University's FOCUS program was developed, targeting three specific areas: fourth grade, secondary language arts, and junior high earth science. This research focuses on the planning, administering and follow-up of one of the junior high earth science program. The goal of this research was to determine if the subject-specific technology integration training of earth science educators makes a difference in teachers' attitude and use of technology in classroom teaching practices. Data from attitude surveys of earth science educators involved in the FOCUS program suggest that teachers' attitude and use of technology in the classroom increase when in-service technology training is subject-specific.

Introduction

The National Governors' Association (Houghton, 1997), the federal government and various state legislatures (Thurlow, 1999) have recommended that teacher training become a part of technology planning, and that approximately 30 percent or more of technology dollars be spent on teacher training. This is in light of the fact that only five percent of the nation's 2.8 million teachers are integrating technology into their regular teaching practices (Parks and Pisapia, 1994). A recent U.S. Department of Education survey (as cited in Thurlow, 1999) indicates that only 20 percent of teachers reported feeling "very well prepared" to integrate technology into classroom instruction. Thurlow suggests that professional development programs be provided for in-service teachers to give them the confidence and skills they need to incorporate technology into their curriculum. Further, Thurlow indicates that many in-service programs focus on providing teachers with basic skills in using hardware and software, but do not provide them with "curriculum-based applications and strategies for integrating them in their instructional activities."

In 1999, Strickland reported the results of a Teacher Technology Mentor program in southeastern Idaho, which strongly indicated that the school mentors were not transferring their technology knowledge into classroom practice. Many of these contemporary teachers, even after being trained how to operate computer systems and tool software (word processors, spreadsheets and databases), were struggling to incorporate this training into their regular teaching practices. Teachers reported that they did not see how the technology could be applied to their subject matter. Strickland recommended that subject-specific technology integration programs be developed to insure better integration of technology in the classroom. Based upon this recommendation, Idaho State University's FOCUS program was developed, targeting three specific areas: fourth grade, secondary language arts, and junior high earth science.

Methodology

This research focuses on the planning, administering and follow-up of one of the eight month long subject specific technology integration programs—the junior high earth science FOCUS program.

In the planning process, it was determined that the junior high earth science program be broken into four subsections: (1) geology, (2) space science, (3) weather science, and (4) oceanography. Teachers would be trained on how to incorporate the Internet, content software, and tool software into each of these subcategories.
To accomplish this task, a notebook and website of materials would be developed with lesson-plan ideas, a list of earth science Internet websites, and a list of recommended software germane to each subsection.

Teacher training consisted of a one-day technology workshop. The one-day workshop supplied teachers with hands-on examples of technology integration in the earth science curriculum; provided educators with a notebook of resources for integrating technology in the earth science curriculum; prepared educators for follow-up classroom visits, WebCT bulletin board postings, technology integration lesson plan writing, and evaluating software and Internet websites.

The FOCUS teacher-training program differs from traditional mentor-type programs described by Thurlow (1999) in that it contains a rigid schedule of teacher follow-up and assessment. Teachers were required to post weekly bulletin board journals on WebCT about how they were incorporating technology into their curriculum; to develop four lesson plan activities that incorporate technology into the curriculum; to evaluate four earth science-related software; to evaluate eight earth science-related Internet websites; and to have classroom visits by a qualified technology instructor.

Findings

Based upon pre- and post-workshop attitude surveys of junior high earth science teachers in southeast Idaho, there was a significant increase in the average attitude scores $t(9)=-2.514$, $p=.033$. Four of the twenty-nine attitude survey questions asked directed question about their use of technology in the classroom. After completing the FOCUS earth science program, the average score of each of these four questions increased. The improvement in Internet resources use was not significant $t(9)=-1.309$, $p=.223$; the improvement of tool software use was not significant $t(9)=-1.152$, $p=.279$; the improvement in commercial software use was not significant $t(9)=-1.714$, $p=.121$. However, the improvement in the use of multimedia presentation software was significant $t(9)=-3.161$, $p=.012$.

Conclusions

When technology integration is subject-specific teachers' attitudes toward technology significantly increases. Teachers are also more likely to incorporate technology into their curriculum, as evidenced by the increase in use of Internet resources, tool software, commercial software and multimedia presentation software. These results seem to confirm Thurlow's (1999) and Strickland's (1999) suggestions that curriculum-based technology training will improve teachers attitudes toward technology integration, and that by improving attitudes toward technology integration teachers will be more likely to use technology in their classroom practices.

Teachers Discovering and Integrating Technology: An National Online Success Story

Glenda A. Gunter
Educational Technology
College of Education
University of Central Florida
United States
ggunter@pegasus.cc.ucf.edu

Abstract: The purpose of this study was to determine if teachers could be taught to use and much more importantly integrate technology into their specific classroom curriculum in a national online graduate level educational technology course for K-12 teachers, Teachers Discovering Computers. Both quantitative and qualitative data were collected and analyzed. The pretest and posttest surveys included fourteen, five-point Likert items, and the posttest contained five open-ended questions. Analyst of quantitative data revealed there was a significant difference between the mean scores of the pretest and posttest scores, p = .000. Qualitative data revealed that 100% of the student had a positive experience in the class and learned how to use and integrate technology into their specific classroom curriculum. The combination of both the statistical and qualitative analysis lead the researcher to conclude that the impact of the course on the student's perception and integration of technology into the curriculum was dramatic.

Introduction

As communities adjust to the dynamics of the 21st century, the continued prosperity of their citizens will depend upon economic stability and growth. Economic stability and growth will depend upon the ability of a region’s K-12 education system to graduate students with the required basic and technical skills needed for employment and life long learning (Draves, 2000).

Without a K-12 educational system producing skilled workers for a region's businesses and industries, continued economic growth becomes stagnated. When schools graduate poor quality students, who lack appropriate skill levels, the entire infrastructure of a region may begin to break down. The most serious problem hindering continued economic development and expansion in many, if not most American communities, is the lack of an educated entry-level worker. As we enter this new century, many American business are experiencing a severe shortage of skilled employees in virtually every area from software engineers, retail and service professionals, to semi-skilled blue collar workers (Perry-Johnson and Millsaps, 1999).

For many reasons, graduating K-12 students has become a very complex social issue. Administrators of K-12 school districts are finding it more and more difficult to: (1) keep students in school and (2) graduate students who possess the required basic skills and technology competency necessary to enter the workforce or to be able to succeed at institutions of higher education. Those students who drop out of school or graduate lacking the proper skills are doomed to join the ever expanding lost generation of American youth. These students simply do not possess the required basic and technology skills necessary to succeed (Trotter, 1999).

Many political leaders are stressing that building a world-class work force must be a national priority for continued economic prosperity in the new global economy. Improving America's capacity to educate and train workers is critical to the future of this county. In the words of former President Bush, "Think about every problem, every challenge we face. The solution to each starts with education." (Blount and Kearn, 1991, p. 1). As we have moved into the 21st century, there has been a movement or a paradigm shift to change the way we teach teachers how to both use and integrate technology (Robyler, 2000). Our society has undergone dramatic changes in this century, yet the way our teachers teach and our students learn has not. In fact, we need to redesign our educational systems to be more hands-on and learner centered (Shelly, Cashman, Gunter, and Gunter, 2000).
Teachers in the nation's schools are charged with teaching students who will spend all of their lives in technology driven society. The computer, as a leading technological device, was expected to be a solution in the restructuring of school systems. Yet, many of these teachers report little knowledge of or the ability to use and more importantly to integrate technology into the curriculum. The discrepancy that exists between what teachers know and what students must learn about technology represents a complex issue, even though computers have been available in schools throughout the nation for years (Trotter, 1999). Federal and state funding initiatives have stressed that school districts should purchase technology at an accelerated rate and link those technologies to the Internet. However, the placement of technology in schools, has not been the salvation that many had hoped or even predicted.

The lack of technical expertise shown by the teachers extends from those teachers who have just entered the profession to those already in the field. United States Secretary of Education Richard W. Riley noted in a speech, “Teaching and learning that uses technology effectively can lead to greater academic success and make a real difference in the lives of students. Unfortunately, only 20 percent of today's teachers feel very well prepared to use this technology” (Riley, 2000). Many researchers and educators from federal and state agencies, institutions of higher learning, and K-12 schools have been focusing on why technology has not made a difference in the classroom and repeatedly the same conclusion arises – teacher training. Unfortunately, most training initiatives to date have concentrated on how to use technology and not how to integrate technology.

Research has shown that properly integrated technology by qualified and caring teachers can significantly enhance student learning, increase attendance and graduation rates, improve test scores, and motivate students to want to improve themselves (Schwartz, 1999). Unfortunately, the dramatic increase in purchasing of technology has not improved student achievement at many of our nation's public schools. The primary reason is a lack of teacher training.

Many institutions of higher learning are looking to the improvements in training that industry, business, armed services, and other educators are observing. Educators are hoping to receive guidance in this move to educate students, any path, any time, and any place. In other words, teaching students in a different medium through the use of distance education (Andrews and Marshall, 2000). Our instructional strategies are going to have to change and undergo major transformations.

Due to the increasingly diverse population, education is changing toward a more global, technology-rich environment designed to meet these diverse and changing needs of students. The creation of easy to use graphical browsers has dramatically increased the popularity of the Internet and the World Wide Web (WWW). The Internet has shifted from being a communication mode of text-only to a powerful multimedia communication system with applications that have the potential to revolutionizing teaching and training. This technology phenomenon has directly impacted and is transforming the way we teach and the way students learn (Geibert, B. & Harvey, S.H., 2001). These changes have brought the WWW to the forefront of instructional strategies for all educators. The World Wide Web removes all barriers of time, place, and physical limitations and opens more training opportunities for teachers.

The purpose of this study was to determine if K-12 teachers could be taught to use and much more importantly integrate technology into their specific classroom curriculum in a national online graduate course educational technology course for teachers, Teachers Discovering Computers (TDC).

Methodology

Teachers Discover Computers, an online graduate level educational technology course, was tested in a pilot study at Hungerford High School in Orlando, Florida at the request of senior business leaders in central Florida. The pilot study was conducted between August and November 1999 and all of the teachers at Hungerford High School participated in the TDC online graduate course. Due to the success of the pilot study, Teachers Discovering Computers is being offered nationally as an online graduate level course to K-12 teachers.

The sample utilized for this study consisted of three sections of students who completed the online national graduate course in Spring of 2000. These courses are thirteen-week online graduate-level technology courses that consists of thirteen extensive online curriculum modules, including an end of course curriculum integration project that requires computer, information, and integration literacy. Of the 101 student enrolled in the class, 29 were high school teachers, 26 middle school, 32 elementary, 12 were taking for certification/recertification in other areas, one student was a private music teacher, and one students was a business professional.

The following is a description of the populations of the three classes: The first class began on November 16, 1999 and ended on February 23, 2000. Thirty-nine students began the first national TDC course on November
16, 1999 with 38 students completing the course on February 23, 2000 for a 97% course completion. The 38 students were from six states (Florida - 12, Massachusetts - 3, Michigan - 3, New York - 13, Ohio - 5, and Pennsylvania - 2). Initial survey results revealed that only four students possessed more than basic computer skills (e-mail and word processing) and only two had integrated technology into their classroom curriculum.

The second class started on January 11, 2000 and ended on April 11, 2000. Thirty-five students began the second national TDC course on January 11, 2000 with all 35 students completing the course on April 11, 2000 for a 100% course completion. The 35 students were from seven states (Florida - 14, New York - 6, Massachusetts - 4, Ohio - 3, Pennsylvania - 3, Virginia - 3, Michigan - 2).

The third and last class of this study started on February 1, 2000 and ended May 2, 2000. Thirty-one students started the third national TDC course. Two students transferred to the April course due to injuries sustained in a car accident. One student dropped out of the course. Twenty-eight students completed the course for a 97% completion rate. The 28 students were from seven states (Florida - 12, Pennsylvania - 5, Michigan - 4, Ohio - 3, New York - 2, Massachusetts - 1, and Virginia - 1).

Findings

Both quantitative and qualitative data were collected and analyzed. The pretest and posttest surveys included fourteen, five-point Likert items, and the posttest contained five open-ended questions. The five open-ended posttest questions: (1) Please explain how this course has increased or decreased your support for the use of technology in K-12 education. (2) As a result of your experiences in this class, how has your attitude changed toward integrating technology in your instruction? (3) What words and phrases would you use to describe your experiences in this class? (4) What is the most important thing that you learned in this class? (5) Where do you see yourself one year from now as a result of this class?

Quantitative data analysis revealed there was a significant difference between the mean scores of the pretest and posttest scale scores from the November, January, and February TDC courses. There were 70 students who completed both of the pretest and posttest evaluations and a Pair wise T test was used for the analysis. The pretest mean was 33.29 with a standard deviation of 8.01, while the posttest mean was 22.56 with a standard deviation of 5.63 A summary of the is provided in Table 1.

Table 2: Paired Samples Test
Qualitative data revealed that 100% of the students had a positive experience in the class and had learned how to use and integrate technology into their specific classroom curriculum. The following are a few examples of the teacher’s answers to the open-ended questions: One teacher stated, “Before taking this course I wanted to integrate technology in the classroom but did not know where to start or where to look for help. I was basically frustrated.” Another teacher felt, “The exposure I have had through this course has opened my eyes to the many possibilities within my classroom.” “The Words that I would use to describe my experiences in this class would be DISCOVERY and LEARNING. Discovering the many ways I could enhance student performance in my classroom by integrating technology effectively. And learning the ways in which to integrate the technologies” was stated by another teacher. This teacher stated, “I have been using computers for sixteen years. I never realized the resources for education available prior to taking this course.” “When I began the course I felt very uncomfortable about integrating technology. Having completing the class, I have no doubts that I am up to the tasks.” “By far the most important thing I learned in this class is that I now have the ability to successfully integrate technology into my instruction. The confidence I’ve gained has made me eager to use technology.” Please note all qualitative data is available for readers to review at http://www.teachereducation.com/tdres.html.

Conclusions

Research studies have revealed that students who are in a supportive, less stressful environment, and are actively involved in the instructional process tend to be more academically successful. Through this online graduate course, teachers felt they were learning in a very supportive environment. The combination of both the quantitative and qualitative analysis lead the researcher to conclude that the impact of the course on the student's perception and integration of technology into the curriculum was dramatic. This study revealed that teachers could be taught to use and integrate technology in an online environment. Finally, the quantitative and qualitative research revealed that teachers could be taught to use and much more importantly integrate technology into their specific classroom curriculum in a national online graduate level educational technology course.

Abstract: The Regional Technology in Education Consortia (R*TEC) program was established by the US Department of Education to help states, local educational agencies, teachers, school library and media personnel, administrators, and other education entities successfully integrate technologies into K-12th grade classrooms, library media centers, and other educational settings, including adult literacy centers. To provide such help, the R*TEC establishes and funds several regional consortia that address professional development, technical assistance, and information resource dissemination. The 2000-2005 South Central Regional Technology in Education Consortium (South Central R*TEC) serving Arkansas, Louisiana, New Mexico, Oklahoma, and Texas is now located at the Southwest Educational Development Laboratory in Austin, Texas. Through a program of focused professional development and information services for teachers and administrators, the South Central R*TEC will enable educational systems in its five state region to use technology to foster student success in achieving state content standards, particularly in schools serving high population of disadvantaged students.

Identifying a Need

The SCRTEC finds that its most critical challenge and its best opportunities for effective action is in helping teachers mesh increased concern for accountability on state content standards with increased interest in the use of technologies for teaching and learning. While national reports indicate that although numbers of computers in schools are increasing and the student/computer ratio is falling, students are not using technology as a tool for learning. According to “Technology Counts” data, only 14% of fourth graders and 13% of eighth graders nationally report using technology daily; moreover, 53% of fourth graders and 39% of eighth graders report “never or hardly ever” using computers.

This gap between the presence of technology and its effective application was foremost on the minds of state and local leaders when the SCRTEC spoke with them about how the SCRTEC could be most helpful. Their unanimous plea was not for basic training in the use of technologies— they already had systems in place for meeting those needs. Their major need was for help in integrating technology into effective teaching and learning.

Given the states’ unanimous call for help with integrating technology into classroom instruction and improving students’ success in achieving state content standards, SCRTEC planning focused on how those
needs could be met through specific objectives and work. SCRTEC identified four distinct groups and their needs: (1) Classroom teachers: What do they need to integrate technology into their classroom practice to address standards? (2) District level educational leaders: What do they need to see to support the integration effort? (3) Service units and higher education: What do they need to provide resources, networks, and support? and (4) State level departments of education: What do they need to prepare and create policy and support to improve systems?

From a working list derived from the needs of all levels, the SCRTEC distilled a set of concentrated, cross-cutting needs to form its current objectives: (1) Build capacity of teachers: the need to enhance teachers' knowledge and skills for integrating technology into learner-centered instruction focused on achievement of content standards. This need addresses both preservice preparation and inservice professional development programs and it presumes an intermediate audience of those who provide preparation and training. (2) Build capacity of leaders at the state, district, and campus levels: the need to enhance the knowledge and skills of education administrators in their effort to support the integration of classroom technology focused on achievement of content standards. This need addresses inservice professional development for campus and district leaders and establishment of professional development communities for state and higher education leaders. (3) Promote use of electronic delivery systems: the need to ensure optimal use of technology-based delivery systems to achieve the widest possible impact from training and resources.

Meeting Needs

SCRTEC will accomplish its objectives through activities conducted in accordance with the program's three prescribed strategies: professional development, technical assistance, and information and resource dissemination. These activities will be carried out collaboratively and with tools available to the SCRTEC from its partners and members. (1) The Active Learning with Technology professional development portfolio from the Southwest Educational Development Laboratory, (2) The Aurora Project's (Oklahoma) web-based development and delivery system, (3) The Technology Leadership Institute's higher education network (TCET at the University of North Texas) with its Evaluation Compendium and Technology Leadership Web Library, (4) Student Diagnostic Database Tool from Hart Elementary School (Austin, Texas), (5) The Electronic Emissary Project from the University of Texas (Austin), (6) A network of Access Centers from SEDL’s Southwest Center for the Improvement of Mathematics and Science Teaching (SCIMAST) in cooperation with the Eisenhower Clearinghouse.

SCRTEC will also develop and promote a Regional Electronic Clearinghouse that will include easy searching of resources linked to content standards, online evaluation tools, regional professional development registry, educator forums, and telecollaborative projects. Concentration will focus on alternative delivery methods including CD-ROM, web-based modules and courses, and videoconferencing and developing partnerships with state departments of education and other technology and content standard initiatives throughout the region. SCRTEC will develop a Master Teachers Network with 25 teachers from each state, a Professional Development Network, and a Higher Education Network.

Materials and Publications

SCRTEC currently has a variety of materials available that are designed to aid teachers in creating constructivist learning environments supported by technology. This portfolio of materials includes:

Connecting Students, Learning and Technology. This booklet is designed to offer teachers practical information on getting started with technology and student-centered practices. The document is available both in print and online from the web site at: www.sedl.org/pubs/catalog/items/tec26.html

Planning into Practice: Implementing and Integrating Instructional Technology. This book was developed in collaboration with the Southeast and Islands Regional Technology in Education Consortium and assists school planning teams in their efforts to implement technology to improve teaching and learning. It helps teams to move from visioning to goals to action.

Constructing Knowledge with Technology: A Review of the Literature. This paper discusses the tenets of constructivist learning theory in light of its role in education and use with technology. Also available from the web site at: www.sedl.org/pubs/catalog/items/tec27.html
The web site – http://www.sedl/tap/resources.html This is an online database of web resources for teachers and professional development providers. There are multiple subject areas with links to web sites that lend themselves to constructivist approaches and technology.

Active Learning with Technology portfolio. These sixteen professional development modules are available for professional development providers and are based on constructivist learning theory and promote active learning through several classroom management models. They have been field tested with both teachers and professional development providers. Each module contains a step-by-step facilitator guide and is downloadable for free in PDF format from this web site: www.sedl/tap/profdev.html Additional modules will be created and added during the tenure of the SCRTEC.

Tap into Learning newsletter. The newsletter offers useful and highly practical information for K-12 educators wishing to use technology to support more constructivist learning approaches. Each newsletter discusses the classroom implications of a particular student-centered approach and offers classroom examples illustrating such an approach in combination with an appropriate type of software application. The newsletter also provides information on using commonly found educational software. It is available in print and online at: www.sedl.org/tap/newsletters

Video Series. This series of six videos is designed to be used as part of professional experiences for educators. They can be used in a variety of ways and suggestions for using these videos are included in the various facilitator guides in the professional development portfolio. Two videos, Engaged Discoverers: Kids Constructing Knowledge with Technology and Classrooms Under Construction: Integrating Student Centered Learning with Technology can be used for visioning activities with both school administrators and teachers. Four videos contain specific classroom teaching episodes from 1st grades through 9th grades with classroom teachers carrying out a variety of activities using technology.

Consortium Members and Partners

The newly formed South Central RTEC is comprised of the following consortium members: the Southwest Educational Development Laboratory (SEDL), Texas Center for Educational Technology (TCET) at the University of North Texas, and the Aurora Project (Oklahoma). Consortium partners include the Regional Educational Technology Assistance (RETA) program at New Mexico State University; the Electronic Emissary Project' University of Texas Austin; Southwest Center for the Improvement of Mathematics and Science Teaching (SCIMAST); Hart Elementary School, Austin Independent School District; and the Dana Center for Education, University of Texas, Austin.

Strengths of the SCRTEC include its concentration of effort on students and teachers in schools serving high populations of disadvantaged students in rural or isolated areas and its network of 450 professional development providers across its five-state region. Each of the partners and members will aim at achieving the goal of enabling educators and educational systems to fully employ the benefits of technology to foster student success in achieving state content standards.
LUMA: The Next Step in a Partnership to Enhance Technology Integration

Claire Smith Hornung
Lehigh University
United States of America
clh6@lehigh.edu

Steve Bronack
Lehigh University
United States of America
bronack@lehigh.edu

Abstract: Technology enriched learning environments have a positive effect on the achievement of students. It would seem, therefore, that the environments of in-service educators must also be rich in technology and technology integration. After developing a partnership that focuses specifically on technology integration with pre-service and in-service educators, a second partnership developed to work with specific academic departments at the Upper School level integrating technology within an established curriculum. The goal of this partnership, LUMA (Lehigh University/Moravian Academy), was to give teachers in specific academic areas access to materials, plans, ideas, and support for integrating appropriate technologies into their class activities. From experience, the developers of this partnership know what doesn’t work—the one-day, one-shot, show-and-tell workshop developed by outside consultants and delivered to teachers. Instead, these workshops were designed to be spread out over an academic semester, involve the teachers in the design and development, and provide support for the teachers between workshops.

Introduction

Technology enriched learning environments have a positive effect on the achievement of students (Schacter, 1999). It would seem, therefore, that the environments of in-service educators must also be rich in technology and technology integration. The CEO Forum in its StaR Report (February 1999) built a strong case for enhancing the education of in-service teachers in technology and curriculum integration. In fact, one of the seven goals of the report deal directly in-service teacher education:

Goal 2: Current teachers and administrators should be proficient in integrating technology into the curriculum.

Yet, according to the report, only 20 percent of teachers feel well prepared to integrate technology into their classroom instruction. Teachers lacking support and encouragement are more likely to give up using technology if something should go awry (Bronack & Hornung, 2000). A National Survey of Teachers’ Use of Digital Content highlighted in Education Week (1999) found that 97% of the teachers surveyed used a computer at home. Of those who use computers for instruction, nearly half of those surveyed claimed that the amount of preparation time necessary for curriculum integration was a large problem. In order for standards to be met and teachers to feel prepared, in-service and pre-service educators must make effective use of technology in learning and show evidence that this learning has taken place (Schacter, 1999). However, teachers must see the relevance of technology integration and what they teach to use technology effectively and show evidence of learning.

A Partnership

Aligning and infusing technology into the curriculum should be a top goal for educators (Fatemi, 1999). In the Fall of 1998 a partnership between Lehigh University and Moravian Academy- a preK-12 independent school, was established to help meet standards and prepare teachers. Throughout these past three years, the partnership has
focused on technology integration in school curriculum. The partnership paired a pre-service, Lehigh University, undergraduate with an in-service, Moravian Academy, mentor teacher. Their goal was to work together on technology integration while balancing classroom management, school philosophies and time. The partnership has seen great success and will continue in the Spring of 2000.

The Partnership Continues

Evaluations from the partnership, however, brought to fruition the idea of working with specific academic departments at the Upper School level to integrate technology within the established curriculum. The goal of this partnership, LUMA (Lehigh University/Moravian Academy), is to give teachers in specific academic areas access to materials, plans, ideas, and support for integrating appropriate technologies into their class activities. From experience, the developers of this partnership know what doesn't work—the one-day, one-shot, show-and-tell workshop developed by outside consultants and delivered to teachers. Instead, these workshops were designed to be spread out over an academic semester, involve the teachers in the design and development, and provide support for the teachers between workshops.

Designing the Partnership

The academic areas of focus for this semester in the LUMA workshops were math and foreign language. A team of three graduate students, from Lehigh University, served as the designers of the workshop materials. The graduate students worked with a designated faculty team member from Moravian Academy in each academic area to gather resources, design materials, and to prepare for each workshop. The faculty member served two functions—to ensure that what is designed by the graduate student fit the needs of the department, and to increase the likelihood that the other department faculty will join in the workshops.

One partnership goal was to spread out the workshop meeting dates over the course of the semester. Therefore, workshops were delivered in September, October and one in December to interested teachers in that academic area. The materials developed for each content area included: development of a course website, gathering of instructive educational websites for each discipline and the introduction and implementation of Webquest. (Webquest is a teaching tool which integrates technology and curriculum directly.) The course website and Webquest materials included identifying and reviewing other websites and software, example activities, assessments, rubrics, and best practice models. The graduate students designed many of these materials and activities, as well as an "instructors guide" for the workshop that can be used by Moravian faculty for future technology integration workshops.

Communication was a key factor in bringing together the many facets this partnership required. At the onset the participants were enrolled in a webcourse designed specifically for the workshop (http://www.blackboard.com/LUMA-educ). Weekly emails updated the Moravian teachers on hot topics and "Tidbits" of information useful to the discussions and practical applications that had been explored during the workshops. This was also the forum for questions and answers. The graduate students shared responsibility in checking the website, answering email questions and adding useful information weekly.

Evaluating the Partnership

Since the inception of the LUMA partnership, the graduate students have been working to structure and implement the fall workshops. Together the graduate students wrote a power-point presentation to outline the workshops for the Moravian Academy faculty team member. The course website created a space for the information collected and used to be kept in one place for all participants to have access to. This also allowed a place for a "journal" to be kept about the progress of the planning and workshop implementation. At the completion of the second workshop, we asked each teacher to provide an evaluation and description of their needs for future planning. This evaluation directed us in planning our final workshop. Our goal was to divide in specific academic areas and work individually with the faculty participants. Perhaps this will be the impetus needed for several of the teachers to use their course workshop as a teaching tool.
Implementing this New Partnership and the Implementation Dip

As with any new program, the implementation dip was prevalent for our Upper School partnership. Lack of time, experience and even interest were some of the factors that hindered the program. Our goal to spread the instruction over the course of several weeks was designed so that the teachers would have an opportunity to work on their own in developing curriculum appropriate work within a course web-site. We felt that beginning our work in September would allow teachers the time to start their school year with fresh ideas. We encountered the opposite to be true. Most of the teachers were overwhelmed with beginning of the year obligations and spent little to no time working on their course website. In addition, the initial time spent introducing the teachers to the course website and design may have overwhelmed our participants from the beginning. Therefore, they may have been reluctant to take future implementation steps.

Lack of experience also hindered some of the educator’s growth. While our attempt to match a graduate student with teachers in specific academic departments appeared ideal, the graduate students were not present to the faculty at Moravian on a regular basis. An on-line presence was established but very few of the teachers took advantage of that assistance. Several of the teachers took advantage of the workshop time to develop together their course websites. This group experience appeared to assist each other and “join” their experiences together. While these educators may not have created their own course website, they did create an academic department website to assist them in teaching. This experience, therefore, may have brought together a new collaboration that was not present prior to the workshops.

Some of those educators who joined the workshop at its inception were unclear of what tools the workshop would provide them. After seeing the varied uses available in a course website, several of the teachers felt that this technology would not be a key tool in their curriculum. Therefore, they chose to not participate further in the workshops. Other factors such as time and experience may have also influenced the several teachers who did not complete the three workshop cycle.

For those teachers who did complete the three workshop cycle, the implementation dip was prevalent. In fact, as far as the researchers can tell, it may take more than one workshop cycle to support and work through the needs of the various educators within each department.

Some Examples of Teacher Needs

At the completion of the second workshop, those teachers present were encouraged to communicate via email what needs they still would like to be met in the course of these workshops. Here are just a few examples of what they shared with the presenters:

"It was great having the time to sit at the computer and play! I never have the chance to do that during the school day. I think this is why I have not had my students do anything with computers as of now. Next week they will have the opportunity to check out that "day of the dead" web site. I would have liked to create my own web site today. Guess I got side tracked. I'm going to try and do that on my own, and if I run into trouble then I will contact one of you guys.” Ali, Upper School Spanish.

"I need lots of time for the simplest concepts to sink in because I rarely see the "big picture" right away. But I am making progress. I went in this morning thinking that a personal web page was a year or 2 down the road, but now I think I may be able to handle this in a few months. However, when simple things like sending Claire an e-mail through the Blackboard site don't work, I get discouraged, put the LUMA stuff away, and don't touch it until the next meeting.” Mimi, Middle School Spanish.

"Since this was my first LUMA workshop, I was mostly "playing" with the Blackboard.com...I am open to researching the use of websites to allow me to post info about my classes and to research useful things for class. I'm not too comfortable with computers- that's something I'm working on... We will have a new textbook next year, which will include lots of software - so next year may be a perfect time for a graduate student to work with me in the classroom. Meanwhile, I'll keep coming to workshops and try to become more comfortable with MACs (I use my PC at home much more often!) " Bonnie, Middle and Upper School French
As we continue to evaluate this partnership, specific areas of further focus will emerge to help us prepare for our next partnership. Questions and concerns that may arise from our evaluation:

- The issue of time and commitment from those involved may emerge.
- Are there other ways and times to incorporate these learning objectives for the teachers?
- What has the teacher gained from participating in this type of workshop?
- What other pieces of technology or curriculum need to be part of the workshop format?

In addition, the teachers will have an opportunity through this evaluation to review the knowledge they have acquired and the direction they wish to pursue for additional learning. Those planning these workshops will also have the opportunity to evaluate the format and direction that the workshops took.

**Future Planning**

We hope that the evaluation from all those who participated in the workshop process will give light to their increasing knowledge and understanding of working with technology within their curriculum. One reason our focus has been on the specific subject areas is in hope that those teachers will feel supported by their colleagues who are also taking part in the workshop. Should the partnership continue at this level we will continue to focus on curricular areas and work with the remaining academic departments. In addition, the support given by the Lehigh University graduate students directly to the individual teachers will provide the Moravian Academy teachers with the encouragement needed to use their new found skills to enhance their teaching. Therefore, we can address the questions of how this format was useful and added to their teaching experience. All this knowledge will assist us in our future planning.

Ways to Integrate Technology in Your Classroom

http://www.hartnet.org/chow/integrate
Choong L. How
Reading Consultant
East Hartford Middle School
Connecticut, United States
chow@hartnet.org

Abstract: This educational web site creates a framework for understanding technology tools and how they can be used for teaching different subjects in the classroom. The site provides links to general education, subject-specific and community sites. Its distinct features are the integrated language arts thematic units developed by teachers in a Connecticut school system to help their students meet the objectives of the Connecticut Achievement Performance Test (10th grade CAPT) and a template to submit your favorite lesson. The web site is organized into four sections: I. Technology Tools II. WWW Educational Resources III. Lessons Database IV. Reading Strategies.

Description

The goal of this educational web site, Ways to Integrate Technology in Your Classroom, is to provide a comprehensive guide to beginning and advanced web users. In addition to providing an overview of technology tools, the site has pages with links to general education and subject-specific sites, sample thematic units for secondary level language arts and a template to submit your favorite lesson plans for publication on the Lessons Plans page.

Technology Tools: Publishing Tools, Productivity Tools, Internet Tutorial

Publishing Tools describes Powerpoint, Hyperstudio and web publishing software. It gives ideas on how teachers and students can use them to present their work and useful addresses for download and usage. For those looking for a server to host their home page and wishing to build a quick home page, there is a download link to Tripod.

Productivity Tools gives suggestions on how to integrate spreadsheets, word-processing and graphics applications in the classroom. It also provides information on software and sites for downloading graphics.

Internet Tutorial consists of three pages: Browser Basics, Search the Web, Users Interact.

Browser Basics tells how to access a web page, view documents, make bookmarks and act on browser errors. Search the Web gives search tips and links to useful tools that can go a long way towards getting quick and efficient search results. For example, putting a phrase in quotes " and using the Metacrawler search engine (www.go2net.com) can drastically reduce the frustration in any search.

Users Interact has links to Hot Mail, the free e-mail service that lets you log on to any computer with an internet connection to check and send your e-mail. It also introduces search tools for usenet groups, to find out what other people have posted on any topic.

WWW Resources

K-12 Web Sites features recommended comprehensive web sites for teachers, Internet Projects conducted by students, K-12 Interactive Web Projects, Internet education, school districts links and professional resources links.

Subjects Links has links to multiple subject areas, shop links as well as homework and multicultural links.
Community Links has links to the Connecticut organizations like the Connecticut State Department of Education, ConneCT-State of Connecticut informational site, and local news and media sites.

Lessons Database: CAPT Thematic Units, Submit a Lesson, Lesson Plans page

CAPT Thematic Units has samples of Integrated Thematic units with lessons developed by teachers in our school system to help our students meet the objectives of 10th grade CAPT (Connecticut Achievement Performance Test). The unit on Cloning aims at developing skills specific to the interdisciplinary segment of the CAPT Language Arts. The unit on Newspapers, complete with lesson plans and worksheets, teaches students how to be critical newspaper readers.

Submit a Lesson Plan is a template that allows anyone to submit a lesson plan and get it instantly published on the site.

Lesson Plans displays submitted lesson plans. Make sure that you proofread your lesson plan before you submit it.
ICT Training for Teachers: a University response to a National Training Initiative in the United Kingdom

Malcolm Hughes University of the West of England, Bristol, UK. Malcolm.Hughes@uwe.ac.uk

Lynne Walker University of the West of England, Bristol, UK. Lynne.Walker@uwe.ac.uk

Abstract This paper seeks to describe a national training scheme currently operating in the United Kingdom, the main aim of which is 'To raise the standard of pupils' achievements by increasing the expertise of serving teachers in the use of ICT in subject teaching, to the level expected of Newly Qualified Teachers who enter the profession, and by improving the competence and confidence of school librarians in their use of ICT'.

An analysis of the requirements and learning intentions of the scheme are offered and examples shown of how one training provider has met the challenge using a combination of multimedia CD-ROMs, on-line training modules, in-school support and the development of a virtual learning community.

"The Lottery-funded training... will focus on helping teachers to use the technology in the classroom to enrich teaching and learning and raise standards - right across the curriculum."

- People's Lottery White Paper, July 1997

The People's Lottery White Paper in July 1997 stated the aim of helping teachers make the most of the new resources being placed in schools. It led to the formation of the New Opportunities Fund (NOF) ICT Training Initiative. The New Opportunities Fund is a National Lottery Distributor created to award grants to health, education and environment projects throughout the UK.

The New Opportunities Fund ICT Training Initiative.

The training started from April 1999, and runs over three years. £230 million has been made available from NOF, to fund the training of serving teachers and school librarians in all maintained schools in the UK, in an initiative for which the expected outcomes are defined by the Teacher Training Agency (TTA).

The main aim of the ICT training initiative is to raise the standard of pupils' achievements by increasing the expertise of serving teachers in the use of ICT in subject teaching, to the level expected of all Newly Qualified Teachers. To ensure that the training focuses directly on helping teachers and school librarians to use ICT appropriately and effectively, Expected Outcomes have been developed by the TTA (http://www.teachtta.gov.uk/ict/nof). The Expected Outcomes define the knowledge, understanding and skills necessary to make sound decisions about when, when not and how to use ICT in subject teaching. It is intended that training provided under this initiative will integrate training in ICT skills with training in the use of ICT in the classroom.

The University of the West of England Faculty of Education

A number of Training Providers have been approved by NOF, of which the ICT Learning Path from the Education Faculty of the University of the West of England is a National Provider for both Primary and Secondary phases of education. Every state maintained school has been sent a Catalogue of Approved Providers by NOF (available from the NOF web-site www.nof.org.uk), and once the funding for an individual school has been approved through the Local Education Authority, the school chooses of Training Provider.

The Faculty of Education of the University of the West of England has over 1000 students currently training to be teachers and a further 600 students who are qualified professionals following post graduate courses of study in a flexible modular programme of awards. The Faculty of Education provides professional development for teachers in seven LEAs and has partnership arrangements with nearly 400 schools for initial teacher training and in-service work. The Faculty of Education aims to train competent professional educators who have the subject...
knowledge, the pedagogic skills and the personal capacities necessary to enhance the educational opportunities and educational achievement of all whom they teach.

The Faculty of Education made a first bid for Regional Provider Status in November 1998 and learned that the bid had been successful in February 1999. The original bid was made because the Faculty believed it had an important contribution to make to the development of training in the use of ICT underpinned by the same pedagogical principles adopted for all training at the Faculty. The Faculty has formed the view that its aims are best achieved through courses of training which adhere to, and are informed by, the principles of reflective pedagogy. Put briefly, that teachers should be offered a balance of academic study and practical experience, and critical reflection on both. Critical reflection, it must be emphasised, is not a passive, contemplative activity, but a key element in the evolution of effective professional practice. As training materials were developed it became clear that the training solution could be delivered to any school in England and so the Faculty bid for National Provider status in July 1999 and were awarded national status from November 1999. By February 2000, the training materials were ready and were published as the ICT Learning Path.

The ICT Learning Path

The ICT Learning Path is a training programme combining on-line subject modules, multimedia interactive CD-ROM materials, in-school support and bespoke training, and on-line subject and technology support. The training usually begins with an on-line audit of skills supplementing the TTA Analysis of ICT Training Needs CD-ROM and the National Grid for Learning (NGfL) on-line audit of Using ICT in the Classroom. The trainee then plans their route through the materials using the Statement of Intent completed with the help of their in-school training co-ordinator (a senior member of the school staff) and the school trainer. The school trainer is appointed to the school from a national team of trainers appointed as Visiting Lecturers of the University.

Trainees work through the materials either independently or in collaboration with their Learning Support Assistants, other teachers in the department or Key Stage, or in the case of small Primary schools as a whole staff. They either work through the relevant subject modules and support their training with IT skills and classroom applications from the CD-ROM materials, or begin with some modules from the ICT Learning Path training modules to gather sufficient confidence to move on to the subject modules. Although the NOF funded scheme does not include Learning Support Assistants, the Faculty took the view that we should offer free training to all LSAs, due to our philosophical commitment to work with all professionals who impact upon the educational opportunities for pupils.

During training, teachers and LSAs can contact tutors and their school trainers at the Education Faculty and submit their responses to tasks and exercises for review by a subject tutor. To finish training, teachers and LSAs complete an Exit Audit of using and applying ICT in the classroom. In this audit trainees compare their professional judgement against that of the course team about when ICT should and should not be used in subject teaching. The responses to the exit audit form part of the ‘portfolio’ created by trainees to share with senior managers within the school, as evidence of successful attainment of the expected outcomes of the training. Completion of training is not an end for teachers and LSAs; rather, it is the end of the beginning. Trainees action plan for the continuation of professional development using materials and additional training available from the University’s web site, ‘Pathways’ (http://pathways.uwe.ac.uk) and from other sources including the National Grid for Learning. (http://www.ngfl.gov.uk/)

Her Majesty’s Inspectors of Schools are currently monitoring the impact of current ICT initiatives in schools, including the New Opportunities Fund (NOF) ICT Training Initiative, and will publish a report in Spring 2002. The provision of such large amounts of public money for a school-based training initiative is unprecedented in the history of education in the UK. The Inspectors will, no doubt, be able to tell the teachers and the wider community whether such an investment is ‘helping teachers to use the technology in the classroom to enrich teaching and learning and raise standards - right across the curriculum.’

Abstract This is a working paper describing a proposal for the development of a networked learning program for participants taking "General Studies" as their elective in the part-time Postgraduate Diploma in Education (PGDE) course offered by the Hong Kong Institute of Education. The objective of the networked learning program is to develop a local multimedia teaching resource bank for the subject "General Studies" in the primary curriculum through collaborative learning. The paper describes the rationale and concept of the networked learning program. The mechanism with 4 stages of development is outlined to illustrate how the networked learning program should be designed. The outcomes, and limitations of the use of the networked learning in developing multimedia teaching resource bank are discussed too.

Working knowledge

Stepping into the new century, it is argued that the traditional education system has to be reviewed. Especially in the adult education, traditional University with fix time, space and curriculum cannot satisfy the "Life Long Learning Objective" of the adult learner. In order to satisfy the "Life Long Learning Objective", learning should be taken place independent of time and place, and can be available at all stages of a person's life. (Bates, 1995)

Education has a role to develop the “working knowledge” in their professional aspect. According to the SHARP project conducted by Goodyear (SHARP Guided Tour, 2000), much of what was learned in formal educational systems were proved not to be accessible outside the context in which it was learned. As a result, “working knowledge” has to be developed. In Goodyear's definition, working knowledge is the knowledge that learners have acquired and which they can use in unfamiliar, real world, problem-solving situations. (SHARP Guided Tour, 2000)

In another Project JITOL, Goodyear stated out several assumptions in the collaborative approach for the development of working knowledge. It was assumed that participants were professionals with lots of useful experience and expertise to share. The shared valuable knowledge in the field was bound up in the working practices of the professionals. And the participates would share their knowledge, opinion, descriptions of their working context and working practices, house methodologies etc, if they were given the opportunity and motivation to do so (Goodyear, 1995/6).

Putting Working knowledge in Hong Kong primary school context

It is agreed that learning should be put into context; and teachers should build up their working knowledge, which may not be taught in traditional college. It is a new concept in Hong Kong to develop the working knowledge of Information Technology (IT) among primary school teachers. And it is worth to start with the participants of the part-time Postgraduate Diploma in Education Course (PGDE) in the Hong Kong Institute of Education (HKIEd).

In order to apply IT teaching in primary school, a lot of multimedia teaching materials should be
produced. This will definitely increase the workload of the teachers. Though there are plenty of educational CD ROMs in the market, most of them are imported from other countries that do not fit into the local context. Some teachers who have great interest in IT teaching, may have already developed some multimedia teaching aids; but many are still IT illiterate that they even do not know how to log on their personal e-mail account issued by the Education Department of Hong Kong.

In light of this, there is a need to develop a multimedia teaching resources bank shared by primary school teachers with the following objectives:

- To share the working knowledge among primary school teachers in the production of the multimedia teaching aids, which are not taught through formal education,
- To narrow down the IT knowledge gap among teachers; some teachers are IT experts while some other teachers are IT illiterate,
- To bring in the collaborative learning concept to primary school teachers, to help them to work together to face the rapid developed technology in education
- To reduce the workload of primary school teachers in the production of local context multimedia teaching aids

Networked Learning in developing multimedia teaching aids

Networked learning may be cost-effective in distance education based on relatively small-enrolled numbers of students and a frequently updated curriculum. (Goodyear, 1995/6). It is the most economic and efficient way to set up a networked learning course first with participants in the part-time teacher education program to achieve the objective of building up the working knowledge in IT teaching. No additional class, venues, lectures and other hardware are needed to organize on such networked learning activities.

The Directed Collaborative Project Model described by Goodyear was taken in building up the networked learning program. This model was developed from the organization of peer interaction occurred in the context of the part-time MS program. The objective of the program was about the continuing professional development and updating through computing mediated conference where interaction is the essential feature of the conference. (Goodyear, 1995/6) The objective of the interaction is to create an information resource bank, or evolving knowledge base containing structured representations of practitioner knowledge and research-based knowledge. On the other hand, according to the SHARP project, putting multimedia in network includes the putting of video, audio, graphic and text. (SAHRP Guided Tour, 2000) However, to produce a video clip for teaching materials is really a problem for most of the teachers of Hong Kong.

In order to solve the technical problem of video production, a video server is built in the Education Technology Services Unit of the HKIEd. A resources bank containing about a hundred video clips covering the "General Studies" subject in MPEG format are stored in the video server. The content of the video clips is produced according to the General Studies curriculum, and video clips run from 30 second to two minutes. Video clips from the resource bank can be inserted and integrate into the multimedia teaching aids. The PGDE participants could log on the Institute Intranet to download the video clips.

With the support of this video clips resource bank, the condition for developing local context multimedia teaching aids in "General Studies" through networked learning is built up, with the principle to help the participants to create an audio visual representation of key teaching concepts in General Studies. And the representation of these teaching concepts can be edited and shared through network to other participants in order to build up their own practices and professional perspectives. (Goodyear 1995)

The networking learning concept is adopted from the model of Goodyear about collaborative learning: a group of participants collaboratively create a working knowledge through network. The participants are situated at different location and can join in the computer mediated conference either synchron or ayschnorous. (Goodyear, 1995/6)

As indicated in a number of research and articles, the successful of the networked learning depend on the active participation of members through interaction. It is also suggested by Salmon (1998) with the constructivist approach, that emphasis should be put on creating an atmosphere of openness, helping students to explore ideas and different interpretations, encouraging ownership of the learning and linking to previous learning. The mechanism to maintain the interaction and active participation of the participants is outlined in the following paragraphs:

The mechanism in developing multimedia teaching aids

The mechanism of building the multimedia teaching aids is inspired by two studies. The first one is the SHARP project which is through the Internet to facilitate computer-mediated conference to build up working
knowledge with video representation. (Goodyear & Steeples, 1999). The project was about to create video
clips for representation of working knowledge and sent into network for collaborative learning. Another study
conducted by Hodges and Mott was about using project-based approach to construct web-based hypermedia
for instruction via the Internet. The target of the project was for the pre-service and in-service teachers on
using HyperStudio software in elementary school classrooms. (Hodes and Mott, 1999)

Based on the two projects, it is found that Internet is a successful medium for the interaction, and the
hypermedia software can be shared in the Internet for members. The successful of the network conference is
depended on the successful of the interaction. Therefore, the mechanism is mainly through Internet and the
Intranet within the Institute, and through the using of Microsoft PowerPoint where the working knowledge in
the preparation of multimedia teaching aids can be shared.

The mechanism of the interaction for networked learning is mainly divided into four stages, and
facilitated by the tutors. The medium for networked learning is the Institute e-mail system with connection to
the video server of the Intranet. The advantage of using the Institute e-mail system is that all the participants
have already familiar with the system and no additional orientation course is needed.

Stage I

According to Hodges and Mott, it is the stage for the participants to introduce themselves to the rest of
the class and at the same time, to master the software such as acquiring image in the Internet (Hodges and
Mott, 1999). In order words, participants should get use to the technology in computer-mediated conference,
and the most important, to try to post something in the conference and start out the collaborative learning
atmosphere.

During this stage, participants are encouraged to produce simple descriptions about themselves with
Microsoft PowerPoint; a 30-second video should be inserted in the MS PowerPoint with whatever content
they like. The video inserted can be produced by themselves or they can make use the video clips stored in
the video server of the Institute. Technical support will be provided to help participants to upload the video
clips to the video servers. Therefore, all participants within the group can view each other MS PowerPoint with video
clips. Figure 1 is a sample layout of the PowerPoint. The advantage of using MS PowerPoint with video
clips inserted from the video server is that they can attach and share with all users within the Institute Intranet
system.

At the same time, the participants are encouraged for joining the computer-mediated conference. The role of
the tutor at this stage is to ensure the participants are welcomed and motivated, and can be helped to gain
access to the system. (Salmon, 1998)

Fig 1, Sample PowerPoint layout, with video inserted from video server

Stage II

According to Hodges and Mott, a project-based approach in online instructional design will provide
teachers with a real-world learning environment task, and as a result, will utilize their strengths to construct
the technology skills for use in classrooms. (Hodges and Mott, 1999)

In order to create a collaborative learning environment, tutors should set out tasks for the participants to
develop the multimedia teaching aids. Participants are free to select any topic. For example, if a participant
is a primary school 1 teacher and he/she wants to produce a multimedia teaching aids about the property of Magnet. Then he/she can prepare the MS Power Point and insert the video clips about the property of magnet from the video server. Fig two shows the simple layout of prepared Power Point.

After that, the participant is encouraged to attach the PowerPoint file in the e-mail and send to other members. Other members are free to discuss, comment or amend the PowerPoint. Participants are also encouraged to ask any questions about the task, such as the technical problem of video inserted, audio inserted, sequence of animated effect in title, text and video etc. The purpose of this stage is to facilitate participants to get use of the e-mail conference and the technique of the production of multimedia teaching aids.

Figure 2: Showing a the layout of PowerPoint prepared by Participant A

The role of the tutor in this stage is to let the participants appreciate the social environment of the conference system and to learn to join in. The response of the e-mail to each other may be largely individual but the tutor should encourage them to make them in public because the students may still need individual emails for support and direction. (Salmon. 1998)

Stage III

At this stage, the participant will use the MS PowerPoint produced in stage II and implement in their real teaching community. It is a real situation to integrate their teaching theory into context of working knowledge about building multimedia teaching aids. To the participants, this is a new experience to them because the application of IT teaching is still uncommon in Hong Kong. This is the stage for the participants to discuss the production and implementation of the IT teaching. The participants are free to discuss the application of learning and teaching theory, the instruction design and the technical problem in IT teaching. At this stage, the role of tutor is gradually fade out and allow participants actively build up their own working knowledge through interaction and collaborative learning. Salmon described this stage as information giving and receiving. The students may appreciate the huge range of information available through the network system, and his/her ability to contribute. (Salmon, 1998)

Stage IV

After thorough discussion through the network, the participants have exchanged their own experience in the application of multimedia teaching aids in the context of primary school teaching. With others' comments, participants will modify their teaching aids, and if possible, implement again in the classroom. At a result, a multimedia teaching resource bank is built among the participants so that they can share with each other and to use in the real situation. Reaching this stage, the participants have gone through the collaborative learning cycle as described by Goodyear. (Goodyear, 1995/6). Salmon described this stage as knowledge construction. It is at this stage that the students work together to generate and make new meanings through their collaboration.

Finally, the evaluation of the effectiveness of networked learning can be done with participants writing a self-evaluation report about what he/she has learnt in the program.
Outcome of the Networked Learning in developing Multimedia teaching aids

A multimedia teaching resource bank in General Studies will be built with the contributions from participants from in-service teachers of Hong Kong. In Hodges and Mott's project, the class of students had developed a true team relationship, and had assisted each other when problems emerged and finally had taken lead roles in facilitating each other through the learning process (Hodges and Mott, 1999). In view of knowledge construction, the students had engaged in discussion and interaction with peers and experts in a process of social negotiation. Knowledge construction did occur among students through discussion about their positions, in an argumentative format, reflection and re-evaluation their positions (Salmon, 1998). It is believed that under the networked Learning program, participants will go through the process of computer-mediated conference and as a result, they will collaboratively construct their working knowledge in developing multimedia teaching aids. They will learn how to organize discussion in network, and understand how to post response, argue and suggest to others during discussion. They will also learn how to produce multimedia teaching aids with the integration of audio, video or text. This is the working knowledge constructed by them and can be applied in their future practice.

Limitation in developing Multimedia Teaching resource bank through network learning

Using E-mail system for computer-mediated conference

According to Goodyear, in the early years of the MSc course of Lancaster University, the main means of communication was e-mail, and which was best suited to one-to-one or one-to-small group communication. However, Goodyear had concluded two main problems for the using e-mail system for computer-mediated conference.

1. Confusion over the addressing of messages
2. Misfiling of message (Goodyear, 1995/6)

The e-mail system is designed basically for an efficient way of information exchange, but not for computer mediated conference. In view of the existing hardware and software of HKIEd, the e-mail system with Internet is the only economic way for the conference. However, there is a lot of limitation as described by Goodyear.

For example, it is proposed to insert video to the MS PowerPoint and attach in the e-mail system. This will cause a lot of burden to the storing capacity of the Institute network. If the file size is too large, it may even break down the system. One way to solve the problem is that the student can create their own homepage and put their MS PowerPoint in the World Wide Web. The students need only to e-mail their homepage address to others members and will not give too many burdens to the Institute network system. However, creating homepage needs a lot of IT knowledge and not all students have adequate knowledge to do so.

The storing capacity of the e-mail system is another limitation. Due to the limited storing capacity assigned to each student, his or her email box will easily be full if for he/she takes active participation in the computer conference. As a result, students have to delete their e-mail messages from time to time. Then the retrieval of past message and the reviewing of the conference will be a problem.

Tutor role in facilitating the active interaction of the participants

The tutor plays an important role in facilitating the interaction of the participants in network learning. If the students do not actively involved in the interaction, the tutor can't do anything. Though the students have shared objective to construct the working knowledge in the context of the primary school, there are some other factors restrict them from actively involved in the interaction. The factors will be:
- Heavy workload in the primary school
- PGDE students do not have adequate knowledge in using the technology in conference
- The personality of Chinese are reluctant to confront with others during discussion
- English is the second language of Chinese. To design a networked learning programme in Hong Kong the medium of language for interaction must be considered. Ideally it should be Chinese, but the Chinese input methods are still a barrier to a lot of Hong Kong teachers. Lack of knowledge in Chinese input will restrict students taking active participation in the conference.
Task for Collaborative Learning: Production of Multimedia Teaching Resources Bank

In designing the networked learning, the task of collaborative learning is to produce the multimedia teaching resources bank. This is under the assumption that there is an urgent need for the primary school teacher to implement the IT teaching in school. However, there is a lot of limitation in the primary schools to implement the IT teaching. For example, there is not adequate number of computers in the primary schools. Some of the primary schools are still waiting for the Education Department to allocate budget to install the computer network system in their schools. At the same time, some hardware provision is needed but not so common in the primary school setting. For example, the fixed LCD projector has not been installed in the most of the Hong Kong primary school classrooms. All this hardware provision will restrict the PGDE students to implement the IT teaching. As a result, they cannot take an active role in the networked learning conference about the production of multimedia teaching aids, due the reason that they do not have any experience to share.

Conclusion

The development of networked learning with PDGE participants and the building up of a multimedia teaching resource bank through collaborative learning are based on the fact that there is a shared objective among the participants. The shared objective is to apply IT in teaching strongly encouraged by the Hong Kong Government. Other than the formal training courses, the networked learning may be a good mean to help the participants building up their working knowledge in application of IT teaching in the local context of Hong Kong.

Wholetheme Learning in the Internet Virtual Community: Some Encouraging Preliminary Results

Asghar Iran-Nejad, Yuejin Xu, and Gopakumar Venugopalan
University of Alabama
United States
airannej@bamaed.ua.edu

Abstract: This study compares data from two different applications of a theoretically grounded wholetheme learning portfolio. The portfolios came from four different sections of the same undergraduate educational psychology course for teacher education students. All students wrote a critical reflection essay on three of their major insights in the course of the semester according to a common schedule and set of guidelines prescribed in their syllabus. Each of the students in two of the sections did and in the other two did not participate in the internet virtual community (IVC) we created. Quantitative results suggest that the IVC participants improved in critical reflection in the course of the semester. Qualitative analysis of the third insight data suggested a trend in favor of an interaction in which better students did better in IVC and poorer students did better in non-IVC conditions.

Introduction
The Wholetheme Learning Portfolio

The results reported here are based on critical reflection on three insights as part of more comprehensive wholetheme learning portfolio (WLP). The WLP is a product of over two decades of research in biofunctional cognition (Iran-Nejad, 1980, 2000) and close to a decade of application in university courses in educational psychology for teachers. One major difference between the WLP and traditional teaching products is the conceptions of learning behind each of the two kinds of artifact (Iran-Nejad & Gregg, in press). These conceptions of learning are presented in Table 1. Whereas the focus on the first two conceptions of learning is on internalization of an external disciplinary knowledge base, the third conception views learning as the wholetheme reorganization of the learner’s own intuitive knowledge base. Critical reflection as reported here was based on this third conception of learning.

</table>
Table 1: Three conceptions of learning based on Iran-Nejad (1990) and their illustration in terms of the metaphor that knowledge is analogous to Clothing.

Specifically, one major implication of the different learning conceptions, as far as the WLP is concerned, is a fundamentally different perspective on critical reflection. The object of critical reflection in the first two conceptions of learning is the declarative or procedural content of a symbolic input stream whose origin is, directly or indirectly, an external disciplinary knowledge base (indirectly, that is, if the message stream comes from a previously internalized representation of that external knowledge base). The kind of critical reflection processes that are assumed to operate on the symbolic and representational message stream are analytic examination of its content, constructive elaboration on it, and/or storage-for-reproduction of it. Critical reflection in the third conception of learning is an entirely different story. It involves turning inward, rather than outward, to one’s own non-disciplinary intuitive self-awareness and learning to use it in the art of self-regulating one’s own brain-mind cycle of reflection for the purpose of whole theme reorganization of one’s own nonsymbolic and nonrepresentational intuitive knowledge base (Iran-Nejad, 2000). As secondary and indirect objects of critical reflection, external knowledge bases (both disciplinary and non-disciplinary), one’s own knowledge of the world, and social nonsocial organizations of learning are all only useful to the extent that they can contribute to the primary goal of self-regulating one’s own brain-mind cycle of reflection. The purpose of the WLP is to help students embark on this type of a journey of their lifetime that must also be, in some extraordinarily fundamental sense, a journey of their own choosing.

The Concept of Internet Virtual Community

Because the nervous system and the learning processes of the brain-mind cycle of reflection have evolved in the real world, the internet social and otherwise organizations of learning are likely to facilitate learning to the extent that they can manage to approximate the social and otherwise organizations of the real world. We designed the IVC to “actualize” this other implication of biofunctional cognition. In real world communities, people live in homes which are nothing like the artificial modern classrooms. People prepare their homes maybe first to their own liking, comfort, and entertainment and next to the liking, comfort, and entertainment of their guests. To harness a parallel set of considerations, we made every individual student in the course the proud owner of an IVC home in which to post her or his whole theme learning portfolio. The homes for the students in each section of the course were also designed into communities of five to seven homes. Within a given community, the owners maintained open house for the duration of the semester for visitation by other members of the community. At the end of every scheduled visit, the guest was to leave a critical reflection and three other brain-min-cycle of reflection ratings of their own experience of the visit.

Methodology

Insight critical reflections (or insights, for short) from 84 portfolios authored by the students in an educational psychology course for undergraduate teacher education candidates were used as the data source. The portfolios came from four different sections of the same course. Most of the participants were white, female, and about twenty years old. There were two different instructors, both advanced educational psychology graduate assistants. One of the two sections of a given instructor participated in the IVC and the other served as the non-IVC equivalent (control). Each student in an IVC section received sign-on instruction to her or his own individualized “home discussion forum” (HDF) as well as to the HDFs of the other members of the same community. The
HDF enabled its owner to post her or his portfolio entries or view responses posted to each entry by other members of the same community or by the instructor. Each community consisted of five to seven HDFs for all members to visit.

All four sections received the same course syllabus, except that the syllabi for two of the sections contained additional instructions for participating in the IVC. Instead of posting them in an HDF, participants in the non-IVC sections e-mailed their portfolio entries to their respective instructors. All entries were posted or e-mailed according to the same schedule prescribed in the syllabus. Students in all sections were also required to compile all their entries into a custom-designed hard copy of their portfolio and turn it in to their instructor for grading purposes by a deadline toward the end of the semester. Thus, each student was required to submit each entry twice, once by posting or e-mail according to a prescribed schedule and once in hard copy included in compiled portfolio. In this fashion, the IVC and the non-IVC sections were different only in that the IVC sections made their portfolios public within their community. In all other aspects of instruction, including their regular class meetings, all four sections of the course were to be identical.

The whole theme learning portfolio was described as a QUILT (RR) portfolio, denoting its content types: questions, insights, lessons, and teaching observation essay as well as a (summative) reflection paper and a (summative) reaction to the portfolio. In this study, we only analyzed the insights. Therefore, the other contents of the portfolio will not be discussed here. For each month during the semester, each student was to reflect on her or his major insights for that month, select one of them, and write a critical reflection on it.

Quantitative Results

Each insight was rated by two raters on a critical reflection scale. There were a total of 248 insights to rate. The inter-rater reliability was 0.85. The ratings of each insight given by two raters were averaged. A preliminary analysis showed no main or interaction effects for Instructor. Therefore, a 3 x 2 repeated measure ANOVA was conducted on the ratings with Time (Insight 1, Insight 2, Insight 3) as the repeated measure and Condition (IVC, non-IVC) as a between-subjects factor. A significant interaction was present, F (2, 156) = 3.195, p < .05). However, none of the main effects were significant. As Figure 1 shows, IVC sections gained in critical reflection from Insight 2 to Insight 3. The critical reflection scores for the non-IVC students went down.
Figure 1: The interaction of time and condition

Qualitative Analysis

We used NUDIST (Q.S.R., Power version, revision 4.0) for a closer look at the data for Insight 3. Upon examining the categories that emerged, we noticed a tendency toward an interaction in which the IVC participants in the top group appeared to be doing better than the control group; but the IVC participants in the bottom group seemed to be doing worse than the bottom control group. Table 2 (See Appendix) shows a sample of the coded sections. To select this sample, we used the criteria of best, common, and worst examples of learning as reorganization. To our estimation, examination of the insight excerpts in the table seems to support the tendency for the interaction we just described.

Discussion and Conclusions

What can we make of this preliminary set of results? According to our quantitative results, participation in the internet virtual community seemed to help between the time that the students wrote their critical reflections on their second and third insights. This was expected. However, during the same period, the opposite effect was apparent for the control students. This was a surprising finding. One tantalizing possibility is that sometime by mid-semester, the IVC participants experienced a crisis in the process of wholetheme reorganization of their own intuitive knowledge base. This crisis then interfered with their critical reflection performance for the second insight. For the non-IVC students, this developmental crisis came a month later affecting their critical reflection performance on their third insight. Whether there is any substance to this highly conjecture remains to be seen.

Our qualitative analysis of the data on the third insight was conducted to see if it could shed any light on the above conjecture. The actual results seem to be cautiously helpful. By the time of the third insight, good non-IVC students seemed to be only slightly behind the good IVC students, indicating that they had already left their wholetheme reorganization crisis behind and were well on their way to recovery from it. Why did, then, the poor IVC students perform worse than the poor non-IVC students? It is possible that the poor IVC students only appear to be doing worse because they are experiencing their wholetheme reorganization crisis at the time of their third insight. The non-IVC students appear to be doing better only because they have not yet reached the wholetheme reorganization phase. The data in Table 2 are consistent with this speculation. It is important to know that this cannot be anywhere near a conclusion. Without further evidence and without any replication data, many similar conjectures can be fabricated for the pattern of results reported here.

Reference

In the above paragraphs, I basically just explain the gospel CDs. The song that was playing said, "Oh what peace we often forfeit; oh what needless suffering that not only was I forfeiting my peace and God made a way. I also realized that all I had to do was pray about my financial situation and I would have been having at the time; and leave them there with God, everything would have been taken care of.

After the shooting was done in Columbine many students for at a weeks time were absent from school, and this only hurts them. How could you not blame a student who is in fear of their life at school of all places not to come? The answer is you don't. Extra protection is the only solution that the schools can give right now and there will be a lot of things out and to forget things. His mother found his mother dead in their block.

I could have offered the students a reward if they would of eaten a well-balanced meal for a week. I would have to use external punishment style of motivation because I could not make sure that I only try to use external motivation to stimulate internal motivation. (31)

I think that this insight has transformed me to an extent as a teacher. I cannot expect my students to just want to do well just because they are all driven to do well. I will have to give some incentives for some of them to want to do well. Some may never be motivated towards doing well in school and I have to make sure that I don't give up on these students at first sight. I will have to look hard to find what does motivate them and tie that into my classroom experience so that they will be motivated to learn. Without this insight, I may have just assumed that these students just didn't have a drive as powerful as mine.

Why did I choose elementary education over obstetrics? I have always wanted to be a teacher, but I also wanted to deliver babies. I really thought, I would be much happier teaching than delivering babies. Then I thought, doctors make about five times as much as teachers make, but what do I really want to do? Doctors are always on call, unlike teachers. Would I enjoy this environment of constant pressure in a hospital or do I want a more relaxed environment in a classroom. … Therefore, I chose teaching.

My name is S and I teach third grade. One of my students went through a traumatizing event not to long ago. He found his mother dead in their house. She had a massive heart attack. Well since this terrible occurrence, he has started to block a lot of things out and to forget things. His father put him through counseling but he seems to be progressing very slowly. He is a very smart boy, always made really good grades. Now he has forgotten things he used to do really well for example division. So it is obvious that he is forgetting information from his long-term memory.

<tr>
<td>Best Wholetheme reorganization example</td>
<td>There was now a clearing in my mind, a new path had been opened. This new path indicated a great new set of possibilities for me in my own approach to my studies. The insight helped me to sort out everything in my mind very much the same way as one sorts out clothing from a laundry basket or food items placed in appropriate parts of the kitchen. My mind could not go down old paths any longer. I resolved to be in control of my self-regulation in terms of my own motivation in my studies. The challenge had been given and now I had decided to accept the challenge within myself. Only I could make this step. Mental adjustments had to be made.</td>
<td>At the same time, I was listening to one of my gospel CDs. The song that was playing said, &quot;Oh what peace we often forfeit; oh what needless pain we bear, all because we do not carry everything to God in prayer.&quot; From that I realized that not only was I forfeiting my peace and happiness, but I was also worrying needlessly. For every time that my mind could not see a way, God made a way. I also realized that all I had to do was pray about my financial situation and any other problems that I may have been having at the time; and leave them there with God, everything would have been taken care of.</td>
<td>While in my placement at Woodland Forest Elementary I witnessed a lot of different things. One of the most profound however was the effect that motivation has on children even in kindergarten. All children are not driven to achieve but some can with the help of a little motivation. Ms. Teacher was very good at this. She motivated in so many ways that it was hard not to want to do your work. One of the ways she motivated was the star chart. Good behavior got a star for the day and the children with the most stars at the end of the week got something special. It's almost like the children were feeding off this motivation. However I thought to myself that maybe she was giving too much motivation at times. Then I reconsidered because how can you measure too much motivation. I see that if any class is to succeed, it has to be driven to.</td>
</tr>
<tr>
<td>Most common Wholetheme non-reorganization example</td>
<td>It is difficult to find sources of motivation for students with disabilities, especially those with limited communication skills. I have discovered that one opportunity for teaching may arise when a student has a desire for an object or task. When working with students in the future I plan to be more observant. I now realize that the students can guide me in the development of individual instructional programs.</td>
<td>Another question I have is how are the other students handling the fear of going to school. After the shooting was done in Columbine many students for a weeks time were absent from school, and this only hurts them. How could blame a student who is in fear of their life at school of all places not to come? The answer is you don't. Extra protection is the only solution that the schools give right now and there will be a lot of things out and to forget things. His mother found his mother dead in their block.</td>
<td>This insight transformed me as a person because it made me look at motivation in a totally different way. It made me realize that I can use both external and internal motivation, yet neither one would be used in the bad sense. Now I can make sure that I only try to use external motivation to stimulate internal motivation. (31)</td>
</tr>
<tr>
<td>Worst non-wholetheme non-reorganization example</td>
<td>I think that this insight has transformed me to an extent as a teacher. I cannot expect my students to just want to do well just because they are all driven to do well. I will have to give some incentives for some of them to want to do well. Some may never be motivated towards doing well in school and I have to make sure that I don't give up on these students at first sight. I will have to look hard to find what does motivate them and tie that into my classroom experience so that they will be motivated to learn. Without this insight, I may have just assumed that these students just didn't have a drive as powerful as mine.</td>
<td>I could have offered the students a reward if they would of eaten a well-balanced meal for a week. I could have also told the students the consequences from not eating from all the 6 basic food groups. This way the students would be able to decide which road they want to choose in healthy eating. In this situation, I could not have used the punishment style of motivation because I could not have taken away something from the students just because they were not eating right. I usually do not eat right myself, much less punish the students for something I do, too. Therefore, I learned there is an appropriate place to use one motivation skill and another place to use the other.</td>
<td>My name is S and I teach third grade. One of my students went through a traumatizing event not to long ago. He found his mother dead in their house. She had a massive heart attack. Well since this terrible occurrence, he has started to block a lot of things out and to forget things. His father put him through counseling but he seems to be progressing very slowly. He is a very smart boy, always made really good grades. Now he has forgotten things he used to do really well for example division. So it is obvious that he is forgetting information from his long-term memory.</td>

Abstract: Providing opportunities for K - 12 educators to further their use and understanding of current technologies in the classroom has never been more important than it is at present. This paper will explore ways that university faculty members can provide K - 12 educators with relevant information and hands-on experiences to develop and enhance their use of technology in the science classroom. An interactive workshop for 15 middle school science teachers provided an opportunity for participating teachers to experience constructivist teaching and learning strategies first-hand. Throughout the workshop, teams of teachers worked to prepare an integrated, technology-based lesson using materials from science, mathematics, as well as the language arts. Highlights of the curriculum developed for the workshop will be presented. Results of a questionnaire given to the teachers will also be shared.

Introduction

Through a Dwight D. Eisenhower Faculty Development Program award, a team of faculty members and graduate students from American University hosted a workshop on the American University campus for a group of 15 middle school teachers from the District of Columbia Public Schools. Teams of three were identified with most teams including a science teacher, a mathematics teacher, and a language arts teacher. Where possible, teams consisted of teachers from the same school. Resources for the workshop can all be found at http://www.american.edu/IRVINE/rke/. The weeklong, interactive workshop provided an opportunity for participating teachers to experience constructivist teaching and learning strategies first-hand. During the week, the teams of teachers worked to prepare an integrated, technology-based lesson using materials from science, mathematics, and the language arts. In the section that follows, highlights of the many workshop activities are outlined. A table summarizing the workshop events is given in the appendix of this report.

Theoretical Framework

The need for the successful implementation of technology into any educational program, especially the innovations within middle school classrooms, must be build upon a genuine educational pedagogy in order for
authentic learning to occur (Dede, 1999). The constructivist model has emerged from the works of developmental theorists such as Bruner, Piaget, and Vygotsky. The cognitive constructivist theory adopts the works and conclusions of Bruner and Piaget as the foundations of its principles. Within this theory, students construct their knowledge of the world through assimilation and accommodation. Within the field of educational computing, the best-known cognitive constructivist theoretician is Papert (1993), who characterizes behavioral approaches as “clean” teaching, and constructivist approaches as “dirty” teaching. The contrast emphasizes the difference between perspectives that isolate and break down knowledge to be learned (clean) versus approaches that are holistic and integrative (dirty) (Papert & Turkle, 1993). Intertwined together, at some level both “clean” and “dirty” approaches serve as the authentic foundations of the constructivist theory. By considering these approaches together, we can get a clearer understanding of how Internet technology, when integrated into any classroom, can be used to create successful distance learning in educational and corporate environments.

Another example of constructivism in educational technology is outlined by Dede and Sprague in a 1999 article, “If I teach this way am I doing my job?” which appeared in Learning and Leading with Technology. The article is based upon the constructivism theory at work in a traditional classroom. Educational technologists have often stated that an effective way to integrate technology into the teaching and learning processes is to follow a constructivist foundation. In other words, educators may have technical skills, but they may not understand how constructivism translates into effective, “hands on” classroom practice. However, the constructivist theory is in fact one of the best theories to intertwine into the daily classroom lifestyle (Dede & Sprague, 1999).

For an authentic constructivist theory to breed successfully in any classroom, students are expected to be more actively involved than in traditional classrooms. They are required to share ideas, ask questions, discuss concepts, and revise ideas and misconceptions (Dede & Sprague, 1999). In order to successfully ensure that the constructivist theory is in practice while using technology, the educator must in most cases change his or her more traditional beliefs. In the constructivist classroom described by Dede and Sprague there is no evidence of neatly lined desks or a type of “dense” order within the classroom walls. Instead, students work in teams, asking questions and moving about the classroom. In addition, the educator, instead of simply repeating a redundant lecture, is engaging in interactive activities with his or her students. The mission of the constructivist method is centered upon the needs and interests of the student. Any constructivist classroom demonstrates that learning can often times go beyond the content area. The main foundation the constructivist scenario is built upon states that authentic learning must be student-centered and meaningful and must encourage the student to engage in real-world experiences, thus allowing him or her to go further in his or her learning and education (Dede & Sprague, 1999).

There are many examples in which the constructivist theory has successfully been implemented with or around technology. Within the model constructed by Egbert, Thomas, and Fischler (2000), the Tigerlake Public School simulation is assessed through substantial research. The model mimics the following concept: if the constructivist theory is successfully implemented with and around technology, students learn authentically. In this situation, student-educators who are the participants in this simulation learn by doing. This simulation offers a way to integrate field experience and alternative technology-based instruction, which combined can help to improve almost any type of student to achieve high levels of competence in technology. The Tigerlake simulation allows the 29 student-educators to interact in a learning environment where “rich” experiences could be achieved. The richer the experience, the richer and more indelible learning takes place. By presenting related practices in learning environments that are simulated, the participants are provided with a set of “experiences” to compare to the current problem or issue. The participants are able to simplify concepts in order to make them understandable, in order to build upon existing understandings of theory and apply it to practice. Again, even among student-educators, the constructivist theory, intertwined with technology, is successful in allowing the participants to gain a better grasp of applying theory to practice (Egbert, Thomas & Fischer, 2000).

**Design**

The basic structure of the workshop involved sharing information and materials with the teachers during the morning sessions. This structure builds on known ideas about infusing technology into the instructional techniques of teachers, as many educators are experiencing a transformation in the ideology of “best-practices” as they once knew it (Balestri, Ehrmann, Ferguson, 1992). Although technology has
influenced methods and practices in almost all educational institutions (Balestri, Ehrmann, Ferguson, 1992), traditional pedagogy should still be used as the foundation for all educational practices (Bopry, 1999). The teams of teachers spent each afternoon in a computer lab learning how to use the internet and world wide web to create constructivist-based integrated lessons. Each afternoon, the participants met in the McCabe Center for Computers in Writing, a lab of Windows98 computers with access to the internet and web-design software. Teachers were given intensive hands-on instruction on educational web design, and created materials and resources to use in the process of integrate this instructional medium into their teaching in math, science, and language arts. Thus, the teachers were given a considerable amount of time to work together within their teams to plan and develop their lessons.

Each morning, the workshop began with a group discussion of the previous day's "reflection questions." Each day participants were given several questions to ponder after the conclusion of the day's events and activities. Participants were asked to go home and keep track of their reflections in a journal. The reflection questions were typically associated with information presented during that day's sessions. The intent of the reflection questions was to give teachers time to digest information they had received during the day, and to reflect on how that information might have relevance to them in their daily teaching activities.

Each day, participants engaged in hands-on activities relating constructivist perspectives into instruction in language arts, mathematics, and science. The participating middle school teachers were engaged by activities such as how to use a learning style approach in the classroom, reading the web using a critical literacy perspective, and an interactive, constructivist-based biology laboratory on DNA. Each day following lunch, participants went to a computer lab facility to work on their team projects. The sessions followed a teaching/training methodology for instruction in using the computer applications in the lab. First teachers discussed general principles of educational web design, and then participated in a whole-group training session on how to use the tools. Then teams were given lab-time to work on their projects with one-on-one assistance from the session leaders. Thus, participants had ample opportunity to ask questions and receive personal assistance from the workshop team.
